Methods: This work is a longitudinal, prospective and analytical study of a cohort of primary school children, aged between 5 and 13 years. Two standardized and validated questionnaires were created, together with digital and physical data collection forms. Questions were harmonized with the Mexican National Health and Nutrition Survey indicators for comparability. One questionnaire was directed to parents and tutors and the other to students enrolled in the public education system. The questionnaires included modules on: identity and geolocalization, anthropometric measures, food security, food intake, sleeping habits, physical activity, household employment status, household deaths directly related to COVID-19, and food assistance programs. Due to sanitary restrictions, data collection was carried out physically and virtually by SNDIF personnel, parents, teachers and government health workers between May and September 2021. A total of 1,096 million completed forms were received, and 816,000 questionnaires were valid for analysis. In the case of anthropometric measurements, a nutritional status was determined according to weight-for-age Z-score, height-for-age Z-score, and BMI-for-age Z-score.

Results: 27 out of the 32 States participated in the survey. A quarter of the households surveyed reported that at least one member of the family had COVID-19, the main family members who became ill were the father (12.3 %) and the mother (9.3%). Moreover, 6.3% of the households reported at least one death in the family related to COVID-19. Of the 200,269 children at risk of food insecurity, 42% receive some support for food. Trends in nutritional status have changed compared to before the COVID-19 pandemic. In general, the prevalence of malnutrition increased. 23.27% of children measured present obesity, compared to 11.91% in 2019 ; 21.10% present overweight, compared to 22.03% in 2019; and 17% present some type of undernutrition, compared to 13.62% in 2019.

Conclusions: The COVID-19 pandemic and its associated factors have had effects on the status of food security and nutrition in children ages 5-13 enrolled in the public education system. All forms of malnutrition are still of concern, being obesity the one that has higher increase rates between 2018 and 2021. Policy measures need to be taken by the SNDIF to adjust Food Social Assistance Programs to the current food security and nutrition context.

Unhealthy food products marketed to Mexican children and adolescents on the internet during the COVID-19 pandemic

Claudia Nieto[1], Isabel Valero-Morales[1], Abad García[1], Alejandra Aviles[1], Mariel White[1], Simón Barquera[1]

1. Instituto Nacional de Salud Pública (Mexico)

Background and objectives: Marketing exposure triggers consumption of unhealthy foods. In the last decade, the use of the internet has risen, along with digital marketing of foods and beverages. During the COVID-19 pandemic, school changed from face to face to virtual lectures and other activities became virtual. The objective of this study was to determine the healthfulness of foods marketed to children and adolescents on the internet during the COVID-19 pandemic.

Methods: In this cross-sectional study we used a crowdsourcing strategy to recruit participants aged 6 to 19 years old. Those with Wi-Fi at home and with enough storage space on their devices uploaded videos of their internet exposure. Trained dietitians performed a content analysis using the protocol of the World Health Organization (Europe Office). For all products advertised, we collected nutrition information, mostly from the products' official websites and from Mexican supermarket websites. All information was recorded into calories or grams/100 grams. To determine if the advertised products were unhealthy, we used the PAHO Nutrient Profile Model (NPM) and the Mexican front of package label NPM.

Results: We received recordings from 347 children and adolescents. Overall, 69.5% of participants were exposed to food digital marketing. The most frequently marketed food categories were: ready-made foods (23%), cakes and biscuits (14%), chocolate, energy bars and desserts (12%), savoury snacks (7%), sugar sweetened beverages (7%), edible ices (6%), breakfast cereals (4%), among others. According to the PAHO, 93.3% of the promoted products had at least one excess nutrient of concern and 61% exceeded the total fat cut-off point. The Mexican NPM classified 8.7% of the promoted products with zero warning labels, while 91.3% were classified with at least one warning label. Half of the products exceeded the saturated fat cut-off point.

Conclusions: Most of the children and adolescents were exposed to unhealthy food digital marketing and most of the products that were marketed on the internet were classified as unhealthy according to the PAHO and the Mexican NPM. This evidence shows the need to enforce strong regulations targeted at digital media that protect children and adolescents from the food industry's tactics.

Balanced Nutrition practiced with limitations during the COVID-19 pandemic: The experience of parents in Subang, West Java, Indonesia

Ju Lan Phan[1], Avita Aliza Usfar[1]

1. Dakra Consultant (Indonesia)

Background and objectives: Food-Based Dietary Guideline (FBDG) is adopted worldwide. Messages that are found across many countries are to consume a variety of foods; consume fruits and vegetables, legumes, and animal-source foods; and limit sugar, fat, and salt. In Indonesia, the FBDG is translated into ten Balanced Nutrition messages, which was released by Ministry of Health in 2014. The purpose of the study is to assess the knowledge on these messages and practices among parents of preschoolers in Subang district, West Java province, before and during the COVID-19 pandemic (before March 2020 vs. October 2021) and to seek differences in the knowledge and practices of parents who attended nutrition training and those who did not attend any nutrition training.

Methods: Google online survey platform was used to collect the data.

Results: Most of the respondents were female (n=71) with age range between 21-49 years. About half of the parents were high school graduates. The top three Balanced Nutrition messages mostly selected by the parents were drink adequate and safe water (85%), consume variety of staple foods (75%), and eat plenty of vegetables and fruits (73%), while the least selected were enjoy variety of foods (42%) and reading food labels (35%). An increase was found in parents who drink adequate water and conduct physical exercise daily during the pandemic, as well as those who wash hands. A decrease was found in parents who consumed fruits, vegetables, and animal protein daily, with statistical difference for vegetables and animal protein. Majority (61%) of the parents perceived that their food quality was poorer during the pandemic and 37% experienced food shortage. Majority (72%) had decreased income, 51% decreased their food expenditure, and 60% (n=52) decreased smoking expenditure. About half (48%) of the parents participated in some kinds of nutrition training in the last four years. The trained parents mentioned more of the Balanced Nutrition Messages, with a gap up to six percentage points.

Conclusions: Parents acquired knowledge on nutrition to some degree, but its application faced limitations during the pandemic. Dissemination of Balanced Nutrition can be done through pre-school teachers.

Are current nutrition policy actions and frameworks equipped to transform food systems? Analysing worldwide regulatory interventions using a framework for ecological regulation.

Tanita Northcott[1], Mark Lawrence[1], Christine Parker[2], Belinda Reeve[3], Phillip Baker[1]

1. Deakin University (Australia), 2. The University of Melbourne (Australia), 3. The University of Sydney (Australia)

Background and objectives: Today's global food systems are contributing to multiple intersecting health, social and environmental crises. Experts and authoritative organisations are calling on governments to take policy action to transform food systems, including using regulatory interventions. Ultra-processed foods (UPFs) merit regulatory attention as substantial evidence shows that UPF consumption harms human health, and increasing evidence points to significant environmental impacts linked to UPF supply chains. The global rise of UPF production and consumption is tied to the industrialisation of food systems, sustained by multiple determinants (e.g., globalised food supply chains, the market power of transnational UPF corporations). To date, few researchers have examined the transformative potential of regulatory interventions and nutrition policy frameworks to tackle the UPF problem and related socio-ecological crises. The objective of this study is to critically examine whether current nutrition policy actions and policy frameworks are compatible with 'ecological regulation', an approach that reorients regulatory tools to socio-ecological goals, in order to transform food systems.

Methods: We conducted a qualitative documentary analysis of national policies from multiple countries, using an integrated theoretical framework that draws on ecological regulation and systems science analyses on leverage points for systems change. We focused on regulatory interventions relevant to nutrition from a whole-of-food-systems perspective. Interventions were analysed in NVivo using codes developed for the integrated framework and also existing nutrition policy frameworks.

Results: Findings suggest that regulatory interventions and nutrition policy frameworks predominantly consider isolated elements of the food system (e.g., food prices, labels) and use a limited range of regulatory tools (e.g., taxes, front-of-pack rating systems). Analysis indicates that they do not adequately address the system's paradigms and goals (e.g., dominant market-based and nutrient-centric ideologies), the synergies or trade-offs among interventions, or the commercial, political, social and environmental dimensions of food systems problems.

Conclusions: Results indicate that the system's paradigms and goals are arguably the most influential places to intervene to generate whole-of-food-systems change, yet appear to be insufficiently targeted in policy actions and frameworks. This study highlights the potential for an ecological approach to regulation, informed by systems science analyses, to contribute to global food systems transformation.

Automating the collection and processing of data for the creation of a comprehensive food composition database by brand name - the Food Label Information Program (FLIP)

Mary L'Abbe[1], Mavra Ahmed[1], Alyssa Schermel[1], Guanlan Hu[1]

1. University of Toronto (Canada)

Background and Objectives: Monitoring the nutritional quality of national food supplies is key to nutritional research, policy development, and monitoring. The Food Label Information Program (FLIP) is a big data approach to the collection and evaluation of brand-name foods in Canada and Latin American countries (LAC). This study describes the automated approach used for FLIP 2020 updated data collection and analysis.

Methods: The University of Toronto's FLIP is a longitudinal cloud-based database of brand name prepackaged foods and beverages collected since 2010 in Canada and since 2015 in LAC. FLIP 2020, used website "scraping" to collect food label information on all foods and beverages available on 7 major Canadian grocery retailer websites. Each website was scanned for an outline of how product information was stored. Using Python-based routines, hyperlinks of product pages were loaded and data extracted into FLIP. Artificial Intelligence-enhanced Optical Character Recognition (AI-OCR), coupled with Machine Learning (ML) and text parsing algorithms were used to locate and process specific text which was extracted from product images, such as ingredients, Nutrient Facts tables, and product identification information. A modified pre-trained BERT model was used to encode texts from the product name, ingredients and brand information for predicting food categories according to Health Canada's table of reference amounts (TRA).

Results: Overall, accuracy of ML/AI-OCR techniques depended largely on the quality of images and consistency of text formatting. Accuracy was >95% when the images were of good quality. The precision of TRA categorizations ranged from 0.93 to 1; 0.99 for desserts, 0.98 for cereals, dairy, fats and oils, water animals, soups, and 0.97 for beverages, fruits, vegetables, snacks, meat, sauces, and combination dishes.

Conclusions: FLIP, with its comprehensive sampling and use of AI-OCR, is a powerful tool for more frequent and extensive evaluating and monitoring food supplies and allows more efficient sampling and processing of large amounts of data. As not all retailers provided all the mandatory food label information on their websites, regulators will need to ensure that consumers have access to mandatory information found of food labels when shopping online, which will aid automated monitoring of the food supply.

The Choices International criteria: a nutrient profiling system to classify food products into 5 levels of healthiness

Gianluca Tognon[1,2], Belen Beltramo[1], Rutger Schilpzand[1], Lauren Lissner[3], Annet J.C. Roodenburg[4], Rokiah Don[5], Krishnapillai Madhavan Nair[6], Ngozi Nnam[7], Herbert Smorenburg[1]

1. Choices International Foundation (Netherlands), 2. University of Skovde, School of Health Sciences, Skövde. (Sweden), 3. School of Public Health and Community Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg. (Sweden), 4. Department of Nutrition and Health HAS, University of Applied Sciences (Netherlands), 5. Nutrition and Dietetics Division, International Medical University, Kuala Lumpur 57000. (Malaysia), 6. Former scientist, National Institute of Nutrition, ICMR, Hyderabad. (India), 7. Department of Nutrition & Dietetics, University of Nigeria Nsukka (Nigeria)

Background and objectives: Food-based dietary guidelines provide a conceptual basis to guide food choices and nutrition policies, but they may not always consider processed food products. Advanced, global, and graded nutrient profiling systems (NPSs) can overcome this limitation and support nutrition policies to prevent and control non-communicable diseases. However, graded NPSs that use an across the board and scoring algorithm are not easily adaptable to specific contexts. This paper examines whether the Choices single-level NPS, which is product group-based and uses thresholds, can be extended to a graded NPS and support a variety of nutrition policies.

Methods: The Choices International Foundation revised its single-level criteria from 2020 by extending them into a 5-level nutrient profiling system (NPS). Four thresholds were determined using a series of benchmarks, including compliance levels calculated in an extensive international food product database, the aforementioned Choices criteria, and NPSs developed by the WHO to restrict marketing to children. Validation consisted of comparison with indicator foods from food-based dietary guidelines from various countries in Europe, Africa, and Asia. Furthermore, the new NPS was compared with the Health-Star Rating and Nutri-Score systems using products from multiple countries.

Results: A 5-level NPS was developed for 33 food product groups and expressed as grams of saturated fat, trans fat, sugar, sodium, and fiber per 100 g of a food product. It can support a variety of nutrition policies such as restricting marketing to children, front of package nutrition labeling, reformulation, taxation, subsidies, etc. As the Choices 5-level NPS is product group-specific and uses thresholds rather than a scoring system, it can be easily adapted to different contexts. In comparison with other NPSs, the Choices 5-level NPS gives a more accurate representation of dietary guidelines.

Conclusions: The new Choices NPS were developed in particular to create a coherent set of public health measures to promote healthier food. The Choices International criteria can be applied to different contexts and support a variety of nutrition policies.

Conflict of Interest Disclosure: None.

Which front-of-package label works best to help adolescents make healthier food purchases? A randomized choice experiment in Indonesia

Lindsey Smith Taillie[2], Maxime Grégoire Paul Bercholz[2], Nabila Ernada, Wendy Gonzalez[1], Aang Sutrisna[3]

1. The Global Alliance for Improved Nutrition, Switzerland (Switzerland), 2. University of North Carolina at Chapel Hill (USA), 3. The Global Alliance for Improved Nutrition, Indonesia (Indonesia)

Background and objectives: Front-of-package labels (FOPLs) are a promising population-level strategy to inform consumers and discourage unhealthy food purchases, but little research has examined their impact in adolescent populations. We conducted choice experiments to test the effect of a traffic light label (TLL) and warning label on Indonesian adolescents' ability to identify unhealthy products and their intentions to purchase them.

Methods: Data were collected from 1,871 adolescents in Indonesia. Participants were randomized to one of the following study arms: 1) a control label (barcode); 2) TLL (color-coded label with numeric nutritional information; or 3) a warning label (black diamond with text 'high in sugar/salt/fat and/or saturated fat'). Participants viewed a set of two products from four categories (tea, cereal, cookies, and yogurt), which included one less healthy option and one healthier option. Products displayed the FOPL according to the assigned study arm. Participants were asked to identify which product was less healthy, which had an excess of critical nutrient(s), and which they preferred to buy. We used a mixed effects linear regression model for continuous outcomes and mixed effects logistic regression for binary outcomes.

Results: In the choice experiment, participants exposed to TLL or warning label were more likely to identify the less healthy product, with 45.1% in the control group correctly selecting the less healthy product compared to 50.5% and 51.9% in the warning and TLL groups, respectively ($p<0.01$). Relative to the control group (53.5%), the warning label and TLL also led to a higher percentage of participants who correctly identified which product was higher in sugar (57.9% and 58.4%, respectively; $p<0.01$ for both comparisons). Relative to the control group (62.6%), only the warning label led to a lower percentage of participants who selected the less healthy product as the one they wanted to buy (58.9%, $p=0.010$). For all three outcomes, there was no statistically significant difference between the traffic light vs. warning groups.

Conclusion: Warning labels and TLLs both influenced Indonesian adolescents' ability to identify unhealthy products and reduced intentions to consume them, with the pattern of

results suggesting that the warning label was slightly more effective.

Sanitation, food safety, and hygiene are suboptimal in public sector basic schools in the Greater Accra Region, Ghana: field observations and perspectives of food service providers.

Phyllis Ohene-Agyei[1], Amos Laar[1], Michelle Holdsworth[2], Gideon Amevinya[1], Richmond Aryeetey[1], Stefanie Vandevijvere[3], Kobby Mensah[1], Charles Agyemang[6], Daniel Sellen[4], Dennis Laryea[5]

1. University of Ghana (Ghana), 2. Montpellier Interdisciplinary centre on Sustainable Agri-food systems (France), 3. Sciensano, Service of lifestyle and chronic diseases (Belgium), 4. University of Toronto (Canada), 5. Ghana Health Service (Ghana), 6. University of Amsterdam (Netherlands)

Background and objectives: School feeding programmes (SFPs) have real potential to improve educational achievement, promote child health, and human capital development. Ghana has been implementing its SFP for over a decade, albeit with several systemic and operational challenges.

The study sought to assess food safety and hygiene practices among school caterers and food vendors (FVs) in selected public sector basic schools participating in the Ghana's SFP.

Methods: The sample included 660 FVs and 129 caterers from 169 schools implementing the SFP in six districts of the Greater Accra Region. Direct observation was used to locate FVs within the immediate premises of the schools. Interviews were conducted with FVs, and caterers involved in the SFP. Descriptive analyses were performed to generate absolute and relative frequencies. Notes from field observations and perspectives of food service providers are presented narratively.

Results: More than three-quarters of caterers and over half (59%) of FVs reported receiving certification from a regulatory body to provide or sell food respectively. Around half of caterers had been medically certified to sell food, versus more than three-quarters of FVs, although only 16% provided evidence of this. Only 42% of FVs and 15% of caterers reported having ever received training on food safety and hygiene. One in four FVs declared having never been visited by food inspectors from regulatory bodies to assess food hygiene and safety. One in two FVs reported lack of water (54%) and soap (61%) for handwashing at vending sites. Almost half (48%) of FV and a quarter (23%) of caterers did not adequately protect food from environmental contaminants; uncovered organic waste was found near 71% of FV sites. About a third (32%) of FVs did not have adequate sanitary conditions at their vending sites.

Conclusions: Environmental sanitation, food safety and hygiene practices, and regulatory compliance were suboptimal. Most FVs and caterers did not receive adequate training on food safety and hygiene issues. Current food safety legislation needs to be implemented more rigorously through a combination of different actions.

Micronutrient adequacy of women's diets in rural Kenya and Uganda: Implications for culturally acceptable food-based recommendations and improving access to nutrient-dense foods in local food environments

Lydia O'Meara[1,2], Kendra Byrd[1,2], Joweria Nambooze[3,4], Julia de Bruyn[5], Anna Rea[6,2], Anne Williams[7], Andrea L.S. Bulungu[8], Paula Dominguez-Salas[1,9], Kate Wellard[1], Elaine Ferguson[8]

1. University of Greenwich (UK), 2. WorldFish (Malaysia), 3. Africa Innovations Institute (Uganda), 4. Kyambogo University (Uganda), 5. University of Melbourne (Australia), 6. CQUniversity (Australia), 7. University of Otago (New Zealand), 8. London School of Hygiene and Tropical Medicine (UK), 9. International Livestock Research Institute (Kenya)

Background and objectives: Micronutrient deficiencies in women-of-reproductive-age (WRA) persist in sub-Saharan Africa (SSA). Our aim was to (i) estimate the percentage of rural WRA at risk of micronutrient inadequacies in select districts from two SSA countries, (ii) propose food based-recommendations to improve micronutrient adequacy, (iii) identify 'problem' micronutrients that would be difficult to address based on current dietary patterns, and (iv) explore nutrient-dense food sources in local food environments.

Methods: Dietary intake was assessed for lactating women from Western Kenya (n=286; 2014) and pregnant, lactating, and non-pregnant/non-lactating (NPNL) women from Eastern Uganda (n=201; 2018) using 24-hour dietary recalls and weighed food records, respectively. The percentage at risk of inadequate micronutrient intakes was estimated with the Intake Modelling Assessment Planning Program. Linear programming analysis using Optifood software was used to identify problem micronutrients and formulate food-based recommendations.

Results: Micronutrient adequacy was poor. In Uganda, over 87% pregnant, 66% lactating and 53% NPNL women were at risk of inadequate intakes for 7,6, and 5 micronutrients respectively, with inadequate intakes of iron, calcium, and vitamin A greater than 79% for each group. In Kenya, over 83% lactating women were at risk of inadequate intakes for 6 micronutrients, with inadequate intakes of iron, calcium, riboflavin, and folate over 95%. Modelling indicates that increased consumption of whole

grains, legumes, dark green leafy vegetables, orange-fleshed sweet potatoes, milk, and small dried fish could help close the micronutrient gap. In Uganda, most of these foods were procured from informal street vendors or weekly markets.

Conclusions: Preliminary findings indicate that food-based approaches to improve micronutrient intake through increased consumption of local, culturally acceptable foods holds promise in rural WRA, yet research is needed on the seasonal availability and affordability of these nutrient-dense foods. Results also highlight the importance of supporting the informal food environment for ensuring access to a nutrient-dense diet during food environment transitions in rural, low-resource settings. However, a realistic food-based approach (based on current dietary patterns) alone will not eliminate the percentage of WRA at risk of inadequate intakes of iron and calcium, indicating that holistic interventions including biofortification and behaviour change may be required.

Keywordss: micronutrient adequacy, food-based recommendations, food environments, women of reproductive age, linear programming

Conflict of Interest Disclosure: Lydia O'Meara is a PhD candidate supported by Research England through the Food and Nutrition Security Initiative (FaNSI) at the University of Greenwich. This funding does not in any way influence the research findings.

OAB(T6)5-1

Trend in the prevalence of anemia in childbearing Mexican women during the last fifteen years

Teresa Shamah-Levy[1], Fabiola Mejía-Rodríguez[1], Armando García-Guerra[1], Vanessa De la Cruz-Góngora[1]

1. National Institute of Public Health (Mexico)

Background and Objective: Globally, around 30% of women and children under the age of 5 are affected by the anemia, nearly 800 million people. In the last two decades, anemia has improved by only 0.2 to 0.3 percentage points per year. In Mexico, recent data on anemia in women of childbearing age, emphasize that is a public health problem. The purpose of this study is to analyze the trend in the prevalence of anemia during the last 12 years (from 2006 to 2018-19) in non-pregnant Mexican women aged 20 to 49 years old.

Methodology: Data from three National Health and Nutrition Surveys [ENSANUT] were used. ENSANUT is a nationally representative probabilistic multistage stratified cluster sampling survey (representative at regional (four regions) and urban/rural level), and it has a methodological design that allows comparisons between them. All the series of ENSANUT (2006, 2012 and 2018-19) were conducted from September to May. The capillary hemoglobin (Hb) sample size for Ensanut 2006 was 20,480 women (rate response (RR)=80%); for Ensanut 2012 of 18,118 women (RR=78%), and for Ensanut 2018-19 of 8,283 women (RR=85%). Capillary drop Hb was measured in the portable photometer Hemocue 201+ and anemia categories were defined as anemia: Hb <12.0 g/dL, moderate anemia: Hb 8.0-10.9 g/dL and severe anemia: Hb <8.0 g/dL, adjusted for altitude. Logistic regression models were used to identify the change over time of survey in the odds for anemia categories.

Results: The prevalence of anemia in Mexican women adjusting by residence area (urban/rural), wellbeing condition index, and education level decreased by half in 6 years (ENSANUT 2006, from 26.6% to 13.3% in 2012, p<0.001). From 2012 to 2018-19, it has a significant increase of 5.8 percentage points [pp (19.1%?)], p<0.05. In the 2018-19 survey the highest prevalence of joint moderate and severe anemia (10.0%) was found compared to 2012 (3.9%, p<0.001) and 2006 (5.8%, p<0.05).

Conclusion: Anemia affects 1 in 5 Mexican women aged 20 to 49 in 2018-19. Nevertheless, caution in the interpretation of this increase is recommended since we cannot discard measurement errors in Hb capillary determination. COVID-19 increased malnutrition and maternal mortality limiting progress towards meeting the 2025 World Health Assembly nutrition targets. Therefore, identifying the main causes of anemia in this population is necessary to opportunely intervene either through diet, food fortified, or micronutrient supplementation in those women at higher risk.

Prospective associations of overall and specific carbohydrate intake with anxiety status evolution: findings from the NutriNet-Santé population-based cohort

Junko Kose[1,2,3,4,5,6], Pauline Duquenne[1,2,3,4,5,6], Margaux Robert[1,2,3,4,5,6], Charlotte Debras[1,2,3,4,5,6], Pilar Galan[1,2,3,4,5,6], Sandrine Péneau[1,2,3,4,5,6], Serge Hercberg[1,2,3,4,5,6], Mathilde Touvier[1,2,3,4,5,6], Valentina A. Andreeva[1,2,3,4,5,6]

1. Nutritional Epidemiology Research Group (EREN) (France), 2. Sorbonne Paris Nord University (France), 3. National Institute of Health and Medical Research U1153 (INSERM U1153) (France), 4. National Institute for Agriculture, Food and Environment U1125 (INRAe U1125) (France), 5. National Conservatory of Arts and Crafts (CNAM) (France), 6. Epidemiology and Statistics Research Center (CRESS) (France)

Background and objectives: There is cross-sectional evidence for the association between carbohydrate intake and anxiety, however, population-based prospective data are lacking. Thus, we investigated the prospective associations between carbohydrate intake from various sources and anxiety status evolution in a large sample recruited from the general population.

Methods: We included 15,602 participants (73.8% female; mean age=53.8 ± 13.1 years) of the French NutriNet-Santé web-cohort who completed the trait subscale of Spielberger's State-Trait Anxiety Inventory (STAI-T) once at baseline (2013-2016) and once at follow-up (2020). High general anxiety was defined

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

as STAI-T score >40 points. Participants were categorized in four groups according to baseline and follow-up anxiety status: 1) None= absence of high general anxiety at any time point; 2) Transient= high general anxiety only at baseline; 3) Onset at follow-up= high general anxiety only at follow-up; 4) Persistent= high general anxiety at baseline and follow-up. Carbohydrate intake was estimated from ≧2 self-administered 24-h dietary records completed within a 2.5-year window around the baseline STAI-T assessment date. Polytomous logistic regression models assessed the associations between quartiles of overall and specific carbohydrate intake and anxiety status.

Results: The mean follow-up time was 5.4 ± 0.9 years; carbohydrate intake was estimated from 8.7 ± 3.8 24-h dietary records. The fully-adjusted models revealed that sweetened beverage intake was associated with higher odds for Transient anxiety (OR_{Q4vsQ1}=1.11 (95% CI 1.02-1.21); p_{trend}<0.02). Intakes of complex carbohydrates (OR_{Q4vsQ1}=1.12 (95% CI 1.01-1.25); p_{trend}<0.02) and starch (OR_{Q4vsQ1}=1.13 (95% CI 1.02-1.25); p_{trend}<0.01) were associated with higher odds for anxiety Onset at follow-up. Percentage of energy from carbohydrates (OR_{Q4vsQ1}=1.11 (95% CI 1.03-1.19); p_{trend}<0.02), intakes of total carbohydrates (OR_{Q4vsQ1}=1.10 (95% CI 1.03-1.18); p_{trend}<0.02), complex carbohydrates (OR_{Q4vsQ1}=1.09 (95% CI 1.02-1.17); p_{trend}<0.01), and starch (OR_{Q4vsQ1}=1.09 (95% CI 1.01-1.16); p_{trend}<0.02) were linked to higher odds for Persistent anxiety. Finally, 100% fruit juice intake showed lower odds for Persistent anxiety (OR_{Q4vsQ1}=0.87 (95% CI 0.81-0.94); p_{trend}<0.01).

Conclusions: This large, prospective study found significant associations between different measures of dietary carbohydrate intake and anxiety status evolution among French adults. The findings could guide dietary interventions aimed at anxiety prevention and management.

1. University of São Paulo (Brazil)

Background and objectives: The evaluation of the performance of simple dietary metrics on comorbidities with high occurrence in the population may contribute to policymakers. We assessed two dietary scores based on the Nova (a name, not an acronym) food classification system, with weight gain.

Methods: The NutriNet-Brasil study (2020-2022) is a web-based prospective cohort. More than 100,000 volunteers have already subscribed to the digital platform of the study. This analysis included 9,544 participants aged 18 years or older who self-reported their height at baseline and body weight at baseline and 14-month follow-up (mean follow-up: 15.2 months). The outcome was excessive body mass index (BMI) gain (≧ 5%) from baseline to follow-up. Dietary intake was assessed at baseline using 3 non-consecutive web-based self-administered short questionnaires. The food items were based on the Nova classification according to the degree of processing. The Nova score of healthy foods (Nova-HF) is comprised of 33 whole nutrient-dense foods (fruits, vegetables, whole grains, legumes, and nuts), and 23 food items are included in the Nova score of ultra-processed foods (Nova-UPF). Each component of both dietary scores was assigned from 0 to 1 point, where 1 point indicated consumption on the day before. The associations were estimated by multivariable logistic regression models adjusted for possible confounders.

Results: The increment of one standard deviation in the Nova-HF score decreased the odds of excessive BMI gain (OR 0.83; 95%CI 0.83 to 0.93), for Nova-UPF score the odds increased (OR 1.20; 95%CI 1.14; 1.27). Compared to those in the first quintile, the high consumers of Nova-HF (fifth quintile) had lower odds of excessive BMI gain (OR 0.69; 95%CI 0.58; 0.83), while participants in the fifth quintile of Nova-UPF score had higher odds of the outcome (OR 1.66; 95%CI: 1.39; 1.99). For both dietary scores, we observed a linear trend (p<0.001).

Conclusions: The higher consumption of whole nutrient-dense foods may prevent BMI gain, and our findings supported the body of evidence concerning the role of UPF in the obesity epidemic in Brazil. Also, we used simple dietary metrics which are easy to communicate to policymakers.

Dominant and modifiable factors associated with Abdominal obesity among older adults in West Africa

Akinkunmi Paul Okekunle[1,2], Osahon Jeffery Asowata[1], Onoja Matthew Akpa[1], Adekunle Fakunle[1], Fred Stephen Sarfo[3], Kolawole Wahab[4], Reginald Obiako[5], Rufus Akinyemi[1], Bruce Ovbiagele[6], Mayowa Owolabi[1]

1. University of Ibadan (Nigeria), 2. Seoul National University (Korea), 3. Kwame Nkrumah University of Science and Technology (Ghana), 4. University of Ilorin Teaching Hospital (Nigeria), 5. Ahmadu Bello University (Nigeria), 6. University of California San-Francisco (USA)

Background and objectives: Abdominal obesity (AO) is a public health problem that threatens the wellbeing and quality of life of populations, but information on the burden and factors associated with AO among older adults, particularly among Africans, is quite limited. This study aimed at characterizing dominant and modifiable factors associated with AO among older adults from West Africa.

Methods: We selected 1852 stroke-free older adults (≧60 years) recruited in the Stroke Investigation Research and Educational Network (SIREN) study from fifteen communities in Ghana and Nigeria. In-person interviews were used to obtain information on sociodemographic and lifestyle factors. Waist circumference (WC) in centimetres was measured by trained personnel at the midpoint between the lower margin of the last palpable rib and the top of the iliac crest using a flexible tape rule in a standing position without compression on the skin using the World Health Organization (WHO) guidelines. Abdominal obesity was defined as WC >102 cm (for males) and >88cm (for females) according to the WHO cut-off points. Odds ratio (OR) and 95% confidence interval (CI) of the association of AO with sociodemographic and lifestyle factors were estimated using logistic regression at a two-sided P<0.05.

Results: The mean age was 69.5±7.9 years, 48.9% were females, and 54.7% reside in urban areas. Mean WC was 90.6±15.7cm, and 54.7% were abdominally obese. Prevalence of AO was higher among females (79.9%) than males (30.2%). In the overall population, Females (OR: 13.0; CI: 10.0, 16.9), high-income earners - >$100/month (OR: 1.3; CI: 1.1, 1.7) and those with at least a formal education (OR: 1.5; 95% CI: 1.1,1.9) presented higher odds of AO. A similar trend was observed among males, but current alcohol use (OR: 2.1; CI: 1.1, 3.9) was associated with higher odds of AO among females only. Country-specific analyses revealed higher odds among Ghanaians (females – OR: 19.5; CI: 11.1, 34.2, urban dwellers – OR: 1.9; CI: 1.1, 3.3, high-income earners – OR: 1.7; CI: 1.1, 2.6 and having formal education – OR: 1.7; CI: 1.0, 2.9), but similar odds among Nigerians (females – OR: 11.8; CI: 8.7, 15.9, and having formal education – OR: 1.5; CI: 1.1, 2.0).

Conclusion: The burden of abdominal obesity is high, particularly among females in this sample of older adults from West Africa. Context-specific interventions targeted at these obesity-related factors are likely to be promising in reducing the burden of obesity among older adults in West Africa.

Beliefs about the consequences of living with obesity: findings from a national survey

Eleni Spyreli[1], Laura McGowan[1], Emily Heery[3], Aoibhin Kelly[1], Helen Croker[4], Cale Lawlor[2], Roisin O'Neill[1], Mirjam Heinen[2]

1. Queen's University Belfast (UK), 2. University College Dublin (Ireland), 3. Houses of the Oireachtas Service (Ireland), 4. University College London (UK)

Background and objectives: Adopting healthier lifestyle behaviours can help individuals manage their body weight. Modifying these behaviours can be influenced by beliefs about the consequences of maintaining a healthy weight. Gaining greater understanding of the interpersonal variability in obesity-related beliefs may enhance the design of effective weight management initiatives. This study aimed to capture the beliefs about the outcomes of living with obesity in a nationally representative sample and to explore their relationship with individuals' characteristics and health perceptions.

Methods: A cross-sectional telephone survey was conducted with 1000 adults from the Republic of Ireland and Northern Ireland. Interviews captured: demographics; information on self-rated health and wellbeing; and beliefs regarding the health-, social- and cost-related consequences of obesity (through the Obesity Beliefs Scale). Univariable analysis drew comparisons in obesity beliefs between participants with healthy weight and those with overweight, with obesity and those who did not report their weight. Multiple linear regression tested the association between obesity-related beliefs with demographics, self-perceived health, diet and physical activity, and self-perceived capacity of improving own health behaviours.

Results: Respondents with overweight and those who did not disclose their weight status supported to a lesser extent that living with excess weight has a negative impact on individuals' social life (P < 0.001). Additionally, respondents with obesity and those with no information on weight showed greater endorsement of the cost related to maintaining a healthy weight. The regression model showed that obesity-related beliefs were significantly predicted by weight status (P < 0.001), self-rated health (P = 0.013), dietary quality (P = 0.004) and perceived ease of improving diet (P = 0.001) and physical activity levels (P = 0.001).

Conclusions: The present analysis highlights that adults living with excess weight and those who struggle to improve their dietary habits display a lower endorsement of the negative outcomes of living with obesity. Our findings come in agreement with the limited existing literature and have implications for the design of effective future obesity interventions.

Association between sugar and starch intakes and type 2 diabetes risk in middle-aged adults: the Japan Public Health Center-based Prospective Study

Rieko Kanehara[1,2], Atsushi Goto[1,3], Norie Sawada[1], Tetsuya Mizoue[4], Mitsuhiko Noda[5], Azumi Hida[2], Motoki Iwasaki[1,2], Shoichiro Tsugane[1,6]

1. National Cancer Center Institute for Cancer Control (Japan), 2. Tokyo University of Agriculture (Japan), 3. Yokohama City University (Japan), 4. National Center for Global Health and Medicine (Japan), 5. International University of Health and Welfare (Japan), 6. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Background and objectives: Evidence on the relationship between sugar (mono- and disaccharides) and starch intake and type 2 diabetes (T2D) risk in Asian populations is currently insufficient. We aimed to investigate the association between sugar or starch intake and T2D risk in middle-aged Japanese adults.

Methods: Participants comprised 27,797 men and 36,880 women aged 45-75 y with no history of diabetes and critical illness before the survey in 1995-1999 in the Japan Public Health Center-based Prospective Study. We calculated the intake (% energy/d) of sugar (total sugar, total fructose, and each sugar subtype) and starch using a validated 147-item food frequency questionnaire. T2D onset during the five-year follow-up period was defined by self-report, the validity of which was confirmed. ORs and their 95% CIs, adjusted for age, area, family history of diabetes, history of hypertension, occupation, physical activity, smoking and alcohol status, dietary habits, number of birth (for women), and body mass index were estimated using multiple logistic regression with categorical and cubic spline models. The lowest quartile and its median intake were used as reference.

Results: During the follow-up, 690 men and 500 women were identified as new T2D cases. In women, the quartiles of total sugar or total fructose intakes were not significantly associated with T2D risk; however, the spline curves showed an increased T2D risk at extremely high intake levels (ORs [95% CI]: 1.88 [1.07-3.31] at 30% energy/d for total sugar and 1.87 [1.10-3.16] at 14% energy/d for total fructose). Starch intake was positively associated with T2D risk among women in the categorical and spline models (ORs [95% CI] from the spline model: 1.55 [1.13-2.12] at 50% energy/d). In men, sugar and starch intakes were not associated with T2D risk.

Conclusions: In this large-scale population-based cohort study, starch intake was associated with an increased T2D risk in women. For extremely high intake of total sugar or total fructose, a possible increased risk cannot be disregarded in women.

Nitrites and nitrates from food additives and natural sources and type-2 diabetes risk: results from the NutriNet-Santé cohort

Bernard Srour[1,2], Eloi Chazelas[1,2], Charlotte Debras[1,2], Nathalie Druesno-Pecollo[1,2], Younes Esseddik[1], Cédric Agaesse[1], Fabien Szabo de Edelenyi[1], Laury Sellem[1,2], Mélanie Deschasaux-Tanguy[1,2], Mathilde Touvier[1,2]

1. Sorbonne Paris Nord University, INSERM U1153, INRAE U1125, CNAM, Nutritional Epidemiology Research Team (EREN), Epidemiology and Statistics Research Center – University of Paris (CRESS) (France), 2. Nutrition And Cancer Research Network (NACRe Network), France, www.inrae.fr/nacre (France)

Background and objectives: Nitrates and nitrites occur naturally in water and soil and are commonly ingested from drinking water and dietary sources. They are also used as food additives in processed meats to increase shelf life and to avoid bacterial growth. The epidemiological literature about the relationship between nitrate and nitrite intakes and the risk of type-2 diabetes (T2D) is very scarce. We aimed to study these associations in a large population based prospective cohort study, distinguishing between natural (food, water) and food additive sources.

Methods: Overall, 104,168 adults from the French NutriNet-Santé cohort study (2009-ongoing, median follow-up time 6.7 years, 78.5% female, mean age [SD]=42.3 [14.5]) were included. Associations between intakes of nitrites and nitrates (evaluated using repeated 24h dietary records, linked to a comprehensive food composition database and accounting for details of commercial names/brands of industrial products) and risk of T2D (ascertained with a multi-source strategy) were assessed using cause-specific multivariable Cox proportional hazard models adjusted for known risk factors (sociodemographic, anthropometric, lifestyle, medical history, and nutritional factors).

Results: During follow-up, 969 incident T2D cases were ascertained. Total nitrites and nitrites from natural sources were both positively associated with higher T2D risk ($HR_{tertile\ 3\ vs.1}$=1.29 (95% CI 1.06-1.56), P_{trend}=0.0043, and 1.27 (95% CI 1.05-1.54), P_{trend}=0.01, respectively). Participants with higher intakes of nitrites from food additives (i.e. above the sex-specific median), and specifically those having higher intakes of sodium nitrite (e250) had a higher T2D risk compared with those who were not exposed to food additive nitrites (HR=1.58 (95% CI 1.28-1.94), P_{trend}<0.001, and 1.59 (95% CI 1.30-1.96), P_{trend}<0.001), respectively). There was no evidence for an association between nitrates of any source and T2D risk (all P_{trend}>0.4).

Conclusions: In this large prospective cohort, higher intakes of dietary nitrites (from both natural sources and food additives) were associated with higher T2D risk. These results need confirmation in other large-scale prospective studies; however, they provide additional evidence in the context of current discussions about updating regulations on the use of nitrites as food additives.

Institut d'Investigació Pere Virgili, Hospital Universitari Sant Joan de Reus, Reus (Spain)

Background and objectives: We aim to assess whether long-term adherence to Mediterranean diet (MedDiet) and leisure-time physical activity (LTPA) were linked to less initiation of chronic, non-cardiovascular medications.

Methods: We assessed the relationship between the cumulative average of MedDiet adherence and LTPA and initiation of the 20 most prescribed chronic, non-cardiovascular medication families in older adults (PREvención con DIeta MEDiterránea trial; sample size: 5,940 [anxiolytics]-6,989 [folate supplements]). Associations per each one-point increase in the MedDiet adherence score and 100 metabolic equivalents of task-minute/day (METs-min/day) of LTPA were studied by multivariable Cox regressions (multiple comparisons: False Discovery Rate 5%). We explored non-linear exposure-outcome associations if models using restricted cubic splines fitted the data better than linear terms. We finally evaluated whether MedDiet and LTPA were synergistically linked to lower drug initiation by applying likelihood ratio tests to Cox models with/without the interaction product-term "MedDiet adherence x LTPA".

Results: One-point increases in MedDiet adherence were related to less initiation of: antidepressants (hazard ratio [HR] 0.72, [95% confidence interval 0.67-0.77]), anxiolytics (HR 0.74 [0.69-0.80]), antipsychotics (HR 0.76 [0.64-0.89]), anticonvulsants (HR 0.77 [0.69-0.85]), antiparkinsonian drugs (HR 0.72 [0.59-0.89]), anti-dementia drugs (HR 0.78 [0.67-0.92]), benign prostatic hyperplasia drugs (HR 0.82 [0.75-0.90]), anti-gout drugs (HR 0.80 [0.71-0.89]), hypothyroidism medication (HR 0.77 [0.67-0.89]), laxatives (HR 0.85 [0.75-0.97]), bronchodilators (HR 0.82 [0.74-0.90]), corticosteroids (HR 0.80 [0.73-0.88]), opioids (HR 0.86 [0.77-0.95]), folate supplements (HR 0.69 [0.56-0.85]), iron supplements (HR 0.76 [0.67-0.87]), calcium supplements (HR 0.88 [0.81-0.96]), vitamin D supplements (HR 0.90 [0.83-0.98]), bisphosphonates (HR 0.85 [0.77-0.93]), and cartilage medications (HR 0.86 [0.77-0.95]). LTPA was linearly associated (per +100 METs-min/day) with less initiation of anticonvulsants (HR 0.83 [0.73-0.94]), benign prostatic hyperplasia drugs (HR 0.91 [0.85-0.98]) and bronchodilators (HR 0.80 [0.72-0.89]), and non-linearly linked to less initiation of antidepressants, anxiolytics, anti-dementia drugs, anti-gout drugs, hypothyroidism medication, laxatives, corticosteroids, opioids, iron, calcium and vitamin D supplements, and cartilage medications (minimum risk: 150-400 METs-min/day). Both combined were synergistically related to less initiation of anxiolytics, hypothyroidism medication, iron and calcium supplements (*p*-interaction: 0.037, 0.017, 0.039, and 0.036, respectively).

Conclusions: Sustained adherence to MedDiet and LTPA were linked to lower initiation of non-cardiovascular chronic medications.

Measuring diet-related consumer behaviours in low- and middle-income countries to advance food systems research: An evidence and gap map of indicators

Ilse de Jager[1], Megan R. Harrison[2], Rosil Hesen[1], Betül Uyar[1], Melissa Vargas[2], Ramani Wijesinha-Bettoni[2], Ana Islas Ramos[2], Fatima Hachem[2], Eric O. Verger[3], Inge D. Brouwer[1]

1. Wageningen University and Research (Netherlands), 2. Food and Agriculture Organization of the United Nations (Italy), 3. French National Research Institute for Sustainable Development (France)

Background and objectives: Coherent and robust interventions along the food system are essential to deliver healthy diets in a more sustainable manner. The design, monitoring and evaluation of such interventions have been impeded by the lack of validated and commonly used indicators to assess consumer behaviours. This study describes indicators that have been used to measure consumer behaviours regarding the acquisition, preparation, storage, eating and disposal of food in LMICs through an Evidence and Gap Map (EGM).

Methods: A systematic search for articles in English, Spanish, and French published in peer-reviewed journals was conducted in April 2021. Eligible studies were those undertaken in LMICs, published between 2011 - 2021, and included (semi-)quantitative indicators on diet-related consumer practices. Of 5935 articles identified, 260 met inclusion criteria. For data extraction and EGM visualization, EPPI-Reviewer software was used. A descriptive analysis identified the frequency of indicator use across different domains and subdomains of consumer behaviours.

Results: A preliminary analysis of 172 articles identified 765 indicators, including 744 unique, non-repeating indicators. Most were used to measure food acquisition (n=325), followed by preparation (n=134), disposal (n=108), eating (n=101) and storage (n=93). Within the acquisition domain, indicators for types of food acquired (n=160), type of vendor (n=100) and food expenditure (n=60) predominated. Hygiene practices (n=110) and of types of foods prepared (n=64) were most frequently measured within the preparation domain, and location of consumption (n=35) and types of foods eaten (n=26) in the eating domain. Indicators used in the food disposal and storage domains were largely used to measure disposal methods (n=77), use of leftovers (n=49), types of foods stored (n=77), storage methods (n=70), and storage hygiene practices (n=58).

Conclusions: There is a severe lack of concordance on measures for assessing diet-related consumer behaviours outside of food intake. The multiplicity of indicators used in research limits the ability to target and monitor strategies to improve diet behaviours, and to identify the aspects of food systems that contribute to them. Evaluating the validity and uptake of these indicators is a critical next step to support indicator selection for planning, monitoring and evaluating interventions in LMICs.

Dietary patterns and brain atrophy in Japanese community-dwellers: the NILS-LSA project

Shu Zhang[1], Giovanni Sala[1], Kaori Kinoshita[1], Yukiko Nishita[1], Rei Otsuka[1]

1. National Center for Geriatrics and Gerontology (Japan)

Background and objectives: Previous empirical evidence has suggested that diet plays a meaningful role in influencing brain atrophy among Western populations. This study evaluates the relationship between dietary habits and brain atrophy in a community-dwelling Japanese population.

Methods: A prospective cohort study with two years of follow-up was conducted as part of the National Institute for Longevity Sciences-Longitudinal Study of Aging (NILS-LSA) project. A total of 1636 participants (815 men and 821 women, aged 40–89 years) were included. Food consumption (g/day) data were collected with a 3-day dietary record. Volumes of gray matter (GM) and white matter (WM) were estimated by T1-weighted brain magnetic resonance imaging and FreeSurfer software. The GM ratio (GMR) and WM ratio were calculated as the percentages of total intracranial volume, respectively. Hierarchical Clustering on Principal Components (HCPC) was performed on dimensions derived by Multiple Factor Analysis (MFA) to obtain dietary patterns (clusters). Associations between dietary patterns and GM and WM atrophy were estimated by multivariable-adjusted General Linear Model. All analyses were performed by sex.

Results: Three different dietary patterns (DP) were identified for men and women, respectively. In women, DP 1 was characteristic of the Western diet (e.g., a high intake of alcohol, red meat and processed meat, coffee, butter, and breads), DP 2 was characterized by a high intake of dairy products, fruits, and coarse grains, and DP 3 represented the traditional Japanese diet. Compared to DP 1, women adherence to DPs 2 and 3 were negatively associated with the annual rate of change of GM volume [(GMR at baseline - GMR at follow-up)/ GMR at baseline/follow-up years×100%] (%) [multivariable-adjusted β (95% CI) = -1.8E-1 (-3.3E-1 to -2.1E-2) and -1.9E-1 (-3.6E-1 to -3.0E-2), *P*-value = 0.026 and 0.020, respectively]. By contrast, no association between dietary patterns and brain atrophy was observed in men.

Conclusions: Western diet was associated with more annual GM atrophy in women. Diet does not appear to be a major risk factor for brain atrophy in men. Perhaps the inhibitory effect of diet on male brain atrophy is offset by the effects of other risk factors.

Intakes of major food groups in China and the UK: results from 100,000 adults participating in the China Kadoorie Biobank and the UK Biobank

Keren Papier[1], Maria G Kakkoura[1], Yu Guo[2], Anika Knuppel[3], Canqing Yu[4], Jun Lv[4], Liming Li[4], Zhengming Chen[1], Huaidong Du[1], Tim J Key[1]

1. University of Oxford (UK), 2. Chinese Academy of Medical Sciences (China), 3. University College London (UK), 4. Peking University (China)

Background and objectives: Different populations may exhibit differences in dietary intakes, which may result in differences in diet-disease associations. We compared intakes of major food groups overall, by sex, and by socio-economic status (SES) between participants of the China Kadoorie Biobank (CKB) study and the UK Biobank (UKB) study. We also investigated associations of dietary intake with BMI in each cohort.

Methods: Data were from approximately 25,000 CKB participants who completed a validated interviewer-administered computer-based questionnaire (2013-2014) and around 74,000 UKB participants who completed ≧3 web-based 24-hour dietary assessments (2009-2012). Intakes of 12 major food groups and five beverages were harmonized and compared between the cohorts overall, by sex and by SES (income and education). Multivariable-adjusted linear regression was used to examine the associations between dietary intakes and body mass index (BMI).

Results: CKB participants reported consuming substantially higher quantities of soy products and rice and much lower intakes of milk, yoghurt, other dairy products, all beverages, fresh fruit, poultry, and other staple foods (other than rice and wheat) compared to UKB participants. CKB participants also reported consuming more eggs and fresh vegetables, and less fish and wheat compared to UKB participants. Red meat intake was similar in both cohorts. In both cohorts, intakes of fish, other staple foods, fresh vegetables, fresh fruit and pure fruit/vegetable juice were higher with higher SES. In CKB higher SES was also associated with higher intakes of red meat, poultry, dairy products, and fizzy and other soft drinks, whereas in UKB opposite results were observed. We observed some similarities in the associations of foods and beverages with BMI among the cohorts (e.g. adults who consumed more red meat, poultry, and soft drinks but less milk had a higher BMI), but most of the associations between diet and BMI were dissimilar between the cohorts (e.g. in CKB participants with higher fish consumption had a higher BMI, while the opposite was observed in UKB).

Conclusions: These findings support the hypothesis that possible differences in observed diet-disease associations observed between China and the UK might relate to differences in dietary intakes and their correlates between these populations.

Is ultra-processed food and drink consumption associated with environmental impact and all-cause mortality in the EPIC-NL cohort?

Reina Elisabeth Vellinga[1,2], Iris van den Boomgaard[2], Jolanda MA Boer[1], Yvonne T van der Schouw[3], Marjolein C Harbers[3], W M Monique Verschuren[1,3], Pieter van 't Veer[2], Elisabeth HM Temme[1,2], Sander Biesbroek[2]

1. National Institute for Public Health and the Environment (RIVM) (Netherlands), 2. Division of Human Nutrition and Health, Wageningen University (Netherlands), 3. Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht University (Netherlands)

Background and objectives: A body of evidence shows the adverse health effects of high ultra-processed food (UPF) and ultra-processed drink (UPD) consumption. However, the associated environmental impact of UPF and UPD consumption remains unclear. We aimed to assess the association of UPF, UPD or their combined consumption (UFPD) with environmental impacts and all-cause mortality in Dutch adults.

Methods: Habitual diets were assessed in 1993-1997 among 38,261 participants of the EPIC-NL cohort using a validated FFQ. Food consumption was categorized according to the degree of food processing using the NOVA classification and summed in grams per day for each category. Pearson correlation coefficients were used to assess the correlation of consumption according to NOVA in g per 1000 kcal with environmental impact indicators: greenhouse gas emissions, blue water use, land use, acidification and fresh- and marine water eutrophication. Vital status was obtained through linkage with registries. Follow-up lasted to December, 31, 2014. Cox proportional hazard models were used to assess the association of intake of UPFD, UPF and UPD with all-cause mortality.

Results: UPFD, UPF and UPD consumption in g per 1000 kcal were weakly correlated with environmental impact indicators, with correlation coefficients ranging from -0.21 (p = <.0001) for UPF and greenhouse gas emissions, to 0.11 (p = <.0001) for UPD and freshwater eutrophication. With every 100 g per 1000 kcal increase of UPFD or UPD, UPFD and UPD consumption were associated with higher all-cause mortality risks ((HR:1.10 (95%CI:1.06-1.13) and (HR:1.10 95%CI:1.06-1.13), respectively. UPF consumption was not associated with all-cause mortality (HR: 1.05 (95%CI:0.94-1.17).

Conclusions: Higher consumption of UPFD, and UPD only, was associated with an increased all-cause mortality risk, however, not with higher environmental impacts. Therefore,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

diets with lower UPFD consumption may benefit public health. Benefits for planetary health were not observed in a comparison with diets high in UPFD consumption.

Keywords: ultra-processed foods, NOVA classification, all-cause mortality, environmental impact, planetary health

The impacts of partial replacement of red and processed meat with legumes or cereals on the dietary protein and amino acid intake: A modelling study in the Finnish adult population

Meri Simojoki[1], Niina E Kaartinen[1], Heli Tapanainen[1], Mirkka Maukonen[1], Hanna Sirén[1], Tiina Sirkjärvi[1], Liisa M Valsta[1], Essi Päivärinta[2], Anne-Maria Pajari[2], Satu Männistö[1]

1. Finnish Institute for Health and Welfare (Finland), 2. University of Helsinki (Finland)

Background and objectives: Plant-based diets are considered healthy and environmentally sustainable. However, plant-based diets may reduce protein and amino acid intakes. This modelling study aimed to assess the impacts of partial replacement of red and processed meat with legumes or cereals on the protein and amino acid intakes in the Finnish adult population.

Methods: We used the cross-sectional data of the National FinDiet 2017 Survey in which the diet was assessed by two non-consecutive 24-hour recalls from 875 women and 780 men aged 18-74 years. Mean daily intakes of protein (E%) and indispensable amino acids (mg/kg body weight) were calculated for the current (reference) diet and four replacement scenarios. In the scenarios, the amount of red and processed meat exceeding 70 g/day (Finnish dietary recommendation), or 30 g/day (EAT-Lancet dietary recommendation) was replaced with the same amounts of either legumes or cereals while keeping the consumption of other foods unchanged. Differences to the reference diet were evaluated by gender and age groups (18-64, 65-74 years) based on non-overlapping 95% confidence intervals.

Results: In 18-64-year-old men, the cereal scenario decreased protein intake, the legume scenario decreased methionine+cysteine intake, and both legume and cereal scenarios decreased histidine and lysine intakes at the 70-g replacement level. At the 30-g level, legume and cereal scenarios decreased the intakes of protein and almost all indispensable amino acids. In 65-74-year-old men, the replacement scenarios introduced no differences at the 70-g level. At the 30-g level, the results were similar as in 18-64-year-old men, except that the legume scenario decreased only the intakes of histidine, lysine, and methionine+cysteine. In women, the replacement scenarios introduced no differences in the protein and indispensable amino acid intakes at the 70-g level. At the 30-g level, the cereal scenario decreased protein intake, the legume scenario decreased methionine+cysteine intake, and both scenarios decreased histidine and lysine intakes, but only in 18-64-year-old women.

Conclusions: Partial replacement of red and processed meat with legumes or cereals might slightly decrease the protein and amino acid intake in dependence of gender and age. The amino acid adequacy in the different population groups warrants further study.

Keywords: amino acids, cereals, legumes, protein, red and processed meat

Qualitative evaluation of a large-scale multi-sectoral nutrition intervention in Nepal: Suaahara's effect on nutrition governance

Bishow Raman Neupane[1], Pooja Pandey Rana[1], Kenda Cunningham[2], Sarah Eissler, Kabita Sah, Shraddha Manandhar[3]

1. Helen Keller International Nepal/ Suaahara II (Nepal), 2. Helen Keller International USA and London School of Hygiene and Tropical Medicine, UK (UK), 3. Huddersfield University, (UK)

Background and objectives: Despite making significant progress over the last two decades in reducing stunting in Nepal, both maternal and child undernutrition in the first 1000-days of life remain major public health burdens. Only few multi-sectoral programs have been implemented at scale, with fewer rigorously evaluated. Suaahara, a USAID-funded initiative since 2011 covers nearly 60% of the country's communities to reduce undernutrition, and along with nutrition-sensitive activities, it supports local, provincial, and national governments to execute Nepal's Multi-sectoral Nutrition Plan (MSNP) for increased allocation and utilization of government funds towards nutrition-specific and nutrition-sensitive interventions. This qualitative study primarily evaluates those interventions' effect at multiple policy levels in improving multisector coordination for MSNP implementation.

Methods: This impact evaluation used a mixed method approach. Fifty-eight relevant nutrition planning and policy documents at all levels were reviewed, and Suaahara monitoring data were analyzed. Semi-structured in-depth interviews, group interviews, and focus group discussions were held with purposively sampled stakeholders including coordinators, representatives, and committee members of key government offices and non-governmental actors. Four intervention districts and four control districts, and two municipalities within each district were selected to represent three geographic zones and five working provinces. Interviews and discussions were

recorded from December 2021 to February 2022 with participants' permission, and transcribed. Qualitative data were analyzed using a deductive and inductive thematic analysis approach. Three authors established inter-rater reliability before coding all transcripts. Nepal Health Research Council granted ethical approval.

Results: Preliminary results suggest Suaahara has helped to improve vertical coordination at policy level to implement and prioritize MSNP activities, driving budget demand. However, limited formal mechanisms to facilitate such coordination, imped fully effective vertical coordination. Budget allocation for and implementation of multisectoral activities in intervention districts were higher than the control districts. Results available in April 2022 will expand upon effectiveness of multilateral coordination, and its effect on improving nutrition governance at each level and effective government budget allocation and utilization.

Conclusions: These will be based on the results to guide future large-scale multi-sectoral programming efforts in Nepal for improving women and child nutrition governance.

Development, validation and item reduction of a food literacy questionnaire (IFLQ-19) with Australian adult

Courtney Thompson[1], Rebecca Byrne[1], Jean Adams[2], Helen Anna Vidgen[1]

1. Queensland University of Technology (Australia), 2. University of Cambridge (UK)

Background and objectives: Food literacy is theorised to improve diet quality, nutrition behaviours, social connectedness and food security. The definition and conceptualisation by Vidgen & Gallegos, consisting of 11 theoretical components within the four domains of planning and managing, selecting, preparing and eating, is currently the most highly cited framework. However, a valid and reliable questionnaire is needed to comprehensively measure this conceptualisation. Therefore, this study draws on existing item pools to develop a comprehensive food literacy questionnaire using item response theory.

Methods: 500 Australian adults were recruited in Study 1 to refine a food literacy item pool using principal component analysis (PCA) and item response theory (IRT) which involved detail item analysis on targeting, responsiveness, validity and reliability. Another 500 participants were recruited in Study 2 to replicate item analysis on validity and reliability on the refined item pool, and 250 of these participants re-completed the food literacy questionnaire to determine its test-retest reliability.

Results: The PCA saw the 171-item pool reduced to 100-items across 19 statistical components of food literacy. After the thresholds of 26 items were combined, responses to the food literacy questionnaire had ordered thresholds (targeting), acceptable item locations (<-0.01 to +1.53) and appropriateness of the measurement model (n=92% expected responses) (responsiveness), met outfit mean-squares MSQ (0.48 - 1.42) (validity) and had high person, item separation (>0.99) and test-retest (ICC 2,1 0.55-0.88) scores (reliability).

Conclusions: We developed a 100-item food literacy questionnaire, the IFLQ-19 to comprehensively address the Vidgen & Gallegos conceptualisation with good targeting, responsiveness, reliability and validity in a diverse sample of Australian adults.

Nitrites and nitrates from food additives and natural sources and risks of hypertension and cardiovascular disease: results from the NutriNet-Santé cohort

Bernard Srour[1,2], Eloi Chazelas[1,2], Charlotte Debras[1,2], Nathalie Druesne-Pecollo[1,2], Younes Esseddik[1], Cédric Agaesse[1], Fabien Szabo de Edelenyi[1], Laury Sellem[1,2], Mélanie Deschasaux-Tanguy[1,2], Mathilde Touvier[S]

1. Sorbonne Paris Nord University, INSERM U1153, INRAE U1125, CNAM, Nutritional Epidemiology Research Team (EREN), Epidemiology and Statistics Research Center – University of Paris (CRESS) (France), 2. Nutrition And Cancer Research Network (NACRe Network), www.inrae.fr/nacre (France)

Background and objectives: Nitrates and nitrites are widely used as food additives, mainly in processed meats. They also occur naturally in water and soil. Some studies suggest a potential beneficial role of dietary nitrites and nitrates in lowering blood pressure. However, to our knowledge, associations between intakes of nitrites and nitrates considering both natural sources and food additives, and risks of hypertension and cardiovascular disease have not been investigated so far. We aimed to study these associations in a large population based prospective cohort study with detailed dietary data.

Methods: Overall, 104,817 adults from the French NutriNet-Santé cohort study (median follow-up time 6.7 years, 78.5% female, mean age[SD]=42.3[14.5]) were included. Intakes of nitrites and nitrates were evaluated using repeated 24h dietary records, linked to a comprehensive food composition database and accounting for details of commercial names/brands of industrial products. Associations with risks of hypertension and

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

cardiovascular disease were assessed using cause-specific multivariable Cox proportional hazard models.

Results: During follow-up, 3810 incident cases of hypertension were ascertained, and 2075 cases of cardiovascular diseases were diagnosed (among which 1004 cerebrovascular diseases and 1079 coronary heart diseases). Participants with higher intakes of nitrites from food additives (i.e. above the sex-specific median), and specifically those having higher intakes of sodium nitrite (e250) had a higher hypertension risk compared with those who were not exposed to food additive nitrites (HR=1.19 (95% CI 1.08-1.31), P_{trend}=0.002, and 1.19 (95% CI 1.07-1.31), P=0.002, P<0.001), respectively). There was no evidence for an association between nitrites or nitrates from natural sources with hypertension risk (all P-values>0.3). There was no evidence for associations between dietary nitrites or nitrates (whatever their source) and risks of cardiovascular, cerebrovascular or coronary heart diseases (all P-values>0.2).

Conclusions: In this large cohort study, higher intakes of nitrites from food additives were associated with higher risk of hypertension. These results do not support any protective association between dietary nitrites or nitrates and cardiovascular outcomes. Though they need to be confirmed in other large-scale prospective studies, these findings provide novel insights in the context of current discussions about updating regulations on the use of nitrites as food additives.

OAB(T6)7-2

Carbohydrate and fibre intake, short-chain fatty acid genetic modifiers, and colorectal cancer risk: a prospective analysis in the UK Biobank

Cody Z Watling[1], Rebecca K Kelly[1], Neil Murphy[2], Marc Gunter[2], Carmen Piernas[1], Kathryn Bradbury[3], Anika Knuppel[1,5], Julie A Schmidt[1,4], Timothy J Key[1], Aurora Perez-Cornago[1]

1. University of Oxford (UK), 2. International Agency for Research on Cancer (France), 3. University of Auckland (New Zealand), 4. Aarhus University (Denmark), 5. University College London (UK)

Background and objectives: Wholegrains and fibre intake may decrease the risk of colorectal cancer, although evidence for intake of specific types and sources of carbohydrates and fibre remains unclear. Moreover, cellular and animal studies have shown that short-chain fatty acid (SCFA) production in the gut, which increases with wholegrains and fibre intake, may be associated with lower colorectal cancer risk. However, it is unknown if genetic factors that influence SCFA production may modify the association of carbohydrate quality with colorectal cancer risk. Our objective was to assess the associations of intakes of carbohydrate and fibre sources with risk of colorectal cancer and further explore if associations were modified by a SCFA polygenetic score.

Methods: Using a minimum of 2 (maximum of five) 24-hour dietary assessments, we assessed carbohydrate types and sources and fibre intake in 114,271 UK Biobank participants who were free from cancer at dietary assessments. We used existing data to create a polygenic score to categorise participants as high or low intestinal SCFA producers, namely butyrate and propionate. Multivariable Cox proportional hazards models were used to determine the associations between intakes of carbohydrate types and fibre sources, and colorectal cancer incidence.

Results: During a median follow-up of 8.8 years, 1,129 participants were diagnosed with colorectal cancer. In multivariable adjusted models, intakes of non-free sugar and fibre from wholegrains were inversely associated with colorectal cancer risk (hazard ratio (HR) per 5% energy/day: 0.92, 95% confidence interval (CI):0.87-0.98; HR per 5g/day: 0.90, 0.82-1.00, respectively). There was evidence of heterogeneity by host genetically predicted SCFA production; participants with high genetically predicted propionate production and consuming higher wholegrains and fibre from wholegrains had a lower risk of colorectal cancer (per 5% energy/day:0.89, 0.80-0.99; and per 5g/day:0.84, 0.70-1.00, respectively) whereas no association was observed for participants with low genetically predicted production of propionate (*p-heterogeneity*=0.028 and 0.045, respectively).

Conclusion: This study suggests that colorectal cancer risk varies by intake of different types and sources of carbohydrates; higher consumption of non-free sugars and fibre from wholegrains may lower the risk of colorectal cancer, and these associations may be modified by host genetically predicted SCFA production.

Association between adherence to the EAT-Lancet diet and risk of cancer and cardiovascular outcomes in the prospective NutriNet-Santé cohort.

Florine Berthy[1], Joséphine Brunin[1], Benjamin Allès[1], Mathilde Touvier[1], Serge Hercberg[1,2], Pilar Galan[1], Philippe Pointereau[3], Denis Lairon[4], Julia Baudry[1], Emmanuelle Kesse-Guyot[1]

1. Sorbonne Paris Nord University, INSERM, INRAE, CNAM, Epidemiology and Statistics Research Center University of Paris (France), 2. Département de Santé Publique, Hôpital Avicenne (France), 3. Solagro (France), 4. Aix Marseille University, INSERM, INRAE, C2VN (France)

Background and objective: The EAT-Lancet commission proposed, in 2019, a planetary, healthy and universal dietary. This highly vegetalized diet could prevent approximately 10 million premature deaths per year worldwide while feeding the entire world population within planetary boundaries. However, this diet has been rarely studied in relation to various health outcomes. We aimed to prospectively estimate the association between the EAT-Lancet diet and cancer and cardiovascular risk.

Methods: The study was conducted among participants of the NutriNet-Santé cohort (2009 – 2021). The endpoints were the incident outcomes (cancer and cardiovascular diseases (CVD) and mortality from this diseases), combined and separately. Adherence to the EAT-Lancet diet was estimated using the EAT-Lancet Diet Index (ELD-I) modelled as quintiles (Q). Multivariable Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (95% CIs), adjusted for potential confounders and moderators.

Results: A total of 62,382 subjects were included, 2,475 cases of cancer and 786 cases of cardiovascular occurred during a median follow-up of 8.1 years. The sample was 76% female, the mean age at inclusion was 51 years (Standard Deviation (SD) = 10.2 years). The ELD-I ranged from -162 to 332 points with a mean score of 45.4 points (SD = 25.6 points). In multivariable models, no significant association between the EAT-Lancet diet and the risk of cancer and CVD combined, and separately, was observed. Alcohol consumption was an effect modifier of the association. A significant association was observed among low drinkers (HR $_{Q5\ vs\ Q1}$=0.86, (95% CI 0.73, 1.02), p-trend=0.02). A higher ELD-I was significantly associated with a lower risk of overall cancer only among females, (HR $_{Q5\ vs\ Q1}$=0.89, (95% CI 0.75, 1.05), p-trend=0.03). Both associations were largely attenuated by body mass index.

Conclusion: Contrary to our hypothesis, our results documented significant associations between adherence to the EAT-Lancet diet and incidence of overall chronic diseases and cancer only in some subgroups (females and low drinkers), and no association with CVD. Some important dietary factors, such as processed meat or excessive energy intake, not considered in the EAT-Lancet diet, should be considered in the future.

Toulouse University, Toxalim (Research Centre in Food Toxicology), INRAE, ENVT, INP-Purpan, UPS (France)

Background and objectives: Acrylamide is found in many industrial compounds, in tobacco smoking and, also, is formed when carbohydrate-rich foods and coffee are prepared at high temperatures and low moisture. Acrylamide has been classified as a probable human carcinogen in 1994 but epidemiological evidence on the detrimental effect of dietary acrylamide is limited. This prospective cohort study aimed to investigate the associations between dietary acrylamide and the risk of breast cancer, accounting for menopausal and hormone receptors status, in the large NutriNet-Santé prospective cohort with detailed dietary data.

Methods: Overall, 80,597 women from the French NutriNet-Santé cohort study (2009-ongoing) were included (mean [SD] age at baseline: 40.8 [14] years), and followed during 8.8 (SD 2.3) years. Acrylamide intake was evaluated using repeated 24h dietary records, linked to a comprehensive food composition database. Associations between acrylamide intake and breast cancer risk (overall, premenopausal and post-menopausal) were assessed by Cox hazard models adjusted for known risk factors.

Results: The mean (SD) dietary acrylamide intake was 30.1 (21.9) µg/d (main contributors: coffee, potato fries and chips, pastries and cakes, and bread). During follow-up, 1016 first incident breast cancer cases were diagnosed (431 premenopausal, 585 postmenopausal), of which 86% were characterized as estrogen-receptor positive (ER^+). A borderline significant positive association was observed between dietary acrylamide exposure and breast cancer risk overall (HR $_{Q4\ vs\ Q1}$= 1.21 [95% CI: 1.00-1.47]) and a positive association was observed with premenopausal cancer (HR $_{Q4\ vs\ Q1}$= 1.40 [95% CI: 1.04-1.88]). Interestingly, restricted cubic spline analyses suggested evidence for non-linearity of these associations, with higher HR for intermediate (Q2) and high (Q4) exposures. Receptor-specific analyses revealed a positive association between dietary acrylamide and ER^+ breast cancer overall (HR$_{Q4\ vs\ Q1}$= 1.31 [95% CI: 1.01-1.71]) and in premenopausal women (HR $_{Q4\ vs\ Q1}$= 1.66 [95% CI: 1.07-2.56]). Acrylamide intake was not associated with post-menopausal breast cancer.

Conclusions: Results from this large prospective cohort study suggest the potential role of dietary acrylamide in breast

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

cancer etiology, especially in premenopausal women. These data provide new insights that should encourage further mitigation strategies to reduce the content of acrylamide in industrial and home-made foods.

Toxalim (Research Centre in Food Toxicology), Université de Toulouse, INRAE, ENVT, INP-Purpan, UPS, Toulouse, (France), 6. INSERM UMR-S 1124, Université de Paris, Paris, (France)

Background and objectives: Food additive emulsifiers are widely used in ultra-processed foods (UPF) to improve texture and lengthen shelf-life. Experimental studies suggested potential detrimental effects of emulsifiers on gut microbiota and inflammation, and carcinogenesis initiation and/or progression. However, to our knowledge, no epidemiological study investigated the associations between food additive emulsifier intakes and overall or location-specific cancer risks. Thus, this study aimed to investigate these associations in a large population-based prospective cohort study with detailed quantitative data on emulsifier exposure.

Methods: This study included 102,485 French adults without prevalent cancer from the NutriNet-Santé prospective cohort study (mean age [SD] 42.1y [14.5], 78.8% female, 2009-2021). Food additive emulsifier intakes were estimated using repeated 24-h dietary records linked to comprehensive, brand-specific food composition databases on food additives. Multi-adjusted proportional hazard Cox models were used to characterise associations with overall, breast, prostate, and colorectal cancer risks.

Results: 3,511 incident cancer cases were diagnosed during follow-up (including 1,026 breast, 431 prostate, and 279 colorectal cancers). Intakes of sodium citrate (E331, HR=1.12, 95%CI=1.02-1.23, p-trend=0.009), xanthan gum (E415, $HR_{high\ vs.\ low}$=1.11, 95%CI=1.02-1.21, p-trend=0.02), and mono- and diglycerides of fatty acids (E471, HR=1.17, 95%CI=1.06-1.28, p-trend=0.001 and total: E471, E472, E472a-b-c-e, HR=1.11, 95%CI=1.02-1.22, p-trend=0.02) were associated with increased overall cancer risk. In addition, higher intakes of E331 (p-trend=0.046), sodium stearoyl-2-lactylate (E481, p-trend=0.01), and total lactylates (E481-482, p-trend=0.01) were associated with increased overall breast cancer risk. Higher intakes of carrageenan (E407, p-trend=0.04), E415 (p-trend=0.02), and triphosphates (E451, p-trend=0.03) were associated with increased post-menopausal breast cancer risk. Moreover, both overall and post-menopausal breast cancer risks were directly associated with higher intakes of total celluloses (E460-468, p-trend=0.03 and 0.03, respectively), carob bean gum (E410, p-trend=0.01 and 0.001), E471 (p-trend=0.006 and 0.03).

Conclusions: In this large prospective cohort study, we observed direct associations between cancer risks and exposures to seven individual and three groups of dietary emulsifiers, which are commonly used in thousands of brands of UPF worldwide. These results provide the first epidemiological insights into the role of food additive emulsifiers on cancer risk, and need to be confirmed in further epidemiological and experimental research.

Estimated impact of modest dietary salt reduction on the burden of stomach cancer and population healthy life years in Vietnam, 2019 – 2030

Leopold Ndemnge Aminde[1], Linda J Cobiac[1], Dung T Phung[2], Hai N Phung[1], J. Lennert Veerman[1]

1. Griffith University (Australia), 2. University of Queensland (Australia)

Background and objectives: Excess salt intake is a recognized risk factor for stomach cancer. However, the longterm impact of high salt intake on stomach cancer in Vietnam is not known. The aim of this study was to quantify the future burden of stomach cancer that could be avoided from population-wide salt reduction in Vietnam.

Methods: A dynamic epidemiological multistate lifetable model was developed to quantify the impacts of achieving the 2018 Vietnam National Health Program (8g/day by 2025 and 7g/day by 2030) and the WHO (5g/day) salt reduction targets. All

adults aged 25 years and above (total of 61 million people, 48.4% men) alive in 2019 were simulated over their remaining lifetime. Data on salt consumption were obtained from the Vietnam 2015 WHO STEPS survey and baseline stomach cancer data were from the Global Burden of Disease 2019 study. Health outcomes were estimated over 6-year (by 2025), 11-year (by 2030) and lifetime horizons. We conducted one-way and probabilistic sensitivity analyses.

Results: Achieving the 2025 and 2030 national salt targets could result in 3,500 (95% uncertainty interval [UI]: 1,590; 5,840) and 7,700 (95%UI: 3,880; 12,685) fewer incident cases of stomach cancer respectively and avert 1,950 (95% UI: 810; 3,410) and 5,200 (95%UI: 2,430; 8,855) stomach cancer deaths, respectively. Achieving the WHO target by 2030 could prevent 9,280 (95%UI: 5,430; 13,960) new cases of, and 6,300 (95%UI: 3,510; 9,741) deaths from stomach cancer. Over the lifespan, this translated to 359,000 (8g/day), 416,000 (7g/day) and 505,000 (5g/day) health-adjusted life years gained respectively. Compared to base case theoretical minimum risk exposure level (TMREL) of 3g of sodium, health outcomes increased by up to 35% and could reduce by 65% for TMRELs of 1g and 5g of sodium, respectively.

Conclusions: A substantial burden of stomach cancer could be avoided, with gains in healthy life years if national and WHO salt targets were attained. Our findings provide impetus for policy makers in Vietnam to intensify salt reduction strategies to combat stomach cancer.

Keywords: Sodium, gastric cancer, incidence, mortality, burden of disease

OAB(T6)8-1

Nudge-Based Interventions in Promoting Healthy Eating Behavior in Brick-and-Mortar Stores

Sayuri Goryoda[1,2,3], Shinji Akimoto[1], Tatsuya Ono[1], Chiaki Sakoi[1], Ken Yamada[1]

1. Tsuji Culinary Institute (Japan), 2. Yamagata University (Japan), 3. Dokkyo Medical University (Japan)

Background and objectives: Developing effortless and sustainable healthy eating behavior is a public health challenge. This study examined the effect of nudge-based interventions, using fast thinking (point-of-purchase advertising) and slow thinking (remembering target products), on consumers' eating behavior in stores.

Methods: Advertisements to promote the appeal of nutritious products were placed in a store in Tokyo, and a month-long intervention was conducted regarding the customers' impressions of the advertisements and their attributes after purchasing the products. Based on the difference-in-differences design, we compared the nudged products with products that had the same sales slope over the last three months to exclude the effect of trend. We calculated the monthly ratio of the sales of target products to estimate the period of the intervention effect.We also examined the background details (age, sex, income, education, marital status, and medical history) of the customers who received the interventions in our analysis from January 2019 to February 2022. (Total number of customers: 41,000)

Results: Sales increased by 68% despite the bad weather and the insufficient replenishment of products. The effects of health advertising and remembering target products-based interventions were maintained for up to eight months before external factors. Additionally, the effect of the interventions may differ based on the background of the customer.

Conclusions: The significant increase in sales could not be attributed to advertising alone it is possible that remembering target products, which requires slow thinking, helped retain the products in the consumers' memory, making the advertisement self-serving and promoted continuous purchases. Furthermore, it is necessary to consider the customers' background for effective intervention.

Socio-economic and Agricultural related Factors Associated with Stunting of Under Five-year Children: Findings from Panel Surveys in Mountains, Dry Zone and Delta Regions of Rural Myanmar (2016-17)

Min Kyaw Htet[1,2], Tran Thanh Do[3], Thet Wah[4], Thant Zin[4], Myat Pan Hmone[2], Shahreen Raihana[2], Elizabeth Kirkwood[2], Lwin Mar Hlaing[5], Michael John Dibley[2]

1. South East Asian Ministers of Education Organization-Regional Center for Food and Nutrition (SEAMEO-RECFON), Pusat Kajian Gizi Regional Universitas Indonesia (Indonesia), 2. The University of Sydney, School of Public Health, Australia (Australia), 3. National Institute of Nutrition (Viet Nam), 4. NutriFirst, Yangon (Myanmar), 5. National Nutrition Centre, Ministry of Health and Sports, Nay Pyi Taw (Myanmar)

Background and objectives: The first Myanmar DHS survey (2015-2016) showed the prevalence of stunting among under-five children was 29.2%. Nonetheless, there is limited information about the factors contributing to stunting in these children. Our objective was to investigate food security, dietary diversity, agriculture, and socio-demographic status of rural households in three agro-ecological zones in Myanmar and the association with under-five child stunting.

Methods: We conducted two repeated cross-sectional surveys among the same rural households in mountainous, central dry and delta areas of Myanmar in early 2016 and revisited in late 2017 to capture seasonal variations. We

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

purposely selected two adjacent townships in each location, randomly selected 20 villages from each township using proportion to population size sampling, and selected 30 households in each village, giving 1200 households with under 5-year children per region. In each survey, we collected data digitally using CommCare, including household characteristics, land access, agricultural access, women's autonomy, dietary diversity, food security and anthropometry data. We constructed village-level scores for agricultural diversity and transportation. We applied univariate and multilevel mixed-effects Poisson regression analysis to identify the risk factors for child stunting.

Results: We recruited 3,231 households and assessed 2049 under-five children in the first-round survey in early 2016. In the second survey in late 2017, we revisited 90.4% of the same households (N=2,921 and assessed 1696 under-five children. Stunting increased from 40.4 % to 42.0 %. The percentage of food secure households and women achieving minimum dietary diversity increased in the second survey. The adjusted Poisson models showed a consistent association of children's age and short maternal stature with child stunting. In Chin, significant contributors to stunting were village-level transportation, crop consumption, and agriculture diversity scores. While in Magway, it was wealth status, land ownership, the number of household members and in Ayeyarwady, women's autonomy and indicators related to hygiene and sanitation.

Conclusions: Children in rural Myanmar are vulnerable to undernutrition. While area-specific factors were associated with stunting, maternal short stature and child age were consistent determinants of stunting across the three regions assessed. Addressing intergenerational malnutrition requires a multi-sectoral local approach, including transportation improvements.

Sustainable Diets Across Socio-Demographic Groups of the Finnish Populations – the case Just-Food

Liisa M. Valsta[2], Heli Tapanainen[2], Merja Saarinen[3], Jani Salminen[4], Laura Sares-Jäske[2], Maria Vaalavuo[2], Xavier Irz[1]

1. University of helsinki (Finland), 2. Finnish Institute for Health and Welfare (Finland), 3. Natural Resources Institute Finland (Finland), 4. Finnish Environmental Institute (Finland)

Background and objectives: Dietary changes form a central pillar of the necessary sustainability transformation of food systems. However, identifying sustainable diets is difficult because of the near-infinite number of food combinations, the possibility of trade-offs among sustainability dimensions and the need for diets to remain socio-culturally acceptable. The research aims at characterizing healthy diets as similar to existing diets as possible but with a reduced climate footprint, considering different socio-demographic groups of the Finnish adult population.

Methods: A diet optimization model minimizes departure from the average diet of a group subject to detailed nutritional constraints, palatability constraints and a maximum level of greenhouse gas emissions (GHGE). The model is calibrated to different socio-demographic groups based on gender, education and income. Three scenarios are simulated by varying the maximum permissible carbon footprint of the diet (1- no restriction; 2- 33% reduction from observed level; 3- 50% reduction). The calibration relies on Finnish dietary intake data (FinDiet2017), the food composition database Fineli, and Life Cycle Assessment (LCA) coefficients. A sensitivity analysis investigates the robustness of the results.

Results: Across all socio-demographic groups, there are large synergies between improvements in nutritional quality of the diets and reductions in climate impact. The primary mechanism for reducing GHGE is the substitution of cereals and potatoes for meat. The secondary mechanism is the intra-category substitution of foods, such as poultry for beef. The simulated climate-friendly diets are best described as flexitarian. Moving towards climate-friendly diets would not create major nutritional problems related to protein and fatty acid quality but iron could be an issue for pre-menopausal women. We find that the initial socio-economic gradient in the climate impact of diets is small and that there are only minor differences in patterns of adjustments to climate-friendly diets across socio-demographic groups. The results are robust to the replacement of LCA coefficients by environmental coefficients derived from the Input-Output model ENVIMAT.

Conclusions: A one third reduction in the climate impact of diets is achievable through moderate adjustments in dietary behaviours. The required adjustments are similar across socio-demographic groups, so that a population-wide policy to promote behavioural change would be appropriate.

Keywords: diet, optimization, sustainability, climate change, environmental impact

Estimating the Costs of Alternative Large-Scale Food Fortification Programs in Burkina Faso: A MINIMOD Tool for Informing Policy Discussion

Stephen A. Vosti[1], Michael Jarvis[1], Quentin Johnson[2], Herve Somda[3], Jerome Some[3], Ann Tarini[2], Reina Engle-Stone[1], Katherine Adams[1]

1. UC Davis (USA), 2. Consultant (Canada), 3. Consultant (Burkina Faso)

Background and objectives: Decisions regarding the types and amounts of micronutrients to include in large-scale food fortification (LSFF) programs should consider costs. The Micronutrient Intervention Modeling (MINIMOD) cost tool estimates the costs of alternative LSFF programs, with focus on the cost burdens to different stakeholders.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: An existing activity-based cost model was adapted to the context of Burkina Faso. Key national characteristics (e.g., population size), and information on existing and hypothetical LSFF programs (e.g., adherence to standards) establish the model's platform. Private- and public-sector costs (as relevant) of designing, implementing, and managing LSFF are included. The model contains a micronutrient premix cost calculator that allows users to examine the costs of alternative premixes. LSFF-vehicle-specific consumption patterns (e.g., g/day of fortifiable wheat flour consumed, based on household survey data) link program costs to program reach. A ten-year planning time horizon is adopted.

Results: The premix required to fortify wheat flour with iron and folic acid (60 mg/kg of ferrous fumarate, 2.5 mg/kg of folic acid – the current standard) is estimated to cost ~$2.11 (2020 USD) per MT of fortified flour, with overall 10-year program costs of ~$2.4m; ~25% faced by industry (e.g., internal quality control), ~23% by government (e.g., external monitoring), and 52% by stakeholders who would cover premix costs (generally assumed to be industry, with some pass-through to consumers). Cost per person and cost per person reached are ~$0.010 and ~$0.023, respectively. Including zinc in this premix (95 mg/kg of zinc oxide) would increase the cost per MT of fortified flour to ~$3.02, total 10-year program costs to ~$3.3m, and cost per person and per person reached to ~$0.014 and ~$0.032, respectively. The premix's share of costs increased to ~54%.

Conclusions: The levels and compositions of the costs should be considered when designing and managing LSFF, in part because different stakeholder groups, including consumers, will be called upon to pay them. Premix costs are one main cost driver; increasing the number and/or amounts of fortificants will increase overall program costs and shift the burden of costs among stakeholders, perhaps putting upward pressure on the price of a baguette in Ouagadougou (currently 150 XOF, or USD 0.25).

Evaluating 10 years of large-scale multi-sectoral nutrition interventions in Nepal: Suaahara's effect on undernutrition, household behaviors and the health system

Ramesh Prasad Adhikari[2], Pooja Pandey[2], Edward A Frongillo[3], Shalini Suresh[6], Deependra Thapa[6], Debendra Adhikari[5], Kenda Cunningham[1,4]

1. Helen Keller International, USA (USA), 2. Helen Keller International, Nepal (Nepal), 3. University of South Carolina (USA), 4. London School of Hygiene and Tropical Medicine (UK), 5. US Agency for International Development (Nepal), 6. Independent Consultant (Nepal)

Background and objectives: Despite significant progress over the last two decades of reducing stunting in Nepal, both maternal and child undernutrition remain major public health burdens. Both health and non-health interventions are important for reducing malnutrition, but few multi-sectoral programs have been implemented at scale and even fewer rigorously evaluated. Suaahara, a USAID-funded initiative since 2011, gradually scaled up to cover nearly 60% of the communities in the country with an aim to reduce undernutrition among mothers and children in the first 1000-days of life. Suaahara works on nutrition, health, family planning, agriculture, governance, and gender and social equality. Many of the interventions target social and behavior change, but Suaahara also has other interventions such as health system strengthening and support to the government at local and national levels to implement Nepal's Multi-sectoral Nutrition Plan. The primary objective of this study is to evaluate the effect of the multiple interventions within this program on reducing maternal and child undernutrition; improving household health, nutrition, and WASH behaviors; and improving knowledge and skills among health workers.

Methods: This impact evaluation uses a quasi-experimental, repeated cross-sectional design. The multi-stage clustering, as of the endline, includes: first, districts (8: 4 program and 4 control); second, Village Development Committees (VDC) (5 per district); third, wards (3 wards per VDC), and fourth, households with children under 2 years of age (17 per ward). The first three stages use the probability-proportional-to-size method and households are selected via simple random sampling. The baseline data collection was done in June-September 2012 and the endline data collection is planned for June-September 2022. Data collection is done by an externally hired survey firm overseen by an external principal investigator and research team. Ethics approval has been granted by the Nepal Health Research Council.

Results: Results will be available in the fall including primary impact estimates for child stunting, wasting, underweight, and anemia; maternal underweight and anemia; and maternal and child dietary diversity. From the health systems evaluation, key indicators will include knowledge and skills related to maternal and child nutrition and health among both Female Community Health Volunteers and health facility workers.

Conclusions: The results will be used to guide future large-scale multi-sectoral programming efforts in Nepal and similar contexts.

Less meat in the shopping basket: a randomised controlled trial in a virtual supermarket

Elisabeth Temme[1], Reina Vellinga[1], Michelle Eykelenboom[2,3], Margreet Olthof[2,3], Ingrid Steenhuis[2,3], Rob de Jonge[1]

1. National Institute for Public Health and the Environment (RIVM) (Netherlands), 2. Department of Health Sciences, Faculty of Science, Vrije Universiteit Amsterdam (Netherlands), 3. Amsterdam Public Health research institute, Amsterdam, the Netherlands (Netherlands)

Background and objectives: Reduced meat consumption benefits human and planetary health. Significant health and environmental gains that could be achieved through fiscal measures targeting meat and combinations of food policy instruments. The aim of the study is to examine the effect of higher meat prices, an information nudge and a combination of both measures on meat purchases in a three-dimensional virtual supermarket.

Methods: A parallel designed randomised controlled trial with four conditions was performed. Participants (older than 18 years) were randomly assigned to the control condition or one of the experimental conditions: a 30% price increase for meat ('Price condition'), an information nudge about the environmental impact of meat production and consumers' role in that regard ('Information nudge condition') or a combination of both ('Combination condition'). Participants were asked to shop for their household for one week. The primary outcome was the difference in the total amount of meat purchased in grams per household per week.

Results: Between 22 June 2020 and 28 August 2020, participants were recruited and randomly assigned to the control and experimental conditions. The final sample included 533 participants. In the 'Combination condition', -386 g (95% CI: -579, -193) meat was purchased compared with the 'Control condition'. Compared to the 'Control condition' less meat was purchased in the 'Price condition' (-144 g (95%CI: -331, 43)), although not statistically significant, whereas a similar amount of meat was purchased in the 'Information nudge condition' (1 g (95%CI: -188, 189)).

Conclusion: Achieving the most pronounced effects on reduced meat purchases will require a policy mixture of pricing and informational nudging. Less meat is purchased in a virtual supermarket after raising the meat price by 30% combined with an information nudge. The results can be used to design evidence-based policy measures to reduce meat purchases.

Estimated health benefits, costs, and cost-effectiveness of eliminating industrial trans-fatty acids in Kenya

Matti Marklund[1,2,3], Leopold Aminde[4], Mary Njeri Wanjau[4], Laura Cobb[5], J Lennert Veerman[4], Jason H Y Wu[1]

1. The George Institute for Global Health, UNSW Sydney (Australia), 2. Johns Hopkins University (USA), 3. Uppsala University (Sweden), 4. Griffith University (Australia), 5. Resolve To Save Lives (USA)

Background and objectives: There is an urgent need to eliminate industrial trans fatty acids (iTFA) from the food supply globally to reduce the burden of ischemic heart disease (IHD). Many countries in Africa have not yet implemented policies targeting the elimination of TFA. The objective of the current study was to model the potential health gains and cost-effectiveness of a mandatory limit of iTFA in Kenyan foods.

Methods: Markov cohort models were used to estimate the effect on IHD burden and cost-effectiveness of a mandatory iTFA-limit (≦2% of all fats) in the Kenyan food supply. Intake of trans-fatty acids was assessed using the 2019 Global Burden of Disease Study. The IHD burden attributable to iTFA was calculated by comparing the current level of iTFA intake to counterfactual settings with complete elimination of iTFA intake. Policy implementation costs (including government spending for legislation and monitoring, and industry spending for product reformulation), avoided IHD events and deaths, health-adjusted life years (HALYs) gained, and healthcare costs saved were estimated over 10 years and lifetime of the Kenyan population. Cost-effectiveness was assessed by calculation of incremental cost-effectiveness ratios (ICER) using net policy cost and HALYs gained (both with 3% discount rate).

Results: Over the first 10 years, complete elimination of iTFA intake was estimated to prevent 1,622 (95% uncertainty interval [UI]: 1,495; 1,752) IHD deaths and 14,852 (95% UI: 13,664; 16,061) IHD events, and to save 98 million USD (95% UI: 90; 106). The corresponding estimates over the population lifetime were 39,812 (95% UI: 36,420; 43,262), 94,362 (95% UI: 86,080; 102,831), and 437 (401; 475). Policy implementation costs (government plus industry) were estimated to ~7.4 million USD over the first 10 years, and ~8.3 million USD over the population lifetime. The intervention was estimated to be cost-saving regardless of the time horizon and findings were robust across several sensitivity analyses.

Conclusions: Findings support legislating a mandatory limit of iTFAs as a cost-saving strategy to avert substantial numbers of IHD events and deaths in Kenya.

OAB(T6)8-8

Acute effects of running on ghrelin concentrations, subjective appetite and energy intake in physically active and inactive young men

Ge Li[1], Yusei Tataka[1], Kayoko Kamemoto[1], Haixin Wen[1], Kazuna Yamanaka[1], Chihiro Nagayama[1], Masashi Miyashita[1]

1. Waseda University (Japan)

Background and objectives: It has been suggested that habitual physical activity influences homeostatic appetite control by increasing the drive to eat through greater energy expenditure. The limited available evidence also showed that physically active individuals compensated for the energy deficits induced by exercise quicker (i.e., energy intake) than physically inactive individuals. However, the acute effects of exercise on acylated ghrelin (an active form of ghrelin and is the only known appetite-stimulating hormone) and des-acylated ghrelin (an inactive but major form of ghrelin) in humans with different physical activity statuses remain unclear. Thus, the present study aimed to compare acylated-ghrelin, des-acylated ghrelin, subjective appetite and energy intake between physically active and inactive men in response to a single bout of exercise.

Methods: Thirty-three, healthy active (n = 15, aged 23 ± 2, mean ± standard deviation) and inactive (n = 18, aged 22 ± 2) men underwent a 2-h laboratory-based experiment. The objective measurement of physical activity using accelerometers was used to allocate participants to the active and inactive groups. All participants performed a 30-min running at 70% of maximum oxygen uptake (0930-1000 h) and then rested until 1130 h. Blood samples and subjective appetite were collected in the fasted state (0930 h), at 1000, 1015 (subjective appetite only), 1030, 1100 and 1130 h. Then, all participants were asked to record their food and beverage intake for the remaining day.

Results: There were no differences in fasting, or the patterns of the plasma concentrations of acylated ghrelin, des-acylated ghrelin or subjective appetite between groups (all for $p > 0.05$). Both total energy intake (active versus inactive groups, 8679 ± 2668 and 7305 ± 3217 kJ, respectively) and relative energy intake (postexercise energy intake corrected for the energy cost of exercise: active versus inactive groups, 7256 ± 2668 and 5976 ± 3171 kJ, respectively) were similar between groups (all for $p > 0.05$).

Conclusions: These findings imply that inactive but otherwise healthy young men may have similar homeostatic appetite control to those of healthy active young men in response to acute energy deficits induced by running.

Keywords: appetite-related hormone, subjective appetite, energy intake, physical activity status

Influence of the particle size of encapsulated chia oil on the bioaccessibility during in vitro gastrointestinal digestion

Rudy Carolina Alvarez[1], Begoña Gimenez[2], Alan Mackie[3], Amelia Torcello-Gomez[3], Alejandra Quintriqueo[2], Felipe Oyarzún-Ampuero[1], Paz Robert[1]

1. Universidad de Chile (Chile), 2. Universidad de Santiago de Chile (Chile), 3. University of Leeds (UK)

Background and objectives: Among vegetable oils, chia oil has been gaining interest in recent years due to its high linolenic acid content (ALA, 18: 3 w3). The aim of this work was to study the influence of particle size of encapsulated purified chia oil (PCO) on encapsulation efficiency and PCO release during in vitro digestion.

Methods: PCO micro- and nano-sized particles with sodium alginate (SA) as an encapsulating agent (ME-PCO-SA and NE-PCO-SA) were designed by micro and nano spray-drying, respectively, applying a central composite plus star point design.

Results: NE-PCO-SA showed smaller particle size and higher encapsulation efficiency of PCO than ME-PCO-SA (0.16 mm vs. 3.5 mm; 98.1% vs. 92.0%). Emulsions (NE-PCO, ME-PCO) and particles (NE-PCO-SA and ME-PCO-SA) were subjected to in vitro gastrointestinal digestion. ME-PCO and NE-PCO showed sustained oil release throughout the three phases of digestion (oral, gastric and intestinal phases), whereas the PCO released from ME-PCO-SA and NE-PCO-SA occurred mainly in the intestinal phase, showing the suitability of SA as intestine-site release polymer. Nano-sized particles showed significantly higher bioaccessibility of individual FFA, such as C18:3 w-3 (NE-PCO-SA, 23.6%; ME-PCO-SA, 7.9%), due to their greater surface area.

Conclusions: Therefore, SA spray-dried micro and nanoparticles showed great potential for vehiculation of omega-3 rich oils in the design of functional foods allowing the preservation of their nutritional properties in the intestine-site release.

Association between coffee consumption and metabolic syndrome: a cross-sectional and Mendelian randomization study from UK Biobank

Tommy Hon Ting Wong[1], Shan Luo[1], Shiu Lun Au Yeung[1], Jimmy Chun Yu Louie[1]

1. The University of Hong Kong (Hong Kong)

Background and objective: Current literature regarding the effect of coffee consumption on metabolic health remains inconsistent. This study aimed to investigate the associations between coffee consumption and metabolic syndrome and its component conditions: high fasting glucose, high triglycerides, central obesity, high blood pressure, and low high-density-lipoprotein cholesterol in adults. The effects of using milk, sugar, and artificial sweetener on these associations were also investigated.

Methods: The cross-sectional analysis included 351,793 white British participants (18 years of age or older) of the UK Biobank. Coffee consumption was measured using food frequency questionnaires and 24-hour recalls and metabolic syndrome was ascertained based on blood biochemistry results and self-reported medication use. Odds ratios were obtained using multivariable logistic regression adjusting for lifestyle and socioeconomic factors. The presence of causal association was assessed using two-sample Mendelian randomization, with the data of the association between single nucleotide polymorphisms and coffee consumption extracted from the Coffee and Caffeine Genetics Consortium and those of metabolic health outcomes from the UK Biobank.

Results: Coffee consumption up to 3 cups per day was inversely associated with metabolic syndrome (1 cup/day, OR: 0.88, 95% CI: 0.85, 0.92; 2 cups/day, OR: 0.90, 95% CI: 0.86, 0.93; 3 cups/day, OR: 0.94, 95% CI: 0.90, 0.99) while associations at higher intakes were near null. Mendelian randomization did not support a causal association between coffee intake and metabolic syndrome. Both self-reported and genetically predicted high coffee consumption (4 cups per day or more) were associated with central obesity. The inverse association between coffee consumption and metabolic syndrome was more profound among ground coffee drinkers than instant coffee drinkers. Results were similar when stratified by the use of milk and sugar, yet the use of artificial sweeteners with coffee was positively associated with metabolic syndrome and all component conditions.

Conclusions: Coffee consumption likely increased risks of central obesity but unlikely impacted the risk of metabolic syndrome. The possible health effect of using artificial sweeteners with coffee warrants further investigations.

Keywords: coffee, metabolic syndrome, Mendelian randomization, artificial sweetener, sugar

Metabolomic assay, *in vitro* and *in vivo* studies of anti-obese and lipid profile improving activity of kombucha drink from *Caulerpa racemosa* as potential functional beverage

Happy Kurnia Permatasari[1], Fahrul Nurkolis[2]

1. Brawijaya University (Indonesia), 2. State Islamic University of Sunan Kalijaga (Indonesia)

Background and objectives: Obesity is currently a global issue and is a major cause of the metabolic disorder. However, currently approved treatments have various limitations including serious side effects, numerous contraindications, and lack of acceptance. *Caulerpa racemosa*, also referred as Sea grapes, is a seaweed known for its various benefits. In order to maximize its health benefits, *C. racemosa* was made using kombucha drink as a carrier medium. This study aims to explore the metabolites profile and assess the effect of Sea grapes kombucha drink on lipase activity *in vitro* and lipid profile *in vivo*.

Methods: Metabolomic profiling was done in the Central Hayati Laboratory Brawijaya University using LC-HRMS and Compound Discoverer with mzCloud MS/MS Library Processing data software to identify three major compounds. A lipase inhibition test was carried out by incubating Sea grapes kombucha drink compared with orlistat as the control in porcine pancreatic lipase and p-nitrophenyl butyrate in reaction buffer. A total of four groups were made, each containing 10 male swiss webster albino mice; group A received standard dry pellet diet as control, group B received cholesterol and fat-enriched diets (CFED), group C and D received CFED and 150 and 300 mg/kgBW of kombucha drink from Sea grapes respectively for 4 weeks. Research protocol No.100/EC/KEPK-KANDOU/VI/2021 (RSUP Prof. Dr. RD. Kandou, Manado), and No. PCTE0000258 (preclinicaltrials.eu Europe).

Results: *Betaine*, 2*,2,6,6-Tetramethyl-1-piperidinol* (TEMPO), *Hexadecanamide* is the major compounds that has been identified and suspected to contribute anti-obesity and lipid profile improving on in *vivo study*. Sea grapes kombucha drink improved lipid profiles in the way of reducing total cholesterol, triglyceride, LDL, and increasing HDL levels compared to CFED and normal groups. The effect was more robust following the incrementing dose of the Sea grapes excluding total cholesterol. The lipase inhibitory activity of Sea grapes kombucha drink was similar to orlistat at a dose of 250 µg/mL, otherwise, orlistat was superior in the lower doses. Sea grapes kombucha drink treatment also induced weight loss and increased level of liver SOD.

Conclusions: Kombucha drink from *C. racemosa* has good potential as a functional beverage with anti-obese and lipid improving activity.

β-Lactolin, a novel whey-derived peptide, improves mood states and enteric microbiome metabolites: A randomized placebo-controlled trial.

Yasuhisa Ano[1], Tatsuhiro Ayabe[1], Jiro Saito[2], Satoshi Umeda[3], Kenji Toba[4]

1. Kirin Holdings Company Ltd. (Japan), 2. Medical Station Clinics (Japan), 3. Keio University (Japan), 4. Tokyo Metropolitan Geriatric Medical Center (Japan)

Background and objectives: In our rapidly aging society and ever-changing social environment, depression and mood disorders have become an important social issue. Preventive approaches have received increased attention. Previous epidemiological studies suggested that intake of fermented dairy products helps reduce the risk of depression and mood disorders. We have previously discovered the novel whey-derived peptide β-lactolin (Gly-Thr-Trp-Tyr tetrapeptide) in fermented dairy products. Orally administered β-lactolin increases dopamine in the frontal cortex via monoamine oxidase B inhibition. β-lactolin has been found to improve depression-like behavior in mice. β-lactolin also improves intestinal microbiome metabolites and anxiety in mice. However, the effects of β-lactolin on human mood states have not yet been investigated. The current study investigated the effects of β-lactolin on mood states of healthy adults with poor mental health in a randomized placebo-controlled trial.

Methods: Sixty healthy adults aged 45~64 years old with poor mental health without diagnosed depression were selected using screening questionnaires (BDI-II and GHQ28). Participants were randomly allocated into the β-lactolin group (tablets containing 1.6 mg β-lactolin once per day) or placebo group. After six weeks, participants completed psychiatric questionnaires (State-Trait Anxiety Inventory (STAI), Perceived Stress Scale, Apathy Scale, and 36-item Short Form Survey (SF-36)) to report mood states and quality of life Participants also provided saliva and feces samples at the baseline and after the intervention for the analysis of IgA and SCFAs, respectively.

Results: The β-lactolin group showed a significant improvement in anxiety (p=0.046), perceived stress (p=0.043), mental health scores (p=0.039), salivary IgA levels (p=0.045), and SCFAs levels compared to the placebo group. In subgroup analysis, the β-lactolin group showed a significant increase in SCFAs including isobutyric acid and isovaleric acid than the placebo group (p=0.033 and 0.035, respectively). Taken together the previous studies, the increases of SCFAs from microbiome and dopamine in the cortex due to β-lactolin might contribute to the improvement of mood state in healthy adults.

Conclusions: The current study is the first to evaluate the effects of β-lactolin on mood state in a randomized placebo-controlled trial. β-lactolin supplementation could be a practical nutritional approach to mitigate stress and anxiety.

Attempt to Evaluate Autonomic Nervous System Activity on Intake of Functional Foods Using Empirical Mode Decomposition: A Comparison with Conventional Methods

Ayaka Yoshino[1], Kazuyoshi Ohashi[1], Mayu Fujita[1], Ryota Akai[1], Harunobu Nakamura[2], Yoshimitsu Okita[1]

1. Shizuoka University (Japan), 2. Kobe University (Japan)

Background and objectives: The effects of functional foods on autonomic nervous system activity (ANSA) have been investigated via heart rate variability (HRV). HRV is the variability of heartbeat intervals and includes linear and nonlinear components. In conventional frequency analysis of HRV, the fast Fourier transform (FFT) has been used for linear analysis. Additionally, a combination of FIR filtering and the Hilbert transform (HT) has been used for nonlinear analysis in some studies. Recently, a combination of empirical mode decomposition (EMD) and the Hilbert transform has been proposed as more suitable for nonlinear signals. In this study, the FFT, HT, and EMD analyses were performed on HRV before and after functional food intake, and the results were compared.

Methods: Six healthy young males participated in two experimental sessions with gamma-aminobutyric acid (GABA) or placebo intake. Electrocardiograms were recorded for six minutes each five times before and after intake. A mental arithmetic stress task was applied for 17 minutes starting 13 minutes after intake. HRV data were obtained from the electrocardiograms and three analysis methods were performed. The low frequency band (LF: 0.04–0.15 Hz) component, high frequency band (HF: 0.15–0.4 Hz) component and LF/HF ratio were calculated as indices of ANSA via HRV.

Results: In the EMD analysis, HF and LF/HF ratio were not obtained for only one subject. LF/HF ratio of the subject in the FFT and HT analyses were two to three times higher than that of the other subjects. In another subject, the standard deviation of normal to normal (SDNN), a time-domain index of HRV, was outside the healthy range. LF and HF of the subject were up to 30 times higher than that of the remaining four subjects in the FFT analysis, but up to four times higher in the HT and EMD analyses. In the remaining four subjects, the HT and EMD analyses tended to show less inter-subject variability in all HRV indices compared to the FFT analysis.

Conclusions: We conclude that the HT and EMD analyses offer the possibility of examining parameter changes in HRV in more detail on intake of functional foods.

Analysis of the mechanism of muscle fiber type determination in muscle satellite cells

Yuto Ohira[1], Mariko Fujita[1], Kaho Takigawa[1], Kiyoshi Yoshioka[2], Yusuke Ono[2], Yasutomi Kamei[1]

1. Kyoto Prefectural University (Japan), 2. Kumamoto University (Japan)

Background and objectives: Muscle fibers are divided into slow muscle fibers and fast muscle fibers. Fast muscle fibers predominantly use glucose for energy. On the other hand, slow muscle fibers predominantly use fatty acids for energy. During sarcopenia, fast muscle predominant muscle atrophy occurs. Muscle satellite cells are undifferentiated stem cells and they are involved in muscle regeneration and hypertrophy. Muscle satellite cells of fast muscles differentiate into fast muscle fibers, and those of slow muscles differentiate into slow muscle fibers. However, the mechanism of how satellite cells differentiate into slow or fast muscle fibers remains unclear. In this study, we performed comprehensive gene expression analysis of satellite cells derived from slow and fast muscle, and searched for factors which are necessary for satellite cells to differentiate into fast muscle fibers.

Methods: We performed comprehensive gene expression analysis of muscle satellite cells derived from EDL (exterior digitorum longus, fast muscle) and SOL (soleus, slow muscle) of C57BL/6J mice. Next, we knocked down Tbx1, Cited1, Hoxa1, and Six2, whose gene expression was higher in satellite cells derived from EDL than those from SOL, by using their respective siRNAs. Finally, we overexpressed Tbx1 in muscle satellite cells derived from SOL by retro-virus infection.

Results: The result of microarray analysis revealed that gene expression of Tbx1, Cited1, Hoxa1, and Six2 was higher in satellite cells of EDL than in those of SOL. Knockdown of Tbx1 decreased gene expression of Myh4 (fast muscle type myosin heavy chain), increased that of Myh7 (slow muscle type myosin heavy chain), and changed the cells to slow muscle-like. On the other hand, gene expression of Myh4 was upregulated, and that of Myh7 was downregulated by overexpression of Tbx1 in satellite cells derived from SOL.

Conclusions: From the above results, we considered that Tbx1 is necessary for satellite cells to differentiate into fast muscle fibers. Decreased ability of muscle satellite cells to differentiate into fast muscle fibers may be the cause of age-related fast muscle predominant muscle atrophy. This study may be helpful to improve age-related fast muscle-dominant muscular atrophy.

Keywords: Muscle satellite cells, fast muscle, slow muscle , transcription factors, differentiation

The difference in the cellular uptake of tocopherols and tocotrienols is influenced by their affinity to albumin

Takashi Nakatomi[1], Mayuko Itaya-Takahashi[1], Yosuke Horikoshi[2], Takahiro Eitsuka[1], Yoshikazu Tanaka[1], Tatsuya Matsura[2], Kiyotaka Nakagawa[1]

1. Tohoku University (Japan), 2. Tottori University (Japan)

Background and objectives: Vitamin E is classified into tocopherols (Toc) and tocotrienols (T3) based on their side-chain structures. Various cell culture studies have shown that T3 exhibits more potent physiological activities (e.g., antioxidative activity) than Toc, possibly due to its higher cellular uptake compared to Toc. However, the mechanism underlying this difference in cellular uptake remained unclear. In this study, we hypothesized that the affinity of Toc and T3 to albumin might be a possible explanation for their differences in cellular uptake, based on our recent findings that the affinity of some food components to albumin affects their cellular uptake.

Methods: Human acute monocytic leukemia monocytes (THP-1) were incubated under different medium conditions. The affinity of Toc and T3 to bovine serum albumin (BSA) was analyzed by the fluorescence quenching technique and docking model analysis.

Results and discussion: The cellular uptake of T3 was indeed higher than that of Toc in 10% fetal bovine serum (FBS) medium for α-, β-, γ-, and δ-analogs which possess different chromanol rings. In contrast, in serum-free medium, their differential cellular uptake was smaller than in 10% FBS medium. Furthermore, the cellular uptake of Toc decreased when BSA was added to this serum-free medium, whereas the cellular uptake of T3 was significantly increased by the addition of specific BSA concentrations. These results indicated that the difference in the cellular uptake between Toc and T3 is induced by albumin. Results from the fluorescence quenching demonstrated that the affinity of T3 to BSA was higher than that of Toc for α-, β-, γ-, and δ-analogs. Moreover, docking model analysis revealed that this difference in affinity was due to the Van der Waals interaction between their side-chain structures and BSA. Hence, the difference in the affinity of Toc and T3 to albumin, caused by their side-chain structures, might be why T3 demonstrates a higher cellular uptake than Toc.

Conclusions: The difference in the cellular uptake of Toc and T3 is influenced by their different affinities to albumin. The results of this study might give better mechanistic insight into the physiological action of Toc and T3.

Keywords: tocopherol, tocotrienol, cellular uptake, albumin, vitamin E

Impact on milk structuring during gastric digestion on the delivery of CoQ10 to the small intestine, a dynamic in vitro digestion study

Alejandra Acevedo-Fani[1], Aiqian Ye[1], Harjinder Singh[1]

1. Riddet Institute, Massey University (New Zealand)

Background and objectives: Milk undergoes major physical changes in the stomach due to interactions of proteins within the gastric environment. The newly formed curd-like structures are shown to affect the rate of delivery of lipids and proteins to the small intestine. The relevance of these structures on modulating the rate of delivery of other components, such as bioactive compounds, is still unknown. Coenzyme Q10 (CoQ10) is a lipid-soluble antioxidant synthetised by the human body. Dietary supplements and functional foods containing CoQ10 are increasing in demand due to their potential health benefits. The objective of this study was to investigate the gastric digestion dynamics of CoQ10-fortified milks and its impact on delivery of CoQ10 to the small intestine.

Methods: Pasteurised skim milk was fortified with two CoQ10-loaded emulsions with different compositions. Milk A contained an emulsion with 20 wt% corn oil, 1 wt% CoQ10, 1 wt% Tween 80. Milk B contained an emulsion with 20 wt% corn oil, 1 wt% CoQ10, 1 wt% sodium casein. Milk was submitted to dynamic *in vitro* gastric digestion using the Human Gastric Simulator (HGS). The physical properties and CoQ10 content of the gastric contents were analysed at different digestion timepoints.

Results: Results showed that the curd formed from milk B disintegrated faster than that formed from milk A. Consequently, milk B emptied from the HGS at a much faster rate than milk A, impacting the delivery of nutrients to the small intestine. CoQ10 was retained within the curd structure, meaning that the disintegration kinetics of the curd during gastric digestion affected the release of CoQ10 into the simulated gastric fluids.

Conclusions: These findings highlight the importance of understanding the disintegration and gastric emptying of foods in the stomach to designing functional foods.

Keywords: CoQ10, milk proteins, in vitro digestions, food fortification, Food structure

Effects of a combined eel and tempe flour supplementation on the improvement of protein serum, haemoglobin and IGF-1: An experimental control trials on malnourished rats

Fahrul Nurkolis[1], Hardinsyah Hardinsyah[2], Nelly Mayulu[3], Nurpudji Astuti Taslim[4], Happy Kurnia Permatasari[5]

1. State Islamic University of Sunan Kalijaga (Indonesia), 2. IPB University (Indonesia), 3. Sam Ratulangi University (Indonesia), 4. Hasanuddin University (Indonesia), 5. Brawijaya University (Indonesia)

Background and objectives: The study aimed to evaluate the effects of a combined Eel (*Monopterus albus*) and Tempe-soy flour supplementation (CETS) on the level of Protein Serum, Haemoglobin and insulin-like growth factor I (IGF-1) in malnourished rats.

Methods: A combine Eel and Tempe-Soy supplementation with the ratio 1:3.5 was produced by a applying oven drying method. A total of thirty white *Rattus norvegicus* aged 3 - 4 weeks and weighed 40.5 ± 5.4 grams was used in this study, they had poor nutrition (malnourished) as a result of low-protein diet for four weeks (LP; 4% b/b protein). After 4 weeks of treatment, rats were divided into 3 groups (10 rats each group). The rats in group A and B remained on a low-protein diet for 4 weeks, receiving a Low-Protein (LP) (4% b/b protein) diet containing the same amount of calories as a normal diet, and getting doses of CETS of 100 and 200 mg/kgBW respectively orally gavage. Group C or control was given a Normal-Protein (NP) diet (23% b/b of protein) and was allowed to feed ad libitum during the trial period or without a dose of CETS. Blood sample for measuring protein serum, haemoglobin and IGF-1 were collected after 4 weeks of the intervention. Data were analyzed using One-Way ANOVA 95% CI. This study was done at the integrated laboratory of State Islamic University of Sunan Kalijaga Yogyakarta with ethical approval from Pre-clinical Trials Europe (www.preclinicaltrials.eu) No.PCTE0000271.

Results: The results showed that protein serum, haemoglobin and IGF-1 of group B was significantly higher compared to group A and C ($p=0.0021$). Similarly, protein serum, haemoglobin and IGF-1 of group A was significantly higher compared to group C ($p=0.0001$). Doses of 200 mg/kgBW CETS are more effective in increasing levels of protein ($p=0.0052$), haemoglobin and IGF-1 ($p<0.0001$) compared to doses of 100 mg/kgBW.

Conclusions: This implies the a combined Eel (*Monopterus albus*) and Tempe flour supplementation potentially use for improving nutritional status via increasing of Protein Serum, Haemoglobin and IGF-1; and a human clinical study is urgently needed (this dose can be used as a reference for clinical trials).

Analysis of muscle atrophy inhibiting mechanisms by compounds that suppress transcriptional activity of FOXO1

Arisa Yamamoto[1], Takumi Onishi[1], Sako Mizutani[1], Ran Uchitomi[1], Yasutomi Kamei[1]

1. Kyoto Prefectural University (Japan)

Background and objectives: Skeletal muscle is the largest tissue in the human body and plays important roles in exercise, energy metabolism and glucose uptake. Skeletal muscle atrophy, which come about upon aging, bedridden conditions, and inactivity, causes poor quality of life (QOL). Sarcopenia, featuring loss of muscle mass and weakness of muscle strength or physical function, has become a problem in aging society. In our laboratory, we observed remarkable skeletal muscle atrophy in mice with transcriptional factor FOXO1 overexpressed specifically in the skeletal muscle and found FOXO1 as an important factor involved in muscle atrophy. In this study, we screened compound libraries to find compounds that suppress the transcriptional activity of FOXO1. Our purposes are to search for compounds which suppress muscle atrophy and to elucidate those mechanisms.

Methods, results, and discussion: We have established a GAL4-FOXO1 reporter assay system which can evaluate the transcriptional activity of FOXO1. We screened 520 compounds and found novel compounds suppressing transcriptional activity of FOXO1, including active vitamin D_3 ($1,25(OH)_2D_3$). In addition, the transcriptional activity of FOXO3a, which has high homology with FOXO1, was similarly suppressed. Furthermore, in C2C12 myoblasts treated with dexamethasone (DEX), the compounds suppressed the increased expression of the muscular atrophy-related gene (Atrogin1). Therefore, it was suggested that the compounds found in this study that suppress FOXO1 inhibit muscle atrophy. Next, in order to investigate the muscle atrophy suppressing mechanism by these FOXO1 inhibitory compounds, we first focused on $1,25(OH)_2D_3$, which is nutritionally important among the hit compounds. $1,25(OH)_2D_3$ increased the expression of transglutaminase 2, which has been reported to cause muscle hypertrophy. Furthermore, $1,25(OH)_2D_3$ suppressed the degradation of branched-chain amino acids (BCAA) which occur under the state of muscle atrophy. Thus, it was considered that $1,25(OH)_2D_3$ promotes protein synthesis and suppresses muscle atrophy. The compounds found in this study are expected to be used for prevention and improvement of muscle atrophy and to be the basis for understanding the molecular mechanism of muscle atrophy suppression by compounds.

Keywords: FOXO1, muscle atrophy, compounds, $1,25(OH)_2D_3$

Effect of cyclic sugars with different number of glucose units on gut IgA secretion

Taisei Miyamoto[1], Naoki Nishino[1], Mao Teraoka[1], Emiko Katsumata[1], Takeshi Tsuruta[1]

1. Okayama University (Japan)

Background and objectives: Cyclic nigerosylnigerose (CNN), α-cyclodextrin (CD), β-CD, and γ-CD are cyclic sugar that consists of 4, 6, 7, and 8 glucose units, respectively. A previous study revealed that oral administration of CNN increases immunoglobulin A (IgA) concentration in mice feces. IgA is a major antibody secreted into the gut and contributes to symbiosis with bacteria. In this study, we compared the effect of cyclic sugars with a different number of glucose units on gut IgA secretion.

Method: Balb/c mice were divided into 5 groups and fed a control diet or a cyclic sugar-supplemented diet for 12 weeks. The feces were collected at week 6 and 12, and suspended with PBS. The fecal supernatant was collected by centrifugation. The IgA concentration in the supernatant was measured by ELISA. At week 12, mice were sacrificed and the colonic tissue and cecal content were collected. The expression of genes related to IgA class switching including *April*, *Tgfb1*, and *Aldh1a2* in the colon was measured by qPCR. The concentration of short-chain fatty acids including acetic acid, propionic acid, and butyric acid was measured by gas chromatography.

Results: The IgA concentration in CNN group was significantly higher than Control, α-CD, and β-CD group at week 6 and than Control and α-CD group at week 12. There was no significant difference in the gene expression of *April* and *Tgfb1* between CNN group and other groups, while that of *Aldh1a2* was significantly higher in CNN group than α-CD, β-CD, and γ-CD group. The butyrate concentration in the cecal content was significantly higher in CNN and α-CD group than in Control, β-CD, and γ-CD group.

Conclusion: CNN exerts a stronger stimulatory effect on gut IgA secretion than α-CD and the effect lasts for 12 weeks after administration. The stimulatory effect of cyclic sugar on gut IgA secretion isn't determined in the number of glucose units-dependent manner. CNN may promote gut IgA secretion via increasing an enzyme expression related to IgA class switching and modifying bacterial fermentation.

OAB(T7)2-4

Suppression of alcohol consumption in mice by foods capable of increasing FGF21 secretion

Sho Matsui[1], Shuhei Morioka[1], Yuma Takahashi[1], Hiroki Iwama[1], Hazuki Ioroi[1], Yasuo Oguri[1], Satoshi Tsuzuki[1], Tsutomu Sasaki[1]

1. Kyoto University (Japan)

Background and objectives: Alcohol use disorder (AUD), which is a condition characterized by uncontrollable alcohol drinking, has been studied traditionally in the context of drug addiction but has not yielded effective medical treatments. Therefore, to address AUD, new research strategies and interventions are needed.

Alcohol is usually consumed together with food in healthy people. Therefore, alcohol drinking could be investigated as ingestive behavior, and this research approach may yield new interventions for AUD that had not been yielded by the drug addiction research. However, physiological mechanisms that control alcohol drinking remain elusive.

Fibroblast growth factor 21 (FGF21) and oxytocin (OXT) individually has been reported to reduce the intake of sugar and alcohol. We previously reported that the FGF21-OXT system regulates preference for sugar; therefore, we tested if the FGF21-OXT system also regulates alcohol drinking. Furthermore, AUD patients may accept food intervention than medications: we searched for FGF21-inducing food ingredients and tested their effect on alcohol drinking.

Methods: We generated OXT neuron-specific FGF21 receptor-deficient (KO) mice by mating *Oxt-ires-Cre* mice with *βKlotho-flox* mice. The preference for alcohol was assessed by two-bottle choice test (water vs. alcohol). Rare sugars for FGF21-inducing ability were screened using primary hepatocytes of wild-type (WT) mice. FGF21 levels in cell culture media or plasma samples were measured using ELISA kit.

Results: KO mice significantly increased alcohol preference. We next screened 46 rare sugars for FGF21-inducing ability. Four rare sugars, d-sorbitol, d-xylitol, d-tagatose and d-allulose, significantly induced FGF21 secretion from primary hepatocytes compared to fructose. Moreover, oral administration of these rare sugars to WT mice significantly increased blood FGF21 levels, while oral administration of d-tagatose and d-allulose decreased alcohol preference. We also searched for a mixture of food ingredients that can induce FGF21 more effectively. We tested the mixture of black vinegar (BV) and kome-koji amazake (KA), both of which are non-alcoholic and fermentation products of rice or ricemalt. Oral administration of 5% BV/50% KA solution to WT mice significantly increased blood FGF21 level and decreased alcohol preference.

Conclusions: These data suggest that d-tagatose, d-allulose and BV/BA mix solution, which may stimulate FGF21-OXT system, suppresses alcohol drinking.

Keywords: FGF21, Oxytocin, Alcohol preference, Rare sugar

Novel soy peptides that improve cognitive function after oral administration

Takumi Morokuma[1], Takanobu Nakajima[1], Taichi Furukawa[1], Maiko Shobako[1], Kentaro Kaneko[1], Yasuhiro Kashima[2], Taiji Matsukawa[2], Kousaku Ohinata[1]

1. Kyoto University (Japan), 2. UHA Mikakuto Co., Ltd (Japan)

Background and objective: Healthy aging is important for the increasing elderly population worldwide. We found that the enzymatic digest of soy β-conglycinin administered orally improves cognitive decline in mice. We then searched for peptides present in the digest that can improve cognitive function.

Methods: Cognitive function was evaluated by behavior tests, such as the novel object recognition test (ORT) and the object location test (OLT), using male mice. We investigated whether orally administered samples improved cognitive decline in mice that were treated with high fat diet (HFD) for one week [1]. The candidate peptides were synthesized by Fmoc strategy and purified by reverse phase HPLC.

Results: Based on the comprehensive analysis information of the digest [2] and homology with known peptides that improve cognitive decline, candidate peptides were chemosynthesized. Among them, we found one decapeptide and one dodecapeptide increased the approach time to the new object after oral administration in mice fed with HFD diet. Thus, we found that these peptides improved cognitive decline induced by HFD intake in the ORT. In the OLT, we also found that they improved cognitive decline. Thus, we demonstrated that the peptides were effective in improving cognitive decline by using different two paradigms.

Acetylcholine (ACh) is known to be a neurotransmitter that plays a critical role in cognitive function. To investigate the involvement of the acetylcholine system, methyllycaconitine (MLA), an antagonist specific for the a7 nicotinic ACh receptor (a7nAChR), was used. Both the soy β-conglycinin digest and the synthetic peptide improved cognitive decline induced by HFD intake, and these improvements were blocked by MLA. These results suggest that the improvements were associated with the a7nAChR system.

Conclusion: we found novel soy protein-derived peptides improving cognitive decline and the effect of peptide is coupled to the acetylcholine system.

Keywords: β-conglycinin, orally active peptides, novel object recognition test (ORT), object location test (OLT), alpha7 nicotinic acetylcholine receptor

Effects of the dietary flavonoids with natural prostaglandin D_2 and its synthetic analogues on the fat storage during the differentiation phase of cultured preadipocytes.

Pinky Karim Syeda K. Fatema[1], Hidehisa Shimizu[1], Kazushige Yokota[1], Nobuyuki Takahashi[2], Kaeko Murota[1]

1. Shimane University (Japan), 2. Tokyo University of Agriculture (Japan)

Background and objectives: Dietary flavonoids exert anti-adipogenic effects on culture adipocytes that could provide health benefits for humans. However, it is unclear whether there is direct interaction of flavonoids with biosynthetic prostaglandin (PG) in 3T3-L1 preadipocytes. PGD_2 is an unstable metabolite of arachidonate-cyclooxygenase pathway that interacts with cell-surface membrane receptors, DP1 and DP2 / CRTH2 in adipocytes to regulate adipogenesis program. The aim of study is to investigate the anti-adipogenic mechanism of dietary flavonoids focusing on the interaction with natural PGD_2 and its synthetic analogues in mouse 3T3-L1 model.

Methods: The inhibitory effect of anti-adipogenic flavonoids (quercetin, apigenin and isovitexin) on PGD_2 or its isosteric analogue, 11-deoxy-11-methylene-PGD_2 or its another synthetic analogue acting as CRTH2 agonist, 15(R)-15-methyl-PGD_2 along with a well-known cyclooxygenase-inhibitor aspirin, was examined after their supplementation in cultured preadipocytes for 45-hours during the differentiation phase (pretreatment), and determined quantitatively the fat storage in matured adipocytes after 6 days of the maturation phase. The protein amount in cultured adipocytes was quantified by Lowry method. The data of cellular fat content was normalized to cellular protein content and expressed as mg-triacylglycerol per mg-protein.

Results: This study found the significant suppressed adipogenesis after co-incubation of flavonoids with aspirin during the differentiation phase compared to control cells. Similarly, pretreatment of flavonoids with PGD_2 and aspirin effectively inhibited the lipid accumulation in mature adipocytes. The fat storage repressed by PGD_2 was attenuated by co-existence of flavonoids with either of both synthetic PGD_2 analogues in cultured adipocytes. The pretreatment of flavonoids with 15(R)-15-methyl-PGD_2 and aspirin cancelled significantly the suppressive effect of triacylglycerol level by PGD_2. Moreover, this recovery of adipogenesis was more effectively exerted by isovitexin, a C-glycosidic apigenin when compared to aglycones, quercetin and apigenin in the treated cultured preadipocytes.

Conclusions: The inhibition of adipogenic effect by pretreatment of flavonoids along with exogenous PGD_2 and cyclooxygenase-inhibitor suggests synergistic or additional effects of flavonoids exerted to PGD_2 in preadipocytes during the differentiation phase. These findings implicate involvement of signaling pathway by DP receptors for the interaction of dietary flavonoids with endogenous prostaglandins in the control of adipogenesis program in 3T3-L1 cells.

Keywords: Dietary flavonoids, Prostaglandins, Adipogenesis, 3T3-L1 preadipocytes, Differentiation phase.

AMC Innova, 30100 Murcia (Spain), 6. Centro de Investigación Biomédica en Red de la Fisiopatología de la Obesidad y Nutrición (CIBERobn), Instituto de Salud Carlos III, 28029 Madrid (Spain)

Background: The gut microbiota is the set of microorganisms that inhabit the intestine, in symbiosis with the human body, playing a relevant role in several of its functions including energy homeostasis and inflammation regulation. However, there are many microbiota profiles due to individual variances, that define various enterotypes; and the effects of specific dietary patterns and foods are still mostly unknown.

Objectives: In the context of the BIOTAGUT project, we have designed eight specific foods with potential prebiotic activity whose capacity to modulate the intestinal microbiota was evaluated in vitro and in vivo.

Methods: The capacity of the eight foods (three functional drinks based on fruits and vegetables, two breads, one herbal infusion, a *Bifidobacterium* yogurt, and bimi) to modify gut microbiota and metabolome composition was tested in an in vitro simulator of the human gastrointestinal tract (Ainia, Valencia, Spain). After that, a total of 120 Spanish volunteers were recruited and divided into 8 groups of 15 volunteers each. Each group was assigned to a different prebiotic food that was included in their habitual diet for 3 weeks. The effects of the experimental foods on gut microbiota were studied by analyzing the hypervariable regions V3–V4 of the prokaryotic 16S rRNA gene in fecal samples collected before and after the 3-week period.

Results: The intake of the all the experimental foods had an impact on the composition of the gut microbioma, and in some cases also in the diversity and richness. However, most of the individuals kept the same microbial enterotype before and after the treatment.

Conclusions: The experimental foods had a mild influence on bacterial species and genus composition, diversity and richness, without the risk of causing a microbial imbalance or even a dysbiosis. The results strongly support the technical procedure (first in vitro, secondly in vivo) to design new functional foods with potential prebiotic activity. Also, this study demonstrates that the intake of specifically designed prebiotic foods constitutes a novel strategy to modulate gut microbiota composition and to revert dysbiotic states with the ultimate goal of providing a benefit for the host.

The Effect of Enzymatically Modified Isoquercitrin on Brain Function via Changing Gut Microbiota and Blood Metabolites in Mice

Hong Liu[1], Ryo Inoue[2], Gen Watanabe[1], Mihoko Koyanagi[3], Shim-mo Hayashi[1], Kentaro Nagaoka[1]

1. Tokyo University of Agriculture and Technology (Japan), 2. Setsunan University (Japan), 3. San-Ei Gen F.F.I., Inc. (Japan)

Background and objective: The brain controls every process regulating our body, and there are many factors influencing brain development, of which diet plays a vital role in affecting brain function. Enzymatically modified isoquercitrin (EMIQ), composed of isoquercitrin and its glycosylated derivatives, is widely used as a food additive, and it has various biological activities such as anti-oxidant, anti-inflammatory, and anti-obesity. However, the data on the effect of EMIQ on brain function is limited. In this study, we investigated the effect of EMIQ on brain function and the potential mechanism.

Methods: Five-week-old male C57BL/6 mice were treated with 0, 0.005%, and 0.05% EMIQ in drinking water for 4 weeks. The behavior test, Real-time PCR, gas chromatography-mass spectrometry (GC-MS), Western blotting and Next Generation Sequencing were used in this study.

Results: The behavior test showed that 0.05% EMIQ treatment significantly improved mice memory function than the control group without affecting mice emotion. This effect was possibly associated with an attenuation in oxidative stress in the hippocampus; as evidenced by changes in the gene levels of superoxide dismutase 1, nuclear factor-erythroid factor 2-related factor 2, and cyclooxygenase 2 by real-time PCR. Interestingly, a metabolite, taurine, was identified that was significantly increased in the 0.05% EMIQ group using GC-MS. Western blotting further showed that taurine could protect SHSY5Y neuroblastoma cell lines against oxidative stress induced by lipopolysaccharide via anti-oxidant activity *in vitro.* EMIQ caused significant alterations in the gut microbiota composition, especially increasing the abundance of genera *Akkermansia*, *Bifidobacterium*, and *Adlercreutzia*, but did not change the alpha-diversity of the microbiota. The correlation analysis revealed that the increase of serum taurine was closely associated with the abundance of the *Akkermansia genus* in the gut microbiota.

Conclusion: Taken together, EMIQ could increase serum taurine metabolism influenced by the gut microbiota composition to improve memory function via the gut microbiota-blood-brain axis. Our result will provide a novel view for understanding the effect of EMIQ on brain function.

Keywords: EMIQ, memory, metabolites, taurine, gut microbiota

Effects of fermented rice bran extracts on colonic barrier integrity and gut microbiota in chronic sleep deprived mice

Li-Han Su[1], Wan-Chun Chiu[1], Ya-Ling Chen[1], Yu-Tang Tung[2], Hsiang-Chi Peng[1], Suh-Ching Yang[1], Hitoshi Shirakawa[3], Chiu-Li Yeh[1]

1. Taipei Medical University (Taiwan), 2. National Chung Hsing University (Taiwan), 3. Tohoku University (Japan)

Background and objectives: Chronic sleep deprivation (SD) is prone to result in compromised colonic barrier integrity and imbalanced gut microbiota. However, fermented rice bran (FRB) was found to be alleviating sleep disorders and maintaining intestinal integrity. Thus, in this study we investigated the effects of FRB extracts on colonic barrier integrity and gut microbiota in chronic sleep deprived mice.

Methods: This study used male C57BL/6 mice given AIN-93M diet or FRB diet containing modified AIN-93M diet with 1% or 5% FRB extracts (*w/w*). Mice were divided into four groups, including normal control (NC), SD, SD+1% FRB, and SD+5% FRB group. After 2 weeks of feeding, mice in the three SD groups were received chronic SD by modified multiple platform method (MMPM) for 6 weeks (16 hours/day, 5 days/week). Mice were sacrificed after the chronic sleep deprivation program.

Results: Chronic SD caused increased stress hormone corticosterone and lipopolysaccharide (LPS), but reduced serotonin levels in plasma. The gene expression of tight junction protein (zonula occludens-1, ZO-1) also decreased in cecum. The richness of gut microbiota in SD group was significantly higher than NC group, and distribution between NC and SD group was obviously different. Compared to NC group, *Bifidobacterium* (genus), *Muribaculaceae* (family), *Dubosiella* (genus), *Faecalibaculum* (genus), *Akkermansia* (genus) were lower, while Lachnoclostridium (genus) were higher in SD group. FRB extracts supplementation decreased corticosterone and LPS, but enhanced serotonin levels in plasma. It also reversed the gene expressions of ZO-1, aryl hydrocarbon receptor (AhR) and antimicrobial peptide (cathelicidin) in cecum or colon. The distribution of gut microbiota in FRB groups were obviously different from SD group. Compared to SD group, lower *ASF356* (genus), *Bifidobacterium* (genus), *Erysipelatoclostridium* (genus), *Enterococcus* (genus), *Faecalibacterium* (genus), and higher *Prevotellaceae_UCG-001* (genus), *Bacillus* (genus), *Candidatus_Saccharimonas* (genus), *Succinivibrio* (genus), *Akkermansia* (genus), *Tannerellaceae* (family) were found in SD+1% FRB or/and SD+5% FRB groups.

Conclusions: These findings suggested that supplementation of FRB extracts modulated gut microbiota, reduced chronic SD-induced stress, and consequently improved gut microbial translocation.

Potential benefits of epidermal growth factor in alcoholic liver disease induced muscle loss

Qian Xiao[1], Yi-Hsiu Chen[1], Ya-Ling Chen[1], Suh-Ching Yang[1]

1. Taipei Medical University (Taiwan)

Background and objectives: Muscle loss is widely occurrence in alcoholic liver disease (ALD) patients. The damages of muscle in ALD majorly result from endotoxemia caused by leaky gut and hyperammonemia. Epidermal growth factor (EGF) is proposed as health-improvement factors in previous studies. Therefore, in this study, potential beneficial effects of EGF on muscle wasting in ALD were assessed by muscle degradation and synthesis as well as intestinal microbiota diversity.

Methods: Six weeks old male Wistar rats were divided into five groups (n=10) according to alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities without differences. All five groups were fed with control liquid diet for first two weeks, and three of them were fed with diets containing EGF. Afterwards, two liquid diet groups without EGF were fed following by control or Lieber–DeCarli alcohol liquid diet as control (C) and ethanol (E) groups respectively. The groups with EGF feeding were further assigned to continually given the same (AEGF-C), ethanol liquid diet without EGF (PEGF-E) and ethanol liquid diet with EGF (AEGF-E).

Results: E group had higher plasma alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities, plasmatic endotoxin and ammonia (p <0.05). H&E stain also indicated more hepatic fatty change and inflammatory cells, along with escalated interleukin 1ß (IL-1ß) in E group. While plasma endotoxin, IL-1ß and IL-6 levels were inhibited in PEGF-E and AEGF-E groups. Also, plasma lipid peroxides and inflammatory cells accumulation were significantly decreased in PEGF-E (p <0.05). The degradation markers (MURF and atrogin-1) illustrated the damage of E group in muscle. In both PEGF-E and AEGF-E groups, MURF and atrogin-1 were significantly inhibited. From microbiota aspects, α-diversity did not differ among all groups. However principal co-ordinates analysis (PCoA) showed that gut microbiota were distinct between alcohol consumption groups (E, PEGF-E and AEGF-E) and those without alcohol (C and AEGF-C). In addition, PEGF-E showed the less differences with C group.

Conclusions: Chronic alcohol feeding led to significant liver injury, muscle degradation and gut microbiota changes. It was assumed that EGF as pretreatment or supplement could alleviate muscle degradation by means of ameliorating liver inflammation, reducing endotoxin translocation, and altering microbiota composition.

Keywords: ethanol, epidermal growth factor, alcoholic liver disease, microbiota, rat

Diallyl trisufide, a Garlic (*Allium sativum* L.) derived organosulfur compound suppresses extrinsic coagulation and arteriosclerosis

Taiichiro Seki[1], Sachiko Okue[1], Manami Yaguchi[1], Ni An[1], Takeyuki Suzuki[1], Atsushi Miura[1], Yori Ozaki-Masuzawa[1], Takashi Hosono[1]

1. Nihon University (Japan)

Background and Objectives: The balance of the blood coagulation/fibrinolysis system determines the fluidity of blood in the vessels. Increased coagulation and/or decreased fibrinolysis cause thrombotic diseases. In addition, the risk of thrombosis increases with the progression of aged-dependent arteriosclerosis. Cardiovascular diseases are the major cause of morbidity and mortality worldwide; the number of deaths per year is anticipated to be over 23.6 million by 2030. Extrinsic blood coagulation pathway is triggering the thromboembolism based on arteriosclerosis. Tissue factor (TF) is a critical initiator of the extrinsic coagulation. Diallyl trisulfide (DATS) is a secondary metabolite of allicin generated in crashed garlic (*Allium sativum* L.). DATS has various pharmacological activity such as anti-platelet aggregation. This study aimed to clarify the effect of DATS on extrinsic coagulation elicited by TF and on the arteriosclerosis to know the property of garlic in cardiovascular diseases.

Methods: The effect of DATS on TF activity was measured by clotting assay using TF-expressing HL60 cells. HL60 cells were incubated for 6 h with PMA to induce TF expression. This HL60 cell suspension was treated with DATS then incubated with $HgCl_2$ to activate TF. Bovine plasma was added to the cell suspension mixture, and TF activity was measured as a function of clotting time. TF and arteriosclerosis relating protein expressions in TNF-α-stimulated human umbilical vein endothelial cells (HUVECs) was examined by qPCR and western blotting. The effect of DATS on arteriosclerosis was also examined by using apolipoprotein E-deficient mice. Serial cryosections of the tricuspid valve of the mice were stained with haematoxylin and eosin for plaque morphology and Oil Red O for lipid deposition, and staining was evaluated.

Results: DATS inhibited TF activity induced by PMA in a dose-dependent manner. TF mRNA/protein expression in TNF-α-stimulated HUVECs were also inhibited by DATS. It has also suggested that DATS suppresses TF expression through the inhibition of JNK signals induced by TNF-α. Induction of mRNAs encoding cell adhesion molecules such as Vcam-1 was also suppressed by DATS in the TNF-a-stimulated HUVECs. The size of atherosclerotic lesion in the apolipoprotein E-deficient mice tended to be reduced by DATS administration in comparison with vehicle treated control mice.

Conclusion: DATS may serve as a dietary constituent with beneficial effects on vascular disease elicited by extrinsic coagulation.

Appetite-suppressing effects of dietary GABA and GABA degradation inhibition in lean and obese mice: a potential strategy for obesity treatment

Thanutchaporn Kumrungsee[1], Tomoka Nagao[1], Noriyuki Yanaka[1]

1. Hiroshima University (Japan)

Background and objectives: Overeating is one of the major factors causing overweight and obesity. However, controlling food intake for weight loss is often difficult to achieve and maintain for obese individuals. We previously found that a high dose (5%) of gamma-aminobutyric acid (GABA) mixed in a normal diet significantly decreased food intake and body weight in lean mice and elevated blood GABA levels. In this study, we examined whether an increase in blood GABA levels, not distaste for the food, is a key factor of appetite suppression.

Methods and results: To increase blood GABA levels, lean-male-ICR mice fed with 2% GABA diet (20 g GABA/kg diet) were administered vigabatrin, a GABA-degradation inhibitor. In the control (no GABA in diet) and 2% GABA without vigabatrin groups, GABA was present in trace concentrations (0.7 ± 0.2 µM). However, 2% GABA diet plus vigabatrin inhibited GABA degradation, thereby significantly increasing blood GABA levels (68.7 ± 12.8 µM). Interestingly, 2% GABA diet plus vigabatrin significantly suppressed food intake (−50%, $P < 0.05$) and body weight gain (−28%, $P < 0.05$) within 2 weeks, whereas no significant differences were observed in food intake and body weight between the control and 2% GABA groups. Moreover, a decrease in food-seeking behavior was observed in the 2% GABA plus vigabatrin-fed mice. Next, we examined these effects in obese mice. Eight-weeks-high-fat-diet-induced-obese-ICR mice were divided into four groups receiving a high-fat diet (control) or a high-fat plus 2% GABA diet with or without vigabatrin administration. We observed that 2% GABA diet plus vigabatrin significantly suppressed food intake (−59%) and body weight gain (−21%) within 2 weeks in obese mice as well, whereas no effects on food intake and body weight were observed in the control and only 2% GABA diet groups. Notably, vigabatrin administration with the control diet (no GABA) suppressed body weight gain by only 5%, suggesting that vigabatrin is not the main effector.

Conclusions: Dietary GABA with GABA-degradation inhibition induces the appetite-suppressing and weight-loss effects in both lean and obese mice. These effects are mainly attributed to blood GABA availability and GABA-degradation inhibition, not food distaste. Our findings may aid the development of appetite-controlling interventions for obesity management.

Effect of high protein and low carbohydrate smoothie drinks versus a diabetes-specific nutritional formula on postprandial glucose homeostasis in type-2 diabetic patients

Pichanun Mongkolsucharitkul[1], Bonggochpass Pinsawas[1], Apinya Surawit[1], Korapat Mayurasakorn[1]

1. Faculty of Medicine Siriraj Hospital, Mahidol University (Thailand)

Background and objectives: The prevalence of type 2 diabetes mellitus has increased drastically in the past decade. Achieving optimal glycemic control is the challenges for patients with diabetes. Most of them have overweight or obesity which worsen insulin resistance and diabetes complications. Nutrition supplement is an alternative nutrition therapy, specifically manufactured for diabetic patients to help control blood sugar. We aimed to determine the effect of high protein and low carbohydrate smoothie drinks on glucose homeostasis, insulin and lipid metabolism in obese type 2 diabetic individuals as compared with a diabetes-specific nutritional formula.

Methods: We compared between a regular high protein smoothie drink (SM) containing 39% carbohydrate, 24% protein and 37% fat or a high protein and low sugar smoothie drink (LS) containing 28% carbohydrate, 28% protein and 44% fat with a conventional diabetic enteral drink (Glucerna) containing 38% carbohydrate, 18% protein and 33% fat. A crossover design study was performed in 41 diabetic participants. Participants consumed 300 kilocalories of each drink at a time with one-week wash out period between drinks and glucose response curves at baseline, 30, 60, 90, 120, 180 and 240 minutes were monitored and compared.

Results: In all three diets blood glucose levels gradually decreased postprandially. Average postprandial plasma glucose levels and the area under the curve (AUC) were higher after Glucerna and SM intake as compared with LS (p-value < 0.05) which demonstrated that LS be the better insulin sensitive formula among of the three formulas. The peak blood glucose level was highest at 60 minutes after Glucerna (175.5 ± 5.38 mg/dL) intake when compared with SM (173.8 ± 5.79 mg/dL) and LS (160.8 ± 5.77 mg/dL), respectively (p-value < 0.0001).

Conclusions: These results suggested the potential of smoothie formulas containing high protein and low carbohydrate for the nutritional support of type 2 diabetes mellitus and its related glycemic control. These smoothies may be a good candidate as promising functional foods for the management and supplementation for diabetes and obese people in the future.

Effects of n-3 LCPUFAs Supplementation on the Body Composition and Fitness Performance in Malaysian Football League Players Undergoing Regular Training

Mahenderan Appukutty[1], Sangeetha Shyam[2], Zi Ying Choo[2], Seok Shin Tan[2], Hueh Zan, Megan Chong[2], Wai Kwong, Alston Choong[3]

1. Universiti Teknologi MARA (Malaysia), 2. International Medical University (Malaysia), 3. University of Malaya (Malaysia)

Background and objective: A proper nutrition plan will play a prime role in enabling football players to manage the training loads and to improve performance on match days. The omega-3 has shown a potential sports nutrition supplement for performance, recovery and injury prevention. The present randomised controlled trial aimed to assess the effects of 8 weeks of supplementation on n-3 long-chain polyunsaturated fatty acids (n-3 LCPUFAs) on the body composition and exercise performance of professional males footballers.

Methods: A total of 27 professional male footballers from Selangor Football Club were randomly assigned into 2 groups: placebo (n=14), and n-3 LCPUFAs (n=13). The n-3 LCPUFAs supplement contained 2.1g of Eicosapentaenoic acid (EPA) and Docosahexaenoic acid (DHA) (1.5g EPA+600mg DHA) were administered in 6 capsules (4 in the morning and two in the evening, 30 min after a meal). The body composition and physical exercise performance of footballers were measured at week 0, week 4 and week 8.

Results: There were no significant differences found between the groups of footballers for anthropometry or body composition components when compared to baseline (p >0.05). The ANCOVA analysis showed that the n-3 LCPUFAs group had significantly higher levels of EPA and DHA when compared to the placebo group at week 8. The aerobic capacity showed significant between-group differences with a large effect size (placebo vs n-3 LCPUFAs group: 69.9 ± 6.5 vs 75.9 ± 6.8, p = 0.021, d = 0.91, large effect).

Conclusion: The n-3 LCPUFAs supplementation improved the exercise performance, particularly on aerobic capacity among the footballers. Future studies also should investigate the protective effect on muscle fatigue during and after exercise as well as the muscle inflammatory reaction.

Keywords: n-3 LCPUFAs, exercise performance, body composition, footballers

Capsaicin alleviates cisplatin-induced muscle loss and atrophy In vitro and In vivo

Ko-Chieh Huang[1], Yi-Fen Chiang[1], Hsin-Yuan Chen[1], Po-Han Lin[1], Shih-Min Hsia[1]

1. Taipei Medical University (Taiwan)

Background and objectives: Cisplatin (CP) is a widely used chemotherapeutic drug with subsequent adverse effects on different organs and tissues including skeletal muscle loss and atrophy as the most common clinical symptoms. The molecular mechanism of cisplatin-induced muscle atrophy is not clearly understood. However, recent significant advances indicate that it is related to imbalance in both protein status and apoptosis. Capsaicin (CAP), is one of the major ingredients in chili peppers. It is a valuable pharmacological agent with several therapeutic applications in controlling pain and inflammation with particular therapeutic potential in muscle atrophy. However, the mechanisms underlying its protective effects on cisplatin-induced muscle loss and atrophy remain largely unknown. The purpose of this study was to investigate the beneficial effects of capsaicin on cisplatin-induced muscle loss and atrophy both in vivo and in vitro.

Methods: Male C57BL/6J mice (5 weeks old) included capsaicin (10 and 40mg/kg, for 5weeks) administration as pretreatment to cisplatin (5mg/kg BW, for 7 days)- induced muscle atrophy animal model for protein and oxidative stress examination as well as grip strength to evaluate the muscle strength. Moreover, we utilized an in vitro C_2C_{12} pretreated with capsaicin (10, 25, 50 μM) and treated with cisplatin (40 μM) myotube formation model where cell viability analysis, immunofluorescence and protein expression were measured to investigate the effect of capsaicin in hampering cisplatin-induced muscle atrophy.

Results: Our study results indicated that cisplatin caused lower cell viability and showed a subset of hallmark signs typically recognized during atrophy, including severe reduction in myotube diameter, repression of Akt and mTOR protein expression. However, pretreatment with capsaicin could ameliorate cisplatin-induced muscle atrophy by up-regulating Akt (up to 1.4 fold, p <0.01) and mTOR (up to 1.8 fold, p <0.01), which stimulates protein synthesis in skeletal muscle as well as down-regulating Myostatin, MAFbx, MuRF-1 (decrease more than 2 folds, p <0.01), the markers of protein degradation. Also, Capsaicin was able to downregulate protein expression of apoptosis related markers (decrease more than 3 folds, p <0.01) which are induced by cisplatin. In Vivo, capsaicin could relieve the oxidative stress and cytokine secretion (up to 1.6 fold, p <0.01) while modulating the autophagy related lysosome fusion. Moreover, Capsaicin improved the grip strength and alleviated cisplatin-induced body weight loss and gastrocnemius atrophy.

Conclusion: These findings suggest that cisplatin can restore cisplatin induced imbalance between protein synthesis and protein degradation pathways, and it may have protective effects against cisplatin-induced muscle atrophy.

Gut microbial metabolism of *in vivo* digested cocoa (poly)phenolics yields bioactive metabolites.

Chris Gill[1], Sara Dobani[1], L.Kirtsy Pourshahidi[1], Dan Del Rio[2], Alan Crozier[5], Kieran Tuohy[3], Gema Pereira-Caro[6], Pedro Mena[2], Gordon McDougall[4], Lietzia Bresciani[2]

1. Ulster University (UK), 2. Univeristy of Parma (Italy), 3. University of Leeds (UK), 4. The James Hutton insitute (UK), 5. King Saud University Riyadh (United Arab Emirates), 6. Andalusian Institute of Agricultural and Fishery Research and Training (Spain)

Background and Objectives: Cocoa is a rich source of flavan-3-ols, whose beneficial effects on human health are likely due to their metabolites including phenyl-γ-valerolactones (PVLs) and phenyl valeric acids (PVAs). Ileostomy studies provide unique insights into *in vivo* food digestion, allowing identification of physiologically relevant dietary phytochemicals and their metabolites, including PVLs and PVAs. Therefore, the objective of this study was to investigate the bioavailability of (poly) phenols from a cocoa-based drink in the upper GIT tract *in vivo* and the of lower GIT using *ex vivo* modelling of (poly)phenol enriched ileal fluid.

Methods: Ileal fluids collected from 5 volunteers before and after (0-8 hr) intake of a flavanol-containing cocoa-based drink, underwent an anaerobic temperature and pH controlled faecal batch fermentation (24 hr). Samples collected after 0, 5, 10 and 24 hr were analysed using 16S rRNA gene sequencing for the microbiome composition and UHPLC-HR-MS for identification/quantification of (poly) phenolic compounds. The ileal samples were obtained from a randomised, double-blinded, two-way crossover acute feeding study (NCT03765606). Ten ileostomates consumed a flavanol-containing cocoa-based drink and a de-xanthinated cocoa-based drink (566 mg or 583 mg of flavan-3-ols, respectively), ileal fluids were collected 0, 0-4, 4-8, and 8-24 hours after consumption and their (poly) phenolic content characterised via UHPLC-MS/MS.

Results: Characterisation of the ileal fluids (poly) phenolic content showed that a significant proportion of the ingested flavan-3-ols reached the colon as methoxy- and/or sulphated-metabolites, with significant inter-individual variability evident. Fermentation of cocoa enriched ileal fluid (0-8h) using an in vitro gut model resulted in minimal changes to relative abundance in microbiota at phylum and genus level and significant increases in flavan-3-ol metabolites especially 3',4'-dihydroxyphenyl-γ-valerolactones. Such Increases in flavan-3-ols metabolites were significantly correlated with gut microbiota genera including *Faecalibacterium* and *Butyricimonas*.

Conclusion: Consumption of cocoa resulted in significant amount of flavanols being available to enter the colon. Twenty-four hour *ex vivo* fermentation of ileal fluids post-cocoa consumption resulted in significant increases in flavan-3-ols metabolites especially, 3',4'-dihydroxyphenyl-γ-valerolactones which were associated with specific bacterial genera.

Development of a food product with probiotic potential and its effect on parameters associated with glucose homeostasis in patients with type 2 diabetes mellitus at the Clinics Hospital of Paraguay

Eugenia Ruiz Diaz-Narvaez[1,2], Rosa Noemi Vega[1], Susan Benitez[1], Maite Sánchez-Giraldo[2,3], Gloria Echaugüe[4], Liliana Sosa[4], Noelia Alvarenga[4], Javier Romero[5], Oriol Rangel Zúñiga[2], Pablo Pérez-Martínez[2,3]

1. FCM-UNA (Paraguay), 2. IMIBIC (Spain), 3. UCO (Spain), 4. IICS-UNA (Paraguay), 5. Chortitzer LTDA (Paraguay)

Background and objectives: Type 2 diabetes mellitus (T2DM) is one of the major health problems worldwide with high morbimortality rates. In fact, several studies link metabolic diseases with intestinal dysbiosis suggesting that certain bacterial strains could play a beneficial role on metabolic parameters (through modulation of the intestinal microbiota). Our objective was to develop a food product containing strains with probiotic potential and to study the effect of its consumption on parameters associated with glucose homeostasis.

Methods: 46 subjects with T2DM from the Endocrinology Department of Clinics Hospital (Paraguay) were included and randomly assigned to three different intervention groups. The first group received 300 g/d of fermented dairy with two strains of the genus *Bifidobacterium* (developed exclusively for this research purpose by the Cooperativa Chortitzer Ltda ¨Lácteos Trebol¨, Paraguay). The second group received 300 g/d of a fermented dairy with conventional cultures, and the third group did not receive any type of fermented dairy. Also, all three groups received nutritional monitoring based on the recommendations of the American Diabetes Association (ADA) during a 12-week intervention period. Biochemical parameters related to lipid profile and glucose homeostasis were determined at baseline and after the follow-up period. Repeated measures analysis and Pearson correlation of the biochemical parameters included in the study were performed.

Results: The results showed that the intake of the developed product induced in the patients a decrease in the HOMA index, although not significant, in contrast to the intervention without fermented dairy which induced a statistically significant increase in the HOMA index after the intervention period compared to baseline (p=0.016). Furthermore, in the baseline situation of the study, a positive correlation between glycemia and CRP levels (p=0.025; r_2=0.576) and HbA1c and CRP (p=0.003; r_2= 0.707) was observed in patients who had consumed the developed dairy.

However, these correlations lost significance after the intervention period.

Conclusions: The consumption of the food product developed with two strains of the genus *Bifidobacterium* would have potential as a nutritional tool in clinical practice, since it could improve glucose homeostasis in patients with diagnosed type 2 diabetes mellitus.

Keywords: probiotics, intestinal microbiota, Type 2 diabetes mellitus, glucose homeostasis

Procyanidin C1 ameliorates bisphenol A-induced developmental toxicity and mitochondrial malformations in zebrafish embryos

Razif Dasiman[1], Norazmir Md Nor[1], Zolkapli Eshak[1], Siti Syaurah Mohd Mutalip[1]

1. Universiti Teknologi MARA (UiTM) (Malaysia)

Background and objective: Consumers around the world are unknowingly exposed to bisphenol A (BPA) via food and beverage containers, and other products. BPA may be harmful to human health because of its ability to disrupt normal biological processes and normal behavioral states, cause DNA damage, and alter epigenome profiling. Procyanidin C1 (PCY1) has been shown in studies to be capable of neutralizing free radicals, mitigating the effects of environmental toxins, and protecting cells from DNA damage. However, little is known about its effects on mitigating developmental toxicity and cytoskeletal malformations in developing embryos, which can disrupt embryonic cleavage and result in developmental failure. Therefore, the purpose of this study is to determine the effects of PCY1 intervention on embryonic development, mitochondrial distributions, and the expression of apoptotic (*baxa, bcl2a, casp3a*, and *tnfa*) and mitochondria-related (*etfa, mfn2*, and <*pink1*) genes in BPA-exposed zebrafish embryos.

Methods: Ninety-six (n=96) zebrafish embryos were employed in this study. Toxicology evaluation of the embryos was performed using the Zebrafish embryo acute toxicity test (ZFET). Every 24 hours until the 96th hour of exposure, toxicological endpoints were monitored. Hatching and heart rate were observed as early as 48 hours after conception, and teratogenicity was discovered at 120 hours. Total RNA was isolated, converted to cDNA, preamplified, and processed with a microfluidic quantitative real-time polymerase chain reaction (qRT-PCR). BioMark Real-Time PCR Analysis Software 4.3.1 was used to analyze the genes.

Results: The study found that, PCY1 intervention improves embryonic development in BPA-exposed conditions by reducing embryonic mortality and malformations. PCY1 intervention significantly reduced the expression of the genes *baxa*, and *casp3a.* Moreover, *bcl2* and *tnfa* were significantly up-regulated. The PCY1 intervention group also had significantly lower expression of the *etfa, mfn2*, and *pink1* genes.

Conclusions: It has been demonstrated that PCY1 can minimize the negative effects of BPA on embryonic development and mitochondrial malformations. Hence, the findings concluded that PCY1 may play a role in protecting embryos from the harmful effects of BPA.

Role of nutraceuticals in the management of dyslipidemia- A meta-analysis

Kaneez Fatima Jawwad[1], Mahpara Safdar[1], Hajra Ahmad[1]

1. Allama Iqbal Open University, Environmental Design, Health & Nutritional Sciences department (Pakistan)

Background: Dyslipidemia is one of the major risk factors for non-communicable diseases (NCD). Its worldwide prevalence depicts that 40% female and 37% male population have raised cholesterol mainly associated with NCDs like cardiovascular diseases, hypertension, diabetes, fatty liver, inflammatory bowel syndrome (IBS), obesity, hypothyroidism, cancers, osteoarthritis, stroke, cerebrovascular disease, causing mortality of 10 million people per year. Globally 30-40% patients are statin intolerant to pharmacological intervention owing to its side effects like kidney & liver failure, muscle weakness, diarrhea, memory loss, andcataracts. The causative factors include unhealthy foods & lifestyle, obesity, smoking, alcoholism, physical inactivity, and diabetes.

Objectives: To explore the most effective nutraceutical improving individual quantities of lipid profile. 2). To identify the highly significant nutraceuticals for the management of dyslipidemia.

Methods: Research design is review based meta-analysis involving 250 RCT studies, with 21,450 subjects, sampled through Prisma flow and PICO (Population, Intervention, Comparison, Outcome) being research instrument. Data collection & inclusion criteria were availability of complete article, human subjects, dosage, regime/day, treatment duration, and fasting lipid profile (TC, LDL, TG and HDL cholesterol) before and after treatment. Paired sample t-test and one-way ANOVA with 95% CI were used for inferential stats.

Results: The result demonstrated amongst 25 nutraceuticals, the most effective for improving individual quantities of lipid profile are Bergamot for TC reduction (p=0.003), Polyphenol reduced LDL (P=0.01), Spirulina reduced TG (p=0.004) & Niacin increased HDL (p=0.02). The highly significant nutraceuticals to treat overall dyslipidemia are (1). Niacin which reduced bad cholesterol (p=0.001) & increased HDL-C (p=0.02), (2) Dietary fiber reduced bad cholesterol (p=0.001) and increased HDL-C (p=0.005) and (3) Berberine reduced bad cholesterol (p=0.007) and increased HDL-C (p=0.05).

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusion: Nutraceuticals work best without side effects, accompanied with healthy diet, DASH diet for hospitalized CKD, diabetic, CVD in Statin intolerant. Bergamot, Polyphenol, Spirulina and Niacin significantly improved TC, TG, LDL and HDL-C, respectively. Niacin, Dietary fiber and Berberine are highly significant to manage dyslipidemia.

Preventive effect of Sesaminol against Parkinson's disease by activation Nrf2-ARE signaling pathway

Akiko Kojima-Yuasa[1], Haruka Kaji[1], Ayano Omura[2], Kunio Kiyomoto[2], Isao Matsui-Yuasa[1]

1. Graduate School of Human Life Science, Osaka City University (Japan), 2. Kiyomoto Co., Ltd. (Japan)

Background and objectives: Parkinson's disease (PD) is a neurodegenerative disease caused by the degeneration of substantia nigra neurons due to oxidative stress. Sesaminol (3,4-methylenedioxy phenol) has strong antioxidant and anti-cancer effects. A method for purifying sesaminol from sesaminol glycoside was established recently. We investigated the preventive effect on PD as a new physiological action of sesaminol produced from sesaminol glycoside using *in vitro* and *in vivo* PD models.

Methods: To prepare an *in vitro* PD model, 6-hydroxydopamine (6-OHDA) was added to human neuroblastoma (SH-SY5Y cells). The neurotoxin rotenone was orally administered to mice to prepare an *in vivo* PD model.

Results: The viability of SH-SY5Y cells decreased dose-dependently following 6-OHDA treatment, but the addition of sesaminol restored viability to the control level. 6-OHDA increased intracellular reactive oxygen species production, and the addition of sesaminol significantly suppressed this increase. No Nrf2 expression in the nucleus was observed in the control group, but a slight increase was observed in the 6-OHDA group. The sesaminol group showed strong expression of Nrf2 in the cytoplasm and nucleus. NAD(P)H: quinone oxidoreductase (NQO1) activity was enhanced in the 6-OHDA group and further enhanced in the sesaminol group. The motor function of rotenone-treated mice was shorter than that of the control group, but a small amount of sesaminol restored it to the control level. The intestinal motility in the rotenone group was significantly lower than that in the control group, but it remained at the control level in the sesaminol group. The expression of α-synuclein in the substantia nigra increased in the rotenone group but decreased in the sesaminol group. The rotenone group exhibited shortening and damage to the colonic mucosa, but these abnormalities of the colonic mucosa were scarcely observed in the sesaminol group.

Conclusion: These results suggest that sesaminol has a preventative effect on PD.

Brown rice inhibits development of non-alcoholic fatty liver disease in obese Zucker (*fa/fa*) rats by increasing VLDL-secretion and lipid oxidation via activation of retinoic acid synthesis

Yuji Yamamoto[1], Tsukasa Suzuki[1], Yu Matsumoto[1], Ken-Ichi Kobayashi[2], Jun Inoue[1]

1. Tokyo University of Agriculture (Japan), 2. Notre Dame Seishin University (Japan)

Background and objectives: White rice and its unrefined form, brown rice, contain numerous compounds that are beneficial to human health. However, the starch content of rice can contribute to obesity, a main risk factor for non-alcoholic fatty liver disease (NAFLD). Therefore, we investigated the effect of rice consumption on NAFLD and the underlying molecular mechanism.

Methods: Seven-week-old male obese Zucker (*fa/fa*) rats, an animal model of NAFLD, were randomly divided into three groups (n = 10 each) and fed one of three diets for 10 weeks: Cont (AIN-93G diet; 53% cornstarch), WR, (AIN-93G diet with cornstarch replaced with white rice powder) and BR (AIN-93G diet with cornstarch replaced with brown rice powder). Liver fat accumulation and gene expression related to lipid and vitamin A metabolism, including retinoic acid (RA) signaling, were analyzed.

Results: Hepatic lipid significantly decreased in the BR group compared with the Cont group by 0.4-fold ($P < 0.05$). The expression of genes related to hepatic fatty acid oxidation such as carnitine palmitoyltransferase 2 was approximately 2.1-fold higher in the BR group than the Cont group ($P < 0.05$). The expression of peroxisomal acyl-coenzyme A oxidase 1 and acyl-CoA dehydrogenase medium chain was also significantly increased, by 1.6-fold, in the BR group compared with the Cont group ($P < 0.05$). The expression of VLDL-secretion-related genes such as microsomal triglyceride transfer protein was also significantly higher in the BR group (2.4-fold) ($P < 0.05$). Furthermore, aldehyde dehydrogenase 1 family member A1, an RA synthase gene, was 2-fold higher in the BR group than the Cont group ($P < 0.05$). Conclusion: Brown rice prevented development of NAFLD in obese Zucker (*fa/fa*) rats via increasing the RA synthesis which therefore upregulated the fatty acid oxidation and VLDL secretion. These finding suggest a novel regulation mechanism of RA synthesis and the beneficial effect of brown rice on lifestyle related diseases.

Blood urea nitrogen, creatinine, and kidney histopathology of rat during subchronic toxicity study of porang (*Amorphophallus oncophyllus*) flour macerated with *Strobilanthes crispus* in Wistar Rats

Veriani Aprilia[1], Daru Estiningsih[1], Rizal Fauzi[1], Eva Nurinda[1]

1. Alma Ata University (Indonesia)

Background and objective: Porang is local tuber that is widely cultivated in Indonesia. This tuber is high in beneficial compound glucomannan, but contain calcium oxalate that may damage the kidney. The maceration of *Strobilanthes crispus* could reduce calcium oxalate levels and proved to safe based on acute toxicity study. Subchronic toxicity test was important as the further study for its safety. This study aimed to investigate the blood urea nitrogen, creatinine, and kidney histopathology of rat after treated with porang (*Amorphophallus oncophyllus*) macerated with *Strobilanthes crispus* (PSC) during 28 days.

Methods: A sub chronic toxicity study was conducted based on The Regulation of The Head of The Food and Drug Supervisory Agency of The Republic of Indonesia. twenty-four male Wistar rats were divided into 4 groups, those were control (without oral administration), P1 (administered with 1000 mg/kg bodyweight/BW), P2 (2000 mg/kg of BW), P3 (4000 mg/kg of BW). Blood was collected from the vena retroorbital by microcapillary technic at day 0 and 28 after treatment for the measurement level of BUN and creatinine. At the end of the study, rats were euthanized by decapitation, the kidney organs were excised carefully, then preserved in 10% buffered formalin before the histopathological study.

Results: this study showed that the levels of BUN were normal after the 28 days of PSC administration (10-16 mg/dL) in all groups. Otherwise, the creatinine levels increased with the dosage increase of PSC administration. Kidney histopathological study confirmed that almost all of rats did not change, except for control, P1, and P2 groups that experienced to interstitial nephritis with the percentage of 40, 40, and 20%. This indicated that PSC did not damage the kidney.

Conclusion: The study concluded that PSC administration for 28 days did not change the normality of BUN and also did not damage the kidney. A further study must be conducted to know the deeper cause of creatinine increase.

Aspartame Consumption, Mitochondrial Dysfunction induced Impaired Oocyte Maturation, and Infertility Risk

Yang Ching Chen[1], Yen-Chia Yeh[1], Yu-Fang Lin[1], Heng-Kien Au[1], Shih-Min Hsia[1], Rong-Hong Hsieh[1]

1. Taipei Medical University Hospital (Taiwan)

Background and objectives: Aspartame is the most popular non-nutritive sweeteners worldwide. No safety of consumption report has been studied regarding women of reproductive age who are preparing for pregnancy. We aimed to explore the harmfulness of aspartame and the potential mechanism by which it increases infertility risk through clinical observation, in vivo, and in vitro studies.

Methods: We established a cohort of 840 pregnant women, and retrospectively obtained their time to conceive. Animal models and a human granulosa-like tumor cell line (KGN) were used for investigating the possible mechanisms.

Results: Aspartame consumption is associated with increased infertility risk among younger women (OR:1.79, 95% CI: 1.00, 3.22). In vivo study revealed that aspartame provoked disturbed estrus cycle, lower anti-mullerian hormone level. Aspartame treatment also suppresses the antioxidant activities and result in higher oxidative stress in the ovary and granulosa cells. This is due to an aspartame-induced decline in mitochondrial function (maximal respiration, spare respiratory capacity, and ATP production capacity), and triggered mitochondrial biogenesis (assessed by energy depletion signaling-related factors SIRT1, pAMPK, PGC-1α, and NRF1 expression level). Aspartame may alter fertility by fewer reserve follicles in the ovary and poor steroidogenesis in granulosa cells.

Conclusions: In summary, these results demonstrated that aspartame consumption may increase infertility risk through mitochondrial dysfunction-induced impaired oocyte maturation. Hence, for women preparing pregnancy, aspartame are suggested to be used cautiously.

Acrylamide: the carcinogen in your food

Chiara Manzi[1], Antonella Cavazza[2], Chiara Bignardi[2], Maria Grimaldi[2], Carmen Laganà[2], Massimiliano Rinaldi[2], Claudio Corradini[2]

1. Cucina Evolution Academy (Italy), 2. University of Parma (Italy)

Objectives: Acrylamide is a potentially cancer-causing substance that naturally forms in starchy food products during high-temperature cooking and low moisture, by Maillard reaction. European Food Safety Autority concluded that they cannot set a tolerable daily intake of acrylamide in food and estimated the dose range within which acrylamide is not a concern for publich health: 1 mcg of acrylamide a day. This dose may be found in 1 g of potato chips or 3 g of first born biscuits. Since potatoes and flours are one of the foods that contribute most to overall dietary human exposure of acrylamide, Chiara Manzi, together with Parma University and Cucina Evolution Academy, investigated the correlation between acrylamide content and color of these foods with the purpose to analyze the best cooking and processing method to reduce the exposure to acrylamide.

Methods: Acrylamide in foods has been detected by liquid chromatography coupled to mass spectrometry in baked potato samples cooked at different time, temperature and steam conditions. With the same tecnique was studied the formation of acrylamide in different types of doughs made respectively with 00 flour, wholemeal flour and a specifix mix of different cereals added in fiber, cooked at different temperatures, from 220 °C to 300 °C and with different timing, from 3 to 6 minutes.

Results: Acrylamide is directly proportional to the intensity of the color assumed after cooking. a Photographic Tool has been developed to help consumers recognize acrylamide in foods. Results showed that the darker the color of the potatoes, the more acryamide is present. A method of cooking potatoes very low in acrylamide has been developed: potatoes were cooked in oven (140°C – 180°C) for 10 to 60 minutes (steam/hot air). A special cereal mix for cooking Pizza very low in acrylamide has been developed and produced.

Conclusions: Daily we are exposed to acrylamide through the ingestion of many foods that contains this process contaminant. However, acrylamide is visible during food cooking and it is therefore essential to become aware of the excessive browning of foods. The best cooking processes for cooking pizza and potatoes have been investigated.

OAB(T8)1-4
Study on lactone formation by thermal oxidation of saturated fatty acids

Kanji Aoyagi[1,2], Shunji Kato[1], Yurika Otoki[1], Kiyotaka Nakagawa[1]

1. Tohoku University (Japan), 2. The Nisshin OilliO Group, Ltd (Japan)

Background and objectives: Lactone is a important aromatic molecule that contributes to flavor in meat and dairy products. Although lactone is generally observed during thermal oxidation of saturated fatty acids, the generation mechanism has not been fully understood. In this study, four saturated triacylglycerols were thermally oxidized and their peroxide value (POV) and resulted lactones were analyzed to obtain the insights on this mechanism.

Methods: Four saturated triacylglycerols (trioctanoate (tri-C8), tridecanoate (tri-C10), tridodecanoate (tri-C12), and tritetradecanoate (tri-C14)) were used as samples. After oxidation under the conditions A (100-200°C, 60 min) and B (180°C, 0-480 min) (n = 5), the POV was measured. Lactones were analyzed by GC-MS.

Results and Discussion: Lactones were detected from all heated triacylglycerols and the carbon number of resulted lactones were mostly consistent with those of constituent fatty acid, i.e., tri-C8 > γ(δ)-octalactone, tri-C10 > γ(δ)-decalactone, tri-C12 > γ(δ)-dodecalactone, and tri-C14 > γ(δ)-tetradecalactone. The POV were 49.8 (tri-C8), 44.4 (tri-C10), 7.1 (tri-C12), and 10.1 (tri-C14) (meq/kg, 180°C, 120 min). These values were correlated with the amount of the generated lactones, which suggests that the formation of hydroperoxide is an important reaction for lactone generation. Lactones are generally known to be produced by dehydration cyclization of microbiologically generated hydroxy fatty acids. Additionally, the formation of saturated fatty acid hydroperoxide during heat treatment was shown by this study. Therefore, regarding the pathway of lactone formation by heat treatment of saturated fatty acids, we predict that hydroperoxyl groups may be formed at C4(C5), which are reduced to hydroxyl groups and cyclized to form γ(δ)-lactones.

Conclusions: This study suggests that hydroperoxyl group formation at C4(C5) is a key for the lactone generation on thermal oxidation of saturated fatty acids. In order to verify whether this mechanism is correct, we are now trying to isolate saturated fatty acid 4(5)-hydroperoxide. The insights obtained in this study is useful for the creation of certain lactones from saturated fatty acids, which will greatly contribute to the food industry.

Assessment of purity and iodine content of sea salt in Visayas and Mindanao, Philippines

Leila Sacdalan Africa[1], Adeliza Abano Dorado[1], Julieta Amante Delos Reyes[1]

1. University of the Philippines Los Banos (Philippines)

Background and objectives: By law, salts sold in the Philippine market must contain at least 97% sodium chloride (NaCl) on a dry matter basis and 30-70 ppm (mg/kg) of iodine (I_2). However, salts may contain a variety of contaminants that are harmful to human health, particularly sea salts. Hence, this study aimed to assess the purity of sea salts produced in existing farms in the Visayas and Mindanao regions of the Philippines by determining their NaCl and I_2 contents.

Methods: Samples were collected from 15 sites for laboratory analyses. Sodium (Na) was determined using flame photometer method, chloride (Cl) by titrimetric method using silver nitrate (AgNO3), and iodine (I) by titrimetric method using sodium thiosulfate (Na2S2O3). The NaCl content of the collected sea salt was computed based on the molar mass of pure salt (39.3% Na and 60.7% Cl) with sodium being the limiting component.

Results: All the salt samples contained <97% NaCl (range: 67% - 94.6%) and <30 ppm iodine content (range: 1.7 - 13.4).

Conclusions: All the salts in the Visayas and Mindanao salt farms were not able to meet the required % of NaCl and level of iodine for Philippine market. These findings point to the necessity for initiatives to ensure that salts sold in the market meet the purity and iodization criteria for human consumption to ensure food safety and eliminate iodine deficiency disorder in the country. To properly analyze the composition and purity of salt in the Philippines, future research should investigate the heavy metal elements of both sea salts in addition to NaCl and I_2.

Glutamate content in Thai and German condiments

Naruemon Wechjakwen[1,2], Jennifer Musiol[3], Ursula Bordewick-Dell[3], Karunee Kwanbunjan[1]

1. Mahidol University (Thailand), 2. Nakhonratchasima Rajabhat University (Thailand), 3. FH Münster University of Applied Sciences (Germany)

Background and Objective: Monosodium glutamate (MSG) is used as a flavor-enhancing additive. The negative effects of MSG at which level consumption are controversial. Objective of this study aims to determine the level of free glutamate content in Thai and German local markets.

Method: The glutamate levels were determined in 13 German and 14 Thai condiments, using Enzymatic Bio Analysis and spectrophotometry.

Results: The average glutamate content was higher in German condiments than that in Thai. Free MSG was found 8,416.67 mg/100 g in popular German condiment sauces and 226.00 mg/100 g in tomato ketchup, whereas found 2,533.33 mg/100 in Thai condiment sauces and fish sauce 741.67 mg/100 g. Tomato salad provide MSG 443.81 mg per serving which commonly consume in Germany, while in Thailand, red curry provide 113.33 mg MSG per serving.

Conclusions: This findings confirmed amount glutamate content in different German and Thai commercial condiments and seasonings. The MSG intake of two countries people depends on the product processing and food behaviors.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Background and objectives: Nearly 162 million children under 5y are stunted worldwide. The Action Against Stunting Hub takes a holistic approach to understand and classify stunting, interdisciplinarily. One aspect is the potential of animal-source foods (ASFs) to prevent stunting, due to their high density in essential nutrients. However, ASFs can also generate foodborne disease, offsetting the benefits. Our objectives were to investigate foodborne hazards of select ASF value chains (VCs), to develop tailored market-based interventions that increase good quality ASF access by pregnant women and their infants, and ultimately alleviate stunting.

Methods: We conducted a systematic literature review to understand the stakeholder practices, the associated biological/chemical hazards and identify gaps and priorities for research in these VCs, in Hyderabad city (India), Lombok island (Indonesia) and Kaffrine county (Senegal), following the PRISMA-ScR approach. At each setting, a cohort of low-income pregnant women was recruited and followed up until their newborns were aged 2. Questionnaires, direct observation and food testing were conducted to identify consumer risk practices. We selected key ASFs for each cohort, based on consumption patterns and potential for upgrading and upscaling. Focus group discussions and key informant interviews were conducted to understand the consumer food environment and other VC aspects such as location of markets and retailers; input and output flows; production, processing and distribution channels, product and stakeholder characteristics; seasonality effects; perceptions in relation to food safety; or governance.

Results: Limited studies were available, but six ASF value chains were reported: dairy, poultry, pork, beef, fish and small ruminants. Key hazards identified were *Brucella spp*, *Campylobacter spp, E.coli, Salmonella spp,* and *Staphylococcus aureus* and Lead. The VCs identified as those with potential to alleviate stunting in the cohorts were egg, fish, and dairy. A conceptualisation map revealed important ASFs VC factors linked to stunting as production factors, infrastructure, governance and seasonality. Thematic analysis revealed the workings of the VCs, nodes where interventions can be targeted, and challenges to upgrading.

Conclusions: Addressing supply chain challenges, risks, and governance is feasible and this research aims to guide policy-makers on approaches to improve availability of nutritious and safe food among consumers.

Evaluating the long-term effect of homestead food production on households in Darchula, Nepal: a mixed-methods assessment, eight years post-intervention

Rojee Suwal[1], Kenda Cunningham[1,2], Pooja Pandey[1], Shiva Bhandari[3], Edward A Frongillo[3], Shradha Manandhar[4]

1. Helen Keller Intl. (Nepal), 2. London School of Hygiene and Tropical Medicine (UK), 3. University of South Carolina (USA), 4. Huddersfield University (UK)

Background and objectives: Despite significant progress over the last two decades of reducing stunting in Nepal, both maternal and child undernutrition remain major public health burdens. Agricultural interventions are known to be important for reducing malnutrition via improved production and consumption as well as income generation and women's empowerment pathways. Previous research studies have shown the effectiveness of homestead food production at improving diets and reducing anemia. No studies to date have assessed outcomes including dietary diversity, anemia, household food security, and wasting nearly a decade after the interventions, despite its importance for understanding the sustainability of improved outcomes. Suaahara, a large-scale, USAID-funded, multi-sectoral program (2011-2023) aims to reduce undernutrition among women and children in the first 1000-days of life via interventions in nutrition, health, family planning, agriculture, governance and gender and social equality. The primary objectives of this study are: 1) to evaluate the effect of the homestead food production (HFP) intervention at improving agricultural practices, household food security, and maternal and child dietary diversity more than eight years after the households received the HFP intervention and 2) to understand why, how, and when steps along the theory of change materialized or broke down.

Methods: The primary impact evaluation uses a quasi-experimental, repeated cross-sectional design with multi-stage clustering. An additional mixed methods endline survey to evaluate the homestead food production component is being done. In one remote mountain district (Darchula) that is part of the primary impact evaluation, about 80 randomly selected households were identified for whom we have baseline data and know when they received inputs (starting 2012-2013). During endline, these original households whose children are now 8 to 11 years of age will be followed as a cohort. Both quantitative and qualitative data will be collected in June-September 2022 by externally hired data collectors, overseen by an external principal investigator and research team. Ethics approval has been granted by the Nepal Health Research Council.

Results: Results will be available in the fall including primary impact estimates for agricultural practices, household food security, and maternal and child diets as well as primary qualitative findings.

Conclusions: The results will be used to guide future large-scale homestead food production efforts in Nepal and similar contexts.

Role of home gardening on food security of rubber farmers in Iguoriaki farm settlement Edo state, Nigeria

Ogeri Rosemary Idika[1], Timothy Esekhade[1], Jeffery Iyare Omoruyi[1], Andrew Ohifuemen[1], Nkeruwem Ndaeyo Ekerete[2]

1. Rubber Research Institute of Nigeria (Nigeria), 2. Department of Home Economics, Nutrition and Dietetics. Faculty of Agriculture. University of Uyo, Uyo. (Nigeria)

Food security is of great public health concern in Nigeria. This is due to the high rate of poverty in the country; it also impacts on the socio economic well being of the general populace, hence the need for the study. This study was conducted to access the role of home gardening on the food security of rubber farmers in Iguoriaki, Edo State, Southern Nigeria. Random sampling was used to select 50 respondents for the study. A well structured questionnaire was used to get information on the demographic characteristics of the respondents. Body Mass Index(BMI), Mid Upper Arm Circumference (MUAC), Dietary Diversity score and Home Gardening practices of the respondents were gotten. Result showed that the respondents do not eat fruits regularly, It also revealed 82% of the respondents had a BMI of 18.5- 24.9 which is within the normal range, while 12% of the respondents are overweight and 6% are obese(30.0-40.0) BMI. The study showed that 46% of the respondents are averagely food secured while 4%are very food insecured. 94% of the respondents own gardens and mostly plants vegetables. 49% of the respondents strongly agree that owning a garden makes them have more food for the family. 25% strongly agree it helps them to afford non food items, the result shows that 74% of the respondents earn less than 120 thousand naira monthly. 35.4% of the respondents also strongly agree that it affords them wider variety of food to eat. The result also shows that 2% of the respondents rear animals in their homes. 90% of the respondents get their primary source of water from borehole and 80% relies on their personal power generators as their primary source of energy. From the result, we see that owning a home garden has tremendous impact on the lives of the rubber farmers. A lot of extension work has to be done to enlighten farmers on the importance of owning a home garden.

OAB(T8)2-6

Improving the nutritional value of recipes for women of childbearing age and children 6-23 months of age from *Vigna radiate* (l.) *Wilczek*. and *Moringa oleifera* in north-Benin

Malikath Bissola Bankole[1], Sam Bodjrenou[1,2], Flora Chadare[1,3], Gloria Codo[1], Julia Bodecker[2], Celine Termote[2], Waliou Amoussa Hounkpatin[1]

1. Faculty of agronomics sciences (Benin), 2. Alliance Bioversity International – CIAT (Benin), 3. National University of Agriculture (Benin)

Background and objectives: Enhancing biodiversity is a simple way to improve food choices and contribute to a diversified diet. This study aimed to improve the quality of foods consumed by women of childbearing age and children aged 6-23 months in the Atacora Department of northern Benin.

Methods: Two locally consumed recipes, *zankpiti* (a mixture of boiled cowpea with maize flour and red palm oil) and *abobo* (boiled cowpea with seasonings) were improved with mung bean (*Vigna radiata* (l.) Wilczek) and moringa leaves (*Moringa oleifera*). The formulation of the different improved recipes was done with Minitab software, version 18 using the mixing design. The optimized recipes were tested through a hedonic test by 62 volunteer couples in each of the three (03) study communes of Atacora. The real nutritional densities of accepted recipes were then determined.

Results: The results of the acceptability test showed that both recipes were well accepted by the mothers and their children. With regard to the real nutritional value, only the energy and vitamin A densities of the two recipes were well above the recommended standard (2.16 kcal/100g and 1084.99 RE ug/100kcal for zankpiti of mung bean (*ZM*); 1.85 Kcal/100g and 1009.75 RE ug/100kcal for abobo of mung bean with moringa leaves (*AMM*)). The nutritional densities of iron, calcium and zinc did not meet the recommended standards. Redarding the coverage rates of the daily children needs, both recipes had very high vitamin A coverage (828.99% and 618.39% for *ZM* and *AMM* respectively). Both recipes covered good levels of their zinc, iron and energy requirements (14.07% for zinc, 21.72% for iron and 34.53% for energy) while the AMM recipe covered a high level only for energy (28.33%). Regarding the daily calcium requirements of children, both recipes covered low levels.

Conclusions: *ZM* and *AMM* had good densities of energy and vitamin A and were well accepted by mothers and their children. However, although they were accepted, the nutrient densities of calcium, iron, and zinc in both recipes should be improved to allow for better coverage of children's daily nutritional needs.

Microbiota identification and their effects on characteristics of dry-aged beef manufactured in Japan

Nana Mikami[1], Takahito Toyotome[1], Yoshitaka Yamashiro[1], Koyuki Sugo[1], Kotone Yoshitomi[1], Masahiro Takaya[2], Kenichi Tamura[3]

1. Obihiro University of Agriculture and Veterinary Medicine (Japan), 2. The Tokachi Foundation (Japan), 3. Kitaichi Meat Co., Ltd. (Japan)

Background and objectives: Dry aging is a traditional method of storing beef carcasses or cuts at refrigerated temperatures without vacuum packaging. Dry-aged beef (DAB) develops a crust including microflora with fungi and bacteria over the aging process. However, it is not well understood on DAB-related microorganisms and the changes in meat qualities caused by them during aging. Therefore, we aimed to determine the microbial distribution and their impact on DAB manufactured in Hokkaido, Japan.

Methods: Two blocks of rump obtained from the right and left sides of an individual Holstein steer were applied for dry or wet (vacuum-packaged) aging. Both portions were placed in a same aging room (2.9℃ and RH 90%) for 35 days, and the portion for dry-aging was allowed to contact with the fungal flora in the room air. After 35 days of aging, identification of fungal species and bacterial quantification on DAB crust were performed by DNA sequence and plate count method, respectively. Additionally, meat qualities such as water holding capacity, instrumental color and shear force were compared between DAB and wet-aged beef (WAB). Furthermore, free fatty acid composition and free amino acid content of DAB and WAB were measured by GC and amino acid analyzer, respectively. Volatile flavor compounds in the meat were prepared by HS-SPME and analyzed by GC-MS.

Results: The psychrophilic molds *Mucor flavus* and *Helicostylum pulchrum* mainly appeared on the crust of DAB, while lactic acid bacteria and coliforms were suppressed in the inner part of the meat. The meat quality, free amino acid and the composition of major fatty acids (C16:0, C18:0, and C18:1) did not differ between DAB and WAB. Dry aging suppressed acids and increased the production of various aroma compounds with mushroom-like, nutty, and other pleasant flavors.

Conclusion: In this study, we identified the furry molds that predominate on the crust of DAB as *M. flavus* and *H. pulchrum.* To our knowledge, this is the first time the combination of *M. flavus* and *H. pulchrum* has been reported on DAB. These results suggested that *M. flavus* and *H. pulchrum* may contribute to the production of unique flavors describing DAB.

Keywords: Dry-aged beef, microbiota, fungi, volatile aroma compound

Preludes to standardize the preparation process of *nah poh*: Effect of emulsifying agent and crude palm oil types on the stability of emulsion

Steve Djiazet[1,3], Blandine Laurette Kenfack Mezajoug[2], Christine Dibongo Nsume[3], Clerge Tchiegang[1,3]

1. National School of Agro-Indusctrial Sciences, University of Ngaoundere, Cameroon (Cameroon), 2. Department of Food Engineering and Quality Control (GACQ), University Institute of Technology (Cameroon), 3. National School of Agro-Indusctrial Sciences, University of Ngaoundere, Cameroonces and Nutrition, National Advanced School of Agro-Industrial Sciences (ENSAI), University of Ngaoundere (Cameroon)

Background and objectives: Producing emulsified traditional food products remains a problem to households and industries. Studies show that emulsion-based beverages are gaining consumer's attention. They are used as vehicle of bioactive compound, and very few exist on the market. In Cameroon there exist a gravy known as yellow *achu* soup or *nah poh*, that the preparation process is based on production of emulsion. When the emulsion is poorly prepared, it quickly destabilises. Due to the importance, we are interested to modernised it to make a commercial food product. In the present study, the effect of emulsifying agents (*kanwa*, burned *kanwa*, *niky*) and crude palm oil types were studied to understand the traditional knowledge related to the preparation of *nah poh*, to ease the intergenerational knowledge transfer necessary for its preparation and bring out a new food product.

Methods: A survey was conducted to collect knowledge related to the traditional practices used to produce more stable emulsion for the preparation of *nah poh*. Data collected were exploited to choose appropriate crude palm oil and to prepare emulsions. The stability of the emulsions was studied by the measurement of conductivity and apparent viscosity.

Results: It was found that there exist three main processes that are traditionally used for the preparation of the gravy. The apparent viscosity of crude palm oil emulsion produced using *kanwa* was higher 103cPthan that produced by *niky 28cP*. Emulsions produced with burned *kanwa* were shown to be more stable, with low variations of conductivity 9.4 to 10.25 mS/cm. Appropriate crude palm oils to produce more stable emulsions for *nah poh* were those with higher phospholipid content (10.33±3.96µg/100g and 9.72±0.93 µg/100g respectively). Oils having high saponification index were also good to produce more stable emulsion.

Conclusion: One can conclude that the stability of crude palm oil emulsion for *nah poh* depends on the phospholipid content, acid value the nature of emulsifying agent used as well as the process of preparation used.

Effect of post-harvest handling processes on the nutrient, chemical composition and sensory properties of silver cyprinid powder.

Abiika Angella[1], Gaston Ampe Tumuhimbise[2], Moses Barigye[1], Erinest Bumba[2]

1. Makerere University (Uganda), 2. Nutrition society of Uganda (Uganda)

Background and Objectives: The proper post-harvest handling processing of the highly perishable silver cyprinid (Rastrineobola argentea) could contribute towards alleviation of food insecurity by directly acting as a food resource or employment for income generation among vulnerable groups. Despite the many processing techniques used, the quality and value of silver cyprinid still remains low. This research was carried out to establish how effective different post-harvest handling processes are in improving the quality (nutrient content, chemical and sensory properties) of silver cyprinid powder and objectives were to develop a process for the production of quality powder from silver cyprinid for utilization as an ingredient in human foods, to determine the effect of different postharvest processes on the nutrient and chemical composition of silver cyprinid powder.

Methodology: The silver cyprinid was subjected to different conditions: soaking in varying concentrations of NaCl (0.5%, 1%, and 1.5%), varying concentrations of acetic acid (0.05%, 0.1% and 0.15%), blanching at varying temperatures (40^{o}C, 50^{o}C, 60^{o}C) and sun-drying as control. Determined the proximate, chemical and sensory properties.

Results: Results showed that the different postharvest handling processes had significant effects on the proximate, chemical and sensory properties of the silver cyprinid powered. Increasing the NaCl concentration led decrease in proximate composition (Total ash, crude fat, moisture content and crude protein). Increase in NaCl also caused increase in chemical properties (pH and Thiobarbituric acid reactive substances (TBARS) of the silver cyprinid powder. Increasing acetic acid concentration caused variations in proximate composition; the moisture and ash content decreased while the protein and fat content increased. Increase in acetic acid concentration also led to a decrease in chemical properties, pH and TBARS. Increasing the blanching temperature on the other hand caused a decrease in all the proximate properties and pH but increased the thiobarbituric acid content. Soaking silver cyprinid in NaCl yielded sauces with higher consumer acceptability than those subjected to other treatments.

Conclusion: The study therefore revealed that treatment with 1% NaCl would be recommended to be used as preprocessing condition that maintains the nutrient and chemical quality of the fish and produces sauces with acceptable sensory characteristics .

Unleashing the health benefits of coloured potatoes

Yang Yue[1], Cathie Martin[1], David Vauzour[2], Arjan Narbad[3]

1. John Innes Centre (UK), 2. University of East Anglia (UK), 3. Quadram Institute (UK)

Potato (*Solanum tuberosum*) is a beleaguered vegetable that has been blamed for the onset of ill-health such as diabetes and hypertension, because of its high calory contribution to the diet and its preponderance in junk food. However, it is a good source of protein and numerous nutrients (iron, phosphorus, and potassium). Nevertheless, inconsistent research outcomes on the role of potatoes in the diet have been obtained from observational and epidemiological studies, adding to the notorious reputation of elite potato varieties (characterised by having white/yellow skin and flesh). Revisiting heirloom varieties might uncover nutritional benefits of coloured potatoes, benefits which may have been lost during crop domestication. Anthocyanins are conspicuous plant pigments underpinning unique coloured potato varieties, and they are some of the best-characterised flavonoids derived from the phenylpropanoid pathway. To disentangle the interaction of phytochemicals and other bioactive components in the food matrix, I have analysed preselected heirloom coloured potato varieties including a standard white variety as a control, based on the similarity in the flavour of 10 pre-commercialisation germplasm varieties. In my preliminary study, anthocyanins were present in both raw red ("Red Emmalie") and purple ("Salad Blue")-fleshed potato tubers compared to the control ("Aura"). Cooking (steaming) affected the retention of anthocyanins in food. "Red Emmalie" has less colour loss during cooking than "Salad Blue." Metabolic analyses confirmed that pelargonidin was the main anthocyanin in "Red Emmalie" while petunidin was found in "Salad Blue". We hypothesized that anthocyanins might behave like proanthocyanidins (PAs) and improve the resistance of starch in potatoes. This was shown by Rapid Visco Analysis (RVA), which provided an indirect measurement of starch viscosity that mimicked the effects of cooking on starch. Our results indicated that starch granules could interact with anthocyanins *in vitro* and shifted the physicochemical properties of starch. In addition, PAHBAH assays were used to validate starch digestion over a time course, "Red Emmalie" was significantly more resistant to digestion compared to "Aura" and "Salad Blue" potato varieties. To gain further understanding of the interactions between starch and anthocyanins *in vitro*, we imaged potato starch granules in both uncooked and cooked potatoes using scanning electron microscopy (SEM). Uncooked starch had uniform oval spherical shape in all three varieties, however, there were smaller starch granules in "Red Emmalie" compared to "Salad Blue" and "Aura". This was also seen for starch granule distribution, measured using a coulter counter. However, the cooked starch was consistently broken into pieces in all three varieties. In addition, confocal image analysis elegantly demonstrated the localization of starch granules and anthocyanins in cross-sections of the three potato varieties. Anthocyanin Vacuolar Inclusions (AVI) were found in "Red Emmalie". Overall, this study holds the promise that coloured potatoes offer the potential for addressing the interactions

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

between anthocyanins and the resistance of starch to digestion. They may also demonstrate that coloured potatoes release the calories from their starch more slowly and so may offer health benefits to the consumer relative to standard white potatoes.

OAB(T8)3-5

Effect of exogenous enzyme on the utilisation of dried cashew apple pulp in broiler chicken diets

Iyabode Kehinde Yisa[1], Oyebiodun Grace Longe[2]

1. CEDAVES/ONG-Asas de Socorro, Guinea-Bissau (Guinea-Bissau), 2. University of Ibadan (Nigeria)

Background and objectives: Cashew apple is hugely wasted in cashew producing countries with less than 10% used in immediate consumption as fruit, alcoholic and non-alcoholic beverage production. This is due to its quick deterioration after harvest. Sun drying cashew apple and its inclusion in poultry feeds is a novel practice which could enhance income for cashew producers and lower cost of production of poultry meat and eggs. However, dry cashew apple pulp (DCAP) has a considerable fibre content which could limit its utilisation in chickens. Exogenous enzymes have been used to improve feed for chickens. This experiment was therefore carried out to study the effect of a multienzyme in the utilisation of DCAP in broiler chickens.

Methods: A total of 288 unsexed Arbor Acre Plus broiler chicks were randomly allotted to six treatments and replicated six times in a 2x3 factorial arrangement in a completely randomized design. There were eight birds per replicate. Six diets each were formulated for starter and finisher phase, three levels of 0%, 15% and 30% DCAP replacement for maize with and without enzymes. The enzyme used was a multienzyme named NATUZYME and contained amylase α-amylase (400,000Ukg^{1}) from *Bacillus subtillis,* β-glucanase (700,000 Bioproton bukg^{1}) from *Trichoderma longibrachiatum*, phytase (1,300,000ukg^{-1}) *Aspergillus niger*, cellulase (6,000,000 Bioproton cukg^{-1}) from *Trichoderma longibrachiatum* , xylanase (10,000,000Bioproton xukg^{-1}) from *Trichoderma longibrachiatum* and protease (700,000Ukg^{-1}). Parameters taken were feed intake, weight gain, feed conversion ratio, digestibility and cost analysis.

Results: There was no significant difference in feed intake. Weight gain was higher in 30% DCAP with enzyme at the starter phase. Enzyme did not have any effect on weight gain at the finisher phase. No significant difference was observed in feed conversion ratio. At 30% DCAP replacement for maize; crude protein, ash, crude fibre, ether extract and nitrogen free extract digestibilities were improved but not dry matter digestibility. There was no significant difference in the cost of feed consumed/weight gain in DCAP replacement for maize.

Conclusions: The multienzyme used conferred benefit to the partial replacement of maize with DCAP only at the starter phase.

Changing directions of agricultural land use in the face of global climate change - the case of Central Europe

Jerzy Banski[1]

1. Polish Academy of Sciences (Poland)

Background and objectives: Agricultural land, as no other form of human economic activity, is dependent on climate and weather phenomena. Each, the smallest climate change or weather anomaly causes serious effects on land management, such as the change of the area of its components and the range of agricultural crops, the modification of the timing of field works, the change of yields. Recognition of relations between global climatic phenomena and agricultural land use is very important for forecasting possible changes and modeling adaptive forms within land management, in the aspect of biodiversity of ecosystems and food security. The aim of this paper is to assess the production possibilities of agriculture in Central Europe in the face of the challenges of climate change, with a focus on adaptation measures in agricultural land use.

Methods: The research used a variety of techniques from the field of analysis of found materials, statistics and spatial analysis, and cartographic methods of presentation. Using statistical methods to examine time-series data, trends in agricultural land management under the influence of climatic factors over the past several decades were determined. Trends in social and economic change were contrasted with trends in changes in climatic factors. This allowed the identification and evaluation of the role of individual climate elements in the agricultural economy. As a result, it was possible to develop characteristics of climate-agriculture interactions.

Results and Conclusions: Climate warming in the coming decades is the most likely phenomenon, confirmed by numerous scientific studies. In agriculture it will bring a spatial polarization of food production. In Central Europe, as a result of increasing temperature and lengthening of the growing season, the production potential will increase, resulting in the introduction of new plant crops and a shift in their range limits towards the north. It can be assumed that there will be rather favourable changes in terms of agricultural production possibilities, although significant areas are increasingly affected by extreme weather events. In Poland, the assumed climatic changes may bring about an increase in production potential, due to the lengthening of the growing season and the possibility of growing thermophilic crops. With optimistic assumptions it will be possible to graze grassland animals all year round. In case of

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

some crops it will be possible to obtain two harvests. Improvement of fodder resources will result from the possibility of growing pre-crops and catch crops. However, it is necessary to take into account the possibility of more frequent extreme weather phenomena, which may reduce the potential for production growth.

Multiplying the efficiency and impact of biofortification through metabolic engineering of rice for the Philippines

Howart Bouis[3], Inez Slamet-Loedin[1], Kurniawan Rudi Trijatmiko[1], Nikolaos Tsakirpaloglou[2], Gela Myan Bueno[1], Mallikarjuna Swamy[1], Mercy Samia[1], Amery Amparado[1], Reynante Ordonio[4], Russell F Reinke[1]

1. International Rice Research Institute (Philippines), 2. Texas A&M AgriLife Research. (USA), 3. International Food Policy Research Institute (USA), 4. PhilRice (Philippines)

Background and Objectives: Recently the Philippine government has approved commercial production of transgenic rice with provitamin A in the milled grains (Golden Rice). Soon analogous approvals will be sought for transgenic high iron and zinc rice. What contribution might transgenic provitamin A, iron, and zinc rice make to intakes of these three key nutrients in Philippine diets?

Methods: Transgenic lines with high densities of provitamin A, iron, and zinc were grown alongside popular conventionally bred varieties. Levels of provitamin A, iron, and zinc were measured after 10 percent milling. Iron and zinc were measured using ICP analysis. Total carotenoids were measured using a spectrophotometer after two months of storage to take account of degradation.The average daily per capita intake of milled rice (300 grams) was applied to these differentials to estimate the increment for any given day where the transgenic rice substitutes completely for conventionally-bred rice.

Results: Each gram of transgenic rice provides +1 RAE whereas there is no provitamin A in ordinary milled rice, and increments of +31.6 mg/kg of Zn, and +7.8 mg/kg of Fe. At a daily intake of 300 grams this provides 300 RAE before cooking, and an extra 10.5 mg Zn and 2.3 mg Fe to average intake. Current intakes are approximately 500 RAE (before cooking) and 9 mg Fe. Further research is being undertaken to estimate zinc intakes in the Philippines from all foods and to disaggregate the analysis by urban/rural, wealth quintile, and age/gender. Rice intakes do not vary significantly by income group, but mineral and vitamin intakes are significantly lower in lower wealth quintiles.

Conclusions: Transgenic rice with provitamin A, zinc, and iron, holds great potential for increasing the daily intakes of these three important nutrients in the Philippines. The key challenge will be to secure wide adoption. Iron and zinc are tasteless and invisible whereas provitamin A gives the milled grains and cooked rice a yellow color which marks the nutritious product. Because of high yields, in equilibrium the transgenic rice should sell for the same price as conventionally-bred rice.

Use of orange-fleshed sweet-potato (*Ipomoea batatas* L.) for the prevention of vitamin A deficiency: the successful experience of Kaffrine, Senegal

Papa Mamadou Dit Doudou SYLLA[1,2], Abdou Badiane[2], Mame Samba Mbaye[1], Laure Tall[3], Fatou Ndoye[4], Bassirou Diallo[3], Adama Diouf[2], Nicole Idohou Dossou[2], Philippe Donnen[5], Kandioura Noba[1]

1. Laboratoire de Botanique et Biodiversité, Université Cheikh Anta Diop (Senegal), 2. Laboratoire de Recherche en Nutrition et Alimentation Humaine, Université Cheikh Anta Diop (Senegal), 3. Laboratoire National de Recherches sur les Productions Végétales, Institut Sénégalais de Recherches Agricoles (Senegal), 4. Université du Sine Saloum El Hadj Ibrahima Niass (Senegal), 5. Centre de Recherche Politiques et Systèmes de Santé-Santé Internationale, École de Santé Publique, Université Libre de Bruxelles (Belgium)

Background and Objectives: The orange-fleshed sweetpotato (OFSP) is interesting for nutrition as it contains a high level of β-carotene, source of vitamin A. However, the agronomic performance and their nutritional composition may vary according to agro-ecological areas and production practices. The aim of this study was to implement the OFSP production in the agroecological conditions of the Groundnut Basin for the prevention of vitamin A deficiency.

Methods: Assessment of the agronomic performance and nutritional composition (proteins, carbohydrates, lipids and β-carotene) of two OFSP varieties (Kandee and Caromex) was conducted during two growing seasons. An acceptability test of the selected OFSP variety was carried out and the effect of regular consumption of OFSP on the plasma concentration of β-carotene was evaluated by a randomized trial study in children 12–23-month-old during 15 days consumption.

Results: In the experiments, the yield of marketable tubers obtained was comparable between varieties and was 21.5, 22.5 t ha^{-1} for Kandee, Caromex respectively. Kandee was the variety with the highest in β-carotene content (101.1 mg/kg; P<0.001). The amount of dry matter of the varieties was correlated with the yield of marketable roots (r=0.54; P=0.04) and the carbohydrates content (r=0.52; P=0.05). The puree of the Kandee variety was accepted by the children and the amount served (50 g) contained 2761.9 µg of β-carotene and covered 25.3% of the vitamin A requirement of children. The consumption of Kandee during the 15 days maintained the β-carotene concentrations of the children in the test group compared to the control group whose β-carotene

concentrations decreased significantly (0.27 µmol/L vs. 0.21 µmol/L; p <0.001) after 15days consumption.

Conclusion: OFSP production has been successful in the agro-ecological zone of the groundnut basin of Senegal with agronomic acceptable performance. The difference observed between these varieties lies in the nutritional composition, particularly in the β-carotene content. The Kandee variety, accepted by children constitute a sustainable solution for the prevention of vitamin A deficiency in rural area.

OAB(T8)4-4

Organic food market in Romania. potential and trends

Silvius Stanciu[1]

1. Dunarea de Jos University of Galati, Romania (Romania)

Background and objectives: Organic production, based on the circular economy and carbon sequestration in the soil, could be profitable for local farmers. The paper aims to highlight the most relevant characteristics of the organic food market in Romania.

Methods: Clarivate Analytics, SCOPUS and ResearchGate were used for documentation. The information was collected from the databases of the NIS, MARD, Eurostat. Data were statistically processed, represented and analysed.

Results: The research showed that in Romania the organically area represents about 3% of the total agricultural area used, well below the European average. The organic area has grown steadily in recent years, being favoured by access to technical information. Organic cereals and industrial crops are the most important, green harvested plants have grown impressively in recent years (by over 40%), while the areas cultivated with permanent crops of vineyards, fruit trees and nuts have exceeded 10,000 hectares. The evolution of ecologically certified livestock is characterized by a decrease in the number of sheep and pigs, constant values in cattle and significant increases in poultry and bees. Over 80% of organic food products consumed in Romania are imported. The Romanian organic agriculture is based on exports, farmers taking advantage of high prices on foreign markets, the trend being accentuated by the lack of processing facilities on the domestic market. Organic food stores are not very widespread in Romania, while the large chains of food retail stores have developed separate sections for organic food, offering a wider variety. Food retailers strive to present organic products as affordable, to encourage customers to buy organic products, the price being perceived as the main barrier to consumption in Romania.

Conclusions: There is a slight tendency to increase the consumption of organic food, with effects in the food service sector as well. The organic food market in Romania is still in an early stage of development compared to the western ones, but it is connected to the European trends, having a significant potential for growth in the future.

Evaluation of pesticide residue and nutritional profile of selected raw foodstuff from three different markets in Ibadan, Nigeria

Aderonke Mosuro[1], Priscilla Oludara Jekayinfa[3], Abimbola Ogundele[1], Elizabeth Aleru[1], Folasade Jemiseye[2]

1. Lead City University (Nigeria), 2. University of Ibadan (Nigeria), 3. Osun State University Teaching Hospital (Nigeria)

Background and objectives: Regulation of storage and methods of preservation of raw foodstuffs in local markets are not uniformly enforced in Nigeria, this has led to variations in market practise and abuse of pesticides and use of unapproved pesticides in food storage. There is a paucity of information on the effect of these irregular practices on the nutritional status and safe consumption of raw food materials without pesticide residues. This research was designed to evaluate the nutritional profile, and pesticide residues in selected raw foodstuff from three different markets in Ibadan, Nigeria.

Methods: Five raw foodstuffs (maize, yam, sweet potato, rice, and cassava grit) purchased from three markets (Eleyele, Gbaremu and Sango) were subjected to chemical assay for (%) determination of proximate composition and pesticide residues using standard procedures. Experimental design was a 3 × 5 factorial arrangement in a completely randomized design. Data were analysed using ANOVA and means were separated at $\alpha_{0.05}$

Results: There were variations in proximate parameters based on market location. Samples from Sango market had the highest mean value for Dry Matter (DM) (62.50±32.08) and Crude Fat (CF) (1.36±1.38), samples from Eleyele market had the highest content of Crude protein (CP), Crude fibre and Ash (5.62±3.11, 1.68±0.72, 3.11±0.93) respectively, while the highest Carbohydrate content (2.44±1.27) was recorded in samples from Gbaremu market. Similar values were recorded for Bifenthrin residues in the samples from all the markets. Samples from Gbaremu market (maize, rice, and yam) contained the highest amounts of Bifenthrin residues compared with other markets. Maize was found to contain the highest mean value of Bifenthrin residues (0.007±0.0002) while potatoes had the least amount of Bifenthrin residues (0.002±0.0005).

Conclusions: Pesticide residues (Bifenthrin) were found in every sample evaluated. This may be due to poor market handling and misuse of pesticides. There is therefore a need for regulation and enforcement on market storage and preservation practices to enhance food safety in Nigeria.

Correction of iron deficiency anemia improves vaccine response to the ChAdOx Covid-19 vaccine in young Kenyan women

Nicole Stoffel[1], Gerco den Hartog[2], Petter Brodin[3], Simon Karanja[4], Hal Drakesmith[5], Michael Zimmermann[1]

1. ETH Zurich Switzerland (Switzerland), 2. National Institute for Public Health and the Environment (Netherlands), 3. Karolinska Institute (Sweden), 4. Jomo Kenyatta University of Agriculture and Technology (Kenya), 5. University of Oxford (UK)

Background and objectives: Increasing immunization efficacy and reducing anemia are key global health goals. Vaccines often underperform in low- and middle-income countries. Iron deficiency anemia (IDA) may impair adaptive immunity. Whether IDA impairs vaccine response and whether iron repletion before vaccination improves response is uncertain. Our aim was to compare vaccine response in IDA women receiving iron treatment or no iron treatment before vaccination.

Methods: 121 women were included into this randomized, open-label, controlled intervention trial. The treatment group (n=61) received intravenous iron (1000mg) 7d before vaccination. The control group (n=60) received no treatment. All women received the first dose of the Oxford-AstraZeneca ChAdOx Covid-19 vaccine. Vaccine response was measured at 28d. Previously to COVID-19 exposed women were excluded from the analyses. Cut-offs of 264 and 506 BAU/ml were used for anti-spike and anti-RBD to define seroprotection.

Results: Overall median (IQR) age was 35 (24-43) years. Median (IQR) hemoglobin (Hb) and plasma ferritin (PF) was 10.3 (9.1-10.8)g/dl and 8 (5-17)µg/L at baseline and increased to 11.3 (10.2-11.7)g/dl and 741 (506-891)µg/L at time of vaccination in the treatment group. In the control group, median (IQR) Hb and PF were 10.1 (9.4-11.0)g/dl and 7 (6-13)µg/L at time of vaccination. Median (IQR) COVID-19 anti-spike and anti-RBD antibodies were 2.52 (2.04-3.10), 4.45 (3.07-8.63) and 2.33 (1.87-3.25), 3.41 (2.61-6.92)BAU/ml in the treatment and control groups at baseline. At 28d after vaccination, anti-spike and anti-RBD antibodies were significantly higher in the treatment group with median (IQR) 66.52 (28.95-278.20), 38.01 (18.03-171.73) and 53.97 (21.47-135.18), 30.00 (14.62-75.86)BAU/ml ($p<0.05$ for both). None of the women were seroprotected at baseline. At 28d after vaccination, 26.7% had seroprotective anti-spike antibody concentrations in the treatment group compared to only 3.4% in the control group ($p=0.010$).

Conclusion: Iron treatment improved vaccine response to the ChAdOx Covid-19 vaccine in IDA women: antibody concentrations and seroconversion were significantly higher in the treatment group at 28d after vaccination. Because ID is so common and the vaccine-preventable COVID-19 disease burden so high, even if IDA only modestly reduces immunogenicity, its prevention could have major benefits. These findings suggest iron nutrition may be a determinant of vaccine response.

Assessing the use of different anthropometric indicators for acute malnutrition surveillance: results from a multi-country study

Estefania Custodio[1], Louise Mwirigi[2], Nigussie Tefera[3], Ana Pérez-Hoyos[3], Barbara Baille[5], Mara Nwayo[4], Jose Rodriguez-Llanes[3]

1. Instituto de Salud Carlos III (Spain), 2. UNICEF (USA), 3. European Commission Joint Research Centre (Italy), 4. UNICEF (Kenya), 5. UNICEF (Senegal)

Background and objectives: Surveillance with anthropometric indicators is crucial for detecting any deterioration in the nutritional status of a population, prioritising interventions and allocation of resources as well as monitoring their impacts. Consequently, it is essential that the indicators used for monitoring yield comparable results. We aimed to compare the results using different indicators across countries in Sub-Saharan Africa and Yemen in the Middle East.

Methods: We calculated the prevalence of acute malnutrition measured by weight for height z score below -2 (WHZ2), middle-upper arm circumference below 125 mm (MUAC125) and middle-upper arm circumference z score below -2 (MUACZ2) in a sample of 682 283 children from 27 countries. We compared the resulting prevalences at global, regional and country levels and stratified the results by age, gender, and stunting status.

Results: In this large sample, the prevalence of acute malnutrition is consistently higher among younger children for MUAC125 and WHZ2, and higher among children for MUACZ2. The prevalence of acute malnutrition is higher among girls when using MUAC125 but higher among boys when using WHZ2 or MUACZ2, and it is consistently higher among stunted children independently of the indicator used.

Conclusions: The prevalence of acute malnutrition in a population varies depending on the indicator used to diagnose, and sampling characteristics in terms of age, gender and stunting status of the children. Thus, for monitoring purposes it is key to report the indicator used for acute malnutrition identification and to provide results stratified by sex, age group, and stunting status.

OAB(T9)1-3

Harmonizing the process for establishing recommended nutrient intake values.

Ann L. Yaktine[1], Patrick J. Stover[2], Janet C. King[3]

1. The National Academies of Sciences, Engineering, and Medicine (USA), 2. Texas A&M University System (USA), 3. University of California, Berkeley (USA)

Background and objectives: In 2005, King and Garza proposed a process for deriving recommended nutrient intakes (RNIs) with the goal to improve the objectivity and transparency of the process for deriving the values; to provide a common basis across countries and regions for establishing consistent public and clinical health objectives and food and nutrition policies, and for addressing trade and regulatory issues.

Methods: In response to this charge, the U.S. National Academies, the World Health Organization, and the United Nation's Food and Agriculture Organization held an international workshop to create a dialog among potential stakeholders for exchanging ideas about ways to achieve the goal of harmonization. Subsequently the U.S. National Academies convened a consensus study with the goal of recommending a framework for deriving RNIs and using case scenarios to demonstrate how the framework could be applied to populations of interest.

Results: An outcome of both the workshop and consensus study was a derivative communication product: a tool kit that built on the discussions of the 2017 workshop and recommendations from the consensus study, as well as current information relevant to the process of establishing RNIs. The tool kit is designed to facilitate the process of deriving core RNIs for all global stakeholders, particularly for those in low- and middle-income countries. It is also intended to serve as a next step in moving forward toward a globally harmonized process for deriving the core RNIs.

Conclusions: Implementing the guidance offered in the tool kit will facilitate the harmonization process by laying the groundwork for developing a plan that builds on the experience, expertise, tools, and resources needed to achieve the harmonization goal. Moving forward will require regional and international working groups and partnerships; leadership in establishing regional and international approaches to harmonization; and support for the model and its importance to national and international audiences.

No wonder everyone is confused - food guidance systems are not always consistent with dietary guidelines

Eleanor Beck[1,2], Caitlin Byron[1], Katrina Kissock[1,2], Elissa Price[1,2], Elizabeth Neale[1,2], Marijka Batterham[1]

1. University of Wollongong (Australia), 2. Illawarra Health and Medical Research Institute (Australia)

Background and objectives: Food guidance systems aim to promote 'healthy' food choices to consumers. National dietary guidelines, based on a significant breadth of evidence, promote foods such as fruits, vegetables and whole grains in public health messaging. National food regulatory agencies provide guidance on health claims on foods and often regulate nutrient profiling systems aimed to guide consumers towards healthier choices. Recently, a body of research has encouraged consideration of the role of consumption of highly processed foods in development of chronic disease (NOVA food classification system). Given the number of varied food categorisation systems available, the current study aimed to determine which food groups or types of foods show the greatest disparity between categorisation systems, to aid the development of a universal system to provide consistent consumer guidance.

Methods: We considered all foods in the 2011-2013 Australian Food, Nutrient and Supplement Database, categorising foods according to the following systems: Health Star Rating (Australian front-of-pack nutrient profiling system), NOVA (differentiating based on minimally- to ultra-processed), application of the Whole Grain Initiative's new whole-grain food definition, and the Australian Nutrient Profiling Scoring Criterion which determines if foods are able to make a health claim on front-of-pack.

Results: Grain products, even those considered core foods and encouraged in health promotion guidelines show particular disparity across classification systems. Nutrient profiling systems in Australia do not include whole grain and therefore may provide inconsistent messaging compared to dietary guidelines which specifically promote whole grain. The NOVA system classifies a majority of whole-grain products (breads and ready-to-eat breakfast cereals) as ultra-processed which means messaging based on NOVA is contrary to dietary guidelines. In addition, discouraging intake of some foods in the current food supply would limit fortified foods which have successfully improved intake of nutrients such as iodine, thiamine and folic acid.

Conclusions: Further analysis of outcomes associated with specific dietary patterns, which consider multiple elements of foods (such as not only nutrients or only processing) are required to ensure consistent dietary messaging to reduce consumer scepticism.

Keywords: Dietary Guidelines, whole grain, nutrient profiling, ultra-processed foods

Conflict of Interest Disclosure: No funding was received for this work. In the past, EJB has been paid to present research findings by General Mills and research funding from Cereal Partners Worldwide.

OAB(T9)1-5

Contesting the future of red and processed meat in healthy and sustainable food systems: how food system actors frame the problem.

Katherine Elise Sievert[1], Mark Lawrence[1], Christine Parker[2], Phillip Baker[1]

1. Deakin University (Australia), 2. University of Melbourne (Australia)

Background and objectives: Reports from international organisations and experts groups call for reductions in production and consumption of red and processed meat (RPM) (in high-income countries in particular) to attenuate associated health and environmental harms. Policymakers have given limited attention to the issue and public discourse is contentious. Framing of RPM as a policy issue by influential actors may be contributing to inertia and confusion. This project investigates the global political challenge of meat reduction by comparing beliefs and worldviews represented in news media and from food system stakeholders.

Methods: Drawing from findings of a media analysis and key informant interviews with 30 stakeholders, this study uses a framing analysis design, using news media sources and key informant interviews analysis to address the aims. Individuals with knowledge and expertise in, or interest in, red and processed meat with relation to; global public health and nutrition policy and/or environmental sustainability OR commercial interests were considered eligible participants for the study.

Results: 150 news media articles were analysed, and 30 participants were interviewed – spanning academia, civil society, intergovernmental organisations, and industry. Meat reduction as a concept in news media was polarising, with industry framing it as part of the 'vegan agenda'. Many interest groups attempted to discredit the reports, citing lacking evidence or conflation of production methods. In contrast, whilst stakeholders perceived the concept to be publicly polarising, there was convergence across all groups on the value of RPM in a healthy and sustainable diet. Many participants cited a lack of nuance in public discourse, with framing on harms and benefits of RPM being over-simplified. Some participants noted that intensive meat production and high consumption levels reflected corporatized/globalised supply chains, and power relations were the most critical factor to address the harms of RPM. Participants also viewed the preference for technology-driven responses (i.e., novel proteins) as reinforcing corporate power in the food system.

Conclusion: This study shows that despite polarised public discourse, more convergence on the issue across food systems stakeholders exists. Furthermore, powerful actors such as the meat and 'novel protein' industries are perceived to be a driving influence in maintaining the market-driven status-quo and are a likely obstacle in achieving healthy and sustainable consumption of RPM.

WHO Nutrient and Promotion Profile Model (NPPM) for ensuring appropriate composition and marketing of food products for infants and children under 3 years of age in the WHO European Region

Holly Rippin[2], Ali Morpeth[1], Janet E Cade[1], Diane Erin Threapleton[1], Kremlin Wickramasinghe[2]

1. University of Leeds (UK), 2. WHO European Office for Prevention and Control of Noncommunicable Diseases (Russia)

Background and objectives: Many commercial food products for infants and young children (FIYC) are inappropriate, exposing this vulnerable group to foods that disregard public health recommendations. Concerns with FIYC are seldom tackled by legislation and include: i) high sugar contents, sweet tastes and free sugar use; ii) marketing from 4 months of age, despite WHO guidance to exclusively breastfeed to 6 months; iii) pervasive use of nutrient, health and marketing claims. The NPPM aims to support countries identify inappropriate FIYC, engage with stakeholders to raise awareness, and effect policy and legislative change to support optimum nutrition and reduce NCD risk in later life.

Methods: The NPPM was developed through an iterative process, accounting for strengths and weaknesses in existing legislation, assessment of documented issues with modern FIYC, a 10-country product evaluation against NPPM requirements, discussion within an expert meeting and through direct consultation with countries. A user-friendly NPPM with an implementation toolkit has been developed by WHO. Application will be supported by an online product assessment tool to rapidly examine acceptable or inappropriate nutritional and promotional features of FIYC.

Results: The NPPM categorises products and sets appropriate nutritional and promotional requirements. To address high sugar exposure, products should not contain free sugars (including fruit juice), meals and snacks should have limited sugar/fruit content, and inherently sweet foods (e.g. fruit puree) should have a clear 'high sugar' indicator on packs. NPPM thresholds also specify energy density, sodium, protein, and total fat contents. No products should be marketed as suitable before 6 months of age, and the NPPM restricts use of marketing claims. The NPPM implementation toolkit will help generate and tailor impact on national policy and legislation through providing guidance on i) stakeholder mapping; ii) working with government/policy audiences; iii) engaging industry; iv) product evaluation; v) illustrative case studies.

Conclusions: The NPPM and toolkit can elevate awareness and support engagement across different key stakeholders to

ensure appropriate sale of FIYC. However, strong political leadership and proactive industry engagement are essential to lead the way in safeguarding vulnerable groups (new parents and infants/children) from overbearing promotional messaging and/or products with unsuitable composition.

Understanding the cost implications of nutrition data collection: Lessons from Nigeria

Yashodhara Rana[1], Helen Connolly[2], Caroline Andridge[1], Natasha Ledlie[1]

1. Results for Development (USA), 2. Global Nutrition Financing Consultant (USA)

Background and objectives: In 2014 the Global Nutrition Report called for a "nutrition data revolution." Since then, there have been increasing calls for more and better nutrition-related data. Collecting these data points, however, comes with additional costs. To explore the cost considerations of collecting nutrition data, we identified potential issues of adding or removing nutrition indicators in five existing data platforms in Nigeria to inform recommendations for improved coordination of national nutrition data collection by Nigeria's Federal Ministry of Health.

Methods: We reviewed publicly available information and consulted with 32 global and Nigerian nutrition data experts to identify cost drivers for five data collection platforms in Nigeria: Demographic and Health Survey, Multiple Indicator Cluster Survey, National Nutrition and Health Survey, Food Consumption and Micronutrient Survey, and Health Management Information System.

Results: Three findings emerge from this study. *First*, adding or removing a nutrition indicator can have significant cost implications across all phases of indicator development, from planning and data collection to analysis and dissemination. *Second*, the extent to which costs are affected in each of these phases varies by the feature of the platform and indicator complexity. Examples of key cost drivers include whether a global questionnaire needs to be adapted to the country context or an indicator reflects a new topic area and requires skills development for data collectors. *Finally,* the additional costs incurred are both monetary and non-monetary. For example, adding questions to a survey can impact data quality through "survey fatigue".

Conclusions: To our knowledge, this is one of the first studies to examine cost considerations when deciding whether and how to collect nutrition indicators. Stakeholders at the country level involved in planning and financing nutrition data collection should consider their data needs against data availability and cost implications to determine the frequency and mode of data collection. Financing strategies should be included in planning stages to ensure adequate resources exist to collect the necessary data while maintaining data quality. This is especially important for nutrition indicators included in multi-topic surveys with competing content and funding priorities.

Keywords: Nutrition indicators, Nutrition data, Nutrition costs, Nutrition household surveys

Conflict of Interest Disclosure: No competing interests were disclosed.

Further Collaborators: This study would not have been possible without the outstanding work of Mashin Muhammad and Oluwapelumi Adeyera who served as data collectors in Abuja, Nigeria. We would also like to thank Rebecca Heidkamp and Elyse Iruhiriye from Johns Hopkins Bloomberg School of Public Health for their feedback.

OAB(T9)2-3

A novel analytical framework for identifying and exploring public health pathways linking COVID-19 with nutrition outcomes developed by the Agile Core Team for Nutrition Monitoring (ACT-NM)

Chika Hayashi[1], Ann Mizumoto, Sharmila Leela Mysore[4], David Hales[1], Giovanna Gatica-Domínguez[2], Elaine Borghi[2], Raphael Makonnen[3], Margaret Holmesheoran[3], Vrinda Mehra[1], Silvia Alayon[4]

1. UNICEF (USA), 2. WHO (Switzerland), 3. USAID (USA), 4. USAID Advancing Nutrition (USA)

Background and objectives: ACT-NM was established in June 2020 by UNICEF, USAID, WHO and USAID Advancing Nutrition to jointly consider nutrition monitoring issues during the COVID-19 pandemic. The team prioritized the development of a comprehensive analytical framework focused on public health pathways linking COVID-19 to nutrition outcomes using the six global targets for maternal, infant and young children nutrition endorsed by the World Health Assembly.

Methods: The development of the analytical framework was done in three interconnected phases: 1) conceptualization; 2) literature review; and 3) design. The conceptualization process identified the critical issues for a framework focusing on the factors and pathways connecting COVID-19 and nutrition outcomes. This process was supported by a pragmatic literature review, which identified 21 existing frameworks/models with structures and/or content relevant to COVID-19 and nutrition. The analysis of the 21 frameworks/models provided multiple insights applicable to the design of a single, comprehensive analytical framework able to capture critical public-health pathways.

Results: The ACT-NM framework is built around five categories of factors directly relevant to the intersection of

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

COVID-19 and nutrition: 1) enabling determinants, or context; 2) underlying determinants, as they relate to food, health, social protection, education and WASH systems; 3) immediate determinants, including behaviors and nutritional status; 4) outcomes; and 5) impact. In turn, the various sub-categories include a range of salient factors, from travel restrictions to access to nutrition services. The framework's left-to-right axis enables users to identify and explore numerous public health pathways. The framework also acknowledges the overall environmental context and the wide-ranging effects of COVID-19 on the five categories. In addition, the framework recognizes the causes and consequences of deepening inequality due to the pandemic.

Conclusions: The ACT-NM framework is a dynamic and visual tool to plot a wide range of proven and potential pathways connecting multiple determinants and factors with nutrition outcomes and impacts. The versatility of the framework makes it applicable in diverse settings, enabling users to look at COVID-19-nutrition pathways from different perspectives, with different priorities and at different levels. In addition, elements can be added to the framework to address new shocks and evolving circumstances.

OAB(T9)2-4

Ongoing challenges in food security among Asia Pacific since COVID-19 pandemic

Yunhee Kang[1], Euiyeon Lim[2], Erica Wetzler[3], Indira Prihartono[1], Soomin Lee[2], Subin Kim[2], Sanghyo Kim[4]

1. Johns Hopkins School of Public Health (USA), 2. Seoul National University (Korea), 3. World Vision US (USA), 4. Korea Rural Economic Institute (Korea)

Objective: Asia-Pacific region is more vulnerable to shocks in food supply and demand. Global attention is required to understand the situation and deal with the problem through continuous monitoring since the COVID-19 pandemic. This study examined the changes in reported livelihood activities and weekly income among poor Asian populations between pre-pandemic and mid-2021 and the time-trend in food security status from mid-2020 to 2021.

Methods: We used survey data collected among World Vision supported communities in Cambodia (n=621), India (n=797), Indonesia (n=951), Sri Lanka (n=684), Laos (n=717), Myanmar (n=678), Nepal (n=602), and Vietnam (n=3,578). Changes in income-generating activities prior to COVID-19 and at the time of the survey (mid-2021) were tested for equality of proportions of each activity. Relative weekly income change, income and job loss since COVID-19, and type of benefits between was compared between rural and urban areas using a paired student t-test or chi-square test. Food security status (food stock availability at households, availability of essential items at markets, and affordability of essential items) were tested for the change between 2020 and 2021 using logistic regression analysis in India, Indonesia, Myanmar, and Vietnam.

Results: By mid-2021, household economic status and livelihood activities in the Asia-Pacific region had not been restored to pre-pandemic levels. Since the outbreak of the pandemic began, livelihoods for income generation in Cambodia and Nepal have been the most severely impacted. In India, Indonesia, and Myanmar, food stock availability in households and availability of essential items in markets improved significantly in 2021 compared to 2020 while the availability of essential items at markets reduced in Vietnam during the time. In 2021, the affordability showed an inconsistent pattern by item and by country, with significant improvement in India and Myanmar but deterioration in Vietnam for rent and loans.

Conclusions: Our results indicate ongoing challenges in food security and livelihood in the region. Long-term social protection programs such as cash transfers and in-kind assistance, need to be carefully designed and implemented to address food insecurity among vulnerable groups, considering each country's market conditions, consumer food purchasing behavior, and financial support size.

Through their eyes and mouths: Inequality in access to food in urban poor settings in Kenya

David Onyango Osogo[1], Elizabeth Wambui Kimani[1,7,8,2], Teresia Njoki Macharia[3,9], Hilda Akinyi Owii[8], Melanie Warwick[4], Claudia Mitchelle[5], Nyovani Madise[6], Paula Griffiths[4]

1. African Population and Health Research Center (Kenya), 2. University of Glasgow (UK), 3. Global Programs for Research & Training (Kenya), 4. Loughbrough University (UK), 5. Mc Gill University (Canada), 6. AFIDEP (Malawi), 7. Stellenbosch Institute for Advanced Study (STIAS), Wallenberg Research Centre at Stellenbosch University, Mostertsdrift, Stellenbosch (South Africa), 8. Brown University (USA), 9. Bristol University (UK)

Background: Ending hunger and achieving food security for all by 2030 is a core target under the Sustainable Development Goals. Globally, food and nutrition insecurity remains a major challenge. In Kenya, the 2010 Constitution provides for the right to food for all citizens, although this right is not actualized for many, particularly those living in poverty. The urban poor are particularly negatively affected, with over 80% of households in these settings being food insecure. We aimed to explore the lived experiences of the urban poor with food insecurity and the right to food.

Methods: We used participatory methodologies to explore the lived experiences with food insecurity among the urban poor living in slums in Nairobi, Kenya, including photovoice, digital storytelling, participatory mapping, participatory theatre,

community radio shows among others. Thematic analysis was performed using NVIVO software.

Results: Data revealed inequality in access to food, characterized across social, economic, physical and cultural factors, with poverty emerging as a major challenge in access to quality food. While it was reported that there was food available in the market, this food was generally said to be inaccessible to many, and also to be of poor quality. Children, mothers, young people and older people were said to be particularly affected. Under these circumstances, many resorted to coping strategies that on the one hand impacted negatively on health and wellbeing, and on the other enabled innovative means of ensuring food security.

Conclusions: We call on researchers, and other relevant actors to investigate the problem of food insecurity using a lens that accurately reflects the lived experiences of those experiencing it. To end hunger by 2030, further research needs to focus on working with communities experiencing food insecurity as partners whose voices guide advocacy and stimulate the dialogue on the ending hunger. We also call on implementing organizations and decision makers to identify and implement viable context specific solutions to food insecurity for the urban poor, taking into consideration the perspectives of the community with regards to their lived experiences.

Keywords: Food security, Right to food, Urban poor, Nutrition

Perspectives on the application of CONSORT guidelines to randomized controlled trials in nutrition

Jessica Rigutto-Farebrother[1], Jan de Vries[2], Sanne Ahles[3], Janet Cade[4], Karen J Murphy[5], Helen M Roche[6], Sangeetha Shyam[7], Carl Lachat[8], Anne-Marie Minihane[9,10], Connie Weaver[11]

1. ETH Zürich, Zürich (Switzerland), 2. De Vries Nutrition Solutions (Netherlands), 3. Maastricht University (Netherlands), 4. University of Leeds (United Kingdom), 5. Nutrition and Activity University of South Australia (Australia), 6. University College Dublin (Ireland), 7. International Medical University (Malaysia), 8. Ghent University (Belgium), 9. University of East Anglia (United Kingdom), 10. Norwich Institute of Healthy Ageing (United Kingdom), 11. San Diego State University (United States)

Background and objectives: Accurate and complete reporting of nutrition trials is essential for correct interpretation and application of research findings and an avoidable source of research waste. The CONsolidated Standards Of Reporting Trials (CONSORT) statement details the minimum requirements for reporting randomized controlled trials (RCT). To date, however, it remains unclear if additional guidance is necessary to improve CONSORT adherence, utility, and consequent reporting quality of nutrition RCTs.

Methods: As a Federation of European Nutrition Societies working group, we assembled an international and geographically diverse committee of experts across a range of nutrition trial domains. First, we applied an iterative process to interrogate the 2010 CONSORT items as they relate to nutrition trials, implemented as a series of regular online consultations over 12 months. Specific CONSORT items potentially requiring additional guidance for nutrition were discussed, and agreement was reached on the main points. In a second step, we will collect feedback from a wider audience of nutrition researchers, journal editors, and other relative experts in the field, asking them to comment on our findings and identify other items and possible gaps, to generate areas of consensus and unresolved matters. Further, in a third step, we plan to also collect feedback via a Town Hall meeting for attendees at IUNS 2022.

Results: Sixteen of the 25 CONSORT items, as well as an additional item not listed, were identified as potentially requiring additional guidance when reporting nutrition RCTs. We will map the findings of the working group from step 1, with those of the peer-review in step 2, to identify areas of consensus and additional items and issues, to capture priority items for future work. The external review process is underway and will be summarized for the IUNS congress.

Conclusions: Adequate reporting is foundational to creating a robust and valid evidence base for informing the development of nutrition guidelines for policy and practice. We provide perspectives for future assessment of whether specific guidance, such as a dedicated extension to CONSORT for nutrition, is warranted, and provide a narrative, documenting items that may need explicit reporting for nutrition trials.

Keywords: Guidelines, CONSORT, nutrition trials, reporting, expert opinion

A case study on the public-private-partnership in "Ghana Nutrition Improvement Project" using MIT D-Lab's P.ACT (Patnreship Co-design Toolkit)

Yasuhiko Toride[1], Saida Benhayoune[2]

1. Tokyo International University (Japan), 2. Massachusetts Institute of Technology (USA)

Background and Objectives: In Ghana, child malnutrition is still a predominant challenge with a national stunting prevalence rate of 21% (2018). The Ajinomoto Foundation (TAF) is leading the “Ghana Nutrition Improvement Project” aiming to improve nutrition of children aged 6 months to 24 months by providing a nutrition supplement called “KOKO Plus”, which is added to traditional complementary food, koko, corn-base porridge. TAF is engaged in a collaboration with Ghana Health Service (GHS), Ministry of Health to deliver effective nutrition education to mothers, which is considered to be a key factor for the success of the project.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Published in 2020, the P.ACT (Partnership Co-design Toolkit) was co-developed by MIT D-Lab and SEED to equip impact practitioners with practical tools and methods to co-create inclusive hybrid partnerships. The objective of this study was to apply the P.ACT to strengthen the public-private partnership for nutrition improvement.

Methods: The Public Private Partnership between GHS and TAF was analyzed by using a selected number of P.ACT tools through participatory workshops (total six on-line workshops) that convened representatives from TAF and GHS and were facilitated by MIT D-Lab.

Results: The P.ACT workshops enabled GHS and TAF to identify key success factors as well as opportunities to improve and strengthen their partnership for the future. The partners identified the following factors as some of the key strengths they can leverage and build upon for the future of the collaboration: strong alignment for impact goals, complementary capabilities, clear value chain roles and balanced returns. The P.ACT engagement also revealed several opportunities to further strengthen the partnership model: co-creating a dashboard of Key Success Metrics (KPIs) and sharing a plan to reach financial sustainability. A follow-up evaluation of the partnership and an assessment of the KPIs were conducted after the P.ACT workshops.

Conclusions: The case study demonstrated that P.ACT is an effective Toolkit in diagnosing and improving public-private partnerships for nutrition improvement projects. It was useful in achieving the key objective of providing effective nutrition education through the partnership.

Keywords: Public-private-partnership, nutrition education, P.ACT toolkit

OAB(T9)3-3

The current status of food environmental policies of public and private sectors in Vietnam

Van Khanh Tran[1], Tu Tran Ngoc Nguyen[1], Nga Thuy Tran[1], Tuyen Danh Le[1], Tu Song Nguyen[1]

1. National Institute of Nutrition Vietnam (Viet Nam)

Background: Public and private policies are important to promote a healthy food environment. A review of nutrition/food policies and a comparison of the extent to which current government policies on food environments across the world can catalyze policies and actions. The benchmarking of private sectors by assessing the commitments of food companies to improving population nutrition usé the Business Impact Assessment on population nutrition and obesity (BIA-Obesity) tool.

Methods: The Healthy Food-Environment Policy Index (Food-EPI) were used to evaluate government policy practice. Rating results were used to identify and propose policy actions. BIA-Obesity good practice indicators for food industry commitments were adapted to the Vietnam context. Euromonitor market share data was used to identify major food, beverage manufacturers, restaurants and retailers (n=29). Commitments and disclosures collected against the BIA-Obesity scoring criteria were assessed by qualified Expert panel and recommendation were formulated by Review panel

Results: Using Food-Epi. no indicators were rated "high", the majority of the index was rated as "low" at 53%, while the "very low" level, following closely behind at 40.5 % and only 6.5% rated as "medium". The top 3 indices were ranked the highest level of performance in the "average" ranking, including (1): index of ingredient list/nutrient statement (52%) (2): school policies to improve healthy food (44%) and (3): develop regulatory systems for health and nutrition claims (43%). The top 3 indexes that received the lowest scores in the "very low" ranking were (1): support and training for the private sector (16%); (2): the policy of food service stores that provide healthy and unhealthy food (18%) and (3): manage regulatory capacity for nutrition (16%). Of the 29 selected companies, none of them agreed to provide more information. The median overall BIA-Obesity score was 10.3%, only 2/29 companies achieve score over 25%. Relationships with organizations (average score of 25.1%) was the highest score domain while healthy product formulation, accessibility, and advertising of healthy food products were scored the lowest (<10%)

Conclusions: Study findings are basic for developing new policies conducive for nutrition/health and strengthen civil society advocacies for government accountability to create a healthier food environment.

Conflict of Interest Disclosure: The authors declare no conflict of interest disclosure

OAB(T9)3-4

The role of Food and Beverage manufacturers in the food system, do they work towards eradicating all forms of malnutrition?

Laura Trijsburg[1], Estefania Marti Malvido[1], Osien Kuumar[1], Mark Wijne[1], Inge Kauer[1]

1. Access to Nutrition Initiative (Netherlands)

Background and objectives: Every day a large part of the global population experiences malnutrition resulting from an unhealthy diet. Our food system is failing to deliver healthy diets at an affordable price for all. A key actor in the food system are food and beverage (F&B) companies. ATNI's Global Index (GI) assesses how the world's largest global F&B companies contribute to addressing malnutrition in all its forms. The work presented here summarizes the changes observed in F&B performance measured by four GI iterations between 2013 and 2021.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: Companies were assessed on their nutrition-related commitments, practices, and disclosure – with regards to governance and management; the production and distribution of healthy, affordable, products; and how they influence consumer choices and behavior. Different indicators, divided across seven topics, are summed up in a total GI score of a company. This includes a Product Profile exercise, which provides an independent assessment of the nutritional quality of companies' product portfolios using the Health Star Rating model.

Results: Overall, a small increase in the average GI score (from 2.2 in 2013 to 3.3 in 2021 out of 10) was observed over the years, more attention for health and nutrition in companies' commercial strategies and strategies related to improving nutrition quality of portfolios led to an increased score for most companies. The largest progress was seen in governance as most companies' business strategies and management systems strengthened focus on nutrition. Affordability is a low scoring topic for most companies as few can show evidence of considering low-income groups when pricing their healthy products. While improvements in the Product Profile scores are observed for some companies, results show that progress is too slow, with only 31% of products meeting the healthy threshold in 2021.

Conclusions: The observed increase in the average GI score indicates a growing awareness amongst leading F&B manufacturers on the importance of producing healthy products and integrating nutrition as part of their broader sustainability strategies. It shows companies are willing to take actions towards eradicating all forms of malnutrition, though more steps need to be taken, especially regarding affordable pricing and delivering healthy products.

The steady increased of Obesity and Non-Communicable Diseases in Indonesia: What needs to be done?

Atmarita Atmarita[1], Razak Thaha[1], Soekirman Soekirman[1], Nina Sardjunani[1], Endang Achadi[1]

1. Institute of Indonesian Nutrition (Indonesia)

Background and Objectives: Obesity is a global public health concern, and has increased significantly worldwide, including Indonesia. This article aims to prove the prevalence of obesity in Indonesia which has had increasing in parallel with the increased of various non-communicable diseases/NCD.

Methods: Descriptive analysis uses available data from the Indonesian National Health Survey 2007 to 2018 to see trends in the prevalence of obesity and its impact on the increasing prevalence of non-communicable diseases. Related factors were also observed regarding the characteristics of the population, and other factors such as consumption of sugar-salt-fat, habits of consuming vegetables and fruits, and habits of physical activity.

Results: Within 5 years (2007 to 2013), the prevalence of Adolescent Obesity rose 5.2 percentage points in younger age adolescents (13-15 years) and up to 6.2 percentage points in older adolescents aged 16 to 18 years. The condition of obesity among adults age 18+ years has also increased from 10.3% in 2007 to 21.8% in 2018. At the same time the trend of NCD for adult aged 18+ years also increased significantly. On the other hand, the population who suffered from various NCD, hypertension, diabetes, cancer, obesity altogether have increased from 33.5% in 2007 to 47.7% in 2013. The risk factor of obesity and NCD needs serious attention. While there are no data available about the relationship between malnutrition in the early life with obesity and NCDs, it has recorded that the proportion of Sedentary Activity more than 6 hours/day among population 10+ years was 24%, less consumption of fruits and vegetables was 93.5%, and 29.7% of population are already excessive in daily intake of Sugar-Salt-Fat.

Conclusions: Indonesia is currently challenged by the needs to take more serious action to decrease the current escalation of obesity and NCD. The national strategy should not only address a healthier life style of adolescents and adult population through the healthy movement program, but also focusing on malnutrition during early life. Regulations on sugar-salt-fat content of food and beverage production need to be implemented immediately.

Food labeling as a tool to investigate the nutritional quality of foods: Results from the food labeling of Italian products (FLIP) study

Daniela Martini[1], Donato Angelino[2], Nicoletta Pellegrini[3]

1. University of Milan (Italy), 2. University of Teramo (Italy), 3. University of Udine (Italy)

Background and objectives: Based on the European legislation, food label includes the nutrition declaration that may be an useful tool to estimate the nutritional quality of food products. The Food Labelling of Italian Products (FLIP) study, performed by the Young Working Group of the Italian Society of Human Nutrition (SINU), aims to 1) systematically investigate the overall quality of prepacked foods sold on the Italian market by retrieving the information reported on the food pack; 2) investigate if specific information present of the food pack (e.g., nutrition claim, organic declaration, brand) may be considered as markers of the overall quality.

Methods: The survey was designed as a comprehensive analysis of food products belonging to different food categories (e.g., bread, meat analogues, breakfast cereals) sold in the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

websites of 13 out of the major retailers present on the Italian market. For each product the nutritional declaration per 100 g of products was collected together with other information reported on the food pack (e.g., brand, nutrition and/or health claims). Statistical analyses of the nutritional values were carried out using IBM SPSS Statistics for Macintosh, Version 26.0. Armonk, NY: IBM Corp, setting the significance level at $p < 0.05$).

Results: Results reported a high variability in terms of nutritional quality, with products belonging to the same category and even type but widely differing for their nutritional content. Moreover, the sub-analysis based on the presence of absence of specific information on the food pack revealed that overall no information such as nutrition claim, brand or organic declaration can be considered as markers of the overall quality of food.

Conclusions: Overall, the present work highlighted a high variability in the nutritional quality of foods currently on the market. Thus, this study supports the importance of reading and understanding the information made on food label.

Compliance of pre-packaged food products with the Nigerian national food and nutrition labelling regulations

Gideon Onyedikachi Iheme[1], Ifeoma M. Egechizuorom[2], Linda O. Edafioghor[3], Linda E. Olah[4], Oluwadamilare E. Kupoluyi[5], Hannah C. Enuka[6], Adimchi D. Adile[7], Hajara Idris[8], Obinna C. Ogbonna[9], Nwabumma C. Asouzu[10]

Jos University Teaching Hospital, Jos (Nigeria), 5. Federal Medical Centre, Abeokuta (Nigeria), 6. University of Nigeria Teaching Hospital, Ituku-Ozalla (Nigeria), 7. Federal Teaching Hospital, Gombe (Nigeria), 8. Federal Medical Centre, Katsina (Nigeria), 9. Obafemi Awolowo University Teaching Hospital, Ile-Ife (Nigeria), 10. Alex Ekwueme Federal University Teaching Hospital, Abakaliki (Nigeria)

Background and objectives: The rising prevalence of non-communicable diseases (NCDs) in Sub-Saharan Africa strengthens the need to furnish consumers with appropriate information on the composition/content of pre-packaged foods. This study was designed to examine the food and nutrition labelling compliance of pre-packaged foods sold in Nigerian markets with the national guidelines.

Methods: A total of 662 pre-packaged foods from 10 broad categories were purposively enlisted from Nigerian stores and supermarkets. The food label information was compared with eleven (11) food and other nutrition labelling requirements stipulated by the National Agency for Food and Drug Administration and Control (NAFDAC).

Results: Results showed that half (50.5%) of the products were manufactured in Nigeria. Almost all of the pre-packaged foods complied with guidelines on food label information declaration (92.9%), product name/description (98.4%), ingredient list (95.1%), net quantity (94.5%), manufacturer's information (92.6%) and date of minimum durability (89.6%). Less compliance was reported for quantitative ingredient declaration (35.6%), instructions for use (45.4%) and allergen declaration (48.7%) guidelines. This accounted for an overall mean food label compliance score of 8.42 $\pm$ 1.74 out of a possible 11.0 score. Adherence to NAFDAC food label requirements was high in breakfast cereals (9.63 $\pm$ 1.52) and noodles/pasta (9.30 $\pm$ 1.67) but low in fats/oil (6.70 $\pm$ 2.00) and meat/fish (6.97 $\pm$ 1.27). Nutrition label information revealed a low prevalence (33.4%) of nutrient claims. For products with nutrient claims, most (64.6%) of these claims were stated in accordance with NAFDAC guidelines. Compliance with the declaration of four micronutrients was low (42.0%) in all products but high (86.9%) in products with claims. A higher likelihood of declaration of these macronutrients in products with nutrient claims (OR = 27.33; 95% CI = 17.32 - 43.12) was observed. Compliance with food labelling requirements was positively correlated with macronutrients declaration ($r = 0.28$; $p = 0.00$).

Conclusion: High compliance with food label guidelines was reported but nutrition label requirements were not adequately met, particularly foods with no nutrient claim. Enforcement of compliance with food/nutrition label guidelines is fundamental to the reduction of NCDs risk.

Keywords: Compliance, food/nutrition labelling, non-communicable diseases, national guidelines, Nigeria

"Stronger With Breastmilk Only" (SWBO) Initiative to Improve Breastfeeding Environment in Burkina Faso: Contribution Analysis of the Advocacy and Partnership Components

Isabelle Michaud Letourneau[1,2], Marion Gayard[2], Purnima Menon[3], Sunny S Kim[3], Maurice Gérald Zafimanjaka[4], Manisha Tharaney[7], Nathalie Likhite[4], Médiatrice Kiburente[5], Estelle Bambara[6]

1. University of Montreal (Canada), 2. Society for Implementation Science in Nutrition (USA), 3. International Food Policy Research Institute (USA), 4. Alive & Thrive (Burkina Faso), 5. UNICEF (Burkina Faso), 6. Ministère de la santé (Burkina Faso), 7. Alive & Thrive (Cote d'Ivoire)

Background and objectives: The practice of giving water before six months of age is one of the most important barriers to exclusive breastfeeding (EBF) in several countries in the West and Central African region, and Burkina Faso is no exception. To address this challenge, an initiative was carried out in Burkina Faso as part of a West African regional initiative called "Stronger with Breastmilk Only" (SWBO). This study assessed if and how the advocacy and partnership activities carried out under the SWBO initiative in Burkina Faso have resulted in a policy and programmatic environment that is more supportive of breastfeeding (BF).

Methods: The study used contribution analysis, a theory-driven evaluation method, in addition to applying two study lenses: 1) a set of metrics proposed for effective advocacy to examine advocacy efforts, and 2) the Breastfeeding Gear Model to appreciate the efforts around BF in the SWBO initiative.

Results: Key advocacy activities - the development of a national strategy for SWBO, advocacy meetings, and training of key actors - were supported by 1) a tripartite alliance, composed of the Ministry of Health, UNICEF and Alive & Thrive, with strong advocacy capacity, 2) a network of committed partners and 3) awareness-raising activities. Carried out at multiple levels (political, organizational, social and community), the advocacy and partnership activities contributed significantly to the commitment of various stakeholders throughout the implementation of the initiative. Their mobilization enabled the adoption of regulations that protect, promote, and support BF, and the allocation of funding to BF efforts. A multi-sectoral committee was key to coordinate partners' efforts toward the same objectives and measures were put in place to better monitor BF programs. Finally, the SWBO initiative acted upon the 8 gears (advocacy; political will; legislation & policies; coordination; funding; training and program delivery; promotion; research and evaluation) of the Breastfeeding Gear Model which helped to achieve progress toward these BF-enabling environments.

Conclusions: Advocacy and partnership activities allowed for the sensitization of key actors, such as government decision-makers, financial partners, journalists or national champions and their subsequent mobilization contributed to strengthening the policy and programmatic environment for EBF.

The Multiple Micronutrient Supplementation Cost-Benefit Tool: A Catalyst for Accelerating Maternal Nutrition Policy and Investment Decisions

Jennifer Frances Busch-Hallen[1], Sarah Nicole Rowe[1], Dylan Walters[1]

1. Nutrition International (Canada)

Background and Objectives: Recent evidence shows multiple micronutrient supplements (MMS) for pregnant women, a daily tablet containing 13-15 vitamins and minerals including iron and folic acid, provide additional health benefits for newborns compared to iron-folic acid supplements (IFAS) alone. MMS is safe for mothers and their newborns and cost-effective. Stemming from this evidence and updated guidance from the World Health Organization (WHO), many low- and middle-income countries (LMICs) are considering transitioning from IFAS to MMS for routine antenatal care programming. The objective is translated economic evidence, to provide national governments with context-specific analyses on cost and cost-benefit for policy and program decisions.

Methods: Nutrition International developed the online MMS Cost-Benefit Tool (The Tool) using a rigorous methodology to estimate potential health impact, budget impact, economic value, cost-effectiveness, and benefit-cost ratio of investing in MMS compared to IFAS. Analyses were conducted and pre-loaded in the Tool for 33 LMICs. The analyses were extracted from The Tool and translated into policy briefs. By request, The Tool was used to model the cost-effectiveness of transitioning to MMS for select LMICs to provide data for the WHO's *Nutritional Interventions update*: MMS during pregnancy (2020)

Results: For all countries in The Tool, analyses show that transitioning from IFAS to MMS would generate substantial health benefits in terms of morbidity and mortality averted, is "very cost-effective", and would provide a high return on investment. The average cost per Disability Adjusted Life Years averted is 23.61 USD and benefit-cost ratio ranges from 41-1,304 USD which demonstrates MMS is good value for money compared to IFAS. Customized country policy briefs translate this evidence to action for ministries of health and finance and other key decision makers. The Tool is informing global action through the WHO guideline update and country-level action,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

including updates to national guidelines throughout Africa and Asia.

Conclusion: With its user-friendly design, open access availability, and dynamic, data-driven analytics, The Tool is a powerful resource for governments and nutrition partners. The Tool provides timely and evidence-based analyses to inform policy-decisions, implementation research, and investments towards the scaling of MMS programs for pregnant women in LMICs.

Cost and affordability of healthy diets in Vietnam

Duong Thi Thuy Van[1], Anna Herforth[5], Huong Thi Trinh[2], Binh Thi Thanh Dao[3], Ha Thi Phuong Do[4], Elise F Talsma[1], Edith JM Feskens[1]

1. Wageningen University & Research (Netherlands), 2. Thuongmai University (Viet Nam), 3. Hanoi University (Viet Nam), 4. National Institute of Nutrition (Viet Nam), 5. Independent consultant and researcher (USA)

Background and objectives: As the essential drivers of dietary quality, the cost and affordability of healthy diets challenge food security, nutrition, and health. In Vietnam, long-term national nutrition and food security success require special attention to the supply and access to healthier foods for all population groups to ensure higher dietary quality. The aims of this study were to estimate the minimum cost to meet the healthy diets recommended by 2016-2020 Vietnamese food-based dietary guidelines, compare the cost differences by food group, region, and seasonality, and assess the affordability of healthy diets.

Methods: The cost of healthy diets was estimated by the Cost of Recommended Diet indicator, based on monthly Consumer Price Index prices data of 176 food items from January 2016 to December 2020. Affordability was determined by comparing the cost of healthy diets to a standard of both food expenditure and income, which are calculated from the three latest Vietnam Household Living Standard Survey (VHLSS), including VHLSS 2016 (9,399 households), VHLSS 2018 (9,167 households), and VHLSS 2020 (9,388 households).

Results: The average cost of healthy diets from 2016 to 2020 in Vietnam was 3.08 dollars in 2017 Purchasing Power Parity (24,070 Vietnamese Dong). The nutrient-rich food groups, including protein foods, vegetables, fruits, and dairy, composed approximately 80% of the total cost of healthy diets in all regions. Particularly, dairy accounted for the largest portion of the total cost. We estimate that approximately 60% of Vietnamese low-income households could not afford healthy diets.

Conclusion: Our findings suggest that it is crucial to facilitate interventions in local food systems to reduce the cost of nutrient-rich foods, supporting the attainment of higher dietary quality in the Vietnamese population, especially for low-income households.

OAB(T9)4-3
Developing a Healthy Diet Basket for global monitoring of the cost and affordability of healthy diets

Anna W Herforth[1,2], Aishwarya Venkat[2], Yan Bai[3], William A Masters[2]

1. Harvard T.H. Chan School of Public Health (USA), 2. Food Prices for Nutrition Project, Tufts University (USA), 3. World Bank (USA)

Background and objectives: The cost and affordability of a healthy diet is crucial to understanding whether people can access healthy diets, such as those recommended in national food-based dietary guidelines (FBDG). The objective of this work was to develop a comparable standard of a healthy diet, for the purpose of calculating and comparing the cost and affordability of healthy diets across countries.

Methods: Recent and quantifiable national FBDG were identified in all regions of the world. These were quantified in terms the range and average amount in dietary energy (kcal) of each food group recommended per day per person, proportionally standardized to meet a total dietary energy value of 2329 kcal (the requirement for an average 30-year-old woman). Average amounts of each food group across guidelines were determined and used to construct a Healthy Diet Basket (HDB). The cost of the HDB and each of the originally quantified FBDG was found by analyzing food price data from 177 countries globally from the World Bank International Comparison Program (2017). The macro- and micronutrient content was calculated for the resulting least-cost set of items in each country.

Results: The Healthy Diet Basket is proportionally similar to the national FBDGs from which it was derived, as well as additional non-quantified national food guides. The cost of the HDB was slightly less than $3.50 on average across countries. Based on analysis of least-cost baskets of foods meeting each guideline, the mean adequacy ratio (MAR) of the HDB was 94%, identical to the average MAR across national FBDG.

Conclusions: The Healthy Diet Basket (HDB) is a transparent, global standard set of criteria that represents commonalities across most FBDG globally and satisfies nutrient needs. It is appropriate to use for comparing the cost and affordability of healthy diets across countries. Even least-cost diets meeting this standard are unaffordable for many people in the world,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

pointing to the need for accelerated action to make healthy diets accessible for all.

Measurement and reach of nutrition sensitive social protection programs in South Asia: an analysis of nationally representative surveys from 2012 to 2019

Sumanta Neupane[1], Samuel Scott[1], Hana Tasic[2], Nadia Akseer[2,3], Sunny Kim[4], Purnima Menon[1], Rebecca Heidkamp[3]

1. International Food Policy Research Institute (India), 2. Modern Scientist Global (Canada), 3. Johns Hopkins University (USA), 4. International Food Policy Research Institute (USA)

Background and objectives: Social protection programs with conditions added to enhance their nutrition sensitivity – such as linking of a cash/in-kind transfer to health service delivery – are termed nutrition sensitive social protection programs (NSSPPs). In South Asia, the global region with the most malnourished individuals, NSSPP coverage remains poorly described. We assessed data availability and examined coverage and inequities of NSSPPs in South Asia.

Methods: After identifying NSSPPs in seven countries (Afghanistan, Bangladesh, Bhutan, India, Nepal, Pakistan, Sri Lanka), we assessed data availability in nationally representative household expenditure and health surveys. Coverage was defined as the percentage of households covered by government cash and/or food transfers in the past year. To understand if NSSPPs reached vulnerable households, we estimated coverage among all households, households with children <5 years, and by wealth quintiles or residence type. Finally, we examined co-coverage of NSSPPs and health/nutrition interventions during pregnancy.

Results: Data on NSSPPs were available only in datasets from three (Bangladesh, India, Nepal) of the seven countries. In Bangladesh, 18% of households reported receiving either cash or food transfers. In India, 52% of households received a subsidized food ration. In Nepal, 22% of households received cash but no data were available on food transfers. Coverage of NSSPPs in households with children <5 years was similar to coverage among all households. In all countries, coverage of NSSPPs exhibited a pro-poor and pro-rural gradient. Although half of women received food during pregnancy in India, only 2% received both food and health/nutrition interventions (having at least 4 antenatal care visits, consuming at least 100 iron folic acid tablets, deworming, and receiving tetanus injections). Co-coverage of cash plus health/nutrition interventions was 1% in India and 21% in Nepal.

Conclusions: Most NSSPPs in South Asia are not captured in routine large-scale surveys. To improve tracking and reach of NSSPPs, efforts are needed to close these measurement gaps. Where data are available, our findings suggest that NSSPPs are reaching poorer households, but coverage remains low. Co-coverage of NSSPPs with health/nutrition interventions is poor, suggesting missed opportunities to reach vulnerable households with multisectoral interventions.

Keywords: NSSPPs, South Asia, Coverage, Co-Coverage, Inequity

OAB(T9)4-5

Development of an innovative global online continuing medical education course for improving health providers' capacity in maternal nutrition

Kristen Hurley, PhD, MPH[1,3], Justine A. Kavle, PhD, MPH[2], Jillian Emerson, PhD[1], Constance Gathi, BSc[2], Avis Sampson, M.Ed.[1]

1. Vitamin Angels (USA), 2. Kavle Consulting (USA), 3. John Hopkins University (USA)

Background: Nutrition in pregnancy is critical for achieving optimal maternal and child health outcomes, yet gaps in facility and community health provider knowledge and key competencies to deliver maternal nutrition interventions during routine health contacts persist globally.

Objective: We developed a free continuing medical education course with the objective of improving nurses, physicians and nutritionists' knowledge of the global burden and consequences of maternal malnutrition, the importance of maternal dietary intake during pregnancy and lactation, appropriate weight gain during pregnancy, and evidence-based interventions to improve maternal nutritional status through diet, and micronutrient supplementation. Health service delivery considerations include improving provider communication and counseling skills, social behavior change interventions, strengthening facility and community linkages, and advocacy for the introduction and scale-up of evidence-based interventions within the policy enabling environment will be explored.

Methods: An online Learning Management System platform will be used for the virtual course-. Learners will be guided through six modules presented by global experts and will gain additional training considerations for inclusion of maternal nutrition in the design and implementation of country programs. Learners can also draw upon lessons learned from country case studies from Latin America, Asia and Africa, which will be developed in collaboration with local professional organizations and in-country nutrition experts. Preliminary data on effectiveness of the course in improving provider knowledge were collected through a pre-post course evaluation, as well as via qualitative methodologies.

Results: The course launched in mid-2022. Key takeaways include: the design in planning and implementation of the course, and initial evaluation data on changes in provider

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

knowledge, as well as content on key lessons learned from the first set of country case studies.

Conclusion: Strengthening provider knowledge and capacity on nutrition is critical to provide quality health services during antenatal care and postnatal care. Expansion of Continuing Medical Education with global reach is much needed to aid in improving maternal nutrition knowledge and skills by combining teachings from global and local experts with practical country case studies.

Keywords: Maternal nutrition, antenatal care, postnatal care, continuing medical education

OAB(T9)4-6

Positioning Nutrition within Universal Health Coverage: optimizing health financing levers to turn commitments into action

Kyoko Shibata Okamura[1], Ali Winoto Subandoro[2], Michelle Mehta[1], Huihui Wang[1], Elyssa Finkel[1], Andrea L. S. Bulungu[1], Naina Ahluwalia[1], Girmaye Dinsa[1], Latifat Okara[1], Shelby Wilson[1]

1. World Bank (USA), 2. Global Financing Facility for Women, Children and Adolescents (USA)

Background: Achieving universal health coverage (UHC) is a top global priority, and nutrition actions are a critical part of meeting that goal to not only reduce the burden of disease, but also prevent permanent physical and cognitive impairments, ultimately staving off future health care costs for both individuals and health systems. However, coverage and quality of nutrition service delivery remains low, despite robust evidence of cost-effective interventions. There are gaps in knowledge on how to deploy health financing levers more effectively to improve the delivery of nutrition services as part of preventive and promotive health care.

Objective: The study aims to provide practical knowledge to policymakers on "how" to use health financing levers—revenue raising, pooling, and purchasing—to improve nutrition service coverage and quality as part of the movement toward UHC, thus bridging the disconnect between known advantages of investing in nutrition with actionable recommendations.

Methods: Based on internal expert consultations, we constructed a five-part analytical framework consisting of: Prioritization of nutrition services in national health plans; Financing arrangements for nutrition within the health system and its challenges on nutrition services; Optimization of health financing levers to improve quality nutrition service delivery; and Roles of other health system features in enabling the optimization of health financing arrangements. Accordingly we conducted literature reviews and key informant interviews for global evidence synthesis and country deep-dive analyses to identify challenges and options for optimization of health financing levers. Peru, Indonesia, Rwanda, Ethiopia and Thailand were selected for country analyses.

Conclusion: The revenue raising lever can be optimized through evidence-based planning and resource allocation based on disease burden of nutrition/diet-related risk factors while innovative fiscal policies, such as diet-related taxation, can also be explored amidst serious fiscal constraints around the world. On pooling, countries can reduce fragmentation by aligning financing sources, harmonizing benefits and facilitating cross-subsidization relative to need. For the purchasing lever, costed and prioritized nutrition package of services need to be explicitly included in the UHC benefits package and reforms on community-based provider contracts is key to delivering quality nutrition services to the most vulnerable.

Operationalizing Multisectoral Nutrition Program to Accelerate Progress: A Nutrition Governance Perspective

Ali Winoto Subandoro[1], SIlvia Holschneider[1], Julie Ruel-Bergeron[1]

1. Global Financing Facility (GFF) and World Bank (USA)

Background: Given the complex, multifactorial, and interlinked determinants of nutritional status and well-being, multisectoral nutrition programming that converges on vulnerable populations has been widely promoted as the most effective way to address the direct and indirect determinants of malnutrition and improve nutrition outcomes. Robust governance systems are essential for implementing multisectoral nutrition interventions and creating cost-effective and sustainable programs.

Objective: The purpose of this report is to delineate valuable lessons learned from selected countries in operationalizing large-scale multisectoral nutrition programs that emphasize and strengthen governance. The focus countries have demonstrated innovative approaches to address systemic governance challenges and highlighting the need for "business not as usual" to accelerate progress.

Methods: The report draws on a desk review of the current literature and project documents on multisectoral nutrition interventions and the role of governance in carrying out these interventions. The review includes the implementation progress of extensive technical assistance and analytics that covers

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

knowledge-sharing, diagnostics to inform evidence-based advocacy, project design and formulation, and support for implementation and monitoring and evaluation.

Conclusion: The report highlights the following areas: (i) continued need strengthening routine data systems that enable continuous tracking of nutritional status, service coverage/utilization, and quality of care; (ii) improvement of public financial management system to enable tracking of nutrition spending across sectors to enhance accountability; (iii) investments in technologies that improve the availability and utilization of high-quality nutrition data, including those that enhance the interoperability across data system; (iv) build capacity and incentives to implement multisectoral interventions at national and subnational levels; and (v) citizen engagement to strengthen community-level decision-making and accountability processes to strengthen the demand for quality services and enhance program course corrections.

Building the case for nutrition: A pilot methodology and approach to mobilize investments for tackling malnutrition in all its forms.

Stineke Oenema[1], Daniel Grafton[2], Daisy Lanvers[2], Emily Roberts[2], Simone Romano[2], Dudley Tarlton[2], Kathryn Ogden[1], Kaia Engesveen[3], Khalifa Elmusharaf[4], Sebastien Poix[4]

1. United Nations Nutrition Secretariat (Italy), 2. United Nations Development Programme (USA), 3. World Health Organisation (Switzerland), 4. University of Limerick (Ireland)

Background and objectives: There is clear opportunity to expand the coverage of nutrition investment cases beyond the common focus of undernutrition in mothers and children, to reach individuals at various stages throughout the life cycle. Under the Global Joint Programme to Catalyse Multisectoral Action on noncommunicable diseases (NCDs), UNDP, WHO, and the United Nations Interagency Task Force on NCDs have developed a methodology to build NCD investment cases. Already 26 investment cases on NCDs have been completed and launched globally. UN Nutrition and UNDP, supported by WHO, will build upon the established methodology to develop an approach for investment cases that address malnutrition in all its forms and will produce a pilot investment case for a country complete with an economic and political analysis. These investment cases will support governments to make a compelling, evidence-informed advocacy case for investments in nutrition interventions that address the growing prevalence of undernutrition, overweight, obesity and diet-related NCDs.

Methods: Our team of policy analysts, health and nutrition experts and economists will develop a list of feasible interventions from the OneHealth Tool (OHT) best suited to address malnutrition in all its forms to be analysed in an economic model, while specifying underlying assumptions and impact pathways. The team will produce a guidance note on methodologies to estimate the burden of malnutrition. The team will finalise economic models and frameworks on the impact, costs and returns on investment (ROI) for nutrition interventions. For a pilot country, the team will cost nutrition interventions and calculate ROIs over 5- and 15-years, monetizing the health benefits and averted treatment costs.

Results: A pilot nutrition investment case with a political component and summary of the economic findings will be developed. A report summarizing the methodology, results, and learning from the pilot investment case will be made available for replication in other countries.

Conclusion: This work can build upon established methodologies to expand the accessibility and reach of nutrition investment cases in countries where they are needed most.

Keywords: nutrition, noncommunicable diseases, investments, modelling, methodology

Correlation of Vitamin D Concentration, Glycaemic Control, Cytokines and Adipokines in Adults with Type 2 Diabetes Mellitus in Mexico

Roxana Valdes-Ramos[1], Mariana Román-Casas[1], Beatriz Elina Martínez-Carrillo[1], Ana Laura Guadarrama-López[1]

1. Universidad Autonoma del Estado de Mexico (Mexico)

Background and objective: Diabetes mellitus is a chronic and multifactorial disease which according to the WHO affects 422 million individuals; 90% have Type 2 Diabetes Mellitus (T2DM). Currently, scientific evidence suggests that patients with T2DM have low concentrations of vitamin D and systemic inflammation; these factors aggravate symptoms and cause complications. The objective was to establish associations between glucose, insulin, cytokines, adipokines and vitamin D in adults with T2DM in Mexico.

Methods: A cross-sectional study was undertaken, which included 93 adults from 25 to 60 years old, both sexes, selected from outpatient public clinics in Toluca, Mexico State. Their participation was voluntary. Clinical baseline markers, anthropometrics, glycemic control such as glucose, insulin, Hb1Ac, HOMA-B and HOMA-IR were calculated; additionally, cytokines, adipokines and vitamin D status were measured. Spearman correlation was used to determine associations.

Results: A significant correlation ($p > 0.05$) was found between IL-1β, 1L-10, IL-8, IL-6 IL-12, TNF-α and IFN-γ and vitamin D serum concentrations. Leptin had a positive correlation with insulin and HOMA-B. Also, glucose correlated with leptin, IL-12, IFN-γ, insulin, HOMA-B and HOMA-IR. Finally, a significant Vitamin D deficiency in all patients was found (<20 ng/ml). No significant associations were found between vitamin D binding protein and other markers.

Conclusion: This Mexican population with T2DM had a significant deficiency of vitamin D, associated with various cytokines.

Glycemic index, glycemic load, and lung cancer risk: a meta-analysis

Tianfeng Zhang[1,2], Hongzhen Du[1,2], Ying Xie[1,2], Bin Luo[1,2], Zengning Li[1,2]

1. Hebei Medical University (China), 2. Key Laboratory of Nutrition and Health of Hebei Province (China)

Objective: Glycemic index (GI) or glycemic load has been investigated in the field of cancer research for several years. However, the relationship between GI or glycemic load and lung cancer risk remains inconsistent. Thus, this study aims to summarize previous findings on this relationship.

Methods: PubMed, Web of Science databases, and Cochrane Library were searched by July 2021. This review was in accordance with the PRISMA guidelines. A fixed-effects or random-effects model was adopted for meta-analysis to compute the pooled relative risks (RR) and their corresponding 95% confidence intervals (CIs). Subgroup analyses, sensitivity analyses, and publication bias analyses were also performed.

Results: In total, nine articles were included with four case–control studies and five cohort studies. After merging the studies, pooled multivariable RRs of lung cancer based on the highest versus the lowest intake were 1.14 (95%CI: 1.03–1.26) and 0.92 (95%CI: 0.86–0.98) for GI and glycemic load. Results persisted in most stratifications after stratifying by potential confounders in the relationship between GI and lung cancer risk.

Conclusion: In this paper, GI typically has a positive relationship with lung cancer risk. This negative finding between glycemic load and lung cancer risk provides evidence on the association issue based on current evidence and suggests that this issue should be studied and verified further to substantiate these findings.

Is thinness and eating disorder associated with an inability to eat beyond hunger?

Charlotte Wright[2], Jia Yin Tay[2], Dalia Malkova[2], Lesley Whiteside[2], Katie Spooner[2], Ada L Garcia[2], Eunice Nortey[1]

1. University of Ghana (Ghana), 2. University of Glasgow (UK)

Background and Objective: Self-regulation of energy intake is essential for health. An inability to eat less following a high energy preload (eating beyond hunger) has been associated with overweight, but it is unclear whether an inability to eat beyond hunger places children at risk of undernutrition. The preload satiation methodology is a standard, within-subject, crossover experiment which generates a measure of energy regulation, the compensation index (COMPX). Our systematic review and meta-analysis of 20 published studies found the average COMPX among healthy children aged 2-7 years to be 68%.

We aimed to measure energy regulation in thin children with severe feeding problems, compared to published data on healthy children.

Methods: Pilot satiation studies were then conducted among thin children (BMI <-1.66 kg/m^2) aged under 7 years attending a UK tertiary feeding clinic. On two visits, >7 days apart they were given similar drinks containing either minimal energy, or 10% of daily requirements, with parents and researcher blinded to the condition. After 30 minutes children were offered a large test meal, the same on each day. The energy consumed was calculated from before and after weighing. Parents rated child's eating behaviour using the International Complementary Feeding Evaluation Tool (ICFET); scores of avidity, food refusal and food frequency were expressed as z scores and compared to the UK population using one sample t-test.

Results: Nine children aged median (range) 55 (28-75) months were recruited and completed the full protocol. They had low mean [SD] avidity (-1.36 [1.2]; P=0.009) and food frequency (-1.3 [1.4]; P=0.024) Z score, but their refusal score was near average (0.45; P=0.4). All children ate less at the meal after the high energy preload, resulting in similar total energy intake (meal plus preload) for both conditions (Low, 246±64 kcal, High, 246±66 kcal). The mean COMPX was 104 ± 39%, 36% points higher than for healthy population (one sample t-test = 0.025) with 4 children over-compensating (>100%).

Conclusion: This pilot study suggests that thin, eating disordered children regulate their energy intake precisely. Further research will consider whether an inability to eat beyond hunger predisposes to childhood undernutrition in lower income settings.

Keywords: Satiation, Energy regulation, compensation, thinness, Malnutrition

PAB(T1)-4

Finding key barriers and enablers influencing the nutrition behavior using a formative research, Barrier Analysis Study in Myanmar

Saw Eden[1], Swe Linn Maung[1]

1. Save the Children International in Myanmar (Myanmar)

Background and objectives: Myanmar is one of the countries with high stunting rate among under 5 children (29.2% in 2016), with continued violence and conflict, and collapsed health system. To increase the effectiveness of the project approach, Save the Children team and the implementing partners conducted formative research using the barrier analysis (BA) methodology in 9 townships in 5 states and regions to study the barriers and enablers of Nutrition, WASH, and Health behaviors. The results of the barrier analysis are to be used to inform and strengthen the behavior change strategy of the project. Specifically, the findings will inform the development of the project activities, the supporting environment for the priority groups, Essential Nutrition and Hygiene Action lessons and job-aids to ensure messages that are context specific, culturally appropriate, and effective in eliciting behavior change through addressing localized barriers and enablers.

Methods: The Barrier Analysis (BA) was selected as the formative research tool to inform and fill gaps within the behavior change strategy.

Results: Getting the information about the significant determinants influencing the nutrition behaviors of the priority groups, Save the Children and Implementing Partners were able to strengthen the Social Behavior Change and Communication projects. This impacts the positive behavior change of the mothers and caretakers who are taking care of the children, increasing minimum dietary diversity from 53% to 60%, and acceptable diet from 52% to 59% in a year in displaced people in Rakhine state, Myanmar.

Conclusions: The BA was the preferred formative research method for two key reasons: the BA is a rapid form of formative research and national field staff can conduct the BA. It can inform the project to design the behavior change framework for the targeted community group in positively changing the nutrition behaviors.

Keywords: Barrier Analysis, Determinants, Formative Research, Minimum Dietary Diversity, Acceptable Diet

Conflict of Interest Disclosure: The authors have used the information and data from Save the Children BHA project, Save the Children BRICKs project and the Barrier Analysis Guideline of Bonnie Kittle.

The shift in “zero” balance values and the variability in 24-h urinary iodine excretion rate: findings from the iodine balance experiment in children

Wenxing Guo[1], Wanqi Zhang[1], Wen Chen[1]

1. Tianjin Medical University (China)

Background and objectives: The iodine balance experiment is commonly used to determine the estimated average requirement (EAR) of iodine. The data on iodine balance experiments in Chinese children are scarce. This study aimed to conduct an iodine balance experiment in Chinese children and provide a scientific basis for children's iodine reference intake in China.

Methods: A three-day iodine balance experiment was conducted in three schools with 29 school-age children. All food and water ingested by the subjects were measured by the weighing method, and 24-h urine and feces were collected. Iodine intake and excretion were assessed.

Results: A nonlinear relationship between the 24-h urinary iodine excretion rate and iodine intake was found. The 24-h urinary iodine excretion rate tends to increase with increasing iodine intake when the iodine intake is lower than 89.6μg/d (β=1.81, 95 CI%=0.49, 3.13), and decreases significantly with increasing iodine intake when the iodine intake is higher than 89.6μg/d (β=-0.07, 95 CI%=-0.09, -0.05). We found that the "zero" balance values increase with iodine intake in the analyses of the simple linear model and the linear mixed-effects models. The corresponding "zero" balance values were 130μg/d, 147μg/d, and 232μg/d for iodine intake of 145μg/d, 191μg/d, and 495μg/d, respectively. The "zero" balance values for children aged 7-10 years and 11-12 years at appropriate iodine intake levels were 130μg/d and 140μg/d, respectively.

Conclusions: The use of the 92% 24-h urinary iodine excretion rate to extrapolate iodine intake is not uniform. The population iodine nutrition background needs to be considered. The "zero" balance values showed a tendency to shift with increasing iodine intake. The "zero" balance values obtained from iodine-appropriate children may be used as a safe recommended level of iodine intake.

Keywords: iodine balance study, 24-h urinary iodine excretion rate, "zero" balance value, children

Conflict of Interest Disclosure: The authors have no conflicts of interest to declare.

Associations between dietary practices and sleep measures during weekdays and weekends among preschool-aged children in Finland

Anna M Abdollahi[1], Ilona Merikanto[1], Eva Roos[2,3], Henna Vepsäläinen[1], Marja Leppänen[2], Maijaliisa Erkkola[1]

1. University of Helsinki (Finland), 2. Folkhälsan Research Center (Finland), 3. Uppsala University (Sweden)

Background and objectives: The importance of sleep is an integral part of growth, development, restoration, and metabolism, particularly in young children. Healthier dietary practices have been associated with beneficial sleep outcomes and unhealthier dietary practices with poorer sleep outcomes. However, routines for both diet and sleep may differ between weekdays and weekends. This study aims to examine the weekday and weekend associations of fresh fruit and vegetable, sugar-sweetened beverage, and added sugar intakes with sleep measures among children.

Methods: This study included 3-6 year-old children with diet and sleep data from at least two weekdays (n=700) and one weekend (n=697) from the Increased Health and Wellbeing in Preschools (DAGIS) study. Consumption of fresh fruit and vegetables, sugar sweetened beverages, and added sugar was measured via 3-5 day (≧2 weekdays and ≧1 weekend) food diary, further divided into tertiles for analysis. Sleep was measured with 24-hour hip-worn accelerometers. For sleep, weekdays were Sunday-Thursday and weekends Friday-Saturday nights. Sleep measures included: adequate nighttime sleep (10-13 hours), later sleep onset (>21:00), and poor sleep quality (sleep efficiency <85%). Logistic regression analyses were adjusted for age, sex, parental education level, and energy intake.

Results: Only 29-43% (weekday-weekend) of preschoolers had adequate sleep, 59-75% had later sleep onset, and 25-29% had poor sleep quality. Compared to children with low consumption, children with high consumption of fresh fruit and vegetables on weekdays had decreased odds of having a later sleep onset (OR: 0.67 (95% CI: 0.46, 0.98)) and poor sleep quality (OR: 0.61 (95% CI: 0.39, 0.94)) on weekday nights. Similarly regarding weekdays, children with higher added sugar intake had increased odds of having a later sleep onset (OR: 1.56 (95% CI: 1.05, 2.34)). No statistically significant associations were observed between sleep and diet on weekends or sugar-sweetened beverages on weekdays.

Conclusions: Poor sleep was prevalent among preschoolers and associated with more unfavorable dietary practices on weekdays. Increased fruit and vegetable consumption and reduced added sugar intake may be beneficial for sleep onset and quality. Further investigations into the differences and direction of the associations between diet and sleep on weekdays and weekends are warranted.

Keywords: food intake, sleep quality, sleep timing, childhood nutrition, actigraph sleep

Conflict of Interest Disclosure: N/A

Protective effects of Sulforaphane on Heart Rate Variability upon calorie-induced inflammatory response: A double-blind, crossover, randomized, placebo-controlled study

Hidde van Steenwijk[1], Aalt Bast[1], Khrystyna Semen[1], Alie de Boer[1], Frits van Osch[1], Ardi Cengo[1]

1. Maastricht University (Netherlands)

Background and objectives: Most non-communicable diseases are partially affected by chronic low-grade inflammation (CLGI). Several bioactive compounds found in fresh fruits and vegetables have been described as anti-inflammatory ingredients, of which sulforaphane (SFN) shows the most promise for clinical testing due to its absorption and metabolism into human tissues and effects on health and specifically CLGI. Heart rate variability (HRV) is a reliable index of cardiac vagal regulation and should be inversely related to levels of inflammatory markers. We have studied the potential beneficial physiological effects of SFN, assessed by HRV parameters, in the setting of a calorie-induced inflammatory response in healthy participants.

Methods: The study was designed as a double-blind, crossover, randomized, placebo-controlled intervention study. On two separate testing days, twelve healthy participants (18-50 years old) received either 16 grams (intervention) of broccoli sprouts (BroccoCress®) or 16 grams of Affilla Cress® (placebo) in randomized order. After 90 minutes, participants received the 'PhenFlex' challenge, a standardized high-fat, high-sugar, and high-calorie drink. On four different time points, HRV parameters were assessed in short term (5 min) ECG recordings obtained in supine position and analyzed as recommended by clinical standards (ESC / NASPE, 1996). Total power, high-frequency power, low-frequency power, and very low-frequency power were derived from the spectral analysis, together with different time-domain indices. The recordings of ECG were performed four times: (i) before administration of investigational product; (ii) before administration of PhenFlex; (iii) 30 min after administration of PhenFlex; (iv) 2 hours administration of PhenFlex.

Results: The first results indicate that sulforaphane has a positive effect on several HRV parameters and that there appears to be a protective effect against the standardized PhenFlex challenge. Preliminary trend analyses indicate that after consumption of BroccoCress®, participants have a higher HRV, devoted to overall better health.

Conclusions: The findings from our study indicate that sulforaphane may have a protective effect on inflammation induced by the standardized PhenFlex challenge, which mimics exposure to CLGI, as measured by HRV parameters. Sulforaphane consumption could thereby elicit a beneficial physiological effect and thus have a health-promoting effect on non-communicable diseases.

Keywords: Nutrition, Sulforaphane, Inflammation, Heart Rate Variability, Non-communicable diseases

Effect of early iron supplementation in breastfed infants living in rural West Africa: a double blinded randomised controlled trial

Mamadou Bah Bah[1,2], Isabella Stelle[3], Andrew M. Prentice[2], Sophie E. Moore[2,3], Hans Verhoef[1], , Carla Cerami[2]

1. Wageningen University and Research & Medical Research Council Unit The Gambia at LSHTM (Netherlands), 2. Medical Research Council Unit The Gambia at London School of Hygiene and Tropical Medicine (Gambia), 3. Kings College London (UK)

Background and Objectives: Recent evidence from the Gambia suggests that the supply of iron to growing tissues, including the brain, is insufficient during the first 6 months of life in breastfed infants. The primary objective of this study was to measure the impact of daily iron supplements for 98 days starting at six- to ten- weeks of age on iron status in infants living in rural Gambia. The study will also determine if iron supplementation at this age will impact on the frequency of adverse events.

Methods: This was a double-blinded randomised controlled trial. One hundred and one participants were recruited and randomised to either intervention (daily 7.5mg of elemental iron as ferrous sulphate) or placebo. Healthy infants (6-10 weeks old of age) were identified and enrolled if informed consent was obtained, they were healthy, exclusively breastfeeding and willing to stay in the study area. Participants planning to use commercial formulas or herbal supplements and those with fever, acute or chronic diseases were excluded. Venous blood and faecal samples were collected for baseline and endpoint evaluation. Participants were followed and supplemented daily for 98 days. Daily morbidity and weekly feeding questionnaires were completed. On days 0 and 99, 3ml of venous blood and faecal sample were collected for laboratory evaluation. Participants were followed to day 112 to monitor for adverse events.

Results: The trial has been completed. Analysis is ongoing and full trial results will be presented at the meeting. Results to be included will be serum iron concentration at Day 99 (after 98 days of iron supplementation and a day wash-out period), haemoglobin, MCV, reticulocyte haemoglobin, reticulocyte number, immature reticulocytes fraction, soluble transferrin receptor, ferritin, transferring saturation, erythroferrone, erythropoietin, and hepcidin concentrations, as well as illnesses/adverse events.

Conclusion: This trial will determine if the critically low levels of circulating iron observed in African children by mid-infancy should be improved by introducing iron supplements much earlier than currently recommended whilst babies are still breastfeeding.

Keywords: Iron, breastfeeding, anaemia, erythroferrone, erythropoietin

Nutrigenetic intervention for reducing body fat and blood lipids in adults with obesity and overweight: A randomised controlled trial

Edgar J Mendivil[1], Yolanda E Pérez-Beltrán[2], Karina Gonzalez-Becerra[3], Erika Martinez-Lopez[3], Omar Ramos-Lopez[4], Mildreth Alcaraz-Mejia[1], Sonia G Sayago-Ayerdi[2], Ingrid Rivera-Iñiguez[3]

1. ITESO, Jesuit University of Guadalajara (Mexico), 2. Instituto Nacional de México, Instituto Tecnológico de Tepic (Mexico), 3. University of Guadalajara (Mexico), 4. Autonomous University of Baja California (Mexico)

Background and objectives: Obesity and dyslipidemias are risk factors for developing cardiovascular diseases. Pathogenesis involves environmental and genetic factors. There are several polymorphisms related to lipid metabolism alterations. Nutrigenetics studies the genetic variants' influence on the physiological processes promoted by foods to provide personalised dietetics guidelines. The objective of this study was to evaluate the effect of a nutrigenetic intervention on blood lipids levels and body composition of adults with obesity and overweight.

Methods: We selected eleven genetic variants associated with dyslipidemias in Mexicans, finding nutrigenetic recommendations for these polymorphisms. For the clinical trial, we included 101 adults with obesity or overweight and allocated them randomly into two arms considering genotyping, 1) standard diet (according to the WHO) and 2) nutrigenetic diet. We followed the participant for eight weeks and evaluated total cholesterol, HDL, LDL, VLDL, triglycerides, glucose, insulin, C reactive protein, as well as anthropometric measurements and body composition. We conducted the interviews remotely via virtual platforms.

Results: 46% (n=46) participants were obese, and 54% (n=55) overweight, by the end of the intervention 35% (n=35) presented obesity whilst 53% (n=54) overweight, and 12% (n=12) normal weight. We observed an improvement in biochemical parameters such as total cholesterol ($p<0.001$), VLDL ($p<0.001$), triglycerides ($p=0.002$), glucose ($p<0.012$), and insulin ($p=0.002$). Although we did not observe a statistical difference between study groups, all participants improved their body composition, weight, and biochemical indicators. There is a clear statistical tendency in the nutrigenetic arm to have better results when compared to the standard diet group.

Conclusions: The present nutrigenetic intervention was able to improve lipid abnormalities in patients with excess weight. Therefore, this strategy could reduce the risk of cardiometabolic diseases such as dyslipidemia, and as a coadjuvant strategy to standard treatments.

Keywords: Nutrigenetics, Dyslipidemia, Nutritional genomics, Obesity, Cardiometabolic risk

Conflict of Interest Disclosure: The authors declare that there is no conflict of interest to be disclosed. The State Council of Science and Technology (COECYTJAL) funded this project.

Effect modification by metabotype in an EWAS of usual dietary food consumption

Jakob Linseisen[1,4,3], Sebastian-Edgar Baumeister[2], Rory Wilson[3], Dennis Freuer[4], Hans Hauner[5,6], Christa Meisinger[4], Melanie Waldenberger[3,7], Fabian Hellbach[1,4]

1. Ludwig-Maximilians-University Munich (Germany), 2. University of Muenster (Germany), 3. Helmholtz-Center Munich (Germany), 4. University Augsburg, University Hospital Augsburg (Germany), 5. Else Kroener Fresenius Center for Nutritional Medicine (Germany), 6. Technical university of Munich (Germany), 7. Leibniz-Center for Diabetes Research at Heinrich Heine University Duesseldorf (Germany)

Background and Objectives: Different metabolic states may effect associations between diet and DNA methylation. This can be captured by metabotypes, clustered subgroups with metabolically homogenous profiles. Our aim was to examine the effect modification by metabotype between habitual consumption of various food groups and white blood cell DNA methylation.

Methods: Habitual dietary intake was estimated based on repeated 24-hour diet recalls and a food frequency questionnaire in participants of the population-based KORA FF4 study. Residuals of energy-adjusted food group intake data were used in this epigenome-wide association study [EWAS]. DNA methylation was measured using the Infinium MethylationEPIC BeadChip providing data on >850 000 loci. Using four standard clinical parameters and BMI, three metabotype clusters were identified by the K-means clustering procedure. The final study sample comprised 1261 participants. Confounder-adjusted linear regression models were used to test for effect modification by metabotype between diet and DNA methylation.

Results: Many significant hits were observed in models including food group-metabotype interaction terms, e.g. >80 hits for cheese and margarine consumption, respectively. Most findings refer to effect modification of food intake (e.g., cheese, whole-grain products, margarine) by metabotype 3, which is the metabotype with the most unfavorable metabolic profile. Many of the significant CpG's in this EWAS could be annotated to genes, which will be interpreted in the context of the study aims.

Conclusion: This research emphasizes the importance of including metabolic information of subjects when identifying associations between diet and white blood cell DNA methylation in EWAS. However, replication in future studies is needed.

A digitally delivered diet and lifestyle intervention to support African and Caribbean migrants in the UK: Results of a 6 months Pilot Study.

Alice Achieng Ojwang[1], Hibbah Osei-kwasi[2], Evans Asamane[5], Adetokunbo Olayanju[4], Robert Akparibo Akparibo[3]

1. The Technical University of Kenya (Kenya), 2. University Of Sheffield (UK), 3. University of Sheffield (UK), 4. Liverpool Hope University (UK), 5. University of Birmingham (UK)

Background and Objective: Weight loss interventions are often not effective among migrant populations. The objective of this study was to evaluate a 6-month digitally delivered culturally adapted diet and lifestyle pilot intervention to support African and Caribbean migrants living in Greater Manchester, United Kingdom.

Methods: Intervention design was pre-post design, and was delivered digitally over 24 weeks. Participants who met the intervention inclusion criteria i.e., lived in Greater Manchester, identified themselves as being of African or Caribbean origin, and 18 years and over, were invited, via social media, to participate. Participants received tailored nutrition and health education, and participated in healthy cooking lessons/demonstrations every Tuesday for 90 minutes over 24 weeks (November 2021-March 2022). On a daily basis, participants interacted by sharing photos of their meals, asking questions and sharing experiences of dietary changes on a WhatsApp platform. Participants also participated in daily 10,000 steps challenge as part of the intervention package, which was monitored using a fitness mobile application. Group discussions (24) involving 20-30 participants helped to explore the views of participants regarding the potential impact of the interventions.

Results: Ninety percent of the participants were females. Africans constituted the majority (86%), and most (78%) had tertiary level education. Over half (57%) were in full-time employment whilst 6% and 12% identified themselves as either housewives or students respectively. 22%, 10% and 4% respectively reported that they have high blood pressure, high cholesterol, and diabetes. At baseline, 32% of the participants were engaged in moderate exercise, and 26% had no exercise plan. Daily fruits and vegetables consumption, was on average less than 3 portions per day, half of the recommendation by UK Eat Well guide, whilst the consumption of processed foods was habitual. After 6 months, intervention participants reported modifications in dietary habits: increased consumption of fruits and vegetables, reduced intake of processed and sugar-sweetened beverages, weight loss, increased daily level of physical activities and feeling healthier.

Conclusion: A digital community tailored lifestyle intervention has the potential to result in dietary behavioural and physical activity modification among Africans and Caribbean migrants living in Greater Manchester communities. A randomised controlled trial is recommended to further test this.

Impact of omega 3 incorporation on the functionality of high-density lipoprotein: Randomized, parallel and controlled clinical trial

Nagila Raquel Teixeira Damasceno[1], Flavia De Conti Cartolano[1], Gabriela Duarte Dias[1]

1. Sao Paulo University (Brazil)

Background and objectives: The antiatherogenic role of high-density lipoprotein (HDL) is related to reverse cholesterol transport (RCT), however recent studies show additional function to HDL. Here, our goal was to evaluate the impact of ω-3 on the fatty acid profile, size and antioxidant capacity of HDL.

Methods: A randomized, controlled, double-blind, parallel clinical study involving 147 adult subjects with cardiovascular risk factors allocated into the ω-3 group (n=77; 3.0 g/day containing 1.8 g EPA + DHA) or the ω-6 group (n=70; 3.0 g/day of sunflower oil containing 1.95 g of linoleic acid). In the beginning (T0) and after 8 weeks (T8) blood samples were collected and, from plasma or serum, were analyzed lipid profile (TC, HDL-C, LDL-C, TG), apolipoproteins AI, CII and CIII, HDL subfractions (Lipoprint®), paraoxonase (PON1) and cholesterol ester carrier protein (CETP) activities, antioxidant capacity of HDL (experimental method), the fatty acid profile and NEFAs content HDL.

Results: The ω-3 and ω-6 groups were similar in relation to age, sex, smoking and medication use, both presenting high prevalence of hypertension and dyslipidemia. In both groups, there was a reduction in all lipid markers except HDL-C concentration, which increased. The effect of time on HDLNEFAs content (Δ=-16.2%), and on the percentage of HDLLARGE (Δ=20.1%) and HDLSMALL (Δ=-5.0%) were observed. Increasing EPA in HDL was associated with a lower chance of enhance PON1 activity (OR=0.446, CI=0.200-0.994), HDLNEFAs concentration (OR=0.275, CI=0.113-0.660), and HDLSMALL (OR=0.337, CI=0.146-0.782). It was also observed that EPA was associated with approximately 3.5 more chances of raising the percentage of HDLLARGE (OR=3.522, CI=1.652-7.507). Increasing DHA in HDL was significantly associated with a decrease in Apo AI concentration (OR=0.351, CI=0.150-0.821), and also PON1 activity (OR=0.226, CI=0.110- 0.639) and concentration of HDLNEFAs (OR=0.275, CI=0.113-0.668). Similar results obtained with EPA were observed for DHA and HDL size. No effect of the incorporation of EPA and DHA on oxidation resistance was observed.

Conclusion: The ω-3 intervention promoted changes in the composition of the HDL particle, increasing the percentage of the larger subfractions, without, however, modifying its antioxidant capacity.

Biochemical Characterization and Analyses of Red Meat Derived sialic acid glycans in different animal species for human health

Bing Wang[1], Marefa Jahan[1], Peter C Thomson[2], Peter Wynn[1]

1. Charles Sturt University (Australia), 2. The University of Sydney (Australia)

Red meat is a good source of protein, iron, B12, zinc, creatine and other nutrients for human nutrition. However, an increasing number of studies show a relationship between the consumption of the red meat-derived, non-human Sia, N-glycolylneuraminic acid (Neu5Gc), and inflammation, cancer progression, cardiovascular disease, and several autoimmune diseases. The level of Neu5Gc in skeletal muscle and organs across animal species remains unknown. We measured Neu5Gc in skeletal muscle and organ tissues from nine animal species using UHPLC. We found that Neu5Gcconcentration in skeletal muscle was the highest in goats (166 ± 48.7 μg/g protein), followed by cattle, pig, sheep, horse, cat and deer. Interestingly, no Neu5Gc was detected in kangaroo and dog muscles. More than 70% Neu5Gc was in the conjugated form. Total Neu5Gc in organ meats was generally about 2- 54% higher than in muscle. Surprisingly Neu5Gc was absent in seven organs of female deer. Similar levels of Neu5Gc were expressed across 9 primal commercial cuts of sheep meat. In conclusion, red meat Neu5Gc expression is species-specific, and absent in some organ and muscles meat. Low expression of Neu5Gc in skeletal muscle and its absence in kangaroo, dog and in all female deer organs suggest that these meats are the most appropriate for human consumption to avoid adverse health outcomes. Our study provides guidelines for the selection of animal meat products for consumers to prevent inflammatory disease and cancer progression.

Keywords: Sialic acid; N-glycolylneuraminic acid (Neu5Gc); muscle & organ tissue; , animal species

Conflict of Interest Disclosure: The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this abstract.

Further Collaborators: The authors would like to greatly thank Sandra Diaz, University of California, San Diego, for her valuable suggestion regarding the sample preparation method used in this study. Association of low serum levels of long chain saturated fatty acids with cancer: A nested case-control study

Tomiyo Nakamura[1], Yasuyuki Nakamura[2,3], Naoyuki Takashima[3,4], Aya Kadota[3], Katsuyuki Miura[3], Hirotsugu Ueshima[3], Yoshikuni Kita[3,5]

1. Ryukoku university (Japan), 2. Yamashina Racto Clinic and Medical Examination Center (Japan), 3. Shiga University of Medical Science (Japan), 4. Kindai University (Japan), 5. Tsuruga Nursing University (Japan)

Background and objectives: Recent studies have implicated impaired epidermal barrier function in cancer. The epidermis is rich in ceramides, important precursors of sphingolipids, which maintain the barrier function of the epidermis. Saturated and monounsaturated C16-C24 fatty acids are the main components of ceramides. However, differences in fatty acid profiles that are important for skin barrier function have not yet been explored between cancer patients and healthy individuals. We aimed to investigate the relationship between serum fatty acids and cancer.

Methods: We conducted a nested case-control study of 43 cancer cases and 43 controls matched by age, among Japanese men who were a part of the Takashima Cohort Study. We collected one 0.5 mL fasting blood sample from each participant into a sodium heparin vacuum collection tube. Serum fatty acid concentration was measured by gas chromatography and presented as a percentage of total lipids by weight. We performed the Spearman rank correlation test to examine the correlation between fatty acids. Logistic regression models were used to evaluate the association between fatty acids and a positive history of cancer, adjusting for age, body surface area, energy intake, smoking, alcohol consumption, and physical activity.

Results: Total serum fatty acid concentration did not differ significantly between men with and without cancer. Palmitic acid (C16:0) and palmitoleic acid (16:1n-7) were strongly positively correlated with each other and negatively correlated with long-chain fatty acids such as arachidic acid (C20:0), behenic acid (C22:0), and lignoceric acid (C24:0). Cancer patients had higher levels of palmitic acid (C16:0) and palmitoleic acid (C16:1) and lower levels of arachidic acid (C20:0), behenic acid (C22:0), and lignoceric acid (C24:0) than the controls.

Conclusions: This study suggests that a low level of serum long-chain saturated fatty acids, which are important components for maintaining skin barrier function, may be associated with cancer.

Keyword: cancer, ceramide, serum fatty acid, very long chain saturated fatty acid, nested case-control study

Transient and eminent decrease in red blood cell copper (RBC-Cu) during metabolic studies in young Japanese females

Mamoru Nishimuta[1,2], Naoko Kodama[2,3], Yuatka Yoshitake[2,4], Mieko Shimada[2,5]

1. Toyo University (Japan), 2. The National Institute of Health (Japan), 3. Tokyo Shokuryo Dietitian Academy (Japan), 4. Meio University (Japan), 5. Chiba Prefecture University of Health Sciences (Japan)

Background and objectives: Roles of RBC on mineral metabolism have not been clarified. Transport mechanisms of Cu are not fully recognized as well.

Methods: Blood was sampled 3 or 4 times in the morning with 3 to 4 days interval at human mineral balance studies conducted by the National Institute of Health and Nutrition. Hematocrit (%), serum (S-) and RBC-Cu were measured by atomic absorption spectroscopy (AAS), after deproteinization of S- and RBC- samples by 0.5 mM nitric acid solution as well as after wet ashing by nitric acid and hydrogen peroxide solution, then calculated RBC-Cu in 41 female and 19 male subjects.

Results: Data by the deproteinization and by the wet ashing were essentially the same. S-Cu and RBC-Cu in female subjects by the deproteinization method at the initial day (mean ± S.D.) are 1.04±0.14, and 0.56± 0.38 (mg/ L), respectively. Correlation between S- and RBC-Cu is not significant, although those in iron (Fe) and zinc (Zn) are positively significant. RBC-Cu showed transient and eminent decrease during the balance studies in most cases in females, while in few cases in males.

Discusion: RBC-Cu showed typical transient changes in females, suggested a transient decrease related to the menstruation cycle. RBC-Cu may invade into mucosa in uterus, facilitate defluxion of the mucosa. Though chemical form of RBC-Cu is not determined, it has some possibility to be something other than ceruloplasmin. Further investigations are needed to reveal the fine mechanism of RBC-Cu, and the relation between menstruation and RBC-Cu.

Conclusions: Transient decrease in RBC-Cu was eminent in female subjects, and we discussed the physiological roles of this phenomenon in the menstruation cycle.

Relationship between serum 5-methyltetrahydrofolate status and one-carbon metabolism-related metabolites in young women

Yoshinori Kubo[1], Akiko Tajima[1], Kumiko Shoji[1], Yasuo Kagawa[1], Yoriko Watanabe[1], Sayaka Horiguchi[1], Hideoki Fukuoka[2], Masazumi Nishikawa[3], Terue Kawabata[1]

1. Kagawa Nutrition University (Japan), 2. Fukushima Medical University (Japan), 3. Miyagi University (Japan)

Background and objectives: One Carbon Metabolism (OCM) consists of the folate cycle and choline metabolic pathway connected to the methionine cycle, and homocysteine (Hcy) in the methionine cycle is partially metabolized by the transsulfuration pathway. In this study, we comprehensively measured OCM-related metabolites in serum of women of childbearing age and investigated how serum 5-methyltetrahydrofolate (5-MTHF) concentrations are related to the choline metabolic pathway, methionine cycle, and transsulfuration pathway.

Methods: In this cross-sectional study, we recruited 227 young Japanese women. Serum concentrations of 18 OCM-related metabolites (5-MTHF, folic acid, choline, betaine, dimethylglycine, methionine, S-adenosylmethionine (SAM), S-adenosylhomocysteine (SAH), total Hcy (tHcy), homocysteic acid, cystathionine, total cysteine (tCys), taurine, serine, glycine, riboflavin, pyridoxine, pyridoxamine) were measured by LC-MS/MS. The association between the concentrations of OCM-related metabolites in serum were evaluated by Spearman's rank correlation coefficient. Serum 5-MTHF concentrations were stratified into two groups, low 5-MTHF group and high 5-MTHF group, based on median values.

Results: Serum 5-MTHF concentration showed a significant positive correlation with betaine in the choline metabolic pathway, SAM in the methionine cycle, and tCys in the transsulfuration pathway, respectively (ρ=0.25, ρ=0.14, ρ=0.15). In addition, 5-MTHF and betaine showed significant negative correlations with tHcy, respectively (ρ=-0.46, ρ=-0.29). Furthermore, when stratified by serum 5-MTHF concentration, the correlation coefficient between 5-MTHF and tHcy was p=-0.38 and betaine and tHcy was p=-0.10 in the high 5-MTHF group. In contrast, in the low 5-MTHF group, the correlation coefficient between 5-MTHF and tHcy was p=-0.36 and betaine and tHcy was p=-0.40. The negative correlation between betaine and tHcy was stronger in the low 5-MTHF group than in the high group.

Conclusions: The results of this study suggest that 5-MTHF status and the metabolic dynamics of the choline metabolic pathway, methionine cycle and transsulfuration pathway may be linked. Although tHcy is remethylated and reduced by 5-MTHF or betaine, respectively, the strength of the correlation indicates which substance is responsible for the remethylation. Our study suggests that tHcy remethylation by betaine may be enhanced in the low 5-MTHF state.

Relationship between a body shape index with traditional cardiovascular risk factors in Peruvian adults: Analysis of cross-sectional study

Anthony Aquino[1], Ivonne Bernui[1]

1.Universidad Nacional Mayor de San Marcos (Peru)

Background and objectives: cardiovascular diseases present traditional risk factors such as obesity, abdominal obesity (AO), dyslipidemia, type 2 diabetes mellitus, hypertension, and non-traditional risk factors such as the A Body Shape Index (Absi). Absi was proposed for the estimation of abdominal adiposity. In Peru, obesity rates and AO are current problems in young adults. We evaluate the relationship between Absi and each traditional cardiovascular risk factor in Peruvian adults in 2017.

Methods: one hundred voluntarily adults participated. The WHO STEPwise Approach to Non-Communicable Diseases Risk Factor Surveillance (STEPS) method was used to assess behavioral risk factors: tobacco use (active/no), alcohol use (use/no), physical activity (sedentary/non-sedentary), unhealthy diet (yes/no) as well as biological risk factors: obesity, AO, raised blood pressure, raised blood glucose, and abnormal blood lipids such as triglycerides, and total cholesterol. Absi was determinate using the formula: waist circumference (WC) / [(BMI 2/3) * (height 1/2)], both WC and height measured in meters. The association between Absi and each risk factor was evaluated by bivariate analysis. For numeric variables, we used Pearson correlation and Spearman correlation, and for categoric variables, chi-square test with a significance level of 5%.

Results: The average age was 46,1 ± 9.78 years and 66% were women. Obesity according to BMI was 23% and 41% have a very high cardiovascular risk according to WC, both indicators were higher in women than in men. The average Absi was 0,0817 ± 0,0031 m11/6 kg2/3 for men and 0,0792 ± 0,0045 m11/6 kg2/3 in women. 91% were moderate physical activity or sedentary and 44% have total cholesterol above 200 mg/dl. Absi and WC presented a positive-moderate association (Pearson correlation coefficient (r)= 0.431, p <;0.0001), the association was decreasing with triglycerides in mg/dl (r= 0.142), total cholesterol in mg/dl (r= 0.089) and blood glucose g/dl (r= 0.047). Absi and BMI presented a non-significant inverse relationship (r= -0.089). Tobacco use, alcohol use, unhealthy diet, and physical activity do not present a statistically significant association.

Conclusions: Absi has a direct relationship with WC; therefore, it's coherent with the literature. But doesn't exist relationship with the other cardiovascular risk factors in Peruvian adults.

Dietary wheat proteins worsen gastrointestinal symptoms in healthy vegetarians.

Sam Netherwood[1], Liberty Bailey[1], Ellen Barr[1], Victor F Zevallos[1]

1.Northumbria University, Newcastle (UK)

Background and objectives: The popularity of a plant based (PB) diet has recently increased in Western countries, mostly driven by concerns about animal welfare / sustainability, and the alleged health benefits. However, the consumption of wheat proteins, key component of a PB diet, have been linked to gastrointestinal inflammation and exacerbation of gastrointestinal (GI) symptoms. Therefore, we would like to evaluate the effect of dietary wheat proteins on GI symptoms and quality of life in healthy vegetarians and omnivores.

Methods: We asked 24 healthy participants (8 vegetarians and 16 omnivores) to reduce their consumption of gluten by at least 70% for 2 weeks. Dietary information, gastrointestinal symptoms, and quality of life were collected before and after the intervention via self-administrated validated questionaries, namely: food diaries, digestive symptoms frequency questionnaire (DSFQ) and a 12-Item Short Form Survey (SF-12).

Results: Participants were mostly females (66%), the mean age was 24.9 ± 8.4 years and consumption of gluten was reduced by ~80% among vegetarians and ~90% among omnivores, during the intervention period. No differences were observed in dietary intake, gastrointestinal symptoms (DSFQ) or physical / mental quality of life (SF-12) among omnivores. However, vegetarians reported a significant reduction (P<;0.05) in gastrointestinal symptoms after 2 weeks on a reduced gluten diet, without affecting quality of life or nutritional status.

Conclusions: Our study suggest that the gastrointestinal health of vegetarians would improve by reducing the consumption of wheat proteins without affecting quality of life. Nevertheless, further studies are needed to confirm these results and to investigate the role of plant proteins on gastrointestinal health.

Regional mean values for biomarker data from a national-scale survey: estimates, predictions, and their interpretations

Hakunawadi Alexander Pawarayi[1], Murray Lark[1]

University of Nottingham (UK)

Background: Globally, billions suffer micronutrient deficiencies, with about 31% suffer Zinc deficiency (WHO). Periodic multistage national scale surveys that use unequal inclusion probabilities at different stages monitor populations' micronutrient status. We use sampling weights that account for the population fraction represented by each stage to calculate design-unbiased population estimates. These estimates become biased if changes are made to sampling practice during the survey so that the original inclusion probabilities no longer hold (e.g., Ethiopia Micronutrient Survey, 2016).

Objective: How to use a linear mixed model (LMM) for population estimates from national-scale surveys that departed in practice from the original sample plan.

Methods: A LMM with a proposed covariance structure which reflected the sample – individuals nested within households (HHs), HHs within enumeration areas (EAs), EAs within regions – for making unbiased population zinc deficiency estimates. Regions specified fixed, and EAs and HHs specified random because all regions were sampled while EAs and HHs were randomly sampled. The prediction of the mean for an unsampled EA or HH, within a sampled region is equal to the estimated mean for that region. However, predicted mean values of EAs and HHs have larger uncertainties than the estimated regional means. Because predictions have uncertainties, true values of predictions that exceed a threshold may have zero probabilities of exceeding the threshold, and vice versa. Consequently, probabilities that measure the likelihood that a prediction of an unsampled unit (e.g., EA) falls below a specified threshold are preferred for policy decisions. The probabilities are communicated using the Intergovernmental Panel on Climate Change's calibrated phrases: <; 0.01, exceptionally unlikely; <; 0.33, unlikely; ≧ 0.66, likely; ≧ 0.9, very likely; and ≧ 0.99, virtually certain.

Results: EAs in Addis Ababa region were unlikely to have Zinc deficiencies. EAs in Amhara, Afar, Benishangul-Gumuz, Dire Dawa, Gambella, Harari, Somali and Tigray were likely to have deficiencies, and EAs in Oromia and SNNPR were very likely to have deficiencies.

Conclusion: We correctly specified the covariance structures of the LMM given the different probabilities of EAs within regions falling below the specified Zinc threshold (65 mg per kg).

Model and predictor ranking based on machine learning algorithms in application to childhood stunting in Popokabaka health zone (DRC).

Freddy Fefe Bangelesa[1], Brandly Kiloka Mbunga[2], Mala Ali Mapatano[1,2], Paulin Beya Mutombo[2]

1.University of Wuezburg (Germany), 2. Kinshasa School of Public Health (Democratic Republic of the Congo)

Background and objectives: The prevalence of childhood stunting in Popokabaka is quite high compared to country average. Many studies have been conducted in the last five years to investigate risk factors of stunting in this area. This study are based on conventional statistical approaches, which are constraints to different assumptions such as normality, sample size, linearity. However, the relationship between risk factors and stunting may not obey to these assumptions '. Machine learning and artificial intelligence algorithms have proven the ability to deal with complex data and has been widely used in different research areas, including public health. This research assesses the performance of the most advanced machine learning algorithms to model stunting and rank its risk factors in order of importance

Methods: We therefore tested random forest, artificial neural network, support vector machine and partial least square linear discriminant analysis. These algorithms were implemented and optimized in Python programming language. The observation was split into calibration (70 %) and validation (30%) datasets prior to analysis.

Results: Among these algorithms, support vector machine shows the lowest misclassification error (overall accuracy = 60 %, sensitivity = 0,27%, specificity = 0,85%), follow by random forest. The three most important variables (in order of importance) are the wealth quantile, the age and the health area.

Conclusions: machine learning algorithms may aid policymakers in reducing malnutrition in DRC.

Keyword: machine learning, variable selection, stunting

Utilization and acceptability of sorghum stem sheath extract and its potential contribution to micronutrient intake of women of reproductive age

Bolanle Rachael Popoola[1], Oladejo Thomas Adepoju[2], Motunrayo Funke Olumakaiye[1]

1.Obafemi Awolowo University (Nigeria), 2. University of Ibadan (Nigeria)

Background and objectives: The global trend of under-nutrition is increasing and simultaneously leads to hidden hunger and affects over 2 billion people, especially children and women of reproductive age (WRA). Dietary intervention is one of the micronutrient-specific interventions proven to help combat micronutrient malnutrition especially among WRA. Sorghum stem sheath the supposed farm waste extract has been research to be good source of vitamin and minerals coupled with its hematopoietic and anti-anaemic characteristics. This study assessed the utilization and acceptability of sorghum sheath extract and its potential contribution to the micronutrient intake of women of reproductive age.

Methods: A semi-structured, interviewer-administered questionnaire was used to elicit information socio-demographic characteristics, knowledge and utilization, frequency of consumption, and evaluation of the extract from about 150 respondents within the WRA age range from three wards in Ibadan Southwest Local Government area. To support the micronutrient need and preference of the women of reproductive age especially taste. The extract from sorghum stem sheath was spiced with ginger 1 %, clove 1 % and sweetened (sucrose and date palm). The extract was formulated based on the sample with the highest Iron and ß-carotene content from established methodologies of sorghum stem extract using the minitab software. The extracts were further subjected to organoleptic assessment among 40 panelist using the nine (9) point hedonic scale to determine the overall acceptability.

Results: Respondents age range 15 – 24 years had low knowledge of the extract despite its availability, low cost and accessibility. About 92 % of the respondents claim the extract to be blood booster and frequent use observed among older (44 – 49 years) while 90% of the preferred extract to supplement intake. The organoleptic characteristic of the extract with sucrose was the most acceptable. Further into the research, nutritional, anti-nutritional, antioxidant properties and contribution to nutrient intake were evaluated using standard method of analysis of AOAC. Statistical analysis showed differences among sweetened samples (p<;0.05). Beta carotene content with increase in nutrient concentration with addition of sweeteners.

Conclusion: The extract could be a good substitute for some carbonated drinks and source of micronutrients foe women of reproductive age.

Anemia, food security, and oyster consumption among women shellfishers in Ghana and The Gambia

Brietta Oaks[1], Zakari Ali[2], Frank Kyei-Arthur[3], Brian Crawford[1], Lalisa Duguma[4], Karen Kent[1], Stepha McMullin[4], Seth Adu-Afarwuah[5]

1.University of Rhode Island (USA), 2. MRC Unit The Gambia at London School of Hygiene and Tropical Medicine (Gambia), 2. University of Environment and Sustainable Development (Ghana), 3. World Agroforestry Centre (ICRAF) (Kenya), 3. University of Ghana (Ghana)

Background and objective: Oysters are rich in iron and their consumption may reduce food insecurity and anemia, however it is unknown to what extent oysters are part of the diet of women shellfishers. Our objective was to examine the associations between oyster consumption and food insecurity and anemia among women shellfishers.

Methods: From Feb-Jul 2021, we enrolled women shellfishers aged 15-49 in Ghana (n=504) and The Gambia (n=214) and used a repeat 24-hr recall to estimate average daily oyster consumption. We collected data on food security using the Household Food Insecurity Access Scale and hemoglobin (Hb) was assessed from a blood sample obtained by finger prick. Linear regression was used to examine the associations between oyster consumption, food security, and hemoglobin. Poisson regression was used to determine the risk of food insecurity and anemia (Hb <; 120 g/L) among women who reported not eating oysters compared with those who ate oysters.

Results: Only 7% of women in The Gambia and 11% in Ghana reported eating any oysters. Most women were experiencing some level of food insecurity (The Gambia: 83%, Ghana: 92%) and severe food insecurity was identified in 43% of women in The Gambia and 78% in Ghana. Anemia prevalence ranged from 20% in Ghana to 41% in The Gambia. In models adjusted for age, wealth index, education, BMI, and country, higher consumption of oysters was associated with lower Hb, although the impact was small; for every 10% increase in oyster consumption, Hb decreased by 0.04 g/L (p=0.037). Higher oyster consumption was not associated with food security (p=0.243). Eating oysters was not associated with either anemia risk [RR (95% CI): 1.05 (0.70,1.570)] or risk of food insecurity [0.76 (0.35, 1.67)].

Conclusions: Nearly half of women in The Gambia and most women in Ghana were experiencing severe food insecurity, however the proportion of women that ate oysters was very low in both countries. Overall, there was no association between oyster consumption and anemia and food security. Further research is warranted to understand the reasons women are not eating the oysters despite high food insecurity.

Comparison of the dietary factors affecting the enterotypes of gut bacteria in a Japanese cohort

Tsubasa Matsuoka[1,2,3], Satoko Maruyama[1,3], Jonguk Park[3], Koji Hosomi[3], Motohiko Miyachi[3,4], Toshiki Kobayashi[1], Jun Kunisawa[3,4,5,6,7], Zentaro Yamagata[2]

1.Hakubaku Co., Ltd. (Japan),2. University of Yamanashi (Japan), 3. National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 3. Waseda University (Japan), 4. Kobe University (Japan), 5. Osaka University (Japan), 6. The University of Tokyo (Japan)

Background and objectives: Gut bacteria can be classified into three enterotypes, which is affected by lifestyle factors such as diet. The factors determining enterotype are believed to be cohort-dependent. In this study, we analyzed the relationships between dietary factors and enterotype in Japanese participants who consumed a traditional diet.

Methods: We conducted a cross-sectional cohort study of participants recruited at a food product company in Japan. We collected information about medical checkups and dietary habits using a questionnaire. Fecal bacterial composition was assessed using 16S rRNA amplicon sequencing, and enterotype was classified into three clusters using genus-level data. After adjustments for age, sex, and energy intake, we used logistic regression analysis to examine the association between enterotype and 26 dietary factors. Variance inflation factors were previously measured, and a variance greater than five was excluded from the model.

Results: The cohort of 256 participants (190 men and 66 women) had all three enterotypes (Bacteroides [n = 115], Faecalibacterium [n = 100], and Prevotella 9 [n = 41]). Participants with the Prevotella type had more lifestyle-related diseases, whereas those with the Faecalibacterium type had fewer lifestyle-related diseases. The Bacteroides type was negatively associated with the consumption of barley (10 g) (OR 0.90, 95% CI: 0.84–0.97) and ice cream (10 g) (OR 0.97, 95% CI: 0.95–1.00). The Faecalibacterium type was positively associated with the consumption of barley (10 g) (OR 1.10, 95% CI: 1.03–1.20). The Prevotella type was positively associated with the consumption of ice cream (10 g) (OR 1.02, 95% CI: 1.0–1.04), liver (10 g) (OR 1.50, 95% CI: 1.18–1.91), miso soup (10 g) (OR 1.01, 95% CI: 1.00–1.01), green tea (100 ml) (OR 1.04, 95% CI: 1.01, 1.07), and coffee (100 ml) (OR 1.04, 95% CI: 1.01–1.06). Dietary fiber intake was associated with Faecalibacterium type bacteria such as Faecalibacterium, Subdoligranulum, and Alistipes.

Conclusions: The Prevotella enterotype was associated with the greatest number of foods. The Bacteroides type was negatively associated with foods such as barley and ice cream. The Faecalibacterium type was associated with barley likely due to the dietary fiber it contains.

Keyword: enterotype, gut bacteria, Faecalibacterium, barley, dietary fiber

Correlation of urinary equol with genetic markers constructed for equol-producing bacteria

Miyuki Kodera[1,2], Tohru Suzuki[2], Kohei Nakamura[2], Takayuki Ezaki[2], Shin-ichiro Yokoyama[1]

Gifu prefectural research institute for food science (Japan), 2. Gifu University (Japan)

Background and objectives: Equol is a metabolite of soy isoflavone by intestinal bacteria and possesses higher estrogenic activity than other isoflavones. Equol is therefore thought to have a considerable impact on human health. The ability to produce equol depends on the individual's intestinal environment, especially the presence of equol-producing intestinal bacteria. Previously, we isolated an equol-producing bacterium, Eggerthella sp. YY7918, from human feces. We also analyzed whole genomic sequence of Eggerthella sp. YY7918 and identified three equol metabolism-related genes (EQLs coding daidzein reductase, dihydrodaidzein reductase, and tetrahydrodaidzein reductase). In this study, we constructed genetic marker for equol-metabolizing intestinal microbiota (EQL marker) and evaluated them in clinical specimens.

Methods: This study was conducted with the approval of the ethics committee of Gifu University (2018-114). The clinical specimens were collected as follows. Healthy adult women (age 19-71 n= 97) were given 50 mg of soy isoflavone for 2 days and fresh urine and feces were collected the next morning. After β-glucuronidase treatment and ether extraction, the urine was subjected to HPLC system. Fecal-derived DNA was subjected to a real-time PCR system using SYBR green. PCR primers were constructed from EQLs.

Results: Seven subjects were excluded due to a shortage of fecal specimens, and 91 were finally analyzed. Since the detection limit for urinary equol was 1,000 nM, we defined subjects with a urinary equol concentration >;1,000 nM as "equol producers". The number of equol producer and non-producer were 37 (41%) and 54 (59%), respectively. Thirty-two (86%) were EQL marker positive out of the 37 equol producers. While, 53 (98%) were the negative out of the 54 non-producers. EQL marker detected log105-8 copy / g feces in most equol producers (84%). The Pearson correlation coefficient between EQL marker and urinary equol quantity was 0.46. While the correlation coefficient between these two values was 0.05 when limited to the equol producers (n = 37).

Conclusions: EQL markers for log105-8 copy / g feces were detected in most equol producers. No correlation was found between urinary equol and the amount of EQL markers.

Lipid related genetic variants panel for precision nutrition interventions: a systematic review

Ingrid Rivera-Iniguez[1], Karina González-Becerra[2], Yolanda Elizabeth Pérez-Beltrán[3], Marian Sophia Chaguen-Hernández[4], Omar Ramos-López[5], Edgar Jair Mendivil Rangel[4]

Universidad de Guadalajara, CUCS (Mexico), 2. Universidad de Guadalajara, CUCIENEGA (Mexico), 3. Tenologico Nacional de Mexico (Mexico), 4. Western Institute of Technology and Higher Education (Mexico), 5. Autonomous University of Baja California (Mexico)

Background and objectives: Dyslipidemias represent an unfavorable prognostic factor for cardiovascular disease. It´s management includes pharmacological and dietary strategies which aim to maintain lipid profile within acceptable values. However, the response to diet can be influenced by the individual genetic background. Personalized nutrition interventions are designed according to key individual characteristics, such as their diet, phenotype, and genotype with promising results. However, it is not clear what are the exact genetic variants related to lipid metabolic abnormalities would help to design DNA-based dietary interventions for dyslipidemias. Therefore, the objective in the present study was to define a panel of genetic variants associated with lipid abnormalities that could be later used in nutrigenetic intervention studies.

Methods: A comprehensive systematic review was conducted following the PRISMA-Protocol. Studies published from January 2010 to December 2020 only in English language and human species were included from PubMed and ScienceDirect databases. Articles that demonstrated a strong association between polymorphisms of genes involved in lipid metabolism and increased risk of dyslipidemia were included.

Results: 3031 articles were identified, but only 54 articles fulfilled the inclusion criteria established on the systematic review protocol. The selected articles were organized according to the related lipid trait. The identified lipid related genetic variants were related to chylomicron synthesis and secretion, triglyceride hydrolysis, lipoprotein metabolism, and lipid clearance.

Conclusions: In this systematic review key lipid related genetic variants demonstrated strong association to lipid abnormalities. These variants can be used to design precision nutrition interventions that may help to effectively prevent and treat dyslipidemia. Specifically, could help to personalize dietary fatty acids quality and quantity according to their individual genetic background.

Can we influence gut bacteria and their metabolites by diet and resistance exercise in older people?

Simon Rønnow Schacht[1], Josue Castro-Mejia[1], Morten Arendt Rasmussen[1], Bekzod Khakimov[1], Kenneth Mertz[2], Astrid Pernille Jespersen[1], Lars Holm[2], Henrik Munch Roager[1], Dennis Sandris Nielsen[1], Inge Tetens[1]

1.University of Copenhagen (Denmark), 2. Bispebjerg Hospital (Denmark)

Background and objectives: Human gut bacteria and their metabolites are potentially important for healthy human aging. Previous studies have indicated that diet and physical exercise can modify gut bacteria composition in older people. However, the effects of specific macronutrient changes as well as the potential effects of resistance training are currently understudied.

Methods: In a one-year parallel intervention study, 208 older Danish men and women (+65 years) were randomized to receive either 40 gram of maltodextrin, collagen or whey protein per day. Study subjects receiving whey protein were further divided into either heavy resistance training, light resistance training or no training. Six and 12 months changes in gut bacteria and fecal metabolites where investigated by 16s rRNA gene amplicon sequencing and proton NMR, respectively. Intervention-dependent changes in gut bacteria and metabolites were analyzed via PERMANOVA.

Results: In total, 184 subjects completed the intervention. Our results showed that gut bacteria as well as gut metabolites responded differently depending on the carbohydrate or protein interventions. Particularly the ingestion of collagen-derived protein affected gut bacteria composition (mostly within the Lachnospiraceae family) as well as metabolites related to protein metabolism in the gut of study subjects. Heavy, but not light intensity resistance training had minor effects on gut bacteria and their metabolites. Effects of heavy resistance training were primarily seen within Bacteroides as well as within metabolites associated with carbohydrate metabolism in the gut. In general, the observed effects of heavy resistance training were smaller than those observed for the dietary (macronutrient) interventions.

Conclusions: Our results suggest it is possible to modulate gut bacteria and their metabolic products via specific macronutrient changes to the diet of older humans. Resistance training has smaller effects on gut bacteria composition compared to dietary changes. Furthermore, it is likely that older people are required to engage in frequent and intensive physical training in order to see effects on gut bacteria.

Habitual intakes of arabinoxylan and associations with gut microbiome composition in the ZOE PREDICT study

Kate M Bermingham[1], Francesco Asnicar[2], Catherine Zhao[1], Jonathan Wolf[3], George Hadjigeorgiou[3], Richard Davies[3], Tim D Spector[1], Nicola Segata[2], Sarah E Berry[1]

1.Kings College London, London (UK), 2. University of Trento, Trento (Italy), 3. ZOE Ltd (UK)

Background and objectives: The dietary fibres arabinoxylan (AX) are non-cellulosic polysaccharides of primary and secondary cell walls found in cereals and grasses. Supplementation with AX has beneficial effects on microbiome species as well as multiple health benefits including increased satiety, cholesterol-lowering activity, reduced type 2 diabetes risk and immunomodulatory activity. However, habitual intakes and the effects when consumed naturally through foods have yet to be elucidated.

Methods: In the PREDICT 1 UK cohort (n=1,001), demographic information, habitual diet (EPIC Food Frequency Questionnaire), and microbiome samples (shotgun metagenomics) were assessed. AX concentrations were estimated from each fibre (non-starch polysaccharides (NSP)) containing food (using pre-published concentrations or extrapolated using monosaccharide (arabinose and xylose) contents) and habitual intakes (grams per day) estimated per participant. Associations between AX, fibre intakes, gut microbiome species (relative abundances) and cardio-metabolic health outcomes were examined.

Results: Mean fibre intakes (NSP) were 17.0±6.6g and AX intakes were 3.3±1.6g (Q1; 2.2g vs Q5; 4.1g). High AX (Q5) versus low AX (Q1) consumers had a lower BMI (by 1.8 kg/m2), visceral fat mass (by 81 g) and higher diet quality (healthful Plant based Diet Index (hPDI) by 3.1). Similar size effects were also observed for high and low total fibre intakes (Q5 vs Q1; BMI by 1.3 kg/m2, visceral fat; 74 g and hPDI; 6.1) and differences in body composition (AX and fibre) were lost after adjustment for diet quality. Foods with the highest contribution to total AX were grain-based, including high fibre cereals (22%), wholemeal pasta (12%), wholemeal bread (10%), muesli (9%) and porridge (7%). AX was strongly correlated with fibre intakes (r; 0.84, 95% CI; 0.81-0.85), however different gut microbiome species were independently associated with AX and not total fibre, including Bifidobacterium adolescentis, Bifidobacterium longum and Roseburia intestinalis species (previously associated with favourable health outcomes).

Conclusions: This study reports habitual dietary AX intakes in a healthy population, Bifodobacteria species, previously shown to increase post AX supplementation, were associated with higher habitual dietary intakes suggesting that dietary AX may favourably influence the microbiome.

The association of ICAM1 gene rs5498 (A>;G) polymorphism, nutritional status and cardiovascular diseases susceptibility on dyslipidemia in Thai population

Naruemon Wechjakwen[1], Karunee Kwanbunjan[2], Amornrat Aroonnual[2], Pattaneeya Prangthip[2]

1.Nakhonratchasima Rajabhat University (Thailand), 2. Mahidol University (Thailand)

Background and objectives: Atherosclerosis is a significant condition to develop cardiovascular diseases (CVDs). The CVDs risk factors included age, gender, food habit, dyslipidemia, obesity, and genetic variation. The intercellular adhesion molecule 1 (ICAM1) gene variant is announed to associate with CVDs progress. However, the impact of the ICAM1 rs5498 polymorphisms on dyslipidemia has not been reported. Therefore, we determine the relationships between single nucleotide polymorphisms (SNPs), including rs5498 on ICAM1 gene and CVDs susceptibility in patients with dyslipidemia.

Methods: The participants were classified as having dyslipidemia; dyslipidemia (n=135) or not (n=143). Food consumption pattern was determined using the semi-food frequency questionnaire (semi-FFQ). ICAM1 SNPs Genotyping was performed by DNA sequencing.

Results: Dominant model rs5498 participants had twice the risk of dyslipidemia (95% confidence interval (CI): [1.24–3.23], P = 0.005). The G allele frequency in rs5498 was 1.69 times higher in participants with dyslipidemia than in controls (95% CI [1.15–2.47], P = 0.007). Participants with the rs5498 AG or GG variants and those with a high LDL-C concentration (≧ 3.36 mmol/L) had 2.09 times the risk (95% CI [1.19-3.66], P = 0.010) of developing CVDs compared with those with low LDL-C levels. Participants carrying the rs5498 AG or GG variants who had tachycardia (resting heart rates (RHRs) >; 100 beats/min) had a 5.02-times higher risk than those with a lower RHR (95% CI [1.35-18.63], P = 0.016). Although, the amount of dietary intake between control and dyslipidemia group did not reach the statistically significant difference. However, the amount of energy intake, fat, and choresterol trend to higher in dyslipidemia group than those control group.

Conclusions: It may consider the robust of G allele in ICAM1 rs5498 is associated with a higher risk of CVDs susceptibility in Thai people with dyslipidemia and is also positively associated with LDL-C concentration, and RHR. This also showed that a food habit of dyslipidemia group trend to have a higher risk of CVDs than control. It might be possible that carrying of G allele, together with unhealthy consumption are co-risk factors to rapidly initiate CVDs.

True ileal digestibility of tryptophan in plant and animal source protein determined by dual isotope tracer technique in Indian adults

Sindhu Kashyap[1], Sarita Devi[1], Anika Andrea[1], Thomas Preston[2], Anura V Kurpad[3]

1.St Johns Research Institute (India), 2. Scottish Universities Environmental Research Centre (UK), 3. St Johns Medical College (India)

Background and Objectives: Tryptophan (Trp), in addition to being an indispensable amino acid (IAA) for protein synthesis, is precursor of important bioactive molecules. Trp is present in sufficient quantities in plant and animal source protein to meet the daily requirement, but its digestibility is unknown in humans. The true ileal digestibility of Trp from any diet matrix is the sum of its digestion and absorption at the ileal level, which is relatively inaccessible. However, this can now be measured by the minimally invasive dual isotope tracer technique. The aim of the present study was to determine true ileal Trp digestibility in legumes and milk protein, in humans, by the dual isotope tracer technique.

Methods: The dual isotope tracer technique compares the ratio of plasma appearance of intrinsically (2H) labelled amino acid (AA) with respect to its enrichment in an ingested test meal to a similar ratio of a simultaneously ingested, but differently (13C) labelled, standard protein of known digestibility. This ratio of ratios provides a measure of true ileal AA digestibility. These AA enrichments were obtained in plateau feeding experiments in healthy adults. The true ileal digestibility of the reference Trp in U-[13C] spirulina (the standard protein) was first measured against a 2H labelled free Trp in an AA mixture. Subsequently, Trp digestibility was measured in intrinsically 2H labelled mung bean, dehulled mung bean, yellow pea, chickpea, and goat milk protein in comparison to reference Trp from U-[13C] spirulina or 13C labelled free Trp in an AA mixture (n=6 in each).

Results: The true ileal Trp digestibility (mean ± SD) of goat milk protein in comparison to 13C labelled free Trp was 93.6 ± 2.8%. Human plateau feeding studies to measure Trp digestibility of U-[13C] spirulina, mung bean, yellow pea, and chickpea have been completed earlier and measurements of Trp digestibility will be reported.

Conclusions: True ileal Trp digestibility of goat milk protein was within the range of reported true ileal IAA digestibility values of milk (90-100%).

Adherence to nutritional supplementation recommendations (ANSR) among women in low- and middle-income countries: A systematic review of behavioral and measurement issues

Bee-Ah Kang[1], Aditi Luitel[1], Alicia Paul[1], Rajiv Rimal[1], Alison Tumilowicz[2]

1. Johns Hopkins Bloomberg School of Public Health (USA), 2. Bill & Melinda Gates Foundation (USA)

Background and objectives: Micronutrient deficiencies among women of reproductive age (WRA) have been disproportionately represented in low- and middle-income countries (LMICs). Although nutritional supplementation is a known strategy for improving micronutrient status among WRA, evidence on intervention approaches and standardized measurement of adherence to nutritional supplementation recommendations (ANSR) is lacking. This systematic review aims to identify ways in which adherence to supplementation has been measured and assess intervention strategies to promote ANSR among WRA in LMICs.

Methods: Literature searches are currently being conducted in PubMed, Embase, and Scopus. Criteria for study inclusion and exclusion were developed by two researchers and finalized upon agreement among a team of four. Eligibility criteria include peer-reviewed research which: targets WRA in LMICs, evaluates an intervention providing nutritional supplements recommended by the WHO for pregnant women, includes implementation research components, and measures behavioral outcomes. Abstracts of all the retrieved articles are being independently screened by two reviewers, with a third reviewer to resolve conflicts.

Results: At present, 1,398 articles from PubMed underwent abstract screening. Of those, 151 were selected for full-text review. Searches using Embase and Scopus, followed by a full-text review and analysis is expected to be completed by September 2022. Preliminary results suggest there is little consensus on how adherence is defined and measured in the context of women's nutrition. Many behavioral trials don't explicitly measure adherence, assuming that those given supplements must have complied. Studies that measure adherence rely on self-reports or retrospective recall measures, and still others rely on third-party accounts. Additionally, the use of multiple modalities to assess adherence through triangulation was indeed rare.

Conclusions: Anticipated results of this systematic review will provide a landscape of the patterns and inconsistencies of adherence measurement among WRA across clinical trials, intervention evaluations, and nutritional-behavioral studies. The conclusions will provide guidance on feasible, cost-effective, and systematic ways of measuring ANSR. Moreover, results of this review will call attention to effective intervention strategies for facilitating ANSR to be applied to real-world settings. Recommendations will draw from diverse cultural, environmental, and social contexts to address a global concern in urgent need of forward thinking.

Social jet lag and chronotype and its relationship with BMI in young people: a systematic review

Paula Jakszyn[1], Nuria Nadal[1], Lucia Iglesias[1]

1.Catalan Institute of Oncology (Spain)

Background and objectives: The prevalence of overweight and obesity in young people has been dramatically suspected in recent years, one of the many reasons for this increase could be sleep disorders. Adolescence is a critical developmental period where sleep deprivation frequently occurs. For this reason, they sleep more on the weekend to compensate, which increases their social jet lag. Much of the existing evidence describes the relationship between sleep quality and body weight, but the relationship of chronotype and social jet lag with weight in this population group has not been extensively studied. The objective of this work was to systematize the scientific evidence on the relationship of social jet lag and chronotype with the body mass index (BMI) in young people.

Methods: Pubmed, EMBASE, and MEDLINE databases were searched for papers on social jetlag and chronotype and obesity, focusing on, adolescents, and young adults. Articles published up to 2020 were searched and those with information on BMI, chronotype and social jet lag, obtained through questionnaires, were included. Information on gender, age, country of publication, as well as the tool to assess sleep patterns was also included.

Results: A total of 21 articles were identified, with data relating BMI to chronotype and/or social jet lag in adolescents. Of the 16 articles that analyze the relationship between chronotype and BMI, 10 found a positive and statistically significant relationship between an evening chronotype and an increase in BMI. Of the 13 articles that analyze the relationship between social jet lag and BMI, in 7 a positive and statistically significant association was found between those adolescents with greater jet lag and those with a higher BMI.

Conclusions: Published studies show that in addition to sleep deprivation, variables such as chronotype and social jet lag must be considered when studying the factors that contribute to obesity in this population. Healthy sleeping patterns need to be incorporate as a key component in the promotion of healthy habits to prevent obesity in this population.

Analysis of genetic polymorphism of bitter taste receptor TAS2R19 and its relationship with alcohol drinking and eating habits in Japanese subjects.

Michiko Yamaki[1,2], Hiroki Saito[1], Takahiro Mimori[3], Yoichi Suzuki[3], Masao Nagasaki[3,4], Kichiya Suzuki[3], Noriaki Shoji[1], Tomoko Goto[1,5], Hitoshi Shirakawa[1], Michio Komai[1]

1.Tohoku University (Japan), 2. Tohoku Seikatsu Bunka University (Japan), 3. Tohoku Medical Megabank Organization, Tohoku University (Japan), 4. Kyoto University (Japan), 5. Miyagi Gakuin Women's University (Japan)

Background and objectives: Five basic tastes are messages that tell us something about what we put into our mouth, so we can decide whether it should be ingested. Among them, the bitter taste sense is thought to have arisen to warn individuals against the ingestion of poisonous substances, many of which have a bitter taste. However, bitter substances are contained in favorite beverages such as tea and beer, etc., and have been widely consumed in usual human life. Bitter substances are perceived by various bitter taste receptors (TAS2Rs), and among them it is well understood that the TAS2R38 gene polymorphisms influence individual differences in bitterness sensitivity to phenylthiocarbamide or propylthiouracil. Some TAS2R has also been reported to be associated with disease defence system. On the other hand, As for the other bitter components in foods, such as naringin in grapefruit, previous studies suggest that TAS2R19 is associated with the relationship between grapefruit preference and genetic polymorphism of TAS2R19 in Western subjects, however, there have been very few reports regarding Japanese subjects, so the present study takes advantage of the Tohoku Medical Megabank Organization (ToMMo) database to investigate the relationship of those in the Japanese population.

Methods: The samples used here were from the TMM CommCohort Study participants, all of whom gave their written consent. The same ToMMo individual genotype construct genome reference panel for the Japanese population (2KJPN=~2000 subjects) was used. So, we extracted the aggregated data from dietary habit by questionnaire, and also analyzed single nucleotide polymorphism (SNP) in TAS2R19. Then we further analyzed if any specific TAS2R19 polymorphism (the 299th amino acid is either cysteine (C) or arginine (R) and other biological data are associated with clinical BMI, smoking habit, alcohol drinking frequency, food preference related to bitterness.

Results: After our detailed analyses, it was shown that the gene frequencies of C299C, R299C, and R299R were approximately 5%, 35%, and 59%, respectively in Japanese ToMMo population. Moreover, there was no significant relationship between the genetic polymorphism of TAS2R19 and clinical BMI, smoking habit, alcohol drinking frequency.

Conclusions: TAS2R19 was not associated with lifestyle-related factors in the Japanese population.

Effects of genetic variation on diet-induced thermogenesis in healthy young women

Naoko Komenami[1], Kanako Yamakawa[1], Kayoko Yamazaki[1]

1. Kyoto Women's University (Japan)

Background and objectives: In modern Japanese society, the diversification of lifestyles has led to meals becoming markedly more Westernized, and there are concerns that these changes may lead to future health issues. Diet-induced thermogenesis (DIT) plays an important role in energy metabolism. Enhancement of DIT is expected to prevent fat accumulation and therefore obesity by increasing energy expenditure in response to overeating. This research aimed to determine whether single nucleotide polymorphisms (SNPs) of thermogenesis-related genes affect DIT after consuming a high-fat meal.

Methods: Participants were 35 healthy young women. We measured oxygen consumption, metabolic rate, respiratory quotient, and heart rate for 360 min before and after a standard (control) meal and a high-fat meal. The standard meal was 650 kcal, with a protein:fat:carbohydrate (PFC) ratio of 16:26:58. the high-fat meal was also 650 kcal, with a PFC ratio of 17:53:30. We asked participants about their lifestyle, measured their body composition, collected oral mucosa, and analyzed 3 SNPs of thermogenesis-related genes, namely, β2 adrenergic receptor (β2-AR), β3 adrenergic receptor (β3-AR), and Uncoupling protein 1 (UCP1). The study was approved by the Kyoto Women's University Research Ethics Committee.

Results: The β2-AR genotype was classified as 34% GG homo, 34% AG hetero, and 31% AA wild type; the β3-AR genotype was classified as 0% CC homo, 34% TC hetero, and 66% TT wild type; and the UCP1 genotype was classified as 20% GG homo, 57% AG hetero, and 23% AA wild type. The genotype of β2-AR and β3-AR did not affect DIT, but the homo mutant type of UCP1 tended to have a significantly lower DIT compared with the hetero mutant and wild type of UCP1 in both the standard and high-fat meals.

Conclusions: The results suggest that DIT might be affected by SNPs of UCP1 regardless of diet composition in healthy young women.

PAB(T1)-34

Food Preferences among Women of Reproductive Age in Mainland Tanzania: A Qualitative Study

Sauli E John[1], Mangi J Ezekiel[2], Winifrida O Akyoo[1], Aika Lekey[1], Germana H Leyna[1]

1.Tanzania Food and Nutrition Centre (Tanzania), 2. Muhimbili University of Health and Allied Sciences (Tanzania)

Background and Objectives: In Tanzania, about 45 percent of women aged 15 to 49 years and 57 percent of pregnant women are anemic, and one in three women suffer from multiple micronutrient deficiencies. These nutrition-associated problems are among the main causes of maternal mortality and generally poor birth outcomes. This trend makes Tanzania lag behind in meeting the Sustainable Development Goal 3 target of <;70 deaths per 100,000 live births by 2030. There is a need to better understand women's food preferences to design interventions to promote nutritious, acceptable dietary practices. The primary objective of the survey is to identify food preferences for women of reproductive age, adolescent girls, and children in Tanzania.

Methodology: This will be a cross-sectional descriptive qualitative study that is being conducted in urban and rural districts in each of the main zones of mainland Tanzania. Primary data is collected through semi-structured interviews and focus group discussions to get insight into food preferences and influential community and macro level factors, and highlight available opportunities and gaps for maternal nutrition. The study primarily targets women of reproductive age (15-49 years)—specifically pregnant women, mothers/caregivers of children aged 6-24 months, adolescent girls, and key influencers, such as health workers and community leaders. Recruitment of study participants took into account rural and urban consideration to gauge variations in perspectives on food preferences. A minimum of three focus group discussions and six semi-structured interviews will be conducted in each region, making a minimum of 21 focus groups and 42 interviews. Data categorization and analysis will be done with the aid of NVivo.

Results: The study is planned to be completed by August 2022. They will provide information on food preferences, factors influencing dietary choices, barriers and facilitators for food choices, as well as existing interventions on nutrition behaviours in the community.

Conclusions: The study findings will inform interventions to promote maternal nutrition counselling on appropriate dietary intake in the communities that are being studied.

A pilot study exploring the association of zinc-related genetic variants with risks for metabolic outcomes among adult Filipinos

Maritess Drapeza Cation[1], Imelda Angeles Agdeppa[2], Von Rovic Bautista[1], Michael Lorenzo Bucu[1], Romel Paul Hilario[1], Marietta Rodriguez[2], Charmaine Duante[2], Vanessa Joy Timoteo[3,4]

1.University of Santo Tomas (Philippines), 2. Food and Nutrition Research Institute, Department of Science and Technology (Philippines), 3. National Yang Ming Chiao Tung University (Taiwan), 4. Academia Sinica (Taiwan)

Background and objectives: Several studies have shown that an imbalance in zinc homeostasis causes increased susceptibility to chronic noncommunicable diseases (NCDs), such as hypertension, diabetes, and coronary heart diseases. These NCDs are the most prevalent diseases among Filipinos, where nutrition is a key factor, but the influence of an individual's genetic makeup must also be considered. Single nucleotide polymorphisms (SNPs) as a genetic risk factor may affect an individual's susceptibility to Zn deficiency, blood zinc status, and increased risks of developing chronic diseases later in life. We investigated in this pilot study the effect of zinc-related SNPs on the risks for various metabolic outcomes among Filipinos.

Methods: Using the 8th Philippine National Nutrition Survey data, we determined the SNPs associated with serum zinc concentration and zinc deficiency risk among ~1,200 adult respondents residing. We then performed multivariate linear and logistic regression analyses to investigate the association of zinc-related SNPs with various health indicators and the risks for diabetes, dyslipidemia, hypertension, obesity, and central obesity following an additive genetic model of inheritance. Models were adjusted for covariates, and a p-value <;0.05 was considered statistically significant.

Results: We initially identified 14 SNPs that statistically demonstrated variations in zinc levels across genotypes, 16 SNPs associated with serum zinc concentration, and 22 SNPs associated with zinc deficiency among study participants. ADIPOQ/ADIPOQ-AS1 rs2241766, IL12B rs3212227, OTOGL rs7315692 and rs7295948, PRKCA rs228883, and SLCO1B1 rs2291075 had shown effects on the genetic determination of both serum zinc and zinc deficiency risk. There are 15 zinc-related SNPs found to influence health indicators and their association with chronic metabolic outcomes. We observed repeated associations as follows: LINC02669/LOC105376360 rs2165468 with diabetes, dyslipidemia, and hypertension; FKBP5 rs1360780 with diabetes, hypercholesterolemia, obesity, and central adiposity; FKBP5 rs9470080 with abnormal lipid profile; PPIG rs13382615 with diabetes and hypertension; PCSK1 rs6234 with hypoalphalipoproteinemia and hypertension; KNG1 rs10937266 with diabetes and obesity; KNG1 rs11927941 with hypertriglyceridemia and obesity; and TMPRSS6 rs1421312 with hypercholesterolemia, obesity, and central adiposity.

Conclusions: This is the first report on genes and SNPs associated with increased risk of zinc deficiency and its influence on chronic metabolic outcomes among Filipinos.

F1kdayswithu app: development and pilot testing of an android mobile application on the first 1000 days of life to improve maternal and infant nutrition

Christian Aaron Ramos Ordas[1], Vianca Clarisse Baligaya[1], Ezekiel Custodio[1], Joan Faith Mendoza[1], Pamela Irish Razon[1], Florimae Paimalan[1], Daniel Salunga[1]

1. University of Santo Tomas (Philippines)

Background and objectives: Maternal and infant malnutrition in the Philippines is still prevalent; however, evidence showed that one effective way to prevent this is through nutrition education. Although mobile phone users have been increasing in the country, there is still no single mobile application that provides nutrition education on maternal, infant, and young children. Therefore, this study aimed to develop a mobile nutrition application that will provide nutrition education and monitoring on the First 1000 days of life.

Methods: The study utilized a design-based research method with a mixed-method approach. A pre-Knowledge, Attitudes, and Practices (KAP) survey was conducted for targeted participants about nutrition in the first 1000 days before the application's pilot testing. The researchers also conducted a post-KAP survey to check the effectiveness of nutrition education using the application and a User Acceptance Test survey for its user acceptance to determine the need for enhancement based on participants' evaluation. Participants were from Malabon City, excluding the application developer.

Results: The developed mobile application has features such as user login, language options of Filipino or English, nutrition education modules on pregnancy, lactation, infancy, young child, push notifications, ToDo task, and monitoring features such as pregnancy weight gain tracker and child's developmental milestones checklist. A total of 21 participants took part in the application pilot testing, and the majority of them (>;50%) had a high user acceptance level of the application. After using the application containing nutrition education, the pregnant women showed a significant improvement in their total nutrition knowledge scores (p=0.002). Mothers with below two-year-old children also showed a significant improvement in their total nutrition knowledge (p=0.026) and total correct nutrition practice scores (p=0.023).

Conclusions: The developed mobile nutrition application is engaging, efficient, easy to learn, and offers effective functionalities of features that cater to the needs of the target users in the first 1000 days of life. Providing nutrition education using a mobile application can help increase the knowledge of pregnant women and mothers. However, a longer duration of app usage may be more effective in changing their attitudes and practices.

Accuracy of estimates of serving size using digitally displayed food photographs among Japanese adults

Nana Shinozaki[1], Kentaro Murakami[1]

1.The University of Tokyo (Japan)

Background and objectives: We developed a digital photographic food atlas as a portion size estimation aid, using dietary records obtained from 644 Japanese adults. This study aimed to evaluate how accurately people estimate the amount of food they serve using images in the food atlas.

Methods: From 209 food items in the food atlas, we selected 14 with various appearances and textures for this study. At a study site, 54 participants (27 males and 27 females) aged 18–33 years were asked to serve each of the 14 foods in the amount they usually eat. After they left, a researcher weighed each food. The next day, the participants answered a web questionnaire asking about the amount of food they served on the previous day based on the photographs of portions for each food item. The weights of foods the participants served (true serving sizes) and those determined using the photographs (estimated serving size) were compared. Moreover, the associations between estimation error and participant characteristics (age, sex, body mass index, occupation, cooking frequency, and hunger level) were evaluated.

Results: In 10 of the 14 foods, there was a significant difference between the estimated and the true serving sizes, ranging from 29.8% underestimation (for curry sauce) to 34.0% overestimation (for margarine). On average, the relative difference was 8.8%. Overall, 51.6% of the estimates were within ±25% of the true serving size, ranging from 18.5% (for Japanese fried chicken) to 81.5% (for simmered squash). Bland–Altman plots showed wide limits of agreement and increased variances with larger serving sizes for most foods. Overall, no association was found between estimation errors and participant characteristics.

Conclusions: The ability to accurately estimate the serving size of foods using digital food photographs was limited, both at the group and the individual levels. This finding indicates that further development, refinement, and testing are needed to improve the accuracy of portion size estimation using the digital food photographic atlas.

Association between robustness of 24-hour pattern of sleep/wake, energy intake, and interstitial glucose level over seven days among young adults

Takahiro Yoshizaki[1], Kana Konishi[1], Fumiharu Togo[2]

1.Toyo University (Japan), 2. The University of Tokyo (Japan)

Background and objectives: Glycaemic variability (GV) is associated with obesity and cardiovascular diseases. Sleep and dietary intake are behavioural factors which impact glucose metabolism. However, no study explains whether robustness of the 24-hour patterns in sleep/wake and energy intake are independently associated with GV. Therefore, our study aimed to explain the associations in young healthy adults.

Methods: Eighty-seven healthy university students participated in this cross-sectional study. They recorded the time of each meal and amount of food and beverage consumed during seven days of actigraphy and flash glucose monitoring under a free-living situation. Additionally, they completed a self-administered questionnaire about demographics, morning-eveningness, and dietary intake over the previous month. The actigraph was continuously worn to record wrist activities every minute with a zero-crossing method. Cole-Kripke algorithm was applied to the recorded data to score sleep or wake (1/0) in each one-minute epoch. Interstitial glucose data were processed using band-pass filtering from 2- to 12-hour for ultradian component and 21.8- to 26.7-hour for circadian component. For the sleep/wake, energy intake, and original and filtered glucose data, the interdaily stability (IS) was calculated. IS measures the similarity in the daily 24-hour pattern. Multivariable linear regressions were performed with IS of glucose level as the dependent variable and IS of the sleep-wake pattern, IS of energy intake, and confounding variables (sex, body mass index, residential status, and experience of working at night) as independent variables.

Results: For the original glucose data and its circadian component, IS of energy intake was significantly and positively associated with IS of glucose level, but IS of the sleep-wake pattern was not. For the ultradian component, lower IS of both the sleep-wake pattern ($\beta = 0.30$, 95%CI = 0.13 – 0.48) and the energy intake ($\beta = 0.78$, 95%CI = 0.50 – 1.05) were significantly associated with a lower IS of glucose level. These results did not change when the morning-eveningness score and/or percentage of energy intake at snack was added to the models.

Conclusions: Robustness in 24-hour pattern of sleep-wake cycle and energy intake may be independently associated with a robustness of ultradian glycaemic rhythm.

PAB(T1)-39

Implementation of process-guided dietetic practice: Comparison of validated methods to collect data for the Diet History

Laura Hoffmann[1], Silvia Heckenhahn[1], Kathrin Kohlenberg-Müller[1]

1.Hochschule Fulda, University of Applied Sciences (Germany)

Background and objectives: Strengthening process-guided and evidence-based dietetic practice is important for improving the quality of dietetic care. The Diet History is a key category for collecting client-related data in the Dietetic Assessment at the beginning of process-guided dietetic practice in the Dietetic Care Process (DCP) and there is a need to propose validated methods. The aim of the present research was to give an overview of the evidence-based methods for the Diet History and to derive recommendations for its use in process-guided dietetic practice.

Methods: The systematically performed literature research and the additional hand search were conducted between October and December 2020 in three databases. They focused on validated survey methods based on respondents' self-reporting. Results were limited to publications from the past 20 years in English and German language. Studies were analysed using the STARD-Standard and Best Practice-Criteria for Self-Report Dietary Assessment Methods by Kirkpatrick et al. 2019.

Results: 31 publications on 24-hour recalls, food records, and photo-based methods were included. Only four studies focused on dietetic practice, the others mainly on nutritional epidemiology. None of the studies explicitly addressed process-guided Dietetic Assessment. There was a clear trend towards electronic dietary assessment instruments, which were used by the participants themselves and were (partly) automatically analysed.

Conclusions: Studies relating validated methods for the Diet History in process-guided Dietetic Assessment are limited. Recommendations for the use of assessment methods especially for the Diet History must be evidence based. Choosing a suitable method for the Diet History should consider individual characteristics of respondents as well as the design and implementation of the dietary assessment methods. Respondent characteristics should focus on demographic and socioeconomic factors, body mass index, literacy and language. Regarding the design of the methods, the instruments should not only include nutrients but also foods. Training sessions and/or help functions should be provided to facilitate the implementation of the methods by participants. There is a clear focus on innovative digital methods with verbal and visual assistance features. For strengthening the evidence-based dietetic practice it is necessary to improve the available evidence for the Diet History.

PAB(T1)-40

Development of behaviour change support for young adults within a randomised controlled trial

Anna Worthington[1], Nicola Gillies[1], Rajshri Roy[1], Andrea Braakhuis[1]

1.University of Auckland (New Zealand)

Background and objectives: Multiple frameworks based on behavioural models exist to guide researchers on the development of health interventions. Utilising the frameworks has the potential to enhance participant adherence, improve research validity and decrease resource waste, although research on the implementation and efficacy of such is limited. Therefore, the objective of this study is to describe the development of a user-centred, theory-based, eHealth behaviour change support (BCS) programme to support young adults' (20-35 years) to adhere to the behaviours of (i) following the prescribed 'healthy' diet, and (ii) record dietary intake on a smartphone app, when participating in a nutrition trial.

Methods: The Nine Principles framework was used to develop the BCS, which involved a literature review, qualitative research through focus groups with experts and end-users, integration of the Theory of Planned Behaviour, and a 10-week pilot trial with 20 participants. Mixed methods outcomes range from focus group inductive thematic analysis, process evaluation, and behaviour adherence and social media engagement during the pilot.

Results: The Nine Principles framework enabled the development of a feasible BCS programme within a nutrition trial. The BCS appeared to support optimal dietary recording, which can be a burdensome behaviour for participants, and helped participants maintain current dietary behaviours. Piloting highlighted the importance of identifying acceptable modes of delivery.

Conclusions: Using a framework underpinned by theory and user-centred design to develop BCS is a promising avenue to enhance adherence in nutrition research trials. Further practical support is needed to guide researchers through this development process.

Description and performance evaluation of two new web-based tools developed to assess and monitor diet quality: Nova-HF and Nova-UPF screeners

Maria laura da costa louzada[1], Francine Silva dos Santos[1], Kamila Tiemann Gabe[1], Caroline dos Santos Costa[1], Renata Bertazzi Levy[1], Carlos Augusto Monteiro[1]

University of Sao Paulo (Brazil)

Background and objectives: The quality of diets and risk of chronic diseases can be difficult to evaluate or monitor in some contexts due to the unavailability of tools that are simple and easy to collect. We developed two web-based tools to assess and monitor diet quality and described their performance against a traditional method of food consumption data collection.

Methods: This analysis included part of the participants of the NutriNet-Brasil study, a web-based prospective cohort that currently counts on more than 100,000 volunteers. A total of 812 adults (18 years or older) answered a 2-minute self-administered questionnaire about the consumption of a set of foods on the day prior to the interview. Food items were based on the Nova food classification system: the Nova screener of healthy foods (Nova-HF) is comprised of 33 whole nutrient-dense foods (fruits, vegetables, legumes, whole grains, and nuts), and the Nova screener of ultra-processed foods (Nova-UPF) includes the most consumed UPF in Brazil (23 food items). Each tool generates a score, which is obtained by the sum of positive answers. We compared the Nova-HF and the Nova-UPF scores to the total energy intake (%) from whole nutrient-dense foods and ultra-processed foods, respectively, obtained through a web-based open-ended 24-hours recall developed and validated specifically for the NutriNet-Brasil study, which considers the food processing degree. We evaluated the relationship between quintiles of each score and the correspondent % of energy intake by linear regression, and the agreement between the quintiles of each method, using the Prevalence-adjusted and bias-adjusted kappa (Pabak).

Results: Quintiles of each score presented a linear relationship with the correspondent % of energy intake (p-value for linear trend <;0.001). Quintiles of both scores presented a substantial agreement with the quintiles of correspondent % of energy intake (Pabak 0.72, 95% CI 0.68-0.76 for the Nova-HF score; Pabak 0.79, 95% CI 0.74-0.83, for the Nova-UPF score).

Conclusions: These two new screeners, applied in a quick and practical manner, presented a good potential in reflecting the dietary share of whole nutrient-dense foods and ultra-processed foods in Brazil, and represent an easy tool to evaluate and monitor diet quality. The evaluation of the characteristics in Washoku by using the food–model SAT nutrition-education system.

Hanae Yamazaki[1], Tatsuya Shimizu[1], Miyo Matsushita[2], Hinako Hayashida[1], Tohru Fushiki[3]

1.Ryukoku University (Japan), 2. Kobe Women's University (Japan), 3. Koshien University (Japan)

Background and objectives: Washoku, a traditional Japanese food is attracting attention both domestically and internationally as a healthy diet. Although there have been many reports examining the effects of individual components of foods used in Japanese meals on the body, there are few examples of examining an entire meal. In this study, we used a food model to examine the nutritional characteristics of Washoku as a whole meal.

Methods: A meal choice experiment was conducted on 166 subjects from 16:00 to 18:30 using a food model system (Iwasaki Co., Ltd.). The food model was divided into two groups, Japanese food and non-Japanese food, using the definition of The Washoku Association of Japan (Ministry of Agriculture, Forestry and Fisheries). There was no limit to the amount or number of meals, and we asked them to freely choose from Japanese food and non-Japanese food once each in a buffet style. Total energy and various nutrient levels were measured by the Food-Model SAT nutrition-education system.

Results: Total energy and total lipid were significantly lower in the Japanese diet than in the non-Japanese diet, demonstrating the characteristics of the Japanese diet that total energy and total lipid can be kept low even when dietary choices are made with no restrictions on diet content or quantity.

Quality comparison of nutrition information on Twitter with and without a secondary share

Cassandra H Ellis[1], Katherine Coyle[1], J Bernadette Moore[1], Charlotte Evans[1]

1. University of Leeds (UK)

Introduction: The internet is a common source of health information for the public but is largely unregulated with anyone able to create and share content1. Social media channels, including Twitter, facilitate easy and rapid dissemination of content, including nutrition and health information2. Therefore, it is increasingly important to be able to differentiate between

higher- and lower-quality nutrition information. Using a novel online quality assessment tool (OQAT)3, this work aimed to assess the quality of online nutrition information disseminated via Twitter from different sources of information and examine those that had >;1 secondary share (retweet) in comparison to unshared content.

Methods: The Twitter API, Tweet Archiver, was used to collect tweets posted on six randomly selected dates in 2021 that included the term 'nutrition'. Tweets were initially screened to identify those containing Uniform Resource Locators (URLs) and sorted based on secondary shares. Each URL was reviewed manually and categorised based on the website source and the content type before being assessed against the 10 OQAT criteria. A higher OQAT score indicated a higher quality article.

Results: Over the collection period, 11,204 URLs were collected from 16,262 Twitter posts (1,646 shared, 9,558 not shared). After manual screening for relevance to human nutrition and health, these represented: 68 news articles (34 shared, 34 no share) and 628 blogs (240 shared, 388 no shares). 10,508 URLs were excluded as out of scope (e.g. advertising, scientific papers, social media accounts). T-test showed a significant difference in OQAT score between blogs (n=628, mean=6.24) and news articles (n=68, mean=7.26), difference= -1.02 (95% CI -1.396 to -0.649), p<;0.001.URLs that did not have a secondary share (n=422, mean=6.47) scored higher on the OQAT than those that had been retweeted (n=274, mean=6.14), difference=0.32 (95% CI 0.065 to 0.606), p=0.008.

Discussion: This investigation of the quality of online nutrition information shared on Twitter, found blogs were the most widely shared content type but were the lowest quality. Articles retweeted were of lower quality than those unshared, as assessed by the OQAT. These data suggest that caution is required when using, and sharing, blogs as a source of nutritional information.

Impact of vitamin B12 supplementation on streptozotocin-induced diabetic rat brain.

Udaykanth Suryavanshi[1], Sudhakar Reddy Vadde[1], Kirankumar Angadi[1], Bhanuprakash Reddy Geereddy[1]

National Institute of Nutrition (India)

Background & Objectives: Diabetes mellitus is associated with increased risk for neurodegenerative disorders. Vitamin B12 is an essential micronutrient, whose deficiency has also been linked to neurodegenerative conditions including cognitive impairment. Accumulation of misfolded proteins altered neurotrophic support, astrogliosis, synaptic dysfunction, and defects in autophagy are associated with neurodegenerative diseases. Hence, in this study, we investigated the neuroprotective role of vitamin B12 and its molecular basis in diabetic rat brain.

Methods: Diabetes was induced in two-month-old Sprague-Dawley rats using streptozotocin and animals were divided into 3 groups: control (CN), diabetes (D), and diabetes with B12 supplementation (DBS). DBS group was fed double the amounts of B12 (50 µg/kg diet) in comparison to the CN and D groups. At the end of four months, the cerebral cortex (CC) tissue was collected. The histopathology was performed using H&E staining and nissil body staining, and cell death by TUNEL assay. Furthermore, markers of neurotrophic support, synaptic density, ER stress, the ubiquitin-proteasome system (UPS), and autophagy were analyzed by immunoblotting and immunofluorescence methods.

Results: Vitamin B12 supplementation to diabetic rats showed a reduction in cellular degeneracy with fewer halos around the cells, increased neuronal cell density, and decreased chromatolysis. Additionally, B12 supplementation restored the neurotrophic factors, improved the synaptic density-related markers, and attenuated the astrogliosis. Furthermore, B12 supplementation reduced the ER stress and alpha-synuclein expression. In tune with these changes, B12 supplementation decreased neuronal cell death.

Conclusion: This study demonstrates a neuroprotective role of B12 in ameliorating diabetes-induced neurodegeneration by modulating ER stress, astrogliosis, neurotrophic support, and abating cell death. This study is likely to help in developing B12 mediated therapeutic strategies for diabetes.

Effect of a mobile app on breastfeeding rates among mothers who have cesarean delivery: A randomized controlled trial

Duong Thi Thuy Doan[1], Ngoc Minh Pham[2], Colin Binns[2], Yun Zhao[2], Andy Lee[2], Thi Thu Ha Bui[1], Thi Phuong Hoa Dinh[1]

1. Hanoi University of Public Health (Viet Nam), 2. Curtin University (Australia)

Background and objectives: Cesarean section has negative impacts on breastfeeding rates. This study is to evaluate the effect of a mobile application on breastfeeding outcomes among mothers who had cesarean section using a randomized control trial in Vietnam in 2020 - 2022.

Methods: A triple–blinded randomized trial of a mobile application was conducted. The mobile application was tailored to Vietnamese culture with two separate versions for the intervention and the control group. The intervention version auto-generated three messages per week and linked the

information in the library content to improve breastfeeding while the control version sent messages on maternal and child health care. Pregnant mothers were recruited during their antenatal visits and randomly assigned to two groups. Outcomes of interest included early initiation of breastfeeding and exclusive breastfeeding rates.

Results: A total of 275 mothers in the control and 293 in the intervention group who had undergone a cesarean section were included in the analyses. Significant increases were observed for early initiated breastfeeding within two hours (aOR= 1.51, 95%CI: 1.01 to 2.27) and exclusive breastfeeding during hospital stay (aOR=1.59, 95%CI: 1.02 to 2.49).

Conclusion: Our results support the use of a theory-based design mobile phone application as a part of a promising intervention to improve breastfeeding outcomes.

Stereo-Camera based vessel dimension and food portion size estimation in Ghana

Viprav B Raju[1], Alex Kojo Anderson[2], Megan A McCrory[3], Benny Lo[4], Gary Frost[4], Matilda Steiner-Asiedu[5], Tom Baranowski[6], Wenyan Jia[7], Mingui Sun[7], Edward Sazonov[1]

University of Alabama, Tuscaloosa, AL (USA), 2. University of Georgia, Athens, GA (USA), 3. Boston University, Boston, MA (USA), 4. Imperial College, London (UK), 5. University of Ghana, Accra (Ghana), 6. Baylor College of Medicine. Houston, TX (USA), 7. University of Pittsburgh, Pittsburgh, PA (USA)

Background and objective: The African continent, particularly the sub-Saharan region including Ghana, is burdened by undernutrition and obesity. Understanding food intake is critical to developing solutions. However, traditional food intake monitoring tools are known to be inaccurate and sensor-based methods are being explored to enhance accuracy. This study explores the use of a stereo-camera to determine eating vessel dimensions and estimate portion sizes of foods and beverages such as soups, stews, rice, and teas from captured images. The study was funded by the Bill and Melinda Gates Foundation.

Methods: Households from rural and urban Ghana in and around Accra participated in this study and their food intake was monitored by the FOODCAM for 3 days. The FOODCAM is a passive, standalone stereo-camera that can be mounted above an eating location. Using stereo-vision, the vessel dimensions were extracted. Essentially, the pixels from one stereo- image were matched with pixels of the second and stereo-camera parameters were used to estimate the same point in 3-dimensional (3-D) space. Vessels were classified as flat plates or cylindrical/ hemispherical/ frustum vessels. The start and end images of eating occasions were used to determine portion consumed. Based on the vessel shape and dimensions the volumes of the consumed food were estimated. Using FAO/INFOODS food database density tables (2012), weights of the portions were estimated and compared with ground truth weights calculated estimated from researcher-conducted weighed food records.

Results: Using the FOODCAM, we estimated vessel dimensions in the laboratory with mean±SD error percentages of -5.83±2.59 in radius/side estimation and -9.27±3.95 in vessel depth, respectively. Preliminary results using FOODCAM images from the field study (15 foods and beverages from 4 households) showed estimated food portion size resulted in an error percentage of -11.27 ± 15.49.

Conclusion: These results show the potential of the FOODCAM and the associated stereo-vision methodology as an accurate, semi-automatic way to estimate the dimensions of eating containers from an overhead food camera and determining food portion size in free-living conditions.

SAHH inhibition induces endothelial senescecne and accerlerates atherosclerosis via epigenetic regulation of Drp1-mediated mitochondrial fission

Yiran You[1], Xu Chen[1], Wenhua Ling[1]

1.Sun Yat-sen University (China)

Background and objectives: Endothelial senescence plays a critical role in the development of atherosclerosis. Elevated S-adenosylhomocysteine (SAH) level results from inhibition of S-adenosylhomocysteine hydrolase (SAHH) is one of the risk factors of atherosclerosis. However, the relationship between endothelial senescence and SAHH inhibition is largely unknown and is the goal of the current study.

Methods: Serial passage human umbilical vein endothelial cells (HUVECs) were used to explore the association between SAHH expression and replicative senescence. HUVECs treated with SAHH-specific inhibitor adenosine dialdehyde (ADA) and SAHH-siRNA, SAHH+/-mice and ApoE-/- SAHH+/-mice were used to assess the effect of SAHH inhibition on endothelial senescence in vitro and in vivo. RNA-sequencing, Whole Genome Bisulfite Sequencing (WGBS) and adenoviral-transfection were conducted in HUVECs for mechanism investigations. In addition, a 1:1 matched case-control study of vascular aging (n=188 for each group) was conducted to verify the conclusion epidemiologically.

Results: As HUVECs were passaged, distinct senescence morphology was observed together with decreased SAHH expression and increased intracellular SAH levels. SAHH inhibition treatment with ADA or SAHH siRNA elevated SA-β-gal

activity, arrested proliferation, and elevated the expression levels of p16, p21 and p53 in HUVECs and the aortas of mice. GO enrichment analysis of both RNA-sequencing and WGBS data revealed that genes related to mitochondria fission were differentially expressed after SAHH inhibition treatment. A fission morphology of mitochondria and downregulation of Drp1 were also observed in subsequent assays. Notably, further knock down of Drp1 using siRNA maintained the mitochondrial morphology and rescued the senescence phenotypes in endothelial cells undergoing SAHH inhibition. After fed on AIN-93G diets for 10 weeks, ApoE-/- SAHH+/-mice showed increased lesion area compared with ApoE-/- littermates. However, Drp1 inhibitor mdivi-1treatment abrogated the effect above. Mechanistically, hypomethylation over the promoter region of Drp1 and downregulation of DNMT1 were found in HUVECs treated with SAHH inhibition. And DNMT1 overexpression using adeno-virus did upregulate the Drp1 expression. The case-control study suggested that plasma SAH levels was the risk factor of vascular aging, with adjusted OR= 3.425 (1.783-6.579) (Q4 vs Q1).

Conclusions: SAHH inhibition induces endothelial senescence and accelerates atherosclerosis via epigenetic regulation of Drp1-mediated mitochondrial fission.

Skeletal muscle mass and expressions of the myostatin and follistatin in vitamin D receptor gene knockout mice, and its gender difference

Naoko Tsugawa[1], Kimie Nakagawa[2], Maya Kamao[3]

1.Osaka Shoin Women's University (Japan), 2. Kobe Gakuin University (Japan), 3. Kobe Pharmaceutical University (Japan)

Background and objectives: It has been known that vitamin D deficiency is linked to muscle weakness and falls. Vitamin D receptor (VDR) is present in normal muscle even at very lower levels than the main target tissues like the intestine, kidney, and bone. To confirm the role of VDR in muscle, muscle mass and the gene expression of myogenic related factors in male and female VDR gene knockout mice (VDRKO) were investigated.

Methods: Littermates of wild-type and VDRKO mice were fed a normal (Ca 1.2%) or high calcium diet (Ca 2.0%, lactose 20%). Muscle mass in the lower leg was measured using the Micro-CT scanners for small experimental animals (Latheta LCT-200, Hitachi, Ltd., Japan). Gene expression of myostatin and follistatin in quadriceps were analyzed using qRT-PCR.

Results: In the feeding of a normal diet, the body weight and muscle mass of VDRKO mice were significantly lower, and expression of myostatin mRNA was higher than those of wild-type mice in both males and females. In the feeding of a calcium rescue diet, hypocalcemia of male and female VDRKO mice were improved, and the muscle mass of female VDRKO mice improved to an equal level of wild-type mice. However, the improvement of the muscle mass of male VDRKO mice was not improved completely. No difference was observed in the expression of follistatin mRNA between wild-type mice and VDRKO in both kinds of diets.

Conclusions: The results suggest that one of the mechanisms for the effect of vitamin D on muscle mass is increased myostatin gene expression mediated by hypocalcemia. Moreover, incomplete improvement of muscle mass was observed in male VDRKO mice despite improved hypocalcemia and myostatin gene expression, which suggests that the effects of vitamin D on muscle mass are more likely to occur in males via androgens or unknown factors.

Data science meets nutrition: A systematic scoping review on the use of computational sentiment analysis to explore the language of nutrition, food and cooking related social media posts

Tracy McCaffrey[1], Eva L Jenkins[1], Linda Brennan[2], Dickson Lukose[1], Annika Molenaar[1]

1.Monash University (Australia), 2. RMIT University (Australia)

Background and objectives: Generally, research on nutrition, food and cooking related information on social media has been limited to manual content analysis and small sample sizes. Sentiment analysis is a data science technique which can analyse the emotion (e.g. positive, negative or neutral) from large datasets, however it is currently unclear of its applicability in the context of nutrition. The aims of this review were to classify the areas of nutrition that have been explored using sentiment analysis, the sentiment analysis techniques used and their potential efficacy.

Methods: Nine databases from both health and data science were searched for journal articles or conference papers that conducted computational sentiment analysis on nutrition, food or cooking social media content.

Results: Searches returned 7325 papers of which 38 papers from 37 studies were eligible. The range of nutrition related topics varied including areas such as dietary patterns and choices, cooking, health status and public health nutrition programs. Not all studies reported the accuracy of the sentiment tool to predict sentiment. Of those that did, accuracy ranged from 33.3% to 98.5%, with neural network engines which were purpose built for the topic having the highest accuracy - up to 98%. Typically, open-source tools were not assessed for accuracy or had accuracy as low as 33.3%. The proportion of sentiments

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

varied, with the proportion of positive posts ranging from 12.9% to 79.2% (average 40.1%), neutral from 5% to 76.9% (average 46.3%) and negative from 6.1% to 82% (average 25.8%). Alongside sentiment analysis, other analyses were often conducted to explore the social media data further. These included topic modelling which uses algorithms to create themes based on frequent words; social network analysis which explores the network of social media users; and classification systems to assess the healthiness of the foods mentioned.

Conclusions: Open-source sentiment analysis methods should be used with caution in the nutrition context as accuracy may be low. Multi-disciplinary work (including data science and nutrition subject experts) and use of techniques beyond sentiment analysis are key to the successful implementation of data science methods that are rigorous, relevant to the specific field and practical.

Development of a method to assess provitamin A bioequivalence from mixed diets by applying model-based compartmental analysis to theoretical datasets for healthy young females.

Tsitsi Chimhashu[1], Michael Green[2], Joanne Balmer Green[2], Alida Melse-Boonstra[1]

1.Wageningen University and Research (Netherlands), 2. Pennsylvania State University (USA)

Introduction: In several studies, model-based compartmental analysis has been used to estimate the bioequivalence of β-carotene (provitamin A) to retinol after subjects ingest stable isotope-labelled β-carotene in oil. Objective: Our objective was to develop a method to determine the bioequivalence of dietary provitamin A in theoretical women that can later be applied in free-living subjects fed mixed diets.

Methods: We postulated retinol kinetic parameters for 6 theoretical women with low, moderate, or high assigned values for vitamin A (VA) total body stores (TBS) and VA intake. We assumed subjects ingested a single dose of [13C] retinyl acetate and that from d 14-28, daily VA supplements (0, 200, 400, 800, 1600, or 2000 µg retinol) were consumed, with the study repeated at each supplement level in each subject. Using a previously published 8-compartment model for whole-body VA metabolism which assumed homeostatic control of plasma retinol concentration, we simulated plasma retinol and plasma retinol specific activity (SAp) using the Simulation, Analysis and Modeling (WinSAAM) software. Then for each subject, we calculated the change in SAp on d 28 for each supplement and developed an equation to predict percentage drop in SAp (bioequivalence) as a function of VA in diet + supplement.

Results: Higher doses of VA supplement resulted in lower SAp such that there was a clear dose response between supplement load on d 14-28 and SAp. Bioequivalence data fit an equation describing saturation kinetics.

Conclusion: These results suggest that, by applying a similar protocol in free-living subjects (single oral dose of stable isotope-labelled VA, a controlled diet varying in provitamin A, and limited blood sampling), compartmental modelling can be used to predict β-carotene bioequivalence from a mixed diet.

Keywords: provitamin A, bioequivalence, model-based compartmental analysis, retinol isotope dilution method, theoretical humans

Effect of ice slurry oral intake before bedtime on sleep

Takeshi Sato[1], Mizuki Nakajima[1], Kimie Nakajima[2], Miyu Kayama[3], Kenichi Egawa[2], Eiji Watanabe[4], Yousuke Murata[5], Megumi Hasegawa[1]

1.Jissen Women's University (Japan), 2. Graduate School of Human Life Sciences, Tokyo Kasei Gakuin University (Japan), 3. Junior College of Kiryu (Japan), 4. Senshu University (Japan), 5. Kyushu Institute of Information Sciences (Japan)

Background and objectives: sleep disorders are a major social problem that prevails in modern society, and urgent action is desired. Currently, many supplements that were supposed to improve the sleeping environment on the commercial market. However, the effect is extremely weak compared to the prescription. Ice slurry ingestion before exercise is based on evidence that reducing one's initial core temperature allows for a greater heat storage capacity during exercise and in turn prolongs the onset of hyperthermia-induced fatigue. It was well-known that major previous sleep studies have observed a decrease in core body temperature from the time of falling asleep. The purpose of this study was to investigate effect of ice slurry intake before bedtime to lead to falling asleep quality in Japanese summer.

Methods: Eleven volunteers (age = 21 ± 3years, height = 1.59 ± 0.14 m,), three male and eight female were participated in this study. It was performed to sleep intake ice slurry (100g/pack, Otsuka Co.) or not as control condition in each own bedroom environment with wearing sensor for sleep assesment and indoor climate environment recording. This experiment was performed from July to August in hot and humid Japanese summer. The study protocol was approved by the Ethics Committee of Jissen Women's University (AC_2019 _11_S) in Japan. All participants provided written informed consent prior to commencing the study. The study complied with the latest version of the Declaration of Helsinki and was conducted according to international standards.

Results: There were recorded totally 196 nights, then acquisition successful 158 night's sleep and indoor climate data. It was a found at the time of sleep as Japanese summer, 30 degrees centigrade and 89% humidity in bedroom climate. There was a significant different in non rem sleep period longer

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

between ice slurry or not.

Conclusions: Consequently, there was a tendency that the deep sleep time was longer when ingested. Therefore, it was suggested that the decrease in core body temperature due to ice slurry improves the quality of sleep.

Keywords: ice slurry, sleep, indoor climate

Daily iron intake through biofortified crops-based complementary foods and impact on iron indices

Samantha Lee Huey[1], Jesse T. Krisher[1], Shobha A. Udipi[2], Padmini Ghugre[2], Varsha M. Thakker[2], Harsha V. Chopra[3], Ramesh D. Potdar[3], Jere D. Haas[1], Julia L. Finkelstein[1], Saurabh Mehta[1]

1.Cornell University (USA), 2. SNDT Women's University (India), 3. Centre for the Study of Social Change (India)

Background and objectives: We conducted a randomized controlled trial (RCT) of complementary foods prepared using iron-biofortified pearl millet (FePM, Dhanashakti) compared to conventional PM (CPM) from 2017–2018 among n=223 children in urban slums of Mumbai (NCT02233764). While there was no overall effect of the intervention on markers or iron status, the RCT results were consistent with previous FePM studies, and improvements in hemoglobin concentrations were observed among male children and children who were iron deficient or depleted at baseline. In this abstract, we aimed to examine the association of daily iron intake with changes in hemoglobin.

Methods: FePM- or CPM-based foods were offered to children 6 days per week (excluding Sundays) for 9 months and weighed before and after eating to measure intakes. From weighed food records, daily pearl millet (g) and iron (mg) intake were calculated. We plotted dose-response curves examining the daily average iron intake to detect threshold effects as well as non-linear associations with hemoglobin and serum ferritin response using restricted cubic splines. Analyses were conducted on subgroups including those who were anemic (hemoglobin <;11.0 g/dL) or iron deficient (serum ferritin <;12.0 µg/L) at baseline.

Results: Children consumed a median (IQR) of 31.6 (28.3, 33.5) g FePM and 32.2 (29.1, 33.7) g CPM daily, resulting in intakes of 3.0 (2.7, 3.1) and 1.0 (0.9, 1.0) mg iron daily, respectively. Daily mean iron intake from FePM was associated with a linear improvement in hemoglobin concentration in children who were anemic at baseline, and iron deficient at baseline, in analyses using restricted cubic splines.

Conclusions: We observed that intake of FePM-based complementary foods for 9 months is associated with an improvement in hemoglobin concentrations among children 12–18 months of age, who are iron deficient or anemic.

Development of a quality assessment framework to support the reuse of existing datasets: a Food Nutrition Security Cloud (FNS-Cloud) project

Laura A Bardon[1], Grace Bennett[1], Eileen R Gibney[1]

1.University College Dublin (Ireland)

Background and objectives: Currently, existing data, tools and services in the area of nutrition, health and agri-food are fragmented, lack critical mass and access is unevenly distributed. The FNS-Cloud project aims to federate existing and emerging tools and datasets, in addition to developing new services into a single 'Cloud' to support their re-use. Whilst promoting the increasing reuse of data, it is imperative for the maintenance of scientific quality that all data selected for secondary analysis be fit for the intended research purpose. Thus, a quality assessment framework is needed in FNS-Cloud to support researchers in the decision-making process to assess whether data is appropriate for their research and ensure scientific quality is maintained. This work aims to describe the development of a quality assessment framework for FNS-Cloud.

Methods: Markers of quality were identified within the literature for dietary intake, lifestyle, demographic, anthropometric and consumer behaviour data domains where quality was considered at a data collection, data management and data analysis level. These markers were assessed and refined by expert researchers within the field of dietary intake, consumer behaviour and lifestyle data and then used to inform the development of a series of flow charts for each data domain.

Results: The flow charts comprise a series of questions relating to an aspect of quality specific to each data domain. Individualised messages specific to the answers given to each question were developed. The design requires researchers to answer a series of questions producing a personalized feedback report with additional considerations to support the researcher in their decision of whether the data they have selected is appropriate for their research question

Conclusion: Future work will focus on the implementation of this framework into the FNS Cloud solution by evaluating its use among a wider group of domain specific experts and translating the framework into an online tool. Work is ongoing in this project with the Cloud expected to be delivered by the end of 2023.

Funding: Food Nutrition Security Cloud (FNS-Cloud) has received funding from the European Union's Horizon 2020 Research and Innovation programme (H2020-EU.3.2.2.3. – A sustainable and competitive agri-food industry) under Grant Agreement No. 863059 – www.fns-cloud.eu

Sociodemographic characteristics according to different food purchase patterns of Finnish households

Jelena Maarit Meinila[1], Maijaliisa Erkkola[1], Henna Reetta Vepsäläinen[1], Hannu Saarijärvi[2], Mikael Fogelholm[1], Jaakko Nevalainen[2]

1.University of Helsinki (Finland), 2. Tampere University (Finland)

Background and objectives: Food retailers' loyalty-card data provide a unique tool for gaining insights into dietary patterns. The aim of this study was to identify differences of purchase patterns in different socio-demographic groups in Finland.

Methods: Loyalty-card holders of the largest grocery retailer in Finland (S Group) received an invitation to share their purchase data for research purposes. Those who gave their consent also filled out a questionnaire on, e.g., sociodemographic characteristics. Purchase patterns of 22,860 participants were identified using factor analysis for 56 aggregated food groups. Pattern scores between sociodemographic groups were compared (means).

Results: The six identified purchase patterns were Traditional, High-energy, Plant-based, Animal-based, Ready-to-eat, and Easy-cooking. Individuals ≧70 years (vs. ≦29 years) had higher scores in Traditional (0.61 vs. -0-62) but lower scores in High-energy (≧70 y: -0.92 vs. ≦ 29 y: 0.23). Those ≧ 70 years vs. ≦ 29 y had also lower scores in Easy-cooking (-0.59 vs. 0.46). Other patterns were not strongly associated with age. Those living in high-income households (≧4000 €/month) vs. low-income households (<;1000€/month) had higher scores in Animal-based (0.32 vs. -0.63) and Plant-based (0.18 vs. -0.21) but lower scores in Easy-cooking (-0.31 vs. 0.21). Those with higher-level tertiary education vs. those with primary school or less as the highest education had higher scores in Plant-based (0.36 vs. -0.40), Animal-based (0.14 vs. -0.31), and High-energy (-0.09 vs. -0.35) but lower scores in Traditional (-0.25 vs. 0.51), Easy-cooking (-0.25 vs. -0.01), and Ready-to-eat (-0.07 vs. 0.17). Families with children compared to households without children had higher scores in High-energy (0.58 vs. -0.33), Easy-cooking (0.33 vs. -0.18), and Animal-based patterns (0.17 vs. -0.11).

Conclusion: Plant-based, but also Animal-based purchase patterns, were more common in those with high education level and high household income. Replacement of animal-based with plant-based foods in these groups should be promoted to mitigate environmental impacts of food consumption. Families with children adhered strongly to the High-energy pattern characterized by high-energy low-nutrient foods, and Animal-based pattern. Therefore, in addition to targeting individuals with low income and low educational level with promotion of healthy food choices, families with children should be targeted. Effects of dietary vitamin D deficiency on markers of skeletal muscle mitochondrial biogenesis, dynamics, and quality control

Song-Gyu Ra[1,2], Hironari Nakagawa[2], Yuki Tomiga[2,3], Hiroki Iizawa[2], Shihoko Nakashima[2], Yasuki Higaki[2], Kentaro Kawanaka[2]

1.Tokushima University (Japan), 2. Fukuoka University (Japan), 3. Saga University (Japan)

Background and objectives: We examined the effects of dietary vitamin D deficiency on markers of mitochondrial biogenesis, dynamics, and quality control in rat soleus muscle.

Methods: Male Wistar rats were fed a chow with no vitamin D (No-D; 0 IU/kg) or a moderate dose of vitamin D (Mod-D; 2000 IU/kg) chow for 8 weeks.

Results: Compared to the Mod-D group, at 8 weeks the No-D group showed significantly lower serum 25(OH)d levels. Although vitamin D deficiency had no effect on body composition, the No-D rats showed significantly decreased levels of PGC-1α, a marker of skeletal muscle mitochondrial biogenesis, and DRP1, a marker of skeletal muscle mitochondrial fission. The change in the PGC-1α protein expression and the serum 25(OH)d concentrations were significantly correlated. The change in DRP1 protein expression and the serum 25(OH)d concentrations tended to be correlated. There was no significant between-group difference in markers of mitochondrial fusion (MFN2 and OPA1) and quality control (PARKIN) in soleus muscle, and no relationship with serum 25(OH)d concentrations.

Conclusions: Our findings may indicate that dietary vitamin D deficiency decreased mitochondrial biogenesis and fission in rat soleus muscle.

Autophagy inhibition induces SREBP1delta-mediated transcription

Nagakatsu Harada1, Ayane Nozaki2, Etsuko Ishikawa2

1.The University of Shimane (Japan), 2. Tokushima University Graduate School (Japan)

Background and objectives: The sterol regulatory element-binding protein 1 (SREBP1) is a transcription factor required for expression of various lipogenic genes. The SREBP1 precursor undergoes proteolytic cleavage at the Golgi apparatus to release the N-terminal nuclear form of SREBP1 (nSREBP1) that transactivates target gene promoters. We previously reported an alternative splicing event that produces SREBP1delta, a constitutively active, nuclear form of human SREBP1 that lacks C-terminal regulatory sequences. The intracellular factors that regulate expression of SREBP1delta are unclear. Here we investigated whether the autophagy system regulates SREBP1delta levels in mammalian cells.

Methods: HEK293 cells transfected with an expression plasmid encoding either precursor or mature SREBP1mRNA were treated with the autophagy inhibitor 3-methyladenine (3-MA; 5 mM) or, as a positive control, a suprapharmacological dose (10 mM) of caffeine, which is reported to increase SREBP1delta expression levels. Immunoblotting was used to assess expression levels of exogenous SREBP1 proteins and LC3 proteins (LC3-I and LC3-II) to monitor the autophagy status of the cells. A luciferase-reporter assay for the SREBP1-responsive glycerol-3-phosphate acyltransferase 1 (GPAT1) gene promoter was conducted to evaluate the function of SREBP1 under the treatments.

Results: Untreated HEK293 cells expressing SREBP1 precursor-mRNA produced exogenous full-length SREBP1 and nSREBP1 protein with no detectable production of the SREBP1delta protein. Treatment of the cells with either 3-MA or caffeine increased levels of both SREBP1delta and canonical nSREBP1. Expression levels of LC3-II, but not of LC3-I, also were increased in the presence of 3-MA or caffeine treatment. However, no further increase in LC3-II was detected in the presence of bafilomycin A1, another inhibitor of autophagy, suggesting that both 3-MA and caffeine suppressed autophagy in the cells. Hence, bafilomycin A1 alone could increase both SREBP1delta and nSREBP1 levels. The luciferase reporter assay showed that 3-MA activated the GPAT1 gene promoter in cells expressing exogenous SREBP1 precursor-mRNA, but not in cells expressing exogenous SREBP1 mature-mRNA that does not undergo alternative splicing and does not produce SREBP1delta protein.

Conclusions: Our results indicated that the inhibition of autophagy could increase cellular lipogenesis by inducing SREBP1delta-mediated transcription.

A valuable tool for measuring skeletal muscle cell contraction force based on the micro-wrinkles on silicone substrate

Yasuko Manabe[1], Hiroki Hamaguchi[1], Kanako Iijima[1], Tsubasa S. Matsui[2], Shinji Deguchi[2], Yasuro Furuichi[1], Nobuharu L. Fujii[1]

1.Tokyo Metropolitan University (Japan), 2. Osaka University (Japan)

Background and objectives: Muscle weakness is leading to increased risks of both physical disability and a wide variety of diseases. No effective drug treatments for muscle weakness have been developed, and one reason for the delay in discovery is that no suitable in vitro screening system has been established to test targeted drugs and supplements. Since a major characteristic of muscle weakness is decreased contractile force, a method that measures the contractile force in myotubes would be a valuable tool to test the effectiveness of muscle-weakness treatments. Here, we constructed a new system for measuring myotube contractile forces evoked by myotube contraction that analyzes the micro-wrinkles on a silicone substrate. We tested the muscle force of a cell model reproducing muscle-weakness disease or hypertrophy to determine whether our system can become a reliable tool for drug and food supplement screening.

Methods: Primary skeletal muscle cells derived from mouse satellite cells were differentiated to myotubes on a two-layer substrate of silicone gel. The myotubes were contracted by an electric pulse, and the contractile force was evaluated by a visualization of the micro-wrinkles and the quantification of the wrinkles' total length. Since the length of wrinkles on the silicon substrate is correlated with the magnitude of the force exerted by cells, we names the wrinkles' length the 'force index.' For an induction of muscle weakness or hypertrophy, myotubes were respectively treated with: dexamethasone, lung cancer cell medium, insulin-like growth factor (IGF)-1, and serum from diabetic mice. We then obtained the force index during electrical stimulation-induced contraction, the myotubes' diameters, and the myosin heavy chain (MHC) protein expression.

Results: The force index in the myotubes treated with dexamethasone, cancer-cell medium, or diabetic mouse serum was significantly decreased, whereas the index in the myotubes treated with IGF-1 was significantly increased. Changes in the force index also reflected atrophic or hypertrophic phenotypes more sensitively than changes in the myotube diameter or MHC expression.

Conclusions: This system is suitable to assess the atrophic and hypertrophic phenotypes of myotubes, which will be useful for the screening of preventive and therapeutic drugs for muscle weakness.

NAFLD milieu alters satellite cell content and muscle regeneration in mice

Siyi Chen[1], Tolulope Peter Saliu[1], Thanutchaporn Kumrungsee[1], Koji Mitsumoto[1], Noriyuki Yanaka[1]

1.Hiroshima University (Japan)

Background and objectives: Muscle wasting is a common complication associated with nonalcoholic fatty liver disease (NAFLD). In this study, we investigated the effect of NAFLD on satellite cell (SC) content and skeletal muscle repair.

Methods: Male CD-1 mice fed a choline-deficient diet for 4 weeks were used as a NAFLD model. We performed histological, mRNA expression analyses, western blotting, and immunochemical staining with single muscle fibers to assess the effect of NAFLD on muscle Pax7+ SCs, and muscle regeneration by intramuscular injection of cardiotoxin.

Results: We found that the total number of Pax7+ SCs in the extensor digitorum longus and tibialis anterior muscles of mice with NAFLD was significantly decreased when compared with that in the control group, in which the depletion of the SC pool possibly impaired muscle regeneration, as evidenced by the smaller size of the regenerating myofibers. Importantly, we found that NAFLD significantly impaired the differentiation ability of SCs, as shown by a decreased number of SCs expressing a myogenic marker, MyoD. Finally, this study indicated that molecular mechanisms underlying a decline in SC numbers may be attributed to the upregulation of proinflammatory cytokines (tumor necrosis factor-a [TNFa]) and an oxidative stress marker (NADPH oxidase-2 [NOX2]) in mice with NAFLD.

Conclusions: The findings demonstrate that a decrease in SC content in the skeletal muscle is an important factor that contributes to muscle wasting in NAFLD. Thus, preservation of the muscle SC pool is a potential therapeutic strategy to reduce NAFLD-associated muscle wasting.

Effects of different energy restriction levels on bone in young female rats

Yuki Aikawa[1], Yusuke Wakasugi[2], Takahiro Narukawa[3], Kazuki Kioka[4], Takenori Yamashita[2], Naomi Omi[4], Makoto Ohtsuki[2]

1.Tsu City College (Japan), 2. Suzuka University of Medical Sciences (Japan), 3. University of Kochi (Japan), 4. University of Tsukuba (Japan)

Background and objectives: An energy intake deficiency impairs bone health. In younger women, the rate of underweight has not improved much, so their bone health is a concern. However, it is unclear at what restriction level of the negative effects occurs, whether there is a threshold for the occurrence, or whether it depends on the level of restriction. Thus, we investigated the effects of different energy restriction levels on bone in young female rats.

Methods: Six-week-old Sprague–Dawley female rats were acclimated for 1 week and then divided into five groups (n = 8 / group): 0%, 10%, 20%, 30%, or 40 % energy restricted. The animals were maintained under these feeding conditions for 10.5 weeks. At the end of the feeding period, blood and bone samples were collected. Bone samples were evaluated for bone mass by the DXA and microstructures by the micro-CT.

Results: By the Jonckheere-Terpstra trend test, significant trends were found between energy restriction and the serum PTH, leptin, and rate of Gla/Glu osteocalcin, the BMD of femur, tibia, and lumbar, and the trabecular thickness and cortical thickness of tibia. Meanwhile, by the Tukey's multiple comparison test, the BMD of tibia in the 0%, 10%, and 20% groups were the same level, but those in the 30% and 40% groups were significantly lower than those in the 0%, 10%, and 20% groups. The BMD of femur in the 40% groups was significantly lower than those in the 10% and 20% groups. However, the serum PTH, leptin, and rate of Gla/Glu osteocalcin were not significantly different among the groups.

Conclusion: Our results suggest that there are dose-response relationships between energy restriction and BMD, bone microstructures, and bone metabolic hormones. Moreover, our results suggest that 30% energy restriction or more decrease BMD in young female rats.

Effects of varying amounts of vitamin B12 and/or folic acid in the diet on the levels of these vitamins present in the liver and plasma homocysteine of rats

Hiromi Katsura[1], Kyohei Koseki[2], Fumio Watanabe[2]

1.Kyoto Women's University (Japan), 2. Tottori University (Japan)

Objectives: Three vitamins, folic acid (FA), vitamin B12 (VB12), and vitamin B6, are involved in intracellular methionine metabolism. We focused on VB12, and FA showing how deficiencies in these vitamins increased plasma total-homocysteine (t-Hcy) levels, a risk factor for cardiovascular disease. The purpose of this study was to investigate whether the accumulated amounts of these vitamins interact with each other (or affect the t-Hcy level in blood plasma) when the intakes of VB12 and/or FA vary.

Methods: Six different experimental diets were prepared with AIN93G (VB12 and FA free) as the base plus the diet combined with methylcobalamin 0.1 or 10 times, and pteroylglulutamic acid 0.1, 1, or 10 times (B12ins-Fdef, B12ins-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Fcnt, B12ins-Fex, B12suf-Fdef, B12suf-Fcnt, and B12suf-Fex). These diets were fed at a rate of 20 g per day to 3-week-old Wistar male rats housed in individual cages for 4 weeks. After feeding, blood and liver samples from each rat were stored at -80°C. The amount of VB12 or FA contained in the liver was quantified by a bioassay using ATCC7830 strain or ATCC7469 strain lactobacillus.

Results and

Conclusions: The amount of VB12 contained in the liver was significantly increased in the B12suf group compared with the B12ins group. However this value was not affected by fluctuations in the amount of FA in the diet. Conversely, the amount of FA accumulated in the liver was significantly increased in rats fed B12suf-Fcnt compared with B12ins-Fcnt, or in B12suf-Fex compared with B12ins-Fex. In other words, when the amount of FA ingested was the same, the amount of FA accumulated in the liver increased in the group ingesting more VB12. Furthermore the plasma t-Hcy level in the B12ins group was significantly higher than that in the B12suf group, and the level was further increased by increasing the amount of FA to the diet. This result suggests that a high level of FA increased non-metabolic FA and decreased the production of 5methy-THF, the methyl group supplier of the methionine synthesis reaction, similar to the findings in the study reported by Koseki et al. (Redox Biology, 37, 101724, 2020).

Ethanol intake impairs niacin nutritional status in mice

Amane Mizutani[1], Chihiro Goto[1], Miu Sato[1], Yasuko Yamamoto[2], Kuniaki Saito[2], Sho Hatayama[1], Tsutomu Fukuwatari[1]

1.The University of Shiga Prefecture (Japan), 2. Fujita Health University (Japan)

Background and objectives: Niacin is involved in many biological reactions relating energy metabolism, redox reactions, DNA repair and longevity. Elucidation of the factors affecting niacin requirement is important to maintain niacin nutritional status. Although several factors are considered to increase niacin requirement from biochemical aspects, less direct evidence has shown in vivo. The objective of the present study is to demonstrate factors impairing niacin nutritional status in vivo. We first established model mice to evaluate niacin nutritional status using kynurenine 3-monooxigenase knock out (KMO-KO) mice which lack NAD biosynthesis pathway from tryptophan, and then investigated the effect of ethanol intake on niacin nutritional status.

Methods: To determine the niacin requirement, 4 weeks old KMO-KO mice were fed 2–30 mg/kg nicotinic acid containing diets for 28 days. To evaluate the effect of ethanol intake, 4 weeks old KMO-KO mice were fed 4 or 30 mg/kg nicotinic acid containing diets with or without 15% ethanol for 35 days. Body weight, NAD related compounds in the blood, liver and urine, and NAD metabolism related enzyme activities in the liver were measured.

Results: The mice fed less than 3 mg/kg nicotinic acid containing diets showed growth retardation, low niacin nutritional markers in the blood, liver and urine. These results showed that niacin requirement for maximum growth is 4 mg/kg nicotinic acid containing diet in the KMO-KO mice. The mice fed 4 mg/kg nicotinic acid containing diet with 15% ethanol showed lower body weight gain, blood and liver NAD, and urine nicotinamide metabolites than in the mice fed the same diet without ethanol. These animals also showed lower enzyme activities in the NAD salvage pathway but not nicotinamide catabolic pathway. Ethanol intake did not affect any indices in the mice fed 30 mg/kg nicotinic acid containing diet.

Conclusion: We established the model mice to evaluate niacin nutritional status. The present study also suggest that ethanol intake impaired niacin nutritional status by enhancement of NAD consumption and suppression of NAD reuse.

Divergent effects of dietary fatty acids on postprandial exosome functionality and their proteomic profile

Sergio Montserrat-de la Paz[1], Elvira Marquez-Paradas[1], Elena Grao-Cruces[1], Maria Carmen Millan-Linares[1], Maria Esther Martin-Rubio[1]

1.University of Seville (Spain)

Background and objectives: Circulating exosomes are small phospholipids-rich vesicles that contribute to intercellular communication and are promising biomarkers of several disease onset and progression. Diet is a cornerstone for disease prevention, but postprandial dietary fatty acid effects on exosome structure and functionality are poorly characterized. We aimed to determine the role of different dietary fatty acids on postprandial exosome functionality and proteomic profile.

Methods: Healthy subjects were given a 15 calorie per kilogram of body weight meals containing either SFAs, MUFAs, MUFAs plus omega-3 LCPUFAs or no fat. Blood samples were collected at baseline, at postprandial peak (2-3 h), and at postpeak (6 h) for analysis. Exosomes were isolated from 1 mL of plasma by an ultracentrifugation method. Purified exosomes were lysed and analysed with the Orbitrap Fusion high-resolution mass spectrophotometer fronted with a NanoESi ion source. Vesicle size was determined by nuclear magnetic resonance and transmission electron micrograph. To evaluate exosome functionality, PBMCs were incubated with or without postprandial exosomes for 24 hours and their effects were analysed by RT-qPCR.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Results: In general, there were over 200 proteins identified by Orbitrap MS in exosome lysed-containing fraction. In this set of exosome-related proteins, there were 31 proteins associated with different immune-related functions in this set, which putatively reflected the major role of exosomes released by immune cells present in the blood. At postprandial hypertriglyceridemic peak, exosome lysed-containing fraction skewed toward a proinflammatory profile and increased the mean particle size. Moreover, postprandial exosomes rich in SFAs made polarized macrophages prone to an M1-like phenotype. In contrast to dietary SFAs, exosomes-derived dietary MUFAs primed circulating monocytes for a reduced postprandial pro-inflammatory profile.

Conclusions: Our findings imply a new understanding of the mechanisms by which dietary fatty acids remodel proteomic cargo in postprandial exosomes. This study demonstrates that the intake of a meal enriched in MUFAs from olive oil, when compared with a meal enriched in SFAs, prevents the postprandial production and priming of circulating pro-inflammatory monocytes and low-grade systemic inflammatory response.

Taurocholic acid, a primary 12α-hydroxylated bile acid, induces leakiness in the distal small intestine in rats

Hongxia Liu[1], Ohji Kohmoto[1], Ayana Sakaguchi[1], Shota Hori[1], Misuzu Tochigi[1], Koji Tada[1], Yeonmi Lee[2], Keidai Kikuchi[1], Satoshi Ishizuka[1]

1.Hokkaido University (Japan), 2. Gachon University (Korea)

Background and objectives: High-fat diets (HFD) increase 12α-hydroxylated (12αOH) bile acid (BA) secretion, of which high fecal level of deoxycholic acid (DCA), a secondary 12αOH BA, has been reported responsible for the leaky gut. Our previous studies have associated HFD with an elevated concentration of taurocholic acid (TCA), a primary 12αOH BA, in the enterohepatic circulation in rats. However, it is unclear whether primary 12αOH BAs play a role in gut barrier impairment.

Methods: To address this question, rats were fed either a control diet or a diet supplemented with cholic acid (CA) (0.5 g/kg diet) for 13 weeks. The relationship between fecal BA profiles and gut permeability was examined every 2 weeks. Changes in genes related to barrier function were compared in ileal and colonic epithelia. Furthermore, rats fed the same diets were administered vancomycin (200 mg/L drinking water) for 6 weeks. Besides, based on the luminal BA concentrations, ex vivo gut leakiness was determined in the Ussing chambers.

Results: CA diet elevated the concentrations of TCA in the small intestine and DCA in the large intestine, which shared great similarity with the BA environment in the body under high-fat intake. Gut permeabilization was initially observed at 2 weeks. Higher fecal 12αOH/non-12αOH BA ratio was associated with gut permeability in multivariate analysis, of which primary BAs correlated with gut permeability in the early phase and secondary BAs in the latter phase. At the end of the feeding period, the CA diet enhanced the phosphorylation of myosin light chain 2 and reduced claudins and antimicrobial peptides expression in the ileal but not colonic epithelia. Notably, the CA diet-induced gut leakiness was not influenced by the coadministration of vancomycin, which suppressed secondary BAs production. Portal TCA concentration was closely correlated with gut permeability ($r = 0.7388$, $P < 0.0001$). In the Ussing chambers, DCA moderately increased permeability in the large intestine, whereas TCA considerably increased the ileal but not jejunal permeability. A Rho kinase inhibitor attenuated TCA-induced ileal permeability.

Conclusions: Overall, the present study demonstrated the significance of TCA, the primary 12αOH BA, in proximal gut leakiness.

Zinc deficiency alters zinc transporters in rat tissues

Takako Suzuki[1], Kazuharu Suzuki[2], Yukio Nakamura[3], Jun Takahashi[3]

1.Tokyo Kasei Gakuin University (Japan), 2. Tokyo University of Agriculture (Japan), 3. Shinshu University (Japan)

Background and objectives: Zinc (Zn) is an essential trace metal required for the catalysis or structural stabilization of over 300 enzymes. Zn homeostasis is primarily maintained by regulation of its influx into cells and efflux out of cells. Several Zn transporters are expressed in various tissues. There are two families of Zn transporters in humans, the Slc39a (Zip) family, with 14 members, and the Slc30a (ZnT) family, with at least 10 members. The Zip family of transporters mediates Zn uptake, whereas the ZnT family of transporters mediates Zn export. However, it is unclear whether dietary Zn deficiency affects alteration of Zn transporters in tissues.

Methods: After a 3-day adaptation period with control diet (30 mg Zn/kg), rats were randomly divided into the control (C) group (n = 8) and the Zn deficiency (ZD) group (n = 8). Rats in the ZD group were provided ad libitum access to a Zn-deficient diet, while those in the C group were pair fed with the control diet to the mean intake of the ZD group. After 1 week of treatment, rats were fasted for 12 h and euthanized for dissection. Blood, duodenum, liver, kidney, and bone samples were collected for analysis.

Results and Conclusions: The serum Zn concentration was significantly lower in the ZD group than in the C group. The mRNA expression of Zn uptake transporter genes, such as Zip1 (in the kidney) and Zip4 (in the duodenum), was significantly increased in the ZD group compared to that in the C group. However, the mRNA expression of the Zn export transporter gene ZnT1 was

significantly decreased in the ZD group compared to that in the C group only in the kidney. These results suggested that the mRNA expression of Zn transporters in several tissues quickly responded to dietary Zn deficiency.

In vitro impact of plant-based protein isolates on hepatic endoplasmic reticulum-mitochondria interactions and insulin sensitivity.

Catherine Lefranc-Millot[1], Caroline Perreau[2], Nadia Bendridi[3], Hubert Vidal[3], Jennifer Rieusset[3]

1.Roquette, La Madeleine (France), 2. Roquette, Lestrem (France), 3. Laboratoire CarMeN, UMR INSERM U1060/INRA U1397, Université Claude Bernard Lyon1 (France)

Background and objectives: Metabolic flexibility is the ability of our organism to switch from fatty acid oxidation to enhanced glucose metabolism between fasted and fed states. Metabolic inflexibility induces hepatic lipid accumulation and insulin resistance, in part through a reduction of Endoplasmic Reticulum (ER)-mitochondria contact sites called mitochondria-associated membranes (MAMs)[i]. Some nutrients can regulate MAMs in the liver impacting metabolic flexibility. Therefore, identifying new nutritional strategies improving MAMs may be useful to prevent metabolic diseases. Here, we aimed at identifying plant-based protein prototypes able to stimulate MAMs and insulin sensitivity in vitro in HuH7 liver cells.

Methods: 1/ HuH7 cells, cultured in presence of bovine serum albumin (BSA, as control) or of palmitate (200µM) to induce metabolic alterations, were co-incubated for 24 hours with 12 protein isolates, beforehand submitted to an in vitro simulated gastrointestinal digestion. ER-mitochondria interactions were analyzed by in situ Proximity Ligation Assays (PLA) and insulin signaling was accessed by measuring insulin-stimulated AKT/PKB phosphorylation. 2/ The impact of 2 selected digests (1mg/ml) on mitochondria dynamics (immunohistochemistry) and function (oxygen consumption) and on lipid accumulation (bodipy staining) was further investigated in both conditions.

Results: 1/ 5 digests were identified as increasing hepatic MAMs and improving insulin signaling in HuH7 cells in lipotoxic conditions. 2/ Pea and fava bean protein digests were selected and their effects on MAMs and on insulin signaling were confirmed. They both prevented palmitate-induced reduction of MAMs (no effects in basal conditions). Moreover, pea protein digest significantly increased insulin signaling at both basal and palmitate stimulated conditions, whereas fava bean protein digest only prevented deleterious effect of palmitate on insulin signaling. Lastly, pea and fava bean protein digests improved both palmitate-induced mitochondria fission and palmitate-induced lipid accumulation.

Conclusion: Altogether, these data highlight beneficial effects of pea and fava bean protein digests on ER-mitochondria interactions, mitochondria dynamic, lipid accumulation and insulin signaling in HuH7 cells. This allows to identify potential candidates for preventive and/or therapeutic nutritional interventions in at-risk populations (obese or at metabolic risk).

Current state and issues of laboratory nutrition analysis for food nutrition labeling in Japan: an assessment of performance data from proficiency testing schemes in 2017-2021

Jun Takebayashi[1], Noriko Takasaka[2], Ippei Suzuki[1], Toshiaki Nakasaka[2], Yasuhito Kumai[1], Naoyuki Hirabayashi[2], Tsuyoshi Chiba[1], Takaho Watanabe[2]

1.National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 2. Hatano Research Institute, Food and Drug Safety Center (Japan)

Background and Objective: Reliable laboratory analysis is essential for correct nutrient declaration for processed foods. Thus, we have provided a proficiency testing (PT) scheme once per year for food nutrition analysis in Japan. This study aimed to clarify analytical precision for mandatory nutrients or others.

Methods: PT rounds were conducted in accordance with ISO/IEC 17043 requirements. We reviewed the results of the PT rounds in 2017-2021 and calculated reproducibility relative standard deviation (RSDR) values to evaluate variation between laboratories.

Results: The number of participating laboratories in each PT scheme ranged from 65 to 89, and more than 65 % of the participants were public organizations responsible for a nutrition-labeling compliance test. The laboratories reporting inadequate analytical values (i.e. z-score ≧ 3 and/or percentage difference >; 20 %) in one or more nutrients for mandatory declaration (energy, protein, fat, carbohydrate, or salt equivalent) ranged from 5 to 18 % of all participants. In the PT in 2017-2018, the food matrices were pork and chicken sausages, and the approximate RSDR values were as follows: protein, 2 %; fat, 3-4 %; ash, 2 %; moisture, 0.4-0.7 %; carbohydrate, 8-9 %; energy, 1-2 %; sodium (salt equivalent), 4 %, calcium, 8 %; and iron, 8 %. On the other hand, in the PT in 2019-2021, the food matrices were grain cereals, and the approximate RSDR values were as follows: protein, 2-3 %; fat, 5-9 %; ash, 2-3 %; moisture, 6-18 %; carbohydrate, 1 %; energy, 1 %; sodium (salt equivalent), 4-26 %; dietary fiber, 4-12 %; calcium, 5-6 %; iron, 5-9 %; copper, 12 %; and potassium, 5 %.

Conclusions: In many cases, variations of reported values between laboratories were less than 10 % as RSDR, suggesting

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

the good performance of the participants. However, large RSDR values were observed in cases where nutrition contents were relatively low. Hence, regulatory authorities need to consider these variations between laboratories to make a proper judgment in compliance tests.

Interaction between the content of HDL and non HDL in EPA, DHA and some apolipoproteins and the severity of hormone receptor negative breast cancer.

Jean-Marie Bard[1,3,4], Hassan Nazih[4,3], Valentin Blanchard[3,6], Mikael Croyal[3,5], Christine Bobin-Dubigeon[1,2,3]

1.ICO Saint Herblain (France), 2. Nantes Université CNRS US2B-UMR6286 (France), 3. CRNHO West Human Nutrition Research Center (France), 4. Nantes Université ISOMER- UR2160 (France), 5. Nantes Université INSERM- UMS016 (France), 6. University of British Columbia-Vancouver (Canada)

Background and objectives: We have shown previously that the severity of hormone receptor negative breast cancer, as assessed by Ki-67 level, is negatively related to the HDL content in apolipoprotein (apo) C-1 and the non HDL content in apo C-2 and positively related to the HDL content in apo D (J. Clin. Med. 2022, 11, 1345). It has been suggested that circulating long chain omega 3 fatty acids (EPA and DHA) may influence breast cancer disease. The present sub-study was undertaken to determine if the EPA and DHA content of HDL and non HDL could influence this relationship.

Methods: 48 EDTA plasma samples drawn from receptor negative breast cancer patients were collected from our biobank at Institut de Cancérologie de l'Ouest, Saint-Herblain, France. Apolipoproteins and EPA/DHA content of HDL and non HDL was determined by LC-MS chromatography before and after precipitation of apo B containing lipoproteins. The relationship between the content of HDL and non HDL in apo and EPA or DHA was established by correlation analyses. Univariate and multivariate logistic regression models were used to establish the association between the content of HDL and non HDL in apo or EPA/DHA and the level of Ki-67 (high Ki-67 ≧30% or low Ki-67 ≦20%).

Results: HDL apo C-1 and HDL apo D were not significantly correlated with either HDL EPA nor HDL DHA, while non HDL apo C-2 was highly correlated with the non HDL content in EPA (p<;0.001) and not DHA (p =0.106). The tumor Ki-67 level was highly correlated with non HDL EPA (<;0.001 [<;0.001-0.026], p=0.029; odds ratio (OR) [95% Wald confidence interval], high Ki-67 vs low Ki-67) in univariate analysis. In the multivariate analysis, HDL apo D remained significantly associated with high Ki-67 (OR=6.66 [1.33-33.43], p=0.021. A tendency was observed for non HDL EPA (OR<;0.001 [<;0.001-1.88], p=0.070) and HDL apo C1 (OR=0.21 [0.04-1.14], p=0.071). Non HDL apo C-2 lost its significance (OR=0.12 [0.01-2.21], p=0.152).

Conclusions: Non HDL EPA seems to be associated to a lower risk of having a high proliferative index tumor. However, this effect could partly depend on its interaction with lipoprotein composition in apolipoproteins.

Search for ornithine decarboxylase expression regulation mechanism and polyamine synthesis mechanism by FOXO1

Sako Mizutani[1], Mamoru Oyabu[1], Yasutomi Kamei[1]

1.Kyoto Prefectural University (Japan)

Background and objectives: FOXO1 is a transcription factor whose expression is increased by starvation and inactivity. FOXO1 transgenic (FOXO1-Tg) mice with skeletal muscle specific overexpression of FOXO1 demonstrated significant muscle atrophy. We have previously found that the expression of ornithine decarboxylase (Odc1) was increased in the skeletal muscle of FOXO1-Tg mice by comprehensive gene expression analysis. Odc1 controls the rate of limiting steps of polyamine synthesis. Polyamines promote cell proliferation, nucleic acid and protein synthesis. On the other hand, it has been reported to activate cell autophagy. The relationship between the role of polyamines, ornithine decarboxylase and muscle atrophy has not been clarified. Therefore, we focused on FOXO1 that increases during skeletal muscle atrophy and analyzed the mechanism of Odc1 expression regulation during muscular atrophy.

Methods, results, and discussion: Gene expression analysis was performed using skeletal muscle samples of mice under the condition of skeletal muscle atrophy with increased FOXO1 expression (FOXO1-Tg mice, fasted mice, plaster-casted mice, denervated mice). The expression of Odc1 was increased under these skeletal muscle atrophy conditions. On the other hand, in mice lacking FOXO1, 3a, 4 specifically in skeletal muscle, Odc1 expression was not increased during fasting. These results suggest that Odc1 expression increases under muscular atrophy conditions in which FOXO1 expression increases. In addition, we have conducted comprehensive analysis of muscle metabolites in FOXO1-Tg mice using CE-TOFMS. As a result, putrescine, which is a type of polyamine was increased in the muscle of FOXO1-Tg mice, indicating that FOXO1 may increase polyamines in skeletal muscle. Consequently, it is possible that Odc1 is the target gene for FOXO1 and FOXO1 regulates intracellular polyamine synthesis.

Gut commensals regulate intestinal mucosal immunity through microRNA-200 gene silencing in lamina propria leukocytes of murine large intestine

Fumina Ohsaka[1], Daiki Honma[1], Yugo Karatsu[1], Yoshihiro Kadota[2], Takumi Tochio[2], Kei Sonoyama[1]

1.Hokkaido University (Japan), 2. B Food Science Co., Ltd. (Japan)

Background and objective: Gut microbiota plays important roles in development and homeostasis maintenance of immune system. MicroRNAs (miRNAs) are small noncoding RNAs that suppress the expression of target genes post-transcriptionally and involved in a variety of physiology including intestinal immune system. However, the role of miRNAs in gut microbiota regulation of intestinal immune system is not fully understood. We investigated the effect of gut microbiota on the miRNA expression and intestinal immunity in mice.

Methods: We compared the expression profiles of miRNAs and mRNAs in lamina propria leukocytes (LPL) in the large intestines of germ-free (GF) and specific pathogen-free (SPF) mice using microarray. A gene ontology enrichment analysis was done using DAVID on the mRNAs in which the expression levels were lower in SPF mice than in GF mice. Target genes of miRNAs in which the expression levels were higher in SPF mice than in GF mice were predicted by TargetScan. Expression level of target genes and their translational products ware analyzed by RT-qPCR and western blotting, respectively. Interleukin (IL)-2 production in cultured LPL upon stimulation with phorbol 12-myristate 13-acetate and ionomycin was measured by ELISA. In separate experiments, miRNA expression in large intestinal LPL was investigated in mice supplemented with 4% (w/v) 1-kestose (KES) in drinking water and mice administered with Bifidobacterium pseudolongum.

Results: By comparing SPF and GF mice, we found that the presence of gut microbiota increased the expression of miR-200 family members and decreased the expression of their target mRNAs, i.e., Bcl11b, Ets1 and Zeb1, in large intestinal LPL. Bcl11b and Ets1 reportedly encode transcriptional factors activating Il2 gene. Indeed, the presence of gut microbiota reduced IL-2 production in cultured LPL. We also showed that KES feeding and B. pseudolongum administration increased the expression of miR-200 family members in large intestinal LPL.

Conclusions: Considering that BCL11B and ETS-1 function as transcription factors to activate the Il2 gene, we propose that the presence of gut commensals, especially B. pseudolongum suppresses IL-2 production in large intestinal LPL, at least in part through post-transcriptional downregulation of Bcl11b and Ets1 genes by miR-200 family members.

Bifidobacterium breve supplementation during infancy attenuates mobility in low-birthweight rats during adolescence.

Masahiro Tsuji[1], Ayaka Itoh[1], Nao Tanaka[1], Sachiko Fukunaga[1], Akiko Nakano-Doi[2], Tomohiro Matsuyama[2], Takayuki Nakagomi[2]

1.Kyoto Womens University (Japan), 2. Hyogo College of Medicine (Japan)

Background and Objectives: Children with low birthweight (LBW) have a higher risk for developing attention-deficit/hyperactivity disorder (ADHD), for which no prophylactic measure exists. The gut microbiota in infants with LBW is different from that in infants with normal birthweight and is associated with ADHD. Oral supplementation with Bifidobacterium has several health benefits, such as suppressing inflammation and reducing infectious disease in newborns with LBW. We hypothesized that early oral administration of B. breve can attenuate altered behaviors observed later in life in individuals born with LBW. The aim of the present study was to investigate whether oral administration of B. breve M-16V in the neonatal and infantile periods has beneficial effects on behaviors during adolescence in rats born with LBW.

Methods: We examined the effect of gavage supplementation with Bifidobacterium breve M-16V in a rat model of intrauterine hypoperfusion. Pups born with LBW were supplemented with either B. breve or vehicle from postnatal days 1 to 21.

Results: The open-field test at 5 weeks of age (equivalent to human pubertal age) showed that rats in the LBW-vehicle group were marginally hyperactive compared with rats in the sham group, while rats in the LBW-B.breve group were significantly hypoactive compared with rats in the LBW-vehicle group. The gut microbiota in the LBW-vehicle group wasdifferent from that in the sham group, while that in the LBW-B.breve group was not. Anatomical/histological evaluation at 6 weeks of age demonstrated that the brain weight and the cerebral areas on coronal sections were reduced in the LBW groups compared with the sham group. Probiotic supplementation did not ameliorate these morphological brain anomalies in LBW animals. The percentage of Iba-1+ cells in the brain was not different among the LBW-B.breve, LBW-vehicle, and sham groups.

Conclusions: B. breve supplementation during early life is suggested to have the potential to help children with LBW attenuate hypermobility in adolescence, although caution is warranted when extrapolating the data on rodent behaviors to children with neurodevelopmental disorders. High-intensity exercise and low dietary intake significantly alter iron metabolism involving hepcidin

Yukiko Kobayashi[1], Midori Tanizawa[1], Midori Ogata[1], Wataru Aoi[1], Masashi Kuwahata[1]

1.Kyoto Prefectural University (Japan)

Background and Objectives: The amount of food intake and digestive tract function is known to decrease during intense exercise, and many athletes consume high energy but do not consume food. However, there are a few direct studies on the relationship between the degree of malnutrition (mild to severe) and exercise-induced anemia. The purpose of this study was to observe changes in iron metabolism of rats due to high-intensity exercise during reduced food intake.

Methods: Thirty-six, 4-wk-old male Wistar rats were divided into six groups after being acclimated to running: rested control, intense exercise, 80% feeding and rested, 80% feeding and intense exercise, 70% feeding diet and rested, and 70% feeding and intense exercise groups. Only three intense exercise groups underwent acute running sessions for 30 min (30 m/min) once a day for 7 d.

Results: Rats did not develop anemia with exercise and food intake restriction. Serum iron levels, transferrin saturation, hepcidin-25, and hepatic iron levels in the exercise groups were lower than those in the respective resting groups. However, these values in the 70% diet groups were slightly higher than those in the 80% diet groups. Serum erythropoietin levels decreased as food intake decreased, but the serum erythropoietin level in the 70% feeding and intense exercise group was similar to that in the rested control group. Serum interleukin-6 levels were significantly lower in the groups with restricted food intake than in the free-fed group, and exercise had no effect.

Conclusions: High-intensity exercise under restricted food intake may significantly alter the iron metabolism to maintain blood cell levels due to the strong promotion of metabolic iron utilization in response to dietary iron depletion, increased iron demand, and excretion.

Rice bran combined with tea seed oil may modulate the liver steatosis and gut microbiota in neuroinflammatory ovariectomized mice

Wan-Chun Chiu[1], Yu-Wen Chao[1], Suh-Ching Yang[1], Yen-Shuo Chiu[1]

1.Taipei Medical University (Taiwan)

Background and objectives: The oxidative stress and inflammation alter the blood-brain barrier permeability, which induces insulin resistance and interfere with the microbiota distribution, especially in postmenopausal estrogen deficiency condition. Dietary rice bran and tea seed oil were thought to benefit the brain with their multiple effects on anti-oxidation, anti-inflammation, blood glucose homeostasis, and gut microbiota modulation. This study aimed to investigate the influence of rice bran, and tea seed oil on the gut-liver-brain axis in high fructose (HF) drink fed ovariectomized (OVX) mice with D-galactose (D-gal) injection.

Methods: Eight weeks old young female C57BL/6 mice and 6-8 months old female mice were assigned into six groups: sham + young mice (SY), sham + old mice (SO), OVX + soybean oil diet (OS), OVX + soybean oil combined rice bran diet (OSR), OVX + tea seed oil diet (OT) and OVX + tea seed oil combined rice bran diet (OTR). Four OVX groups were given D-gal (100 mg/kg/day) by s.c. and 15% (v/v) fructose drink for 8 weeks. The rice bran and tea seed oil contents were 10% (w/w) in the modified AIN-93M experimental diet. Results The hepatic TG and TC content, the plasma AST and ALT level, and the relative abundance of endotoxin-producing gut f_Tannerellaceae significantly increased in the OT group. The relative abundance of f_Tannerellaceae in the cecum was positively associated with pro-inflammatory cytokines, hepatic lipids, and the plasma AST and ALT. The above results show the correlation of the brain-liver-gut axis. The alteration of gut microbiota and increased fecal butyrate production in the OTR group could lower the hepatic lipids, the plasma AST, ALT, and 8-OHdG level. These might alleviate the neuroinflammation of the brain. Conclusions Rice bran may ameliorate the fatty liver and inflammation through downregulating circulating 8-OHdG and the gut f_Tannerellaceae level in this neuroinflammatory OVX mice model.

Dietary biotin supplementation increases energy expenditure via interscapular brown adipose tissue activation in rats

Masahiro Yuasa[1,2], Tomoe Takashi[2,3], Koji Kawabeta[2,4], Momoe Uemura[2], Kazunori Koba[2], Hiromi Sawamura[5], Toshiaki Watanabe[6]

1.Kobe University (Japan), 2. University of Nagasaki (Japan), 3. Tokushima University (Japan), 4. Nagasaki International University (Japan), 5. Chugoku Gakuen University (Japan), 6. Osaka Aoyama University (Japan)

Background and objectives: Biotin is a water-soluble vitamin functioning as a cofactor for biotin-dependent carboxylases. Our previous study indicated that short-term, high-dose dietary biotin intake increases energy expenditure, fat oxidation, and liver carnitine palmitoyl transferase (CPT) activity in Sprague–Dawley (SD) rats. However, the biotin concentration in the experimental diet was higher than the recommended safe dose, with a short biotin-supplementation period. Therefore, in this study, we evaluated the effect of long-term and safe dosage of dietary biotin supplementation on energy metabolism and its mechanism in rats.

Methods: Five-week-old male SD rats were fed AIN-93G and biotin-supplemented diets of three different concentrations (0.004%, 0.020%, and 0.080% of diet) for 9 weeks. Respiratory gas analysis was conducted at weeks 2, 4, and 8. The rats were sacrificed at 14 weeks of age, and plasma, liver, interscapular brown adipose tissue (iBAT), mesenteric white adipose tissues (mWAT), and gastrocnemius muscle (GM) were collected. Body weight, energy metabolism, biochemical parameters in plasma and liver, CPT activity, gene expression, and biotin concentrations were assessed.

Results: In the 0.080% biotin group, a decrease in body weight and an increase in energy expenditure were identified after week 2. Fat oxidation elevated in the 0.080% biotin group at weeks 2 and 4; however, carbohydrate oxidation remained unchanged. In the 0.080% biotin group, triglyceride levels in the plasma and liver decreased and plasma adiponectin concentration increased. CPT activities in the liver and iBAT were elevated in the 0.080% biotin group, whereas those in mWAT and GM were the same among the dietary groups. In the 0.080% biotin group, gene expressions of Cpt2, acyl-CoA oxidase 1, long-chain acyl-CoA dehydrogenases, peroxisome proliferator-activated receptor-gamma coactivator-1α were increased in iBAT and uncoupling protein 1 gene expression was tended to increase. These gene expressions in the liver were not different between the dietary groups. Biotin concentrations of iBAT increased in the 0.080% biotin group, whereas those in the liver remained unchanged.

Conclusions: These results suggest that long-term and safe dosage of dietary biotin supplementation increases energy expenditure via activation of iBAT. This may be due to a high level of biotin accumulation in iBAT.

Prematurity alters the regulation of insulin signaling to protein synthesis in skeletal muscle

Teresa Davis[1], Agus Suryawan[1], Jane Naberhuis[1], Marta Fiorotto[1], Marko Rudar[2]

1.Baylor College of Medicine (USA), 2. Auburn University (USA)

Background and objectives: Postnatal growth faltering is common after preterm birth and is associated with reduced lean mass accretion. Recently we showed in a preterm piglet model that premature birth impairs normal postnatal weight gain and the protein synthesis response to feeding in skeletal muscle. Because the increase in muscle protein synthesis with feeding in the neonate is driven, in part, by the rise in insulin after a meal, the objective of this study was to identify key regulators in the insulin signaling pathway that are responsible for the blunted anabolic response to feeding in skeletal muscle of the preterm.

Methods: Piglets delivered by Cesarean section 11 d (preterm; equivalent to 32 weeks human gestational age) or 2 d (term) before term birth were fed by total parenteral nutrition. On day 3, after 4 h fasting, piglets were fasted one additional h or fed orally a milk replacer meal (per kg body weight: 31.5 kcal, 1.3 g carbohydrate, 2.7 g amino acids, and 1.6 g lipid). Positive and negative regulators of insulin and translation initiation signaling in longissimus dorsi muscle were determined by Western blot.

Results: Feeding increased the phosphorylation of positive regulators of the insulin signaling pathway, i.e., Akt1, Akt 2, PDK1, and mTORC2, leading to an increase in the phosphorylation of mTORC1 and downstream regulators of translation initiation, i.e., 4EBP1 and S6K1 (P<;0.05) in skeletal muscle of pigs born preterm and at term. However, prematurity blunted the feeding-induced activation of these positive regulators of insulin signaling and translation initiation (P<;0.05). The abundance of inhibitors of insulin signaling, PHLPP and SHIP2 were higher in muscle of preterm than in term (P<;0.05).

Conclusions: These results show that the feeding-induced activation of positive regulators of insulin signaling is reduced by preterm birth, whereas the abundance of negative regulators is enhanced. Our findings suggest that premature birth impairs the activation of insulin signaling that is essential for channeling dietary nutrients for anabolism. This attenuated response likely contributes to the postnatal growth faltering of prematurity.

Effects of Chronic L-α-glycerylphosphorylcholine (α-GPC) Ingestion on Spatial Memory in Adult Male Rats

Atsuhiro Ishii[1], Taichi Hatakeyama[1], Maiko Kawaguchi[1], Takeshi Ohkubo[2]

1.Meiji University (Japan), 2. Sendai Shirayuri Women's College (Japan)

Background and objectives: Chronic α-GPC intake is known as an enhancer of memory. However, the molecular mechanism of this improvement is still unclear. Studies investigating the effect of α-GPC on memory in animal models have focused on juvenile or elderly animals, but not on adults. Thus, the purpose of this study is to determine whether chronic feeding of α-GPC in the diet of healthy adult rats can improve their spatial memory, and to identify the molecular mechanism underlying any α-GPC-induced memory improvement.

Methods: Twenty-four 10-week-old male Wistar-Imamichi rats were divided into two equal-sized groups. One group (SUP) received a special diet containing 1.5 % α-GPC of total diet weight, while the other group (STA) were fed a standard diet. Water and food were available ad libitum throughout the experiment. At 20 weeks of age, all rats underwent a spontaneous place recognition (SPR) test. Each rat was exposed to two identical objects, and then after a retention interval of 24 hours, they were tested with one of the objects moved to a novel location. The SPR test utilizes the tendency of rats to explore novelty, so if the rats remember the original object location, they would tend to explore the novel object's location in the test. After the SPR tests, microarray analysis was conducted on the hippocampal formation taken from all the rats.

Results: In the SPR test, the SUP group showed a preference for the novel object location, but the STA group did not. Microarray analysis showed some differences in gene expression in hippocampal formation between the SUP and STA groups. These results indicate that these genes could be associated with memory ability, supporting the results of previous studies.

Conclusions: We found that chronic α-GPC ingestion improved the spacial memory of rats, and could change a molecular mechanism underlying spatial memory depending on hippocampus.

Development of measurement system for fructose-derived AGE, glucoselysine, in human serum

Hiroko Yamaguchi[1], Hikari Sugawa[1], Mime Nagai[1], Ryoji Nagai[1]

1.Tokai University (Japan)

Background and objectives: Metabolic disorders progress by unbalanced lifestyles such as excessive intake of nutrients and lack of exercise, carbohydrates in our body are nonenzymatically react with proteins to form advanced glycation end products (AGEs). Accumulation of AGEs is increased in normal aging, and enhanced by the unfavorable lifestyle and pathogenesis of diabetes. Thus, the measurement of AGEs is expected as a predictive marker for diabetic complications. When hyperglycemia is prolonged, the glycolysis system becomes saturated then promotes glucose metabolism via the polyol pathway, resulting in the production of fructose. Glucoselysine (GL), one of AGEs, is produced by the reaction of fructose with lysine residues on proteins, resulting in the production of various denatured proteins in our body. However, the measurement system for GL in blood has not been developed yet. The present study aimed to develop a measurement system for GL in serum.

Methods: Human serum was filtered by a molecular-weight 3,000 cut filter to collect free GL and GL-modified peptides, and then acid hydrolysis was performed. The hydrolysate was applied to a cation exchange column and eluant was analyzed by liquid chromatography-tandem mass spectrometry (LC-MS/MS).

Results: the precursor ion of GL was m/z 309, and the fragment ion of m/z 210 was detected in serum samples, indicating that GL is detectable in peripheral blood samples.

Conclusions: It is expected that the change in the involvement of the polyol pathway between healthy subjects and diabetic patients, and the progression of diabetic complications can be evaluated by monitoring GL in the future.

Synergistic effect of exercise training and linoleic acid supplementation on tetra-linoleoyl cardiolipin biogenesis in skeletal muscles

Tomoki Sato[1], Nao Kuwabara[1], Chiho Magome[1], Nanami Senoo[1], Yuki Tamura[2], Yasutomi Kamei[3], Hideo Shindou[4,5], Shimizu Takao[4], Shinji Miura[1]

1.University of Shizuoka (Japan), 2. Nippon Sport Science University (Japan), 3. Kyoto Prefectural University (Japan), 4. National Center for Global Health and Medicine (Japan), 5. The University of Tokyo (Japan)

Background and objectives: Cardiolipin (CL), localized mainly to the mitochondrial inner membrane, is a unique glycerophospholipid with two phosphate headgroups and four acyl chains. Tetra-linoleoyl CL (CL (18:2)4) is the dominant CL species in skeletal muscles. Accumulated evidence suggests that the intercellular fatty acyl environment could affect cardiolipin composition. In particular, the cellular balance of linoleoyl (18:2) and oleoyl (18:1) residues in phospholipids (PL) (18:2-PL/18:1-PL ratio) is of pivotal importance for CL (18:2)4 content. Exercise training is widely known to enhance mitochondrial biogenesis. Interestingly, CL (18:2)4 biosynthesis may be associated with mitochondrial biogenesis; however, the exercise training effect on CL (18:2)4 content and intercellular 18:2-PL/18:1-PL ratio in skeletal muscles remain elusive. In this study, we investigated whether exercise training could increase the CL (18:2)4 content via changing the 18:2-PL/18:1-PL ratio. Moreover, since mammals cannot biosynthesize linoleic acid, dietary intake of linoleic acid may strongly affect the intercellular 18:2-PL/18:1-PL ratio. Therefore, we also verified whether linoleic acid supplementation during exercise training enhanced the beneficial effects of exercise by increasing CL (18:2)4 content.

Methods: C57BL/6J mice, classified into the sedentary (Sed) and exercise training (Tr) groups, were fed with oleic acid-rich (OA) and linoleic acid-rich (LA) diets, respectively. The PL composition and activities of citrate synthase (CS) and mitochondrial respiratory chain in skeletal muscles were measured 2 weeks after exercise training and dietary intervention.

Results: The 18:2-PL/18:1-PL ratio and CL (18:2)4 content in skeletal muscles were 5.4- and 2.5-fold higher, respectively, in the Sed-LA group than those in the Sed-OA group and even higher in the Tr-LA group but not observed in the Tr-OA group. The training-induced increase in CS activity was observed in both Tr-OA and Tr-LA groups. Mitochondrial respiratory chain activity in the Sed-LA group was higher than that in the Sed-OA group and even greater in the Tr-LA group.

Conclusions: This study showed that linoleic acid supplementation with exercise training increased the 18:2-PL/18:1-PL ratio and CL (18:2)4 levels and improved mitochondrial function in the skeletal muscles. Thus, simultaneous linoleic acid supplementation with exercise training was necessary for these effects.

Dietary protein restriction increases plasma soluble leptin receptor levels and suppresses the appetite-reducing effect of administered leptin

Asako Takenaka[1], Mizuki Uchiyama[1], Yu Takei[1], Tamaki Toyama[1]

1.Meiji University (Japan)

Background and objectives: Leptin, a hormone secreted by the adipose tissue, suppresses appetite and regulates body fat mass. We found that the liver leptin receptor (Ob-R) mRNA and plasma soluble Ob-R (sOb-R) levels increased in mice fed a low-protein diet. In this study, we investigated the physiological function of increased plasma sOb-R on leptin action by administering leptin to low-protein diet-fed C57BL/6J and ob/ob mice.

Methods: Four-week-old C57BL/6J mice and 7-week-old ob/ob mice were fed a control diet with 20 % protein or a low-protein diet (with 5 % protein for C57BL/6J mice or 1 % protein for ob/ob mice) for 11 days. On the last four days, 2 mg/kg leptin was intraperitoneally injected into half of the mice in each diet group, and the vehicle was injected into the other half. Five hours after the last injection, the mice were dissected, and blood and organ samples were retrieved.

Results: Hepatic Ob-R mRNA levels were increased, and Ob-R protein levels were decreased by protein restriction in both C57BL/6J and ob/ob mice. Plasma sOb-R concentration was increased by protein restriction in C57BL/6J mice but not in ob/ob mice. The appetite-suppressing effect of leptin was decreased in mice fed a low-protein diet in C57BL/6J mice, but not in ob/ob mice. The mRNA levels of genes involved in appetite regulation were altered in response to leptin administration in both diet groups in ob/ob mice, whereas alterations in the expression of these genes could not be detected in C57BL /6J mice.

Conclusions: Plasma sOb-R levels did not increase in ob/ob mice, which demonstrates that the presence of normal leptin was required to increase plasma sOb-R levels during protein deficiency. The absence of increased sOb-R levels may be responsible for the lack of suppression of leptin action in ob/ob mice, indicating that increased sOb-R levels may suppress leptin action.

Fermentation metabolites of 14C-labelled aromatic amino acid, tyrosine, detected in the brain in a pig model

Margaret Murray[1], Anne Gibbon[1], Lisa Kaminskas[2], Sophie Selby-Pham[1], Gary Williamson[1], Louise Bennett[1]

1.Monash University, Clayton, Victoria, 3800 (Australia), 2. The University of Queensland, St. Lucia, QLD 4072 (Australia)

Background and objective: Mood disorders (depression and anxiety) are debilitating and represent a major public health concern. There is growing understanding that diet and gut microbiota influence brain function. Processed foods undergo processing techniques that can cause proteins to become resistant to normal digestion. Enzymatic resistance and transport of resistant protein to the colon promotes its fermentation by gut microbes and may produce neuroactive metabolites that can access the brain and alter mood. This study examined biodistribution of metabolites of the aromatic amino acid and neurotransmitter precursor, tyrosine, following colonic microbial fermentation. The tyrosine was delivered to the colon as a model of tyrosine released from dietary resistant protein by the fermentative hydrolytic processes of a resistant protein-primed microbiota.

Methods: A proven model of human digestion and metabolism, weanling pigs were fed a high resistant protein diet for four weeks to prime their gut microbiota towards protein fermentation. One pig was administered radiolabelled tyrosine in two acid-resistant capsules (each containing 0.1 mg [14C(U)]-L-tyrosine, with 10 MBq radioactivity, 84 mg citric acid, 50 mg methocel), to deliver the tyrosine to the colon. Three pigs were administered similar capsules with unlabelled tyrosine. Blood, urine, faeces, intestinal contents and organ samples were collected three days after capsule administration. Biodistribution of tyrosine metabolites across tissues was measured by liquid scintillation counting. Analyses of metabolites present in non-radiolabelled samples are not reported here.

Results: Approximately 49% of the radioactivity was excreted in urine and faeces. Of the original dose, 7% was recovered in the organs (stomach, small intestine, colon, liver, pancreas, kidney, spleen, heart, lungs and brain). The highest quantity of radioactivity was detected in the small intestine (3.1%) and liver (2.2%), and highest concentration in the liver (0.008 % dose/g) and pancreas (0.007 % dose/g). Radioactivity of 0.008 % dose/g was detected in the colon digesta. 0.14% of the radioactivity was detected in the brain, with the greatest concentration detected in the cerebellum (0.003 % dose/g).

Conclusion: In a pig model, metabolites of tyrosine, fermented by a resistant protein-primed gut microbiota, are able to enter the brain where they could potentially have neuroactive effects.

Effects of protein deficiency and sex-dependent variations on VLDL receptor expression

Jiuxiang Cao[1], Takashi Morisaki[1], Ryota Sato[1], Yuki Yokobori[1], Asako Takenaka[1]

1.Meiji University (Japan)

Background and objectives: We have previously demonstrated that the expression levels of the liver VLDL receptor (VLDLR) increases during protein deficiency. In this study, using Vldlr knockout mice, we investigated the relationship between increased Vldlr gene expression and the physiological function of VLDLR in hepatic lipid accumulation during protein deficiency. In this experiment, the hepatic Vldlr gene expression varied with sex. Thus, we also analyzed sex-dependent variations in Vldlr expression in male and female gonad-depleted rats.

Methods: The association between increased hepatic Vldlr expression and liver fat accumulation due to protein deficiency was investigated using four-week-old male and female Vldlr-knockout mice (KO) and their wild-type littermates (WT). All the mice were fed either a control diet with 20 % protein or a low-protein diet with 2 % protein for 21 days. Sex-dependent variations in liver Vldlr expression were analyzed using male and female Wistar rats that underwent gonad removal surgery. The mRNA and protein expression levels of VLDLR, amount of liver triglyceride (TG), mRNA levels involved in lipid synthesis and degradation, and the mRNA level of Asns, the target gene of the transcription factor ATF4 which controls VLDLR expression, were measured.

Results: In the WT mice, the liver Vldlr mRNA levels increased under protein deficiency in males, but not in females. Increase in liver fat due to protein deficiency was observed in both male and female WT and KO mice, indicating that lipid uptake by VLDLR is not the main cause of hepatic lipid accumulation. Increased gene expression involved in fatty acid synthesis was observed in the protein-deficient groups, indicating its contribution to the increase in liver fat. VLDLR expression was higher in females than that in males; however, this sex-dependent variation was inconsistent with ATF4 activity. Ovariectomy increased VLDLR expression with ATF4 activation, whereas orchiectomy increased VLDLR expression without ATF4 activation.

Conclusion: Hepatic Vldlr expression and TG content increased with protein deficiency. However, increased VLDLR was not the cause of hepatic fat accumulation. Furthermore, testis-derived hormones may be responsible for the sex-dependent variation in Vldlr expression that females are higher than males.

Vitamin D deficiency and insufficiency leads to cardiac atrophy in a rat model.

Athira A S[1], Ayesha Ismail[1]

1.Indian Council of Medical Research - National Institute of Nutrition, Hyderabad, Telangana (India)

Background & Objective: Vitamin D receptor and the enzymatic machinery to synthesize the active hormonal form of vitamin D are present in extra-skeletal tissues, heart being one such tissue. Vitamin D deficiency is leads to cardiac hypertrophy both in animals and humans. In the present study, using a rat model we examined if vitamin D deficiency or insufficiency altered proteolytic systems in the heart leading to cardiac atrophy.

Methods: A vitamin D deficient or insufficient rat model was employed for the study. Serum parameters were estimated using standard methods or commercial kits. Electro cardiography was recorded using three lead ECG. Total protein degradation (TPD) was measured by release of tyrosine in the media, while total protein synthesis (TPS) was measured by 14C-tyrosine taken up by atria. Proteasomal enzymes, calpain and cathepsin activities were measured using specific fluorogenic substrates. Gene expression was done by qPCR, and protein expression was assessed by western blotting. Histological analysis was performed on heart sections using H&E and Masson trichrome stains.

Results: The heart weight/tibia length ratio was significantly decreased in the vitamin D deficient [VDD] group compared to the other two groups. Serum levels of 25OHD3 which reflect Vitamin D status were significantly decreased in both the VDD & low vitamin D [LVD] groups compared to the normal vitamin D [NVD] group. The ECG data demonstrated that the heart rate was significantly higher in the VDD group, indicative of 'Arrythmia'. The TPD was increased, while the TPS was decreased in the atria of the VDD rats. Catalytic activities of the 26S proteasome, calpain and cathepsin were elevated in the VDD heart compared to controls. Expression of atrophy markers, proteasome subunit genes and autophagy markers were increased in the heart of the VDD group compared to control group. Histological analysis of the heart showed disarray of fibres and interstitial fibrosis in the VDD group.

Conclusion: Our data reveals that chronic vitamin D deficiency leads to cardiac atrophy.

Histidine enhances memory formation and retrieval in mice.

Tamau Kawashima[1], Nene Kabayama[2], Yuki Odagiri[2], Toshiyuki Tanimizu[1,2], Rie Ishikawa[1], Satoshi Kida[1,2]

1.Univ. of Tokyo (Japan), 2. Tokyo Univ. of Agriculture (Japan)

Background and objectives: Histidine (His), one of the essential amino acids, is metabolized to neurotransmitter histamine, in the brain. Histamine controls arousal, feeding, and cognitive functions via three types of histamine receptors (H1, H2, and H3). Learning and memory consist of multiple processes including encoding, formation of short-term memory (STM) and long-term memory (LTM), retrieval, reconsolidation and extinction. However, the roles of histidine in each memory process still remains unknown. In this study, we elucidate the effects of histidine administration on memory formation and retrieval in mice.

Methods: In social recognition memory task, adult mice(C57BL/6) were exposed to juvenile mice for 1.5 min every 24 hours (day1: training, day2: test). Mice were assessed social recognition memory by measuring and comparing duration of social investigation behaviors during training and test. Mice received systemic injection or oral administration of histidine with or without antagonists for histamine receptors before training or test.

Results: Systemic injection of His 2 or 6 hours rather than 30 min,12, or 24 hours prior to training improved social recognition memory; mice injected His, but not vehicle, showed significant reduction of social investigate time during test compared to training. These observations suggested that His enhances memory formation. Similar memory enhancing effects of His were observed when mice received a low dose or oral administration of His. Interestingly, systemic injection of His before test improved retrieval of social recognition memory. Co-systemic injection of His with H2 or H1 antagonist blocked improvement of memory formation and retrieval by His, respectively.

Conclusion: We showed that His promotes formation and retrieval of social recognition memory. Our observations suggest that His functions as a memory enhancer that improves memory performance.

Amino acid metabolites enzyme in mouse milk plays an essential role in forming gut microbiota and brain gene expression during infancy.

Jun Kambe[1], Kento Usuda[1], Masahiko Ito[2], Kazuhiko Hirayama[3], Ryo Inoue[4], Gen Watanabe[1], Kentaro Nagaoka[1]

1.Tokyo University of Agriculture and Technology (Japan), 2. Hamamatsu University School of Medicine, (Japan), 3. The University of Tokyo (Japan), 4. Setsunan University (Japan)

Background and objectives: In a mammalian infant, milk components such as amino acids (AAs) are essential for gut microbiota formation. In addition, the brain is dramatically developed during infancy. Thus, it has been considered that there might be a relationship between milk AAs, gut microbiota formation, and brain development. However, there were no useful animal models to clarify this relationship. An amino acid metabolites enzyme, L-amino acid oxidase 1 (LAO1), is secreted in breast milk and catalyzes several AAs. We previously reported that milk LAO1 affects the pup's gut microbiota formation in mice. Here, this study aims to investigate the impact of milk LAO1 on brain gene expression and ascertain the association of the gut microbiota with the brain gene expression using LAO1 KO mice. Methods and

Results: Focusing on the function of LAO1 in the milk of maternal origin, we performed foster mother exchange on the day of birth using the pup's genotype LAO1 KO and mother WT or LAO1 KO. Microarray analysis revealed that myelin-related genes, Plp1 and Mbp, decreased in the pups drinking LAO1 KO milk. Metabolomics analysis identified the difference in several AAs metabolite levels between WT and LAO1 KO milk. To define the importance of gut microbiota differences on the change of the myelin-related genes expression, fecal microbiota transplantation (FMT) was conducted using germ-free (GF) mice. In GF mice inoculated with feces from the pups drinking LAO1 KO milk, Plp1 expression was also decreased. Metagenomics analysis for gut microbiota composition showed still apparent differences after FMT. Moreover, feces and serum from GF mice were analyzed by metabolomics to explore a critical molecule that connected gut microbiota and brain gene expression. In GF mice inoculated with feces from the pups drinking WT milk, several metabolites levels, for example, 3-Hydroxybutyric acid, were commonly increased in feces and serum.

Conclusions: These data indicate that milk LAO1 contributes to the development of the myelin in the hippocampus through gut microbiota control. Further analysis is required to evaluate whether metabolites, including 3-Hydroxybutyric acid, produced by the gut microbiota could influence the brain gene expression during mouse infancy.

Dietary phosphate reduces skeletal muscle mass in mice

Naoko Oda[1], Mami Fujibayashi[1]

1.Setsunan University (Japan)

Background and objectives: In recent years, the use of prepared foods and processed foods has increased in Japan. These foods contain large amounts of phosphate compounds. Excessive phosphorus intake has been shown to reduce kidney function, increase parathyroid function, inhibit calcium absorption, however, its effects on skeletal muscle have not been fully elucidated. Therefore, in the present study, we investigated the effects of excessive phosphorus intake on skeletal muscle mass in mice.

Methods: Fourteen five-week-old male C57BL/6J mice were included in the study, of which seven mice were fed a control diet (0.4% phosphate; CP) and the other seven mice were fed a high phosphate diet (1.2% phosphate; HP) for eight weeks. Their body masses were measured before and after the intervention, and the gastrocnemius muscle, soleus muscle, tibia anterior muscle and extensor digitorum longus muscle were measured after the intervention.

Results: The HP group showed lesser weight gain after 8 weeks of administration of the test diet as compared to the CP group. In addition, skeletal muscle measurements after the intervention showed that the gastrocnemius mass (0.29±0.02 vs. 0.32±0.02‚ p=0.03) and tibialis anterior muscle mass (0.10±0.01 vs. 0.12±0.02‚ p<;0.01) were significantly lower in the HP group as compared to those in the CP group.

Conclusions: The present study revealed that long-term excess phosphorus intake significantly suppressed the development of gastrocnemius and tibialis anterior muscle masses. Although we could not clarify the mechanism of skeletal muscle mass loss due to excessive phosphorus intake from this study, it was suggested that the long-term overconsumption of prepared foods and processed foods may lead to skeletal muscle loss.

Absorption and metabolism of glycerophosphocholine and lecithin

Shiho Inui[1], Ryoko Nakashima[1], Tatsuya Kawaguchi[1], Noriyasu Ohshima[2], Takuya Suzuki[1], Yoshiko Nakagawa[3], Tetsushi Sakuma[1], Takashi Yamamoto[1], Thanutchaporn Kumrungsee[1], Noriyuki Yanaka[1]

1.Hiroshima University (Japan), 2. Gunma University (Japan), 3. Kumamoto University (Japan)

Background and objectives: Choline is an essential nutrient for normal cellular functions such as cell-membrane phospholipid signalings, acetylcholine synthesis, and methyl-group metabolism. Phosphatidylcholine (PC), the main component of lecithin, is an important food factor as a source of choline, whereas alpha-glycerophosphocholine (GPC), a deacylated form of phosphatidylcholine, has been currently expected as a useful choline supplement. On the other hands, choline-containing compounds are reportedly metabolized by the intestinal microflora to trimethylamine (TMA) and subsequently converted to trimethylamine N-oxide (TMAO) in liver, which is associated with the development of various diseases such as cardiovascular disease. In this study, we focused on dietary GPC and tried to elucidate how GPC is absorbed in the digestive tract and metabolized in vivo. Results &

Conclusions: We conducted long-term feeding and oral administration of choline and GPC to show the differences in absorption and metabolism with TMAO production level. Higher TMAO level was observed with in high-dose GPC supplementation than that of choline. In contrast, in the case of low-dose GPC supplementation, TMAO level was similar to those with other choline supplements. Next, we analyzed the absorption of GPC via a transwell system using human colonic epithelial Caco-2 cells. This study showed that GPC supplementation in apical medium increased choline level in both apical and basolateral medium and suggested that GPC is metabolized to choline in Caco-2 cells and in apical medium. GDE5 was previously identified to be an intracellular enzyme that selectively hydrolyzes GPC to choline and to be highly expressed in mouse intestine and Caco-2 cells, suggesting a possible role for GPC metabolism in intestinal epithelial cells. Because intestinal epithelial cells-specific GDE5-deficient mouse (GDE5 KO mouse) was recently generated and, in this study, in order to elucidate the mechanism of GPC absorption and metabolism, we will examine if GDE5 deficiency can affect absorption and metabolism of dietary GPC and further investigate the functional involvement of GDE5 in the metabolism of PC, the main component of lecithin, in the intestinal tract.

Aromatic amine production in human gut bacteria: the role of aromatic amino acid decarboxylase in serotonin production

Yuta Sugiyama[1], Emiko Nagai[2], Akira Nakagawa[2], Hiromichi Minami[2], Mikiyasu Sakanaka[2], Noriho Iida[3], Takashi Koyanagi[2], Takane Katayama[4], Shigefumi Okamoto[3], Shin Kurihara[5]

1.Gunma University (Japan), 2. Ishikawa Prefectural University (Japan), 3. Kanazawa University (Japan), 4. Kyoto University (Japan), 5. Kindai University (Japan)

Background and objectives: It has been reported recently that gut bacteria can serve as a source of aromatic amines in the colon. The kinetic parameters of aromatic amino acid decarboxylase (AADC), which catalyzes the decarboxylation of aromatic amino acids to produce aromatic amines, have been characterized in some gut bacteria. However, most previous studies on aromatic amine production in gut bacteria focused on non-proteinogenic aromatic amino acids, and limited studies have addressed the production of aromatic amines from proteinogenic amino acids. Furthermore, the physiological activities of aromatic amines in the colon remain unclear. The purpose of this study is to elucidate the mechanism of aromatic amine production by gut bacteria from proteinogenic aromatic amino acids and to clarify the physiological effects of gut bacterial aromatic amines, especially phenylethylamine, on the host.

Methods: Aromatic amine-producing gut bacteria were cultured in a medium containing L-phenylalanine, L-tyrosine, and L-tryptophan (1 mM each), and then the aromatic amines in the culture supernatant were quantified. The aromatic amines in the culture supernatant of Escherichia coli transformants expressing aadc or its homologs from aromatic amine-producing gut bacteria were also quantified to compare their aromatic amine productivities. The correlation between phenylethylamine production and aadc amounts in human feces was analyzed after culturing the human feces with L-phenylalanine. To examine the effect of gut bacterial phenylethylamine on the host, Enterococcus faecalis wild-type, aadc-deleted, and aadc-complemented strains were colonized in mice, and colonic serotonin level was measured.

Results: We identified five aromatic amine-producing gut bacteria, and aromatic amine productivity varied among the gut bacterial species. Aromatic amine production was observed in E. coli heterologously expressing aadc or its homologs. Fecal culture experiments showed a significant positive correlation between the abundances of phenylethylamine and aadc of Ruminococcus gnavus. Colonic serotonin level of mice colonized with En. faecalis aadc-complemented strain was higher than that of mice colonized with wild-type or aadc-deleted strains.

Conclusions: We identified five aromatic amine-producing gut bacteria and showed that aadc is indispensable for aromatic amine production. Mouse experiments showed that gut bacterial AADC and its reaction product phenylethylamine participate in the colonic serotonin production in the host.

Enhancing zinc absorption via a zinc transporter–targeting strategy

Ayako Hashimoto[1], Taiho Kambe[2]

1. Kyoto Women's University (Japan), 2. Kyoto University (Japan)

Background and objectives: Zinc is an essential trace element that functions as a structural, catalytic, and signaling component. So, dietary zinc deficiency puts human health at risk. Zinc deficiency is a serious nutritional problem in developing countries, and in recent years, a marginal zinc deficiency has become a nutritional concern in developed countries. The dietary zinc absorption rate is as low as nearly 30%. Therefore, to prevent zinc deficiency, increased efficiency of zinc absorption in the gastrointestinal tract is warranted. ZIP4 and ZNT1 are zinc transporters that function to absorb dietary zinc in the intestinal tract. ZIP4, located on the apical membrane on the luminal side, is an essential component to take dietary zinc ions up into enterocytes, and ZNT1, located on the basolateral membrane, transports the zinc ions to the blood. In this study, we searched for food-derived components increasing ZIP4 or ZNT1 expression, and subsequently increasing zinc absorption.

Methods: We established a system to screen factors promoting ZIP4 and ZNT1 expression using mouse Hepa and human Caco2 cells, and searched for factors that increased their expression. Food extracts from nuts, grains and spices were prepared using various solvents and adding them to the culture medium of cultured Hepa or CaCo2 cells at final concentrations of 0.1–0.5%. After 24 h culture, the expression level of ZIP4 and ZNT1 was detected by western blotting.

Results: We have identified a number of food extracts from nuts and spices that increased ZIP4 or ZNT1 expression levels. Some extracts additionally contributed to the suppression of ZIP4 degradation and then increased the abundance. Furthermore, these extracts increased the cellular zinc level. In-depth analyses of food extracts that increase ZNT1 expression are necessary in future studies.

Conclusions: Our results suggest that a zinc transporter–targeting strategy may be an effective strategy to improve zinc absorption and thereby prevent zinc deficiency.

Effect of elemental diets on intestinal permeability and immunoglobulin production in indomethacin-induced intestinal injury rats.

Yuko Kikuchi[1], Madoka Kumai[1], Ayako Tanimura[2], Hisanori Minami[3]

1.Nagasaki International University (Japan), 2. Prefectural University of Kumamoto (Japan), 3. Kobe Gakuin University (Japan)

Background and objectives: Crohn's disease (CD) is an inflammatory bowel disease of unknown etiology. Immunological dysfunction and increased intestinal permeability are one of important factor of pathogenesis in CD. Administration of indomethacin (Indo) to rats induces intestinal ulcers similar to those seen in CD patients. Elemental diet (ED) is commonly used as a nutritional therapy for CD in Japan. Despite many hypotheses have been proposed to explain the beneficial effects of ED in CD patients, the mechanisms underlying the effects of ED remain unknown. In this study, to clarify the mechanisms of ED on protection of CD, we evaluated the changes in intestinal permeability of food allergens, expression of tight junction protein and immunoglobulin production in Indo-treated rats.

Methods: Male Sprague-Dawley rats were maintained on standard laboratory chow diet (standard chow group) or commercially available elemental diet (ED group) for 2 weeks. To evoke intestinal damage, Indo was injected subcutaneously (9 mg/kg body weight) once daily for two consecutive days. Two days after the first injection, rats were fasted overnight and the suspension of dried egg white (EW; 0.2 g / 100 g body weight) was administered intragastrically. At 60 min after administration, blood samples were obtained and ovalbumin (OVA) concentrations in plasma were determined by ELISA. Expression of TJ proteins in intestinal mucosa were assessed by quantitative real time PCR. Lymphocytes, isolated from mesenteric lymph nodes (MLN) and spleens, were cultured and concentrations of immunoglobulins in the cultured media were analyzed by ELISA. Result: In standard chow group, the administration of Indo induced mucosal lesions and increased in the intestinal permeability of OVA. Expression of claudin-2 increased and that of claudin-4 reduced. Furthermore, the production of IgA and IgG by MLN and spleen lymphocytes in Indo-treated rats were higher than those in non-treated rats. In contrast to standard chow group, none of Indo-induced changes were observed in the rats ED group.

Conclusion: These findings suggest that the mucosal lesion induced by Indo were due to increased mucosal permeability and changes in mucosal tight-junction proteins. ED may contribute to protect intestinal injury by modulating intestinal permeability.

LPGAT1/LPLAT7-mediated regulation of acyl chain profiles in muscle phospholipids affects endurance capacity in mice

Shinji Miura[1], Tomoki Sato[1], Noriyuki Miyoshi[1], Yuki Sugiura[2], Naoko Goto-Inoue[3], Hiroki Kawana[4,5], Hideo Shindou[4,6], Yasutomi Kamei[7], Takao Shimizu[6], Junken Aoki[4,5]

Advanced Research & Development Programs for Medical Innovation (Japan), 6. National Center for Global Health and Medicine (Japan), 7. Kyoto Prefectural University (Japan)

Background and objectives: Skeletal muscle consists of both fast- and slow-twitch fibers. Phospholipids are essential structural components of cellular membranes; and the diversity of their fatty acid compositions affects membrane fluidity and permeability. Although some studies have shown that acyl chain species in phospholipids differ among various muscle fiber types, the mechanisms and physiological roles underlying these differences are unclear. Therefore, in this study, we analyzed the phospholipid profiles, and the mechanism and physiological role of regulating the muscle fiber type-specific acyl chain profiles of phospholipids.

Methods: The differences in the acyl chain profiles of phospholipids, such as phosphatidylcholine (PC) and phosphatidylethanolamine (PE), in the murine extensor digitorum longus (EDL; fast-twitch) and soleus (slow-twitch) muscles were analyzed using liquid chromatography-mass spectrometry (LC/MS) and imaging MS. In order to reveal the mechanisms and physiological roles of controlling fatty acid species binding to PC and PE, PC and PE molecular species and endurance capacity were analyzed in genetically modified mice models.

Results: In the EDL muscle, the vast majority (93.6%) of PC molecules contained palmitate (16:0-PC), while in the soleus muscle, in addition to 16:0-PC, 27.9% of PC molecules contained stearate (18:0-PC). Most of the palmitate and stearate were bound at the sn-1 position of 16:0- and 18:0-PC, respectively, and 18:0-PC was found in type I and IIa fibers. The amount of 18:0-PE was also higher in the soleus than in the EDL muscle. Peroxisome proliferator-activated receptor γ coactivator-1α (PGC-1α) induces changes in the muscles' PC profile. Lysophosphatidylglycerol acyltransferase 1 (LPGAT1) was highly expressed in the soleus compared to the EDL muscle, and was upregulated by PGC-1α. LPGAT1 knockout decreased the amount of 18:0-PC and 18:0-PE in murine skeletal muscle, which explains the LPGAT1-mediated regulation of myofiber type-specific acyl chain profiles of PC and PE. Moreover, loss of muscular LPGAT1 expression affected endurance capacity.

Conclusions: In this study, we clarified some of the control mechanisms of myofiber type-specific acyl chain profiles of phospholipids and showed that regulating the acyl chain profiles of phospholipids by LPGAT1 in skeletal muscle had physiological significance in skeletal muscle function. PAB(T1)-90

Regulatory expression of interleukin-6 in brown adipocytes

Xiajie Fu[1], Osamu Hashimoto[2,3], Tohru Matsui[1], Masayuki Funaba[1]

1.Kyoto University (Japan), 2. Nihon University (Japan), 3. Nagahama Institute of Bio-Science and Technology (Japan)

Background and objectives: There are three kinds of adipocytes, white, brown and beige. White adipocytes accumulate excess energy as fat, whereas brown/beige adipocytes expediate energy as heat. In addition to the role as a regulator of energy balance, white adipocytes secrete various bioactive molecules named as adipokines. In contrast to white adipocyte-derived adipokines, less information is available on adipokines from brown/beige adipocytes. The present study explored adipokine production in cultured brown adipocytes.

Methods: HB2 brown preadipocytes, RAW264.7 macrophages, and C2C12 myoblasts were used. HB2 cells were differentiated into brown adipocytes by culture in the presence of insulin, and C2C12 myotubes were induced by culture under the reduced serum. During differentiation of brown preadipocytes and myoblasts, cells were treated with forskolin (an activator of protein kinase A (PKA) pathway), lipopolysaccharide (LPS, an inducer of interleukin (IL)-6 in macrophages), ascorbic acid 2-phosphate (AsAp, a vitamin C), and U0126 (an MEK1/2 inhibitor). Macrophages were treated with forskolin and LPS one day after cell plating. Adipokine expression was evaluated by RT-qPCR analysis.

Results: Short-term treatment with forskolin induced expression of IL-6 in HB2 brown adipocytes. AsAp treatment during the differentiation also increased IL-6 expression. U0126 inhibited AsAp-induced but not forskolin-induced IL-6 expression. IL-6 has proinflammatory effects as well as anti-inflammatory effects depending on cell context. Forskolin did not affect expression of tumor necrosis factor-α and IL-1β, proinflammatory cytokines, whereas it increased mRNA levels of an anti-inflammatory cytokine fibroblast growth factor 21 in brown adipocytes. LPS expectedly increased IL-6 expression in RAW264.7 macrophages, but forskolin did not affect IL-6 expression irrespective of presence of LPS. IL-6 is also known as a myokine that is secreted from muscular cells. Forskolin but not AsAp increased IL-6 expression in C2C12 myotubes.

Conclusions: 1. Activation of the PKA pathway induces some anti-inflammatory cytokines in brown adipocytes. 2. Mechanism underlying PKA-induced IL-6 expression is different from IL-6 induction by vitamin C, in which extracellular signal-regulated kinase pathway is involved. 3. Role of PKA and vitamin C in IL-6 induction is cell type-dependent. Thus, the present study uncovers regulatory expression of IL-6 as an adipokine in brown adipocytes.

Keywords: interleukin-6, brown adipocyte, macrophage, muscular cell.

Growth retardation induced by protein and indispensable amino acid deficiencies cannot be catch up by a supplementation in growing rats.

Gaetan Roisne-Hamelin[1], Catherine Chaumontet[1], Juliane Calvez[1], Claire Gaudichon[1], Daniel Tome[1], Dalila Azzout-Marniche[1]

1.Universite Paris-Saclay, AgroParisTech, INRAE, UMR 914 PNCA, 75005, Paris, France (France)

Background & Objectives: In developing countries, children are exposed to a growth retardation risk due to their low protein (LP) intake or poor quality of protein sources. However, the specificity of each indispensable amino acid (IAA) and the ability of children to catch-up their growth retardation remains unclear. The aim of this study was to assess the supplementation efficiency following a protein or IAA (lysine, threonine, and methionine) deficiencies in growing rats, and to identify the specific IAA deficiency effect.

Methods: Sixty growing rats were fed by a control (20% of proteins; P20), a LP (5% of proteins; LP) or IAA deficient (25% of the rat's requirement in lysine, threonine, or methionine; L25, T25 and M25) diets for 3w. Thereafter, all rats were supplemented by the control (P20) or a control-equivalent diet containing free AA. Body weight (BW) and food intake were daily recorded. Naso-anal length (NAL), bone mineral density (BMD) and body composition were measured at the end of each period.

Results: During the deficiency, IAA as LP diets reduced BW gain from day 2 for LP, L25 and M25 and from day 1 for T25. The BW was reduced by 30% for L25 and M25, 50% for LP and 60% for T25. The NAL was also reduced by 9, 18, 25% for L25 /M25, LP and T25. At the end of the deficiency, all groups had less lean body mass (LBM), whereas only LP and T25 had a decreased BMD. During the supplementation, growth resumes and the weight's gap between each group was reduced, but remains after supplementation. The BW were reduced by 15, 25 and 35% for L25/M25, LP and T25, respectively. For NAL and LBM, the gap slightly reduced too, but the difference remains after the supplementation. Indeed, the NAL was reduced by 5% for L25 and M25, 8% for LP and 10% for T25. All groups had reduced kidney, muscle and carcass weight, and LP and T25 had a reduced liver weight and BMD.

Conclusions: A single IAA deficiency as LP induced growth retardation, and the LBM is highly affected. A supplementation allows growth resume, but the growth retardation cannot be catch up.

The association of adipose triglyceride lipase and hormone-sensitive lipase gene expression in subcutaneous and visceral adipose tissue with habitual dietary carbohydrate intake

Emad Yuzbashian Yuzbashian[1,3], Maryam Zarkesh[2], Golaleh Asghari[1], Mehdi Hedayati[2], Parvin Mirmiran[1], Catherine Chan[3,4]

1.Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran (Iran), 2. Cellular and Molecular Endocrine Research Center (CMERC), Research Institute for Endocrine Sciences of Shahid Beheshti University of Medical Sciences (Iran), 3. Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada (Canada), 4. Department of Physiology, University of Alberta, Edmonton, Alberta, Canada. (Canada)

Background and objectives: Little is known about how habitual dietary carbohydrate quality and quantity regulate adipose tissue lipolysis and whether such regulation is altered by body weight status. Hormone-sensitive lipase (HSL) and adipose triglyceride lipase (ATGL) play important roles in the mobilization of stored lipid in adipose tissue and have been implicated in various metabolic disorders. Thus, this study aimed to determine if carbohydrate quality and quantity were linked to ATGL and HSL gene expression in subcutaneous (SAT) and visceral fat (VAT) in adults.

Methods: This is a cross-sectional study that recruited 179 patients aged 19-75 years who were candidates for elective abdominal surgery. During the surgery, SAT and VAT were collected to measure ATGL and HSL mRNA expression via Real-Time PCR. Food intake was assessed using a reliable and validated semi-quantitative FFQ to estimate the habitual dietary intake of total carbohydrate, glycemic index (GI), and glycemic load (GL) as measures of carbohydrate quality. The residual method was used for all dietary exposures to control for the effect of energy intake. Multivariable regression models were used to estimate standardized (STZ) β showing the associations of ATGL and HSL with carbohydrates after adjusting for body mass index (BMI), sex, age, total energy intake, and HOMA-IR.

Results: In VAT, ATGL mRNA showed a negative association for total carbohydrate intake (STZβ=-0.655, P<;0.001) and GI (STZβ=-0.417, P<;0.001). However, in SAT, ATGL associated inversely only with total carbohydrate intake (STZ=-0.302, P=0.02). Gene expression of HSL in VAT was strongly negatively associated with GI (STZβ=-0.769, P<;0.001). Marginally significant interactions with BMI categories were found. Stratified analyses across the BMI groups (non-obese (29.9 <;BMI<;30) and obese (BMI>;31 kg/m2)) revealed substantially different patterns. In the obese group, the associations were stronger for ATGL and HSL gene expression, meaning the expression of these two lipolytic enzyme genes depended on BMI status. There was no significant association of GL with ATGL and HSL.

Conclusions: Dietary carbohydrate quantity, rather than quality, is more likely to modulate ATGL and HSL gene expression from VAT and SAT.

Rottlerin decline lipid accumulation by inhibiting adipogenesis and de novo lipogenesis via LRP6 degradation and mTOR signaling pathway in 3T3-L1 adipocytes

Ye Jin Kim[1], Gwang-Woong Go[1]

1.Hanyang university (Korea)

Background and objectives: Rottlerin is a PKCδ inhibitor, a natural polyphenol compound from Mallotus japonicus. Rottlerin is known as anti-allergic, antioxidant, and anti-cancer. However, the anti-obesity activity of rottlerin has not been demonstrated. We hypothesized that rottlerin decreases adipogenesis and de novo lipogenesis via LRP6 and mTOR signaling pathways.

Methods: 3T3-L1 preadipocytes were treated with rottlerin at each concentration for 24 h. 3T3-L1 cells were cultured in 6-well-plates with a differentiation medium and treated with rottlerin at each concentration to confirm the lipid accumulation phenotype by Oil Red O staining. Also, our study measured the anti-obesity activity of rottlerin through RT-PCR and western blot.

Results: As a result, cell cytotoxicity was confirmed to be stabilized at 4 µM of rottlerin by LDH assay. At a concentration of 8 µM, the cytotoxicity was about 10% (p<;0.05). Lipid accumulation is reduced in a dose-dependent manner (p<;0.001). C/EBPα and PPARγ, representative adipogenesis markers, were decreased by rottlerin in mRNA expression and protein levels (p<;0.05). The mRNA expression and protein levels of SREBP1, FAS, and SCD1, representative de novo lipogenesis markers, were significantly reduced by rottlerin (p<;0.001). Furthermore, rottlerin induced total LRP6 degradation (p<;0.001) and diminished phosphorylation of mTOR, AKT, S6K, and S6 (p<;0.05).

Conclusions: These results suggest that rottlerin regulates adipogenesis and de novo lipogenesis via LRP6 degradation and mTOR signaling in adipocytes. Taken together, rottlerin is a potential nutraceutical compound that supports treating obesity and fatty liver.

Generation and characterization of chemosensory cells from digestive tract-derived primate organoids

Ken Iwatsuki[1], Kosuke Sakaguchi[1], Ayane Arinaga[1], Koji Sato[2], Akihiko Inaba[3], Hiroo Imai[3], Takumi Yamane[1], Yuichi Oishi[1]

1. Tokyo University of Agriculture (Japan), 2. The University of Tokyo (Japan), 3. Kyoto University (Japan)

Background and objectives: It is evident that consuming food contributes and provides energy to us. However, at the same time we are facing a risk of intaking unwanted compounds that come along with the food we consume. As there isn't an appropriate in vitro cell model available that allows us to study both nutrition and hazardous chemicals on primate cells, we aimed to generate organoid cell cultures from taste tissues, intestines and pancreatic ducts.

Methods: To generate in vitro cultures, we introduced organoid culture methods to selectively maintain stem cells in the tongue, small intestine and pancreas. Organoids were generated by embedding stem cells in the Matrigel followed by Wnt3a, R-Spondin, Noggin, IGF-1 and FGF-2 supplementation in DMEM/F12 medium. Attempts were made to induce cell differentiation of the organoids we generated by changing cell culture condition. After cell differentiation, chemosensory functions were investigated using these organoids.

Results: We succeeded in generating organoid cultures from three different tissues. By RNA-Seq analysis and immunostaining, each organoid culture represented characteristic of their origin. We further confirmed that cells in the organoid could be induced to become mature cells that express chemosensory machinery such as taste receptors and their downstream molecules. Differentiated organoid were able to respond to nutrients and bitter compounds indicating that there are at least two different chemosensory cells existing within the gustatory tissue we investigated.

Conclusions: By generating primate organoids from taste tissues, the small intestine and pancreas, we are now able to utilize these cells to study the mechanisms of how these cells respond to nutrients or noxious compounds. We concluded that this newly developed organoid culture system is a suitable system to analyze the chemosensory function(s) of the gut in vitro.

Zinc deficient diet feeding induce drastic and irreversible olfactory disorder in mice.

Kazumi Osada[1], Akira Hosono[1], Motoko Ohata[1], Michio Komai[2]

1.Nihon University (Japan), 2. Tohoku University (Japan)

Background and Objectives: Previous studies indicated that Zinc (Zn) deficiency-induced taste disorder, but the consequence to the olfactory function remains elusive. Here we show that the administration of Zn-deficiency diet feeding induces acute and critical olfactory deficits detected in the odor training mice. To assess the physiological effects of zinc deficiency diet feeding, serum zinc level and mRNA expression of zinc transporters in the brain and small intestine were quantified.

Method: The experimental plan for the present study was approved by the Animal Research-Animal Care Committee of Nihon University. Using a Y-maze system, 8th weeks old C57BL/6J mice were trained to odor sensor mice to distinguish between 1000~1ppm citronellal 2.5% ethanol solution and solvent odor with a drop of water as a reward. After successful training, generalization trials were then instituted to test novel odor samples without reward and thus ensure that the trained mice learned to distinguish the essential distinction (citronellal vs solvent) rather than learned to distinguish the individual samples used during training. After successful training and testing to discriminate between 1 ppm of citronellal solution and solvent, trained mice fed was assigned to 1 of 3 experimental diets as follows, zinc-deficient (Def; 2.2 ppm Zn), low-zinc (Low; 4.1 ppm Zn) and Zinc sufficient (Suf; 33.7 ppm Zn) diets. After that, the Y-maze trials were continuously instituted at an average frequency every other day. Blood sampling was conducted from the tail vein on the 2-4th day and the 8-9th day from the dietary change.

Result and Conclusion: Def diet feeding immediately decreased the percentage correct of Y-maze training score and thus could scarcely conduct generalization trials. Low diet feeding also progressively lowered the score of trained mice over time. A generalization trial did not distinguish the citronellal odor. Even though Def and Low diets change to commercial diets (>;50ppm Zn), these odor disorders remained critical. On the other hand, the Suf diet did not alter the olfactory function of trained mice. Administration of the Def and Low diet significantly attenuated the olfactory functions of the learned mice over time and in a dose-dependent manner.

High-intensity exercise training induces oxidative modification of mitochondrial proteins in skeletal muscle

Maki Takami[1], Wataru Aoi[1], Chinatsu Ando[1], Yoji Kato[2], Yukiko Kobayashi[1], Masashi Kuwahata[1]

1.Kyoto Prefectural University (Japan), 2. University of Hyogo (Japan)

Background and objectives: Generation of reactive oxygen species (ROS) is increased in skeletal muscle during exercise. In muscle cells, mitochondria is a major source of ROS, with elevated oxygen consumption. Oxidative stress induces oxidation of cell components, leading to impaired metabolic system. However, the effect of oxidative stress induced by high-intensity exercise training on energy metabolism in mitochondria has not yet been elucidated. The activity of proteins can be regulated by various oxidative post-translational modifications. Therefore, we hypothesized that high-intensity exercise training may cause oxidative modification of metabolism-related proteins. The purpose of this study was to examine the oxidative modification of mitochondrial proteins in an exercise mouse model.

Methods: ICR mice (10 weeks old) were divided into two groups, consisting of sedentary control and exercise groups. In the exercise group, mice performed treadmill running 5 times per week for 2 weeks. On the next day of the final exercise, gastrocnemius muscles were collected. The level of proteins modified by N-hexanoyl lysine (HEL), 4-hydroxy-2-nonenal (HNE), 3-nitrotyrosine and dihalogenated tyrosine was measured in the muscle. Thereafter, HEL- and HNE-modifications of aconitase 2 (ACO2), carnitine palmitoyltransferase 1 (CPT1), dynamin-related protein 1 (DRP1) and malate dehydrogenase 2 (MDH2) were examined.

Results: Oxidative modifications of proteins extracted from muscle tissues were not significantly different between control and exercise groups. HEL- and HNE-modifications of mitochondrial proteins showed a tendency of higher in the exercise group than the control group. Moreover, HEL- and HNE-modifications of MDH2 were significantly higher in the exercise group. In contrast, HEL- and HNE-modified ACO2, CPT1 and DRP1 were not significantly different between control and exercise groups.

Conclusions: Oxidative stress induced by high-intensity exercise training post-translationally modified MDH2 in skeletal muscle, which may cause impaired metabolic system.

Establishment of diet-induced zebrafish obesity model for the metabolic studies

Nanase Konishi[1], Seina Asano[1], Yori Ozaki-Masuzawa[1], Takashi Hosono[1], Taiichiro Seki[1]

1.Nihon University (Japan)

Background and Objectives: Obesity is a global threat to the health of individuals that is characterized by the excessive accumulation of triglycerides in adipose tissues, including in visceral and subcutaneous adipose tissues. Obesity is an independent risk factor for the promotion of arteriosclerosis followed by the onset of thrombotic diseases, such as myocardial infarction. Zebrafish (Danio rerio) are a common research model in fish studies of toxicology, developmental biology, and molecular genetics; it has also been proposed as a promising model organism for nutrition and growth studies in fish. Zebrafish have advantages as a model organism that include their small size, short generation time interval, their capacity to produce numerous offspring, breed easily and very amenable to manipulation in a laboratory tank. Based on these given advantages, this study was aimed to establish suitable model for the study of obesity and metabolic disorders using zebrafish.

Method: Original automated feeding machine for the powdered diet was designed and used for the feeding in this study. Male healthy adult zebrafish were assigned to diet-induced obesity (DIO) group and control group (5 fish/2 L tank) and kept in the water tanks maintained at 28.5oC under a controlled 14-h:10-h light/dark cycle. The commercially available fish diet (Gemma micro ZF300, SKRETTING) was fed 6 times (20 mg x 6/fish/day) during light-period for the DIO group and once a day (20 mg/fish/day) for 4 weeks. Body weight and length were measured once a week with/without anesthesia. Plasma triacylglycerol and cholesterol concentrations were measured by using Determiner reagentsTM.

Results: The body weight and length were significantly increased in DIO group in comparison with the control group. The anesthesia (low-temperature (12oC)-anesthesia or tricaine) during the body size measurement did not show significant effects on the parameters. Plasma triacylglycerol and cholesterol concentrations were not significantly different in the DIO group compared with control group at 4 weeks after the feeding.

Conclusion: The zebrafish which have high genetic similarity to humans are widely used as a model organism for vertebrate. The DIO zebrafish model established in this study may contribute the obesity research.

Generation of induced pluripotent stem cell-derived beta cells in blood amino acids-like medium

Marwa Ali[1], Yusuke Kato[1], Nobuaki Shiraki[1], Shoen Kume[1]

1.Tokyo Institute of Technology (Japan)

Background and objectives: Classic cell culture media do not accurately represent the availability of the nutrients in plasma. They usually contain a super-physiological concentration of nutrients such as glucose, amino acids, etc. These high nutrients can alter the metabolism of cultured cells and induce metabolic phenotypes that don't reflect in vivo conditions. Refinement of media formulations has a potential application in maturity modulation of stem cell-derived β cells (SC-β) generation in vitro. This has the potential importance in regenerative medicine for curative diabetes treatment. Previous reports from mice studies have shown that amino acid levels progressively decreased between embryonic day 19 and postnatal day 9. Moreover, elevated amino acid levels have been linked to the activated mammalian target of rapamycin complex 1 (mTORC1) pathway, an increase in islet cell proliferation, accompanied by a low level of maturation. It has been demonstrated that late-stage culture in low levels of amino acids promoted the maturation of SC-β and improved their glucose-stimulated insulin secretion (GSIS) function. To the best of our knowledge, the effect of the physiological level of amino acids on the whole differentiation process has not been investigated. In this study, we asked whether SC-β cells could be derived in media that better recapitulates the composition of human plasma amino acids. And whether it would promote differentiation.

Methods: We established a culture system to derive SC-β cells using a blood-like amino acids medium (BALM). We used a human pluripotent stem cell (hiPSC) line, RPChiPS771-3G, for differentiation and performed real-time PCR, immunohistochemistry, western blot analysis, and GSIS to evaluate differentiation efficiency and maturation level.

Results: We demonstrated that supraphysiological nutrients interfere with endodermal differentiation through upregulation of the mTOR pathway. Moreover, hPSCs can be efficiently differentiated into definitive endoderm, pancreatic progenitors, endocrine progenitors, and SC-β using BALM. The differentiated cells secreted C-peptide in vitro in response to various insulin secretagogues and high glucose levels and expressed several pancreatic β-cell markers

Conclusions: The physiological level of amino acids is sufficient for the derivation of functional SC-β cells.

Effects of extracellular and intracellular advanced glycation end products in an intrauterine hyperglycemic environment on fetal skeletal muscle

Hitomi Yoshizaki[1], Ritsuko Kawaharada[2], Haruka Okami[3], Akiyo Toriumi[4], Saki Tsutsumi[1], Akio Nakamura[1]

1.Jissen women's University (Japan), 2. Takasaki University of Health and Welfare (Japan), 3. Gunma University (Japan), 4. Tokyo Medical and Dental University (Japan)

Background and objectives: In gestational diabetes mellitus (GDM), maternal hyperglycemia exposes the uterus to a hyperglycemic environment through the placenta. As a result, excessive protein glycation in a hyperglycemic environment produces advanced glycation end products (AGEs). AGEs is separated into extracellular AGEs taken up into the cell through receptors and intracellular AGEs generated in the cell. In this study, we examined the effects of two types of AGEs produced in the intrauterine hyperglycemic environment on skeletal muscle using mouse skeletal myoblasts (C2C12) and skeletal muscle in infants of GDM rats (IDM rats) and infants of control mother rats (ICM rats).

Methods: For the effect of extracellular AGEs, C2C12 cells were treated with glucose-induced AGEs (AGE-1) or glyceraldehyde-induced AGEs (AGE-2) at 1.2 mg/mL for 48 hours to examine skeletal muscle cell viability and reactive oxygen species (ROS) generation. Furthermore, the effects of intracellular AGEs were examined by Western blotting of AGEs formation and Akt and AMPK phosphorylation in skeletal muscle from IDM and ICM rats.

Results: In C2C12 cells, AGE-1 and AGE-2 decreased skeletal muscle cell viability by 17 % and 24 % of control, and increased ROS generation by 166 % and 174 % of control. This indicates that AGE-2 is more cytotoxic than AGE-1 in myoblasts. Additionally, in skeletal muscle in IDM rats and ICM rats, phosphorylation of Akt and AMPK was 0.3 times and 0.5 times lower in IDM rats than that in ICM rats. Moreover, AGE-1 and AGE-2 production was 1.6- and 2.8-fold higher in ICM rats than in IDM rats.

Conclusions: We have shown that extracellular AGEs decreased skeletal muscle cell viability and caused ROS generation. Contrary to expectations, however, skeletal muscle from IDM rats exposed to intrauterine hyperglycemia showed decreased intracellular AGEs production, although Akt and AMPK phosphorylation was abrogated. It was suggested that in the intrauterine hyperglycemic environment, insulin resistance inhibits glucose uptake into skeletal muscle cells, resulting in reduced levels of intracellular AGEs production. We would like to further examine the effects of AGEs production in an intrauterine hyperglycemic environment on skeletal muscle differentiation by analysing cellular signaling and myogenic gene expression.

Influence of excess intake of asparagine, methionine, tyrosine and valine on plasma concentrations of amino acid-amadori products in chickens

Naho Seino[1], Kazumi Kita[1]

1.Iwate University (Japan)

Background and objectives: Glycation is a non-enzymatic chemical reaction in which carbonyl groups of reducing sugars form Schiff bases with amino groups of proteins and amino acids. The Schiff base undergoes Amadori rearrangement to form Amadori products (APs). Chickens are hyperglycemic animals, and seven amino acid-APs (Ile/LeuAP, LysAP, PheAP, TrpAP, TyrAP, and ValAP) have been detected in chicken plasma. It was also found that the plasma concentration of amino acid-APs correlated to the plasma concentration of amino acids other than the substrate amino acids. Furthermore, even under in vitro conditions, the concentration of specific amino acid-APs correlated to the concentrations of non-substrate amino acids. These results suggests that amino acids other than the substrate may function as catalysts for the generation of amino acid-APs in vivo. In this study, therefore, Asn, Met, Tyr, and Val, which promoted the formation of amino acid-APs under in vitro conditions, were excessively fed to chickens to examine their influences on plasma amino acid-APs concentrations.

Methods: Animals - 10-day-old single comb White Leghorn male chickens were fed diets with 2 % excess of Asn, Met, Tyr and Val, respectively, or a control diet for 3 days. Samples - Blood was collected from the heart under isoflurane anesthesia, and the blood was centrifuged at 5,000 x g for 20 min at 4 ℃ to separate plasma. Plasma samples were defatted and deproteinized, and LC/MS was used to determine plasma Asn and GluAP concentrations in the Asn excess group, plasma Met and TrpAP concentrations in the Met excess group, plasma Tyr and Ile/LeuAP concentrations in the Tyr excess group, plasma Val and PheAP concentrations in the Val excess group were measured.

Results: Excess Val intake significantly increased plasma PheAP concentration, while excess Asn, Met, and Tyr intake did not significantly affect plasma GluAP, TrpAP, and Ile/LeuAP concentrations compared to controls. Plasma GluAP, TrpAP and Ile/LeuAP concentrations showed a significant positive correlation to substrate amino acid concentrations, and plasma PheAP concentration showed a significant positive correlation to plasma Val concentration.

Conclusion: It is suggested that Val may catalyze the formation of PheAP in vivo.

Cystine supplementation sustains plasma mercaptalbumin levels in rats fed low-protein diets more effectively than methionine

Chihiro Maeda[1], Yukimi Yano[1], Ichiro Kaneko[2], Yukiko Kobayashi[1], Wataru Aoi[1], Masashi Kuwahata[1]

1.Kyoto Prefectural University (Japan), 2. University of Hyogo (Japan)

Background and objectives: In recent years, a relationship between the oxidized/reduced state of plasma albumin and inflammation has been suggested. We recently reported that dietary cystine maintained plasma mercaptalbumin levels in rats fed low-protein diets. Cystine is the oxidized dimer of cysteine, which can be synthesized from methionine. The present study aimed to compare the influence of cystine and methionine on plasma mercaptalbumin levels and the gene expression of inflammation-related molecules in blood cells of rats fed low-protein diets.

Method: Male Sprague-Dawley rats were fed a 20% soy protein isolate diet (control group), 5% soy protein isolate diet (low-protein group) or 5% soy protein isolate diet supplemented with either methionine (low-protein+Met group) or cystine (low-protein+Cyss group) for 1 week. The percentage of mercaptalbumin within total plasma albumin was analyzed by high performance liquid chromatography. The gene expression of inflammation-related molecules in blood cells were analyzed by real-time PCR.

Results: The percentage of mercaptalbumin within total plasma albumin in both the low-protein+Met and low-protein+Cyss groups was significantly higher than in the low-protein group. However, the percentage of mercaptalbumin within total plasma albumin in the low-protein+Met group was significantly lower than in both the control and low-protein+Cyss groups. Treatment with buthionine-(S,R)-sulfoximine, an inhibitor of glutathione synthesis, did not influence the percentage of mercaptalbumin within total plasma albumin in rats fed the low-protein diet supplemented with cystine. Supplementation with cystine and methionine represses the increase in the mRNA levels of tumor necrosis factor-α, interleukin-6, interleukin-1β and cyclooxygenase 2 in the blood cells of rats fed low-protein diets. On the other hand, no significant differences in the levels of these mRNA were observed between the low-protein+Met and low-protein+Cyss groups.

Conclusions: Supplementation with cystine may be more effective than that with methionine to maintain plasma mercaptalbumin levels in rats with protein malnutrition. Cystine might regulate plasma mercaptalbumin levels via the glutathione-independent pathway.

The combination of Pediococcus acidilactici CECT9879 (pA1c), chromium picolinate and oat beta-glucans has blood sugar-regulating effect and alleviates metabolic syndrome-related comorbidities in mice

Deyan Yavorov Dayliev[1,2], Fermín I. Milagro[2,3,4], Josune Ayo[1], María Oneca[1], Paula Aranaz[2,3]

1.Genbioma Aplicaciones SL. (Spain), 2. University of Navarra (Spain), 3. Navarra Institute for Health Research (Spain), 4. Centro de Investigación Biomédica en Red de la Fisiopatología de la Obesidad y Nutrición (Spain)

Background and objectives: Different probiotics and bioactive compounds have emerged as a natural alternative to the classic treatments of metabolic syndrome-related diseases such as obesity, insulin resistance and diabetes. Previous data from our group suggest that Pediococcus acidilactici CECT9879 (pA1c) could be effective in regulating blood glucose. Hence, the objectives of this study were to verify the effectiveness of pA1c on glycemic regulation, to compare its effect with other normoglycemic compounds (chromium picolinate (PC) and oat beta-glucans (BGC)) and to evaluate the possible synergistic effects of the combination of pA1c with these bioactive compounds on the regulation of glucose and lipid metabolism in diet-induced obese mice.

Methods: To induce diabetes and obesity, 4-week-old male C57BL/6J mice were fed a high fat/high sucrose diet (HFS) for 6 weeks. Animals were then divided into eight groups for ten weeks (n=12 animals/group): control diet group, high fat/high sucrose (HFS) group, pA1c, PC, BGC, pA1c+PC+BGC, pA1c+PC, and pA1c+BGC. Fasting blood glucose determination was assayed, and a glucose tolerance test was performed in week nine. Fat depots, liver and other organs were weighed, and different serum biochemical parameters were analyzed. Gene expression analyses were conducted by real-time quantitative-PCR.

Results: All the groups supplemented with the probiotic significantly ameliorated glucose tolerance after an intraperitoneal glucose tolerance test what verifies the blood sugar-regulating effect of pA1c. Further, although no effects were observed on body weight, animals supplemented with pA1c+PC+BGC exhibited lower proportion of visceral adiposity and higher proportion of lean muscle tissue, together with an improvement in the brown adipose tissue in comparison with HFS group.

Conclusions: Our data confirm the effectiveness of pA1c on glycemia regulation and suggest that the combination of pA1c with PC and BGC could be a potential synbiotic for blood sugar regulation and may help to fight diabetes and obesity.

Effect of a high sucrose/high fat diet on blood fat-soluble vitamins levels in diabetes

Sakiko Inaba[1], Noriaki Wakana[2], Kazuhiro Homma[2], Naoto Fukuyama[2]

1.Graduate School of Tokyo University of Agriculture (Japan), 2. Tokyo University of Agriculture (Japan)

Background and objectives: Diet is closely involved in the onset and progress of diabetes mellitus (DM). Oral intake of fat-soluble vitamins, calcium, unsaturated fatty acids, zinc, and iron is reported to prevent the onset and advance of DM. However, the concentration of these nutrients in the body is rarely measured, and the relationship between the progress of DM and their concentration in the body has not been clarified. Therefore, in this study, we focused on fat-soluble vitamins. We investigated the changes in the blood levels of fat-soluble vitamins caused by DM and a high sucrose/high fat (HSF) diet using an SDT fatty rat model of obesity-induced type 2 DM.

Methods: Five male SD rats and SDT fatty rats were randomly divided into two groups. One group was provided a standard experimental diet (CE2) and the other group was provided an HSF diet for 40 weeks. At the end of the experiment, blood parameters (fasting blood glucose, chemistry, and fat-soluble vitamins), pancreatic insulin gene expression, liver fat-soluble vitamin levels, and serum vitamin-binding protein levels were examined.

Results: Serum retinol was significantly higher in SDT fatty rats than in the SD+CE2 rats. There was no significant difference in hepatic retinol and retinol palmitate levels among the four groups. Serum RBP4 levels were significantly higher in the SDT fatty+CE2 than in the other three groups. Serum 25(OH)D3 was significantly lower in SDT fatty rats than in the SD rats; further, it was significantly lower in the SDT fatty+HSF than in the SDT fatty+CE2. However, there was no significant difference in 1α,25(OH)2D3 between the 4 groups. The serum VDBP levels were not significantly different between the 4 groups. The α-tocopherol and MK-4 levels were significantly higher in the SDT fatty+HSF rats than in the other three groups. PK tended to be higher in the SDT fatty+HSF rats than in the other three groups.

Conclusions: Serum fat-soluble vitamin levels fluctuate with DM. Further, HSF load in DM alters the serum 25(OH)D3, α-tocopherol, and vitamin K levels.

A potential mechanism underlying paternal transmission of diet-induced metabolic stress through angiogenin-mediated tRNA fragmentation

Eunbi Lee[1], Seo Yoon Choi[1], Jihye Park[2], Anders M. Lindroth[2], Yoon Jung Park[1]

1.Ewha Womans University (Korea), 2. National Cancer Center (Korea)

Background and objectives: Offspring from diet-induced obese mice showed metabolic dysregulation phenotype despite of normal diet feeding. It has been reported that tRNA fragments, increased by metabolic stress in germline, function as a mediator for transgenerational effects. Angiogenin is one of ribonucleases involved in generation of tRNA fragments. Although multiple studies have shown the increase of tRNA fragments due to cellular stress, it is not fully understood how the tRNA fragmentation are induced. We investigated a potential molecular mechanism underlying the upstream of angiogenin-mediated tRNA fragmentation.

Methods: Small RNA sequencing and tRNA methylation analysis were conducted for sperms of control diet (CD)- and high fat diet (HFD)-fed mice. RNA expression of tRNA modifying genes were measured by qRT-PCR using SYBR Green kit and protein expression and activation of AMPK signaling were measured by western blots. For functional validation, Compound C (an AMPK inhibitor, CC)-treated or non-treated NIH/3T3 cells were further analyzed for qRT-PCR, western blots, and mRNA sequencing.

Results: According to the results from sperm smRNA sequencing, 3' fragments from tRNA-Gly, Lys, and Pro were particularly increased in HFD compared to CD, although the overall amounts of tRNA fragments were not changed overall. Among tRNA modifying genes, tRNA methyltransferases, Dnmt2 and Nsun2 were upregulated in testis in response to HFD, but methylation status was not changed. Angiogenin expression was significantly increased and AMPK-mTOR pathway, a potential upstream regulator, was altered in HFD. Changing activity of AMPK-mTOR pathway using CC led to Angiogenin induction in the NIH/3T3 cells, resulting to increase of tRNA fragments including tRNA-Gly.

Conclusions: Our data suggested that alteration of AMPK activity by diet stress might mediate Angiogenin-mediated tRNA fragmentation which is a key mediator of transgenerational mechanism of metabolic dysregulation.

Keywords: Angiogenin, tRNA fragment, AMPK, transgenerational effects, metabolic stress

Kynurenine metabolism is involved in the link between nonalcoholic fatty liver disease (NASH) and chronic kidney disease (CKD)

Mayuka Takahashi[1], Misaki Suzuki[2], Maiko Takasuga[1], Mika Kittaka[1], Mamiko Ishikawa[3], Junko Ohki[3], Alato Okuno[4], Yoshiko Mori[2], Ken-Ichi Kobayashi[1,2]

1.Graduate School of Human Life Sciences, Notre Dame Seishin University (Japan), 2. Department of Foods and Human Nutrition, Faculty of Human Life Sciences, Notre Dame Seishin University (Japan), 3. Department of Health and Nutrition, Sanyo Gakuen Junior College (Japan), 4. Department of Health and Nutrition, Faculty of Human Design, Shibata Gakuen University (Japan)

Background and objectives: Kynurenine (KYN) pathway (KP) is the principle route of tryptophan metabolism, and many metabolites of the KP, such as KYN and quinolinic acid (QA), have physiological activity in the central nervous system. We have shown that accumulation of QA may be involved in the pathogenesis of chronic kidney disease (CKD). Non-alcoholic steatohepatitis (NASH) is a metabolic disease associated with hepatic fibrogenesis caused by obesity. Recently, the NAD salvage pathway has been reported to be affected in NASH. And, the possible link between NASH and CKD recently has attracted considerable scientific interest. In this study, we aimed to clarify the association of NASH with renal fibrosis that is a complication of CKD, and how the KP affected there.

Methods: Seven-week-old male C57BL/6J mice were fed Gubra Amylin NASH (GAN) diet, a sample containing high fat (40%), high fructose (22%) and high cholesterol (2%) for 26 weeks. Sera from these animals were subjected to biochemical analysis. Liver and kidney were subjected to HE staining and Sirius Red staining, and quantitative PCR was performed for the gene expression levels of fibrosis-related factor (Col1a1 and a-SMA) and KP enzymes.

Results: NASH group was obese with a marked increase in body weight, liver weight and fat weight. In the NASH group, a significant increase in Col1a1 gene expression in the liver and a slight increase in Sirius Red staining positive images were observed, indicating that mild fibrosis of the liver had occurred. Biochemical analysis of serum showed significant increases in total protein, ALT, and other parameters, indicating an inflammatory state. Interestingly, a significant increase in Col1a1 and a-SMA gene expression was observed in the kidneys, and an increase in Sirius Red staining positive image was observed, indicating that renal fibrosis also was accelerated. KYN metabolism-related gene expression in the NASH liver showed decreased, but QPRT gene expression in the kidney of NASH showed increased.

Conclusions: We demonstrated that renal fibrosis is present in the GAN feed-induced NASH model, and that NASH and CKD are coupled. In addition, we suggested that KP, especially QA, may be involved in the link between NASH and CKD.

Keywords: chronic kidney disease, Kynurenine pathway, Non-alcoholic steatohepatitis, NASH, renal fibrosis

Studies on the vitamin E metabolism in Otsuka-Long-Evans-Tokushima-Fatty rats

Saiko Ikeda[1], Riko Toji[2], Ryotaro Shiga[2], Yuka Tanaka[2], Dongho Kim[2], Misato Kobayashi[1], Tomoko Banno[3], Shigeru Saeki[2]

1.Nagoya University of Arts and Sciences (Japan), 2. Osaka Metropolitan University (Japan), 3. Nagoya Women's University (Japan)

Background and objectives: The distribution and transport of vitamin E, a fat-soluble vitamin, are affected by lipid metabolism and lipoprotein metabolism. However, the effects of changes in lipid metabolism in metabolic syndrome on vitamin E metabolism are not fully understood. The purpose of this study is to characterize vitamin E metabolism in the Otsuka-Long-Evans-Tokushima-Fatty (OLETF) rat, which is a metabolic syndrome-model animal spontaneously developing obesity, hyperlipidemia, hypertension and type 2 diabetes mellitus generated with age. In this study, young OLETF rats were used to measure changes in vitamin E metabolism before the onset of metabolic syndrome.

Methods: Male OLETF rats and control LETO rats (5-week-old) were fed an AIN-93 diet containing 50 mg/kg of RRR-α-tocopherol for 2 weeks. The α-tocopherol concentration in plasma and tissues and the urinary excretion of α-CEHC, a metabolite of α-tocopherol, were measured by HPLC.

Results: Food intake and final body weight of OLETF rats were higher than those of LETO rats. α-Tocopherol concentration in the liver was lower in OLETF rats than in LETO rats, while that in the plasma, kidney, and perirenal adipose tissue was not significantly different between OLETF and LETO rats. In addition, urinary excretion of α-CEHC was lower in OLETF rats than in LETO rats.

Conclusions: Thus, the storage of α-tocopherol in the liver was reduced and its catabolism was suppressed in OLETF rats, although the intake of α-tocopherol was higher in OLETF rats than in LETO rats. The data suggest that the bioavailability of vitamin E already decreases even before the onset of metabolic syndrome.

Smek2 is a multi-function regulator of three major nutritions

Yasutake Tanaka[1], Michio Kawano[1], Makoto Asahina[1], Katsumi Imaizumi[1], Masao Sato[1]

1.Kyushu University (Japan)

Backgrounds and Objectives: Suppressor of mek1, homolog 2 (Smek2) was identified by author's research group as the responsible gene for diet-induced hypercholesterolemia in exogenously hypercholesterolemic (ExHC) rat. Although it is becoming clear that it is the same gene as protein phosphatase 4 regulatory subunit 3B (Ppp4r3b), function of Smek2 is not fully discovered. We investigated the function of Smek2 by analyzing the phenotypes of ExHC rats that have almost lost Smek2 function by a 10-bp deletion mutation.

Methods: For analysis, we established ExHC.BN-Dihc2BN (congenic) strain by backcrossing. Congenic rat has an allele, the region on chromosome 14 containing Smek2, derived from Brown-Norway (BN) rats. Sprague-Dawley (SD) rats, ExHC rats, and congenic rats were fed a high-cholesterol diet for 2 weeks. After feeding period, we measured biochemical parameters and gene expression levels related to the metabolism of the three major nutrients in the liver and blood.

Results: Congenic rats did not develop diet-induced hypercholesterolemia after the high-cholesterol diet. In ExHC rats, the triacylglycerol (TAG) levels were lower in both blood and liver than in SD rats. The mRNA levels of lipogenic genes in the liver of ExHC rats were significantly lower compared with those of SD and Congenic rats. The mRNA expression of phosphofructokinase liver-type (Pfkl), the rate-limiting reaction in glycolysis, was decreased and the substrate of Pfkl, fructose-6-phosphate, was increased in the liver of ExHC rats. These changes were not observed in the liver of congenic rats. Taken together, ExHC rats exhibited glycolytic deficiency caused by Smek2 dysfunction, and the resulting TAG deficiency was the causative background of diet-induced hypercholesterolemia. In addition, ExHC rats showed high blood homocysteine levels and extremely low expression of sarcosine dehydrogenase (Sardh), a gene involved in one-carbon metabolism. It was suggested that Smek2 also affected amino acid metabolism.

Conclusion: Smek2 is a gene that can affect the metabolism of all of the three major nutrients.

Liver-specific release of SMP30 into serum exosomes is mediated by the activation of CINC-1/STAT3 signaling in ODS rat

Kohta Arakawa[1], Hirofumi Inoue[1], Akihito Ishigami[2], Hiromu Morimoto[1], Nobuyuki Takahashi[1], Mariko Uehara[1]

1.Tokyo University of Agriculture (Japan), 2. Tokyo Metropolitan Geriatric Hospital and Institute of Gerontology (Japan)

Objective: Osteogenic Disorder (ODS) rat has a hereditary defect in ascorbic acid (AsA) biosynthesis and is a valuable animal model for elucidating the physiological role of AsA. Senescence marker protein 30 (SMP30), which regulates the biosynthesis of AsA in many mammals, except primates and humans, was recently recognized as a kind of enzymes, gluconolactonase. However, the precise relation between SMP30 and AsA-deficient condition is not completely understood in humans. Therefore, this study investigated whether SMP 30 has new physiological functions in ODS rats except for gluconolactonase activity.

Method: The mechanisms by which AsA deficiency provokes inflammatory responses in the liver were investigated in ODS rats. Male ODS rats (4-wk-old) were pair-fed with a diet containing sufficient 0.1 % AsA (an AsA-suf group) or without AsA (an AsA-def group) for 14 days.

Results: On day 14, the hepatic SMP30 expression was significantly lower in the AsA-def group than in the AsA-suf group, whereas renal SMP30 expression did not differ. In contrast, serum, hepatic and renal AsA concentration was significantly decreased in the AsA-def group. In serum exosomes, expressions of SMP30 and hepatic-derived exosome markers (haptoglobin and ASGPR1) in the AsA-def group were significantly increased compared with the AsA-def group. However, renal-derived exosome marker NGAL expression did not change. Previous study showed that CINC-1/STAT3 signaling activates the exosomes released in the liver. Therefore, we determined whether AsA deficiency stimulates CINC-1/STAT3 signaling and provokes proinflammatory responses in the liver. As a result, serum CINC -1 levels, hepatic STAT3 activity, hepatic CXCR2 (CINC-1 receptor), and expressions of STAT3-targete genes (haptoglobin, AGP, SOCS3) were significantly increased in the AsA-def group. Furthermore, the AST/ALT ratio, a liver-specific inflammatory marker, was also elevated in the AsA deficient-condition. These results showed that AsA deficiency induces the liver-specific release of SMP30 into the serum exosomes via the activation of CINC-1/STAT3 signaling, resulting in liver injury.

Conclusion: This study revealed that hepatic-derived exosome SMP30 expression is a potential biomarker of liver injuries in ODS rats. Significantly, this mechanism is mediated by the CINC-1/CXCR2/STAT3 signaling. These results suggest that exosome release of SMP 30 may be an indicator of AsA deficiency.

Scheduled access to a highly palatable food changes the activity pattern of orexin-containing neurons in the lateral hypothalamus

Jamin Ku[1], Yasunobu Yasoshima[1]

1. Osaka University (Japan)

Background and objectives: Our preliminary studies suggest that diurnal, intermittent access (2 h) to a highly palatable food (HPF) increased its intake and decreased intake of normal chow (NC; 22 h) in mice, resulting in no change in total caloric intake a day. Dissection of the olfactory nerve abolished the increase of the HPF intake, suggesting that odor of HPF contributes to the gradual increase of HPF intake during the light period of time. To explorer underlying mechanism by which the olfactory cue increased food intake, we focused on the activity of neurons which have feeding-related neuropeptides such as orexin and melanin-concentrating hormone (MCH) in the lateral hypothalamic area, which is called the feeding center.

Methods: We examined whether the odor of the HPF specifically increased c-fos expression, a neuronal activation marker, in orexin- and MCH-containing neurons in the hypothalamus. Two groups (HPF-fed, NC-fed) of mice received intermittent, scheduled access to the HPF or NC for 2 hours during the period of time for 8 days. On day 9 at the time of HPF presentation, half of each group (HPF-fed/HPF-odor, NC-fed/HPF-odor) received only the odor of HPF; the other half (HPF-fed/NC-odor, NC-fed/NC-odor) was exposed to the odor of normal chow. Additionally, we also examined c-fos expression by period of time (ZT1, ZT6.5).

Results: We found that c-fos expression in orexin-containing hypothalamic neurons significantly increased in HPF-fed groups (HPF-fed/HPF-odor, HPF-fed/NC-odor) when each group received HPF or NC odor on test day, respectively. Furthermore, the activity of orexin neurons in ZT1 was more active than in ZT6.5. In addition, at specific coordinates (-1.3 mm from bregma), orexin neurons were more active in HPF-fed groups than in NC-fed groups.

Conclusion: Our present results suggest that scheduled access to HPF alters the activity pattern of orexin-containing hypothalamic neurons during the light period. The diurnal activation of orexin-containing hypothalamic neurons may contribute to increase of HPF intake during the light period in mice.

Serum Metabolic Profiling of Rat Fed Folate and Vitamin B12 Depleted Diet

Shigeo Takenaka[1,2], Megumi Natsuhara[2], Kotomi Fujita[2], Saki Okamoto[1,2], Shigenobu Matsumura[1,2], Toshio Iwaki[1,2], Hiroaki Kanouchi[1,2], Miyu Tanaka[1,2], Takeshi Izawa[1,2], Mitsuru Kuwamura[1,2]

1.Osaka Metropolitan University (Japan), 2. Osaka Prefecture University (Japan)

Background and objectives: Folic acid and vitamin B12 are essential nutrients involved in C1-metabolism. These deficiency causes pernicious anemia and they are also important in the normal function of many metabolisms including amino acids and nucleotides. Here we examined the changes of metabolism of rat fed the folate and vitamin B12 depleted diet.

Methods: Rats were fed the folate and vitamin B12 depleted diet (AIN-93G) for 7 and 10 weeks and then sacrificed under anesthesia. Folate and vitamin B12 were measured by the bioassay. Homocysteine was measured with HPLC. Serum was analyzed with a GCMS/MS system to obtain metabolic profiling. Liver was stained with HE.

Results: Rats fed folate and vitamin B12 depleted diet for 7 weeks showed the moderate and for 10 weeks showed severe deficient status judged from the vitamins and homocysteine status. The liver of folate-depleted rat showed lipid accumulation and inflammation and the status was severe in the rat fed folate and vitamin B12 depleted diet. The metabolic profiling using GCMS/MS revealed the metabolite profiles were gradually changed according to term of the feeding. Some organic acid and amino acid including homocysteine levels in the serum from the rats fed the folate depleted was found. The change of the profile caused the depletion of vitamin B12 was small.

Conclusion: Metabolic profile of folate deficiency was proceeded the term of feeding the diet and the effect of vitamin B12 on it was small.

Regulation of glucoprivation-induced carbohydrate selection by NPY-CRH neural axis in the paraventricular nucleus of the hypothalamus

Nawarat Rattanajearakul[1], Ken-ichiro Nakajima[1,2], Yasuhiko Minokoshi[1,2]

1. National Institute for Physiological Sciences (NIPS) (Japan), 2. The Graduate University for Advanced Studies (SOKENDAI) (Japan)

Background and objectives: Feeding is important to maintain energy homeostasis and control macronutrient metabolism in animals. While neural mechanisms responsible for the regulation of total calorie intake have been extensively studied, that of food selection remains elusive. Our lab previously reported that a subset of corticotropin-releasing hormone (CRH) neurons expressing fasting-responsive AMP-activated protein kinase (AMPK) in the paraventricular nucleus of the hypothalamus (PVH) is necessary for a high carbohydrate diet (HCD) selection over a high fat diet (HFD) during refeeding after fasting. Here, we investigated the role of neuropeptide Y (NPY)-CRH neural axis in the PVH in 2-deoxy-D-glucose (2-DG)-induced change in food selection in mice. Two-diet choice experiment revealed that intraperitoneal (IP) injection of 2-DG increased HCD intake while it decreased HFD intake. Intracerebroventricular (ICV) or intra-PVH NPY injection increased HCD intake along with a slow increase in HFD intake. Chemogenetic inhibition of PVH CRH neurons and preferential knockdown of AMPK in PVH CRH neurons suppressed both 2-DG and NPY-induced HCD intake but not HFD intake. Importantly, intra-PVH injection of antagonists for Y1R and Y5R blocked 2-DG-induced HCD intake preferentially. By contrast, PVH injection of melanocortin-4 receptor (MC4R) agonist, Melanotan II (MTII), inhibited HFD intake but not HCD intake after the intra-PVH NPY injection. We found that 2-DG increased the expression of a neural activation marker, c-fos, in PVH-projecting NPY neurons in several brain areas including the nucleus tractus solitarius (NTS). Optogenetic activation of PVH-projecting NPY neurons in the NTS increased c-fos expression in the PVH and increased HCD intake along with a slow increase in HFD intake similar to those observed after ICV or intra-PVH injection of NPY. Collectively, these results suggest that NPY-CRH neural axis in the PVH is necessary for 2-DG-induced HCD selection and HFD selection is mediated by a distinct neural circuit in the PVH.

Hydroponics as a route to generate vitamin B12-biofortified plants that allow consumers to meet the Reference Nutrient Intake

Olla Al-Jaibaji[1], Proyash Roy[1], Mark Philo[1], Emad Shehata[1], Shikha Saha[1], Sree Javvadi[1], Martin Warren[1], Paul A Kroon[1]

1.Quadram Institute Bioscience (UK)

Background and objectives: Vitamin B12 (cobalamin) plays an important role as a cofactor in various metabolic processes, including DNA synthesis and red blood cell maturation. In humans, vitamin B12 can only be synthesised by colonic microorganisms, but because the colon is not a site of B12 absorption, it is not available to the host. Therefore, human vitamin B12 nutrient requirements can only be met through the consumption of vitamin B12-containing foods or supplements, or via injections. Plants do not require vitamin B12 and do not synthesise it, so only animal-derived foods are useful sources of vitamin B12. Accordingly, those following vegetarian and especially vegan diets are at risk of not consuming sufficient B12 to meet their nutritional needs. Supplements can be part of the solution, but if B12 supplements are not taken with food, absorption of vitamin B12 is likely to be limited because secretion of the intrinsic factor depends on the secretion of gastric acid. The overall aim of this research was to investigate the biofortification of food plants with vitamin B12.

Methods: We grew a variety of small leafy green vegetables and herbs from seeds using hydroponic systems and once established added cyanocobalamin to the standard nutrient solution. Samples were collected over time and analysed for cyanocobalamin using an LC-MS/MS method developed in-house.

Results: Cyanocobalamin was detected in all the tested plants grown in 20 µM cyanocobalamin but there were large differences in the concentrations with lettuce having the lowest content (0.03 ± 0.001) and mizuna the highest content (0.52 ± 0.09). Cyanocobalamin contents increased as the concentration in the nutrient solution increased (5-20 µM), and uptake of cyanocobalamin increased with exposure time. Mizuna was fortified with up to 3 µg (g fresh weight)-1 cyanocobalamin. For a mix of plants, 2-4 g of plant tissue was sufficient to achieve the UK reference nutrient intake (1.5 µg/day).

Conclusions: We have demonstrated that plants take up cyanocobalamin via their roots and accumulate it at µg/g fresh weight concentrations, which is sufficient to achieve RNIs. Future research should focus on determining the bioavailability of vitamin B12 from plants. [Conflict of Interest Disclosure] The authors declare no conflict of interest.

Identification of psychological and brain responses profiles related to eating habits in healthy young women: Towards the use of neurofeedback to prevent eating disorders

David Val-Laillet[1], Yentl Gautier[1], Ambre Godet[1], Yann Serrand[1], Alexandra Fortier[1], Elise Bannier[2,3], Ronan Thibault[1,4], Aymery Constant[1,5], Romain Moirand[1,6], Nicolas Coquery[1]

1.INRAE, INSERM, Univ Rennes, CHU Rennes, Nutrition Metabolisms and Cancer, NuMeCan (France), 2. Inria, CNRS, Inserm, IRISA IMR6074, Empenn U1228, Univ Rennes (France), 3. CHU Rennes, Radiology Department (France), 4. Unité de Nutrition, CHU Rennes (France), 5. EHESP, School of Public Health (France), 6. Unité d'Addictologie, CHU Rennes (France)

Background and objectives: People with obesity or eating disorders often present anomalies in brain areas involved in hedonic and cognitive control of eating. First, we aimed at exploring the brain responses of normal-weight healthy young women with high or low consumption of Western-type (WT) foods (i.e. sweet, fatty, transformed) to identify individual profiles at risk and brain targets for preventive interventions. Second, we aimed at developing functional near-infrared spectroscopy (fNIRS) neurofeedback to train subjects to increase their prefrontal cortex activity and related inhibitory control.

Methods: Between 2018 and 2021, we performed a questionnaire study in 655 normal-weight female students to investigate cognitive and behavioral components of eating and other life and consumption habits. Fifty volunteers with high or low WT food consumption were subjected to blood oxygen level-dependent functional magnetic resonance imaging (fMRI) during a cognitive food choice task and functional connectivity (FC) during resting-state fMRI. Thirty additional healthy volunteers were subjected to a fNIRS neurofeedback (NF) single session where they were instructed to voluntarily increase the activity of their dorsolateral prefrontal cortex (dlPFC, via real-time visual gauge).

Results: The questionnaire study revealed risky eating habits in healthy female students, such as transient emotional hyperphagia (from 50% in 2018 to 90% in 2021 during COVID). High vs. low consumers of WT foods presented different psychological components of eating, brain responses and FC in the frontostriatal circuit involved in the hedonic and cognitive control of eating. These data and previous papers justified our choice to perform NF on the dlPFC, which is involved in the inhibitory control. Twenty-two participants (73%) of the one-session NF experiment managed to increase their dlPFC activity during their 10 best trials over 15.

Conclusions: Our data showed that high consumption of WT foods is associated with specific psychological traits and brain functions related to food reward and inhibitory control of eating. Training people to regulate their dlPFC activity might favor a better control overeating, and our preliminary results on one-session NF are promising for the next step of our project, which is to implement this strategy with multiple-session NF in young women with emotional hyperphagia.

The effects of long-term almond consumption on whole-body insulin sensitivity, postprandial glucose responses, and free-living glucose patterns in men and women with prediabetes: A randomized controlled trial

Jogchum Plat[1], Elske Gravesteijn[1], Ronald P. Mensink[1]

1.Maastricht University (Netherlands)

Background and objectives: Healthy diets rich in nuts as part of lifestyle interventions can prevent the development of prediabetes into type 2 diabetes by improving glucose metabolism. So far findings concerning the effects of almond consumption on glucose metabolism are inconclusive which might relate to body weight gain. We here investigated the effects of long-term almond consumption on glucose metabolism in a free-living setting without detailed dietary instructions in overweight or obese men and women with prediabetes.

Methods: Forty-three participants volunteered in this randomized, cross-over trial with a control and intervention period of 5 months separated by a wash-out period of 2 months. In the intervention period participants consumed 50 g whole almonds per day. At the end of both periods whole-body insulin sensitivity was assessed by a hyperinsulinemic euglycemic clamp, and postprandial glucose responses, and 48h free-living glucose patterns were measured.

Results: Five months almond consumption significantly decreased insulin sensitivity (P=0.002), and increased postprandial glucose concentrations (P=0.019), as well as fasting insulin concentrations (P=0.003) as compared to the control period. The AUC for 24h glucose concentrations just did not reach statistical significance (P=0.066). Almond consumption also significantly increased BMI (P=0.002), and waist circumference (P=0.013), which was supported by the increased energy intake (P=0.031) during the intervention period based on data from the food frequency questionnaires (FFQ). The effects on glucose metabolism could only partly be explained by the observed increase in body weight as the almond effect remained after correcting for BMI changes.

Conclusions: In prediabetic participants, long-term almond consumption showed adverse effects on insulin sensitivity and glucose metabolism. Effects could only partly be explained by changes in BMI and energy intake, suggesting that the almonds did not fully replace other food items. Therefore, it might be necessary to provide more supporting guidelines on how to incorporate energy-dense foods like nuts into healthy diets.

A comparison of zinc absorption from zinc biofortified and regular (yellow) potatoes in young Andean women

Maria Reyna Liria[1,2], Mary E Penny[1], Gabriela Burgos[3], Paul Antony Kroon[4], Jack Dainty[5], Christophe Zeder[6], Michael B Zimmermann[6], Kenneth Brown[7], Janet King[7], Susan Fairweather-Tait[5]

Background and objectives: Zinc biofortified potatoes have considerable potential to reduce zinc deficiency due to their low levels of phytate, an inhibitor of zinc absorption, and their high level of consumption especially in the Andean region. The purpose of this study was to evaluate fractional and total zinc absorption comparing biofortified potatoes with non-fortified potatoes in a test meal.

Methods: We undertook a randomized crossover study using a stable isotope approach in which 37 females consumed 1 kg/day of test meal from each biofortified and non-fortified potato. Venous blood samples and urine samples were collected in order to determine fractional and total zinc absorption.

Results: The zinc content of the biofortified potato was 0.47 ± 0.05 mg/100 grams and the non-biofortified was 0.31 + 0.03 mg/100 grams. The fractional zinc absorption of the biofortified variety was 18% lower than that of the non-biofortified (p <; 0.01). However, due to its higher zinc content, on average 24% more zinc was absorbed from the biofortified variety than from the non-biofortified variety (p<;0.01).

Conclusions: This study demonstrated that biofortified potato resulted in a significant increase on the total zinc absorption from a meal. This would be expected to contribute to reducing zinc deficiency in population where potatoes are a staple food. [Conflict of Interest Disclosure] The authors declared there was no conflict of interests [Further Collaborators] We acknowledge the valuable contribution of the following people: Olla Al-Jaibaji (Quadram Institute Bioscience), Eric Boy (HarvestPlus - IFPRI) and Richard Hurrel (ETH Zürich). Involvement of gastrointestinal hormones in the thermic effect of dietary protein in rats

Keita Ochiai[1], Yusaku Iwasaki[2], Tohru Hira[1]

1.Hokkaido University (Japan), 2. Kyoto Prefectural University (Japan)

Background and objectives: Glucagon-like peptide-1 (GLP-1) is a gastrointestinal hormone secreted from enteroendocrine cells after a meal and has various postprandial physiological effects such as inducing satiety and suppressing blood glucose elevation via promoting insulin secretion. Among the three major nutrients, proteins potently stimulate GLP-1 secretion. Protein intake is a potent inducer of diet-induced thermogenesis, an important postprandial physiological effect. However, the involvement of GLP-1 is unknown. In this study, we examined the thermic effects of various nutrients, including dietary proteins, by measuring rectal temperature in rats, and the involvement of gastrointestinal hormones, including GLP-1, in this effect.

Methods: Rectal temperatures of rats fasted for 4 hours were measured using a thermocouple thermometer before (0 h) and after an oral administration of nutrients. In other studies, various antagonists were administered intraperitoneally immediately after an oral protein administration, and rectal temperature was measured as above. Each test was performed under awake, normal housing conditions (22°C).

Results: Of the energy-producing nutrients (isocaloric carbohydrates, lipids, and proteins), oral administration of protein raised rectal temperature the most. Among five dietary proteins (casein, whey, rice, egg, and soy) examined, soy protein had the highest thermic effect. This rectal temperature increase was attenuated by intraperitoneal administration of a GLP-1 receptor antagonist (exendin-9). In contrast, various receptor antagonist treatments of other representative gastrointestinal hormones, GIP, CCK, and PYY, had no effect. In addition, intraperitoneal administration of propranolol, a nonselective beta-adrenergic receptor blocker, did not affect the rectal temperature increase induced by soy protein administration.

Conclusions: These results suggest that soy protein induces postprandial body temperature increase via GLP-1 signaling, independently of brown adipose tissue activation.

Hyperspectral imagery and machine learning assisted dietary assessment; classifying toppings in between double breaded sandwiches

Esther Kok[1], Aneesh Chauhan[1], Edith Feskens[1], Guido Camps[1]

1.Wageningen University & Research (Netherlands)

Background and Objectives: Dietary assessment has proven to be an invaluable tool in efforts to reduce prevalence of nutrition related non-communicable diseases. To improve the current dietary assessment tools, machine learning is applied to automatically detect food items in images based on shape, size, color, and texture. Hyperspectral imaging (HSI) is emerging as a relevant addition to automated dietary assessment. Near infrared or shortwave infrared light measured by HSI can provide information about food chemical composition beyond surface level. We propose a proof of concept where machine learning applied to HSI looks inside a combined food item, i.e. closed sandwiches, to automatically detect their composition.

Methods: For data acquisition, sandwiches were assembled with white or wholewheat bread, optional butter, and six different toppings. Hyperspectral data was captured with the IMEC SWIR Snapscan using 108 bands in the range [1116.141162nm, 1670.623839nm]. Data pre-processing, including spectral filtering and ROI selection, reduced each hypercube (n=24) with dimensions (512, 640, 108) to a region of interest with dimensions (200, 100, 108) and finally to individual pixels (20,000, 180). Data (n=480,000) were randomly split into a train set (n=336,000), used to train a multilayer perceptron on sandwich contents, and a test set (n=144,000) to predict the characteristics of previously unseen pixels to evaluate the performance of the model.

Results: The accuracy score for the classification of bread type was 0.8322, 0.5922 for presence of butter, and 0.2652 for classification of toppings. All classifications performed better than random.

Conclusions: Most test errors were found in sandwiches with high nutritional overlap, e.g., fatty cheese versus low fat cheese and butter. Changing the hyperspectral capturing range may improve the error rate, other wavelengths could be considered to reliably measure the light penetrating the lowest layers of the sandwich. Due to nutritional overlap the training labels are not represented as mutually exclusive. The model might improve by predicting macronutrients instead of the components of the sandwich. This work indicates that machine learning applied to HSI can automatically detect food composition beyond surface level and shows that these technologies are a promising pursuit to improve automated dietary assessment.

A randomized controlled trial of long-term nicotinamide mononucleotide supplementation in healthy adults

Kentaro Naito[1], Takeshi Katayoshi[1], Sachi Uehata[1], Noe Nakashima[1], Takahisa Nakajo[1], Natsuko Kitajima[1], Masakatsu Kageyama[1]

1.DHC Corporation (Japan)

Background and objectives: Numerous preclinical studies have shown that nicotinamide mononucleotide (NMN) supplementation promotes epigenetic rejuvenation and reverse metabolism and function in aged organs and tissues. However, there is limited evidence on the clinical efficacy and safety of NMN. In this study, we evaluated how a 12-week NMN supplementation affects metabolic health parameters in humans.

Methods: Thirty-six healthy male and female participants were enrolled in this randomized, double-blinded, placebo-controlled, parallel study. Participants ingested one capsule of either 125 mg NMN or placebo twice a day after meals for 12 weeks.

Results: NMN supplementation significantly increased the blood levels of the NAD metabolite nicotinamide, indicating that the ingested NMN was utilized in the blood. These results indicate that long-term NMN supplementation at a dose of 250 mg/day is safe and effectively elevates nicotinamide adenine dinucleotide (NAD+) metabolism in healthy middle-aged adults. We also found that a 12-week supplementation with 250 mg NMN tended to reduce brachial-ankle pulse wave velocity (baPWV) values, although no significant differences were observed between the two groups.

Conclusions: This study reveals that long-term NMN supplementation in healthy middle-aged individuals is safe, and beneficial for activating NAD+ metabolism and reducing baPWV. To our knowledge, this study is the first to show that NMN supplementation could help reduce cardiovascular diseases risk and may be useful for advancing larger-scale studies in the future.

Effects of Vitamin C deficiency on increased anxiety-like behavior induced by social-defeat stress in mice Taiga

Kawai[1], Mayu Numagami[1], Akihito Ishigami[2], Ayami Sato[2], Asako Takenaka[1]

1.Meiji University (Japan), 2. Tokyo Metropolitan Institute of Gerontology (Japan)

Background and objectives: We have previously shown that Vitamin C (VC) deficiency for 1 week increases anxiety-like behavior in osteogenic disorder Shionogi rats, which are unable to biosynthesize VC. To investigate the effects of VC deficiency on stress-induced behavioral changes, we measured anxiety-like behavior under social-defeat stress using senescence marker protein–30 (SMP30)/gluconolactonase (GNL) knockout (KO) mice, which are unable to biosynthesize VC.

Methods: 3-week-old male SMP30/GNL KO mice were divided into two groups; one was provided with water containing sufficient amount of VC (VC+) and the other with water without VC (VC-) for 42 days. On days 25–34, half of the mice in each group were exposed to social-defeat stress by being repeatedly subjected to larger and aggressive ICR mice (S+), while the other half were not exposed to social-defeat stress (S-). On days 35–38 and 41, anxiety and depression levels were assessed by the elevated plus maze test (EPMT), open field test (OFT), and tail suspension test (TST), respectively. Dissection was performed on day 42; plasma and organs were collected, and the levels of plasma and brain VC, brain neurotransmitters, plasma corticosterone, and brain TBARS were measured.

Results: Body weight did not differ significantly among the four groups throughout the experimental period. Total VC levels in plasma and cortex were significantly reduced by VC deficiency. In the EPMT, mice in the VC-/S+ group did not appear in the open arm for the first 5 minutes and demonstrated significantly reduced open arm activity compared with that of the mice in the VC+/S+ group; however, decreased open arm activity due to VC deficiency was not observed in the non-stressed mice. Center area activity in the OFT was decreased and plasma corticosterone level was increased owing to social-defeat stress but was not affected by VC deficiency. In the TST, there were no significant differences in immobility time among groups. Prefrontal cortex dopamine levels were significantly reduced and cerebellar TBARS levels were significantly increased by VC deficiency but were not affected by social-defeat stress.

Conclusion: Vitamin C deficiency augments increased anxiety-like behavior with social-defeat stress in the EPM test.

NMN reduces oxidative stress by increasing NQO-1 expression through SIRT1 activation in HUVECs

Takahisa Nakajo[1], Natsuko Kitajima[1], Takeshi Katayoshi[1], Kentaro Naito[1]

1.DHC Corporation (Japan)

Background and objectives: Oxidative stress causes endothelial dysfunction associated with vascular aging and is causally related to the pathogenesis of cardiovascular diseases. Preclinical studies indicate that a nicotinamide adenine dinucleotide (NAD+) precursor nicotinamide mononucleotide (NMN) restores age-related NAD+ depletion and alleviates oxidative stress in aged vessels, providing vasoprotective effects. However, few studies have investigated how NMN reduces vascular oxidative stress at the cellular level. We aimed to identify a possible mechanism that underlies the protective effect of NMN on oxidative stress.

Methods: Human vascular endothelial cells (HUVECs) were pretreated with NMN for 24 h and then stimulated with hydrogen peroxide (H2O2). Cell viability was assessed by WST-8 assay. The mRNA and protein expressions were analyzed by qPCR and western blotting, respectively. Actin cytoskeleton was visually evaluated using immunostaining and fluorescence microscope. Cellular reactive oxygen species (ROS) levels were measured with a microplate reader using the fluorescent CM-H2DCFDA probe.

Results: NMN inhibited H2O2-induced cell death, disorganized actin cytoskeleton, and cellular ROS production. In addition, NMN also suppressed the expression of senescence-associated proteins, including p16 and p21, in H2O2-treated HUVECs. We found that NMN increased mRNA and protein expression of an anti-oxidant enzyme NAD(P)H: quinone oxidoreductase 1 (NQO-1). Interestingly, the expression of NQO-1 markedly increased after NMN treatment, whereas the increase in other nuclear factor erythroid 2-related factor 2 target gene expressions were modest. A SIRT1 inhibitor EX527 abrogated the effect of NMN on NQO-1 expression, suggesting that NMN-inducible NQO-1 is involved in SIRT1 activity.

Conclusions: NMN regulates oxidative stress by modulating NQO-1 expression via activating the SIRT1-dependent pathway and provide a new insight into the mechanism by which NMN exert protective effects on vascular oxidative stress.

Background: Folic acid (FA) containing supplements are recommended for women who are planning to get pregnant, one month before conception up to 12 weeks of gestation to prevent neural tube defects. There are suggestions that increased FA intake in late gestation has been associated with adverse health outcomes in children. Excess circulating FA as 'unmetabolised folic acid' (UMFA) has been proposed as a biomarker of excess. Our aim was to determine if removing FA from prenatal supplements after 12 weeks' gestation reduces maternal serum UMFA concentration.

Methods: A double-blind, parallel group, randomised controlled trial. Women between 12 and 16 weeks' gestation were randomised to receive a daily multi-vitamin and mineral supplement containing 800 µg of FA or no FA from enrolment until delivery. The primary outcome was serum UMFA concentration at 36 weeks' gestation. Secondary outcomes included serum and erythrocyte folate concentrations. UMFA concentrations were determined using a multiple reaction monitoring assay on a triple quadrupole mass spectrometer. Serum and erythrocyte folate concentrations were measured using microbiological assay.

Results: Eighty seven percent (n=90/103) women completed the trial. The proportion of women with detectable UMFA was significantly lower in the no FA group compared to the 800 µg FA group (71.7% vs. 97.7%]; p = 0.001), but a mean difference could not be quantified. Maternal serum and erythrocyte folate concentrations were significantly lower in the no FA group compared to the 800 µg FA group at 36 weeks' gestation (23.2 vs. 49.3 nmol/L, 1335 vs. 1914 nmol/L, respectively; p<; 0.001).

Conclusions: Although removing folic acid from supplements reduced the proportion of women with detectable UMFA, serum concentrations were low overall. This suggests UMFA may not be the best biomarker to determine chronic excess folic acid exposure. Further work is needed to establish if excess folic acid in late pregnancy contributes to adverse childhood clinical outcomes.

The association between ultra-processed foods and atherogenic lipoproteins is partly mediated by microbiome in the ZOE PREDICT study

Emily Rose Leeming[1], Jia Yi Lee[1], Francesco Asnicar[2], Inbar Linenberg[3], Kate M Bermingham[1], Lucy E Francis[3], Nicola Segata[2], Tim D Spector[1], Sarah E Berry[1], Rachel Gibson[1]

1.King's College London (UK), 2. University of Trento (Italy), 3. Zoe LTD (UK)

Background and objectives: Ultra-processed food (UPF) intake is associated with unfavourable cardiometabolic outcomes, although mechanisms are unclear. The aims of this study were to; 1) characterise cardiometabolic risk measures associated with level of intake of UPF, unprocessed and minimally processed foods (MPF), and 2) identify partially mediating gut microbial species.

Methods: The NOVA classification was applied to weighed food diaries (14 days) from the UK ZOE PREDICT 1 cohort (n = 966) collected by mobile application. Metagenomic microbiota samples were collected prior to clinic visit, anthropometric measures and serum lipid based metabolomics were assessed at clinic visit. Linear mixed effect model, PERMANOVA and mediation analyses explored associations between level of food processing, cardiometabolic risk measures and the gut microbiota after adjusting for confounders (sex, age, race/ethnicity, smoking, education, physical activity, zygosity and family number).

Results: In a free-living setting UPF intake was strongly associated with nutrient intakes; higher carbohydrate and total sugar intake, and lower alcohol and protein intake (all %EI) (p <;0.001 for all) but not mean energy intake (kcal) or body weight (kg). UPF intake was associated with increased abdominal obesity (beta = 0.003, p = 0.01) and an atherogenic lipoprotein phenotype (elevated triglycerides, ApoB/ApoA1 and lower L-HDL subparticles) (P<;0.05 for all). The gut species, Roseburia hominis, was negatively associated with UPF intake (beta -0.015, q = 0.003), and partially mediated the associations of UPF with atherogenic lipoproteins (triglycerides, serum monounsaturated fatty acids (MUFA)). Conversely, MPF intake was associated with a favourable lipoprotein profile, reduced GlycA concentrations (beta = -0.8 x10-4, p = 0.05) and lower visceral fat mass (beta = -2.89, p = 0.02), all partially mediated by multiple gut microbial species including F. plautii.

Conclusion: An unfavourable association between UPF and atherogenic lipoproteins, independent of energy intake or body weight, highlights a novel potential mechanism linking modern food processing with ill-health. The role of the gut microbiota adds to the growing body of evidence for key diet-microbiome-host health interactions.

Prevention of dietary obesity: Impact of N-3 polyunsaturated fatty acids on autophagy process in connection with the colonic mucus layer secretion and the gut microbiota

Amina Bourragat[1], Sandrine Bellenger[1], Audrey Geissler[2], Michel Narce[1], Jérôme Bellenger[1]

1.INSERM U1231 University of Burgundy, Dijon (France), 2. CellimaP, Dijon (France)

Background and objectives: During the onset of dietary obesity, a dysbiosis of the intestinal microbiota contributes to the alteration of the intestinal barrier function by increased permeability of the intestinal epithelium, and alteration of the colonic mucus layer linked to low grade inflammation. It has recently been shown that an autophagic process is essential for the exocytosis of mucin granules by intestinal caliciform cells. Our hypothesis is that, in the context of an obesogenic diet, n-3 polyunsaturated fatty acids (n-3 PUFAs) could modulate this autophagic process at the colonic level and thus prevent the alteration of the barrier function and the intestinal homeostasis.

Methods: To do so, four groups of Wilde Type (WT) and fat1 mice (with tissue enrichment in n-3 PUFA) were fed with an obesogenic (HFD) or control (CTL) diet for 12 weeks. Weight monitoring and a glucose tolerance test were performed. The expression of proteins and autophagy genes (LC3B, ULK1, ATG5) as well as the mucin MUC2 were analyzed, the measurement of the thickness of the mucus layer was performed after staining with alcyan blue. Finally, the composition of the mucus layer was assessed by electron microscopy. In addition, four groups of Wilde Type mice were transplanted with, either caecal content of fat1 (WTF) or Wilde Type mice (WTWT), then were fed with an obesogenic (HFD) or control (CTL) diet for 12 weeks. In the same way, weight monitoring, glucose tolerance test and the measurement of the thickness of the mucus layer were performed. The expression of proteins and autophagy genes as well as MUC2 were analyzed.

Results: Our results show that unlike WT HFD mice, fat1 HFD mice were protected against dietary obesity, glucose intolerance, the intestinal permeability and the increased of the thickness of the mucus layer. Furthermore, regardless of diet, the expression of the initiation and elongation autophagy genes ULK1, ATG5 and LC3B tended to increase.

Conclusions: Finally, WTF HFD mice were able to partially reverse weight gain and to normalize glucose tolerance. They were protected from the alteration of the thickness of the mucus layer barrier compare to WTW HFD and the expression of autophagy genes ULK1 and LC3 tended to increase. It would be now interesting to investigate the composition of fat1 gut microbiota and study its effect on mucus secretion during obesity. It would also be interesting to study the effect of short-term obesogenic diet on the thickness of the mucus layer because, according to previous studies, 4 weeks of High fat diet was sufficient to induce a significant reduction of the thickness of the mucus layer.

Micronutrient Dose Response (MiNDR) study among women of reproductive age (WRA) and pregnant women (PW) in rural Bangladesh: study protocol for a double-blind, randomized, controlled trial

Towfida Jahan Siddiqua[1,2], S. M. Tafsir Hasan[3], Hasmot Ali[1,2], Khalid Bin Ahsan[1], Eleonor Zavala[2], Daniel Erchick[2], Tahmeed Ahmed[3], Kerry J Schulze[2], Parul Christian[1,2], On behalf of MiNDR study team

1.Johns Hopkins University, Bangladesh (Bangladesh), 2. Johns Hopkins Bloomberg School of Public Health (USA), 3. Nutrition and Clinical Services Division (Bangladesh)

Background and objective: Improving nutritional status of women can benefit their own health, prepare them for pregnancy, support nutritional needs during pregnancy, improve pregnancy outcomes, and impart nutrient stores to offspring in utero and during lactation. A multiple micronutrient supplement (MMS) (with "UNIMMAP" the most common formulation, containing ~1 RDAof 15 micronutrients) is superior to the current standard of care for antenatal use, iron-folic acid (IFA), at reducing adverse birth outcomes. MMS has been recommended for use in the context of rigorous research by WHO. However, while MMS improves pregnancy outcomes, it might not completely resolve vitamin and mineral deficiencies in undernourished settings. We aim to conduct a bioefficacy study using different doses of a MMS product to determine a minimum dose at which sufficiency is achieved for a variety of micronutrients. Secondary objectives are to discover novel functional biomarkers of nutrient status and examine response based on baseline characteristics and underlying nutritional status.

Methods: In rural northern Bangladesh, two dose-response trials (n=240 participants/trial) using a double-blind, randomized, controlled design will be conducted to test increasing levels of a variety of micronutrients, some of which will be between RDA/ AI and the UL. These four-arm trials will be done among WRA and PW and test three different levels of

nutrients vs a control of ~1 RDA, similar to the UNIMMAP formulation. Balanced energy and protein (BEP) supplementation will be done simultaneously to ensure adequate protein and caloric intakes. Features of the trials will include gestational assessment using ultrasound (PW), directly observed supplementation, diet and morbidity recalls, understanding side effects, and monitoring adverse events and state-of-the-art biochemical analytics, with creation of a biospecimen repository of blood, urine, stool, and human milk specimens. Statistical modelling will be used to determine the amount of each nutrient at which nutritional status for the group is optimized without evidence of nutrient excess.

Results: To be determined. These findings will be pertinent to a large swathe of the rural South Asian population.

Conclusions: This study is an important undertaking to fill a large knowledge gap regarding optimal levels of nutrient intakes to achieve adequate status, especially in settings where long-standing micronutrient deficiencies exist among WRA and PW.

Effect of eating rice balls (Onigiri) as a supplementary food after training in college student middle-distance track and field athletes on subjective fatigue after exercise and after the next day

Shiori Alzawa[1,2], Megumi Matsumoto[1], Takayuki Koyama[1], Junichi Nagasawa[1]

1. Nihon University (Japan), 2. euglena Co. Ltd. (Japan)

Background and objectives: Cooked rice is one of the foods whose main ingredient is α-starch, which is one of the polysaccharides, and Japanese people prefer to eat as “rice balls (Onigiri)”. Elite athletes also eat “Onigiri” for important competition and recovery on site, but few studies have objectively measured the effect of “Onigiri” on after exercise recovery from fatigue. In this study, we compared the effect of eating “Onigiri” as a supplementary food after training within 30 minutes subjective fatigue and hunger from the next day onwards, and compared it with physiological data, aimed to verify the effectiveness of “Onigiri”.

Methods: The subjects were 7 male college student middle-distance track and field athletes, were participated in the experiment that take supplementary food (Onigiri) immediately after training and the control that don't take anything (control group) by crossover trial method. “Onigiri” was prepared as follows so that the intake of carbohydrates was 1.1g/kg of body weight: omelet and ham in Energy:384-465kcal, Carbohydrate:62.2-80.0, Protein:12.6-13.8g, Fat:7.7-7.8. All subjects ate lunch 2 hours after the end of training. For 3 days before and after training, changes in blood glucose levels were observed using a continuous glucose monitoring (CGM), and dietary surveys were also conducted. Furthermore, we surveyed the physical condition, subjective fatigue and hunger questionnaire.

Results: In changes in blood glucose levels was higher the control group than the experiment at 3:00, 4:00, and 5:00, and tended to be higher the control group than the experiment at 6:00 and 7:00 from bedtime to early morning on the day after training. They were observed significant interaction. In the subjective fatigue questionnaire after training, "fatigue" was higher the control group than the experiment, and "hunger" was tended to be higher the control group than the experiment.

Conclusions: In this study, “Onigiri” may affect glucose metabolism and may be a suitable food as a portable supplementary food after training. In the future, it will be necessary to conduct comparative experiments and laboratory experiments to investigate in detail whether “Onigiri” has psychological factors such as preference as factors that affect subjective fatigue.

Butyrate-induced anti-obesity effects via changes in gut microbiome and muscle oxidative metabolism

Jinyoung Shon[1,2], Seungmin Song[1,2], Soyoung Kwon[1,2], Khuhee Na[1,2], Yoon Jung Park[1,2]

1.Department of Nutritional Science and Food Management, Ewha Womans University (Korea), 2. Graduate Program in System Health Science and Engineering, Ewha Womans University (Korea)

Background and objectives: A large body of evidence has convincingly demonstrated the impact of the gut microbiota and microbially-produced metabolites such as butyrate on obesity. However, it remains to be elucidated whether and how butyrate intake as diet influences gut microbiome and body weight control. This study was aimed to investigate effects of butyrate supplementation on diet-induced obesity (DIO) and their underlying molecular mechanisms.

Methods: The 5-week-old Sprague Dawley male rats were divided into three groups: high-fat diet (HFD), short- and long-term sodium butyrate-supplemented HFD (SSB and LSB) for two or fourteen weeks, respectively. Tissues and feces were collected, and the mRNA and histone were extracted from tissues for quantitative analysis. The feces were used for 16S

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

rRNA gene sequencing for microbial analysis.

Results: Dietary butyrate supplementation attenuated weight gain in LSB, despite augmenting food intake, compared to HFD group. The colonic proglucagon (Gcg) gene, encoding appetite suppressing hormone glucagon-like peptide (GLP-1), was downregulated in LSB along with elevated food intake. The fecal energy output was not changed, indicating that prevention of DIO was not caused by energy output. Gut microbiome analysis showed a higher abundance of Firmicutes in LSB with increasing tendency of Firmicutes and Bacteroidetes (F/B) ratio than HFD. Additionally, butyrate supplementation reduced species evenness of alpha-diversity and increased beta-diversity. The butyrate transporter encoding gene solute carrier family 16 member 1 (Slc16a1) was upregulated in muscle, but not the liver and adipose tissue, suggesting increased butyrate influx into the muscle cells. Additionally, peroxisome proliferator-activated receptor gamma (Pparγ), Pparδ, and fatty acid oxidation-related genes, including PPARγ coactivator 1-alpha (Pgc1α) and uncoupling protein 2 (Ucp2) were upregulated in LSB and SSB. Consistent with gene expression results, the global acetylation levels of histone H3 and H4 of LSB were only elevated in muscle, not in the liver. Interestingly, butyrate prevented weight gain, likely via changes in microbiota and muscle oxidative metabolism.

Conclusions: These results pointed a distinct role of dietary butyrate in regulating muscle histone acetylation and gene expression, and consequently anti-obesity effect. Further studies are required to elucidate how the butyrate affects gut microbiota.

PAB(T1)-127

FADS1 and FADS2 as biomarkers of Zn status – a systematic review and meta-analysis

Marija Knez[1], Ana Pantović[1], Elad Tako[2], Erick Boy[3]

1.University of Belgrade (Serbia), 2. Cornell University (USA), 3. HarvestPlus (USA)

Introduction: Despite enormous research efforts, a single sufficiently sensitive and reliable biomarker for the assessment of Zn status has not been identified to date. Over the recent years, several new indicators have been proposed as potential candidates for more accurate determination of Zn status, one of them being FADS1 and FADS2 activity. Aim: The objective of the current work was to do a systematic review of experimental animal and human studies on the efficacy of FADS1 and FADS2 to respond to Zn interventions and to define the current applicability and suitability of FADS activities to act as biomarkers of Zn status in humans.

Methods: A systematic review was conducted following PRISMA guidelines. The systematic search was performed in PubMed, Web of Science, Scopus, Web of knowledge, and Central with strictly defined criteria. Risk of bias was assessed with RoB2 tool in randomized controlled trials, Newcastle-Ottawa Scale in cross-sectional studies and with SYRCLE tool in animal studies.

Results: 21 studies were included, 8 animal and 13 human studies (5 randomized controlled, 2 feeding non-controlled trials and 6 cross-sectional studies). The qualitative synthesis demonstrates the potential of FADS1 and FADS2 activity to be used as additional biomarkers of Zn status. The activity of desaturase enzymes corresponds to dietary Zn manipulations, both in animals and humans and potential covariates and confounders of these relations are identified. The changes in FADS2 activity and plasma/serum Zn following a Zn intervention in both cases demonstrate that the pooled estimates were not significant, however, the standard mean difference of FADS2 activity was higher.

Conclusion: This review provides a summary of major findings and some novel insights on FADS1 and FADS2 activities in relation to Zn intake. Additional higher quality experimental animal model studies and clinical trials are necessary to evaluate the observed interrelations further. The work provided should be used as a guideline for conducting future clinical trials that will explain the proposed relationships further and assist in confirming the efficacy of the FADS1 and FADS2 activity to act as Zn status indicators, individually or in combination with some other biochemical markers.

PAB(T2)-1

Consumption of high protein foods and their impact on health of Mauritians

Hanaa Amiirah Sohawon[1]

1.Naturhouse (Mauritius)

Background and Objectives: Dairy products and pulses are rich sources of proteins and can be used as substitutes for red meat, chicken and eggs which, apart from being protein-rich foods, are also high in saturated fats and cholesterol. The aim of this study is to investigate whether or not Mauritians know the importance of dairy products and pulses as alternative and rich sources of proteins, whether these are included in their daily diets, and their impact on health.

Methods: A survey-based questionnaire was designed to carry out a cross-sectional study among 500 respondents. Questions included were on socio-demographic factors, socio-economic factors, lifestyle factors, health and nutritional status, and consumption pattern of red meat, chicken, eggs, dairy products and pulses.

Results: Data showed that although a majority of respondents knew the importance of dairy products and pulses as rich sources of proteins in the diet, they did not consume these adequately. Respondents who consumed more of these

foodstuffs everyday were consequently healthier than respondents who consumed red meat, chicken or eggs on a daily basis. Links were found between daily dairy product and pulses consumptions and low prevalence of non-communicable diseases among the respondents who consumed more of these foods, as opposed to those who consumed red meat, chicken or eggs everyday.

Conclusion: The study revealed that awareness must be raised on the importance, health impacts and on the adequate inclusion of alternative protein food sources such as dairy products and pulses in the daily diet of Mauritians.

Systematic error and association between total protein intake from Food Frequency Questionnaire and from the gold standard differ between individuals with low- and high-socioeconomic status in a Dutch general population

Yinjie Zhu[1,3], Jochen O. Mierau[2,3], Ineke J. Riphagen[4], Louise H. Dekker[5], Stephan J.L. Bakker[1,3], Gerjan J. Navis[1,3]

1.University Medical Center Groningen (Netherlands), 2. Aletta Jacobs School of Public Health (Netherlands), 3. University of Groningen (Netherlands), 4. Certe Medical Diagnostics and Advice (Netherlands), 5. National Institute for Public Health and the Environment (Netherlands)

Background and objectives: Adequate nutritional assessment is particularly important in individuals with low socioeconomic status (SES) to better predict disease outcomes, given their vulnerability to a whole spectrum of diseases. Dietary intake of nutrients, including protein intake, is commonly assessed by means of food frequency questionnaires (FFQ). However, little is known regarding the difference in bias between subjects with low- and high-SES. This study investigated if total protein intake assessed from FFQ was associated with protein intake assessed from 24 h urine, and to what extent this association differed between individuals with low- and high-SES in a Dutch population.

Methods: We included 1302 participants aged 65 ± 4 years old from the Lifelines-MINUTHE cohort study, who had valid and reliable FFQ and 24 h urine data. SES was determined by education attainment and a total of 43.2% individuals had low SES. Total dietary daily protein intake was calculated from an externally validated FFQ as well as calculated from 24 h urine using Maroni's formula. We used linear regression analysis to examine the association between protein intake from FFQ and Maroni's formula, and to investigate whether this association was modified by SES.

Results: Overall, estimated protein intake from FFQ (0.92 ± 0.25 g/kg/d) was lower than from Maroni's formula (1.1 ± 0.28 g/kg/d). The difference of protein intake assessed from FFQ and urine was smaller in individuals with low SES than that of individuals with high SES (0.16 ± 0.29 g/kg/d and 0.22 ± 0.29 g/kg/d, p<;0.001). After adjusting for covariates, total protein intake from FFQ was positively associated with protein intake calculated from 24 h urine (β (SE): 0.65 (0.05), p<;0.001). SES modified the association (pinteraction= 0.01), with higher magnitudes of association observed among people with high SES (β (SE): 0.67 (0.06), p<;0.001), compared to people with low SES (β (SE): 0.63 (0.07), p<;0.001).

Conclusions: We found a positive association between objective and subjective assessment of protein intake. However, this association was less pronounced among people with low SES. Promoting objective assessment of nutrients might help mitigate the reporting bias among socioeconomically disadvantaged individuals, and therefore could better facilitate monitoring health conditions among them.

The way of counseling system from Ages, Gender, Obesity, Hypertension and Hyperlipidemia differences for glucose tolerance abnormality considered by 75g OGTT

Chikako Hibino[1], Kazue Sugawara[1], Rumi Takahashi[1], Kayoko Abe[1], Hiroshi Tamura[1]

1.Hiroshi Tamura Hill-top Clinic (Japan)

Background: According to the Ministry of Health survey in 2019, the 19.7% of male and the 10.8% of female are strongly suspected of having diabetes in Japan. We know all that the early recognition of impaired glucose tolerance during a 75-g oral glucose tolerance test (OGTT) in patients with an HbA1c of 6.0-6.4 % is reducing to diabetic in the future. Objective: To show the past records of similar cases to the impaired glucose tolerance as well as to the future ones who are patients of the difference about age, gender, obesity, and hypertension and dyslipidemia.

Method: The objects came from the patients who tested OGTT from Jan.2017 to Oct.2021, and there were 129 people (79 male, 50 female,57.6± 12.9 years, 39 elderly people (over 65 years old), HbA1c:6.0-6.4% (6.2 ± 0.1%), BMI:26.7 ± 5.2kg/m2) were investigated due to their differences during the OGTT (0,0.5,1.0,1.5,2.0hour).

Result: Patients were to be classified into the normal type(11%), borderline type(68%), or diabetic type(21%).27 diabetic type patients(HbA1c6.24±0.15%) were higher than both 88 borderline type patients(6.16±0.13%) and 14 normal type patients (6.12±0.11%) (p<;0.05) (p<;0.01). The study also showed the average of OGTT of the patients over 65 years old and under 65 years old weren't significant, and the average of the patients over BMI25kg/m2 and under BMI25kg/m2 also weren't

significant. However, the average of OGTT (0.5h,1.0h,1.5h) of male was higher than female. The average age 42 patients of Hypertension and dyslipidemia(60.8±11.2years) were older than 31 patients without Hypertension and dyslipidemia(51.5±14.9years)(p<;0.01),and the group of 2.0hGTT(179.4±37.6 mg/dl) was higher than the group without Hypertension and dyslipidemia 2.0hGTT(159.7±43.7 mg/dl) (p<;0.05).

Conclusion: We recognized the difference of the gender for the impaired glucose tolerance. Also, the impaired glucose tolerance is reflected the people over 60 years old who has both hypertension and dyslipidemia was the high level of after 2hours glucose level. Before the result of OGTT, our tendency helps the consultation before being diabetic.

Effect of potato salad intake on postprandial plasma glucose: Difference in the amount of seasoning added

Kumiko Kawakita[1], Naoko Sugio[1], Tsuneo Ogawa[1]

1.Minami Kyushu University (Japan)

Objectives: The blood sugar easily increases after eating potatoes because the glycemic index of potato is high. As an example, potato salad is mainly made by potatoes and some vegetables like carrots and onions, but it also contains mayonnaise which may interfere with glucose metabolism. In this study, we examined the effects of potato salad on postprandial blood glucose and feeling satiety. We also examined the effects of the amount of mayonnaise added to the salad.

Methods: Thirty six healthy female university students were enrolled. They were asked to take three different meals, i.e., (1) potato-only meal, (2) a potato salad with high amount of mayonnaise, and (3) a potato salad with low amount of mayonnaise. The total amount of carbohydrate in each meal was adjusted to almost 30 g. In each experiment, blood sugar was measured from the fingertip before and 30, 45, 60, 90, 120 min after taking each meal. Visual Analogue Scale (VAS), an indicator of satiety, hunger and appetite, was also measured before and 30, 60, 120 min after taking each meal.

Results: The postprandial glucose after eating potato salad was significantly decreased and VAS was significantly increased compared to potato-only meal. Potato salad with high amount of mayonnaise prevented blood glucose increase more strongly than that with low amount of mayonnaise. Because mayonnaise contains a lot of fat, potato salad with high amount of mayonnaise contains 67% of fat while low amount of mayonnaise contains 45% of fat.

Conclusions: The fat in mayonnaise highly contributed to the prevention of the blood sugar increase. Also the dietary fiber of vegetables in the potato salad helped a little. In this study, even a small amount of mayonnaise suppressed the increase in blood glucose level. Therefore, it is advisable to adjust the amount of mayonnaise depending on the health condition of each person.

Keywords: potato salad, amount of seasoning, blood glucose level

Maternal time spent in childcare and its association with dietary adequacy among 12-23 months old rural Eastern Ugandan children

Joweria Nambooze[1,2], Haeun Lim[4], Andrea Spray[4], Gwen Varley[3], Lora Forsythe[3], Njeri Kimere[4], Kate Wellard[3], Elaine Ferguson[4]

1.Kyambogo University (Uganda), 2. Africa Innovations Institute (Uganda), 3. University of Greenwich (UK), 4. London School of Hygiene and Tropical Medicine (UK)

Background and objectives: The causes of under-nutrition are multi-factorial but dietary adequacy and child care are important contributing factors. Maternal time constraints result in trade-offs between time in domestic and productive work, which might have a negative impact on child nutrition. The current study aimed to determine whether maternal time allocated to childcare or feeding the child was associated with dietary adequacy for children 12-23 months.

Methods: A cross-sectional survey was conducted in Eastern Uganda. Maternal time use data was collected using 15 –hour observation, child's dietary data was captured using 1-day weighed food record. Estimated percentage of children at risk of inadequate nutrient intakes was calculated using EAR fixed cut-point or probability approaches, after adjusting the intake distribution using external variance ratios and assuming low Fe & Zn bioavailability. Indicator of overall dietary adequacy used the mean probability of adequacy (MPA) for micronutrients based on the estimated best linear unbiased predictor (BLUP) of usual nutrient intakes.

Results: More than 30% of children were at risk of inadequate intake of Fe, Ca, Zn, thiamine, riboflavin, niacin, vitamin A, B6, folate, and B12 (ranging from 30-100%), although <;15% were at risk of low protein and vitamin C intakes. The median IQR for MPA was 0.41 (0.30, 0.57). Women spent on average 11.8 hours/day on child care of which 1.75 hours/ day, 2.5 hours/day and 0.5 hours/day were spent feeding, breastfeeding, and playing with the child, respectively. The majority of time spent in childcare was combined with other activities. Factors significantly associated with MPA included child feeding time (β=0.077; p<;0.001), child's breastfeeding status (β= 0.048; p<;0.005) and availability of an adult alternative childcare giver such as an older sibling or an aunt within the household (β= 0.053; p<;0.05).

Conclusions: The time spent in child feeding and the presence of alternative adult caregivers were positively associated with MPA. The results indicate the need for more care services and more engagement from adult care givers within the

household. These findings may have implications for policy and programme planning for children in the first 1000 days of life.

PAB(T2)-6

Dexamethasone-induced muscle atrophy in rats: effects of age and vitamin D deficiency

Yuna Oi[1], Natsuko Yoshida[1], Kaho Hashimura[1], Yasuyuki Kitaura[2], Yoshiharu Shimomura[1]

1.Chubu University (Japan), 2. Nagoya University (Japan)

Background and Objectives: Since skeletal muscle plays an important role in energy metabolism, human health is supported by maintaining a suitable amount of the muscle. Age-related muscle loss is known as sarcopenia. Recent studies have suggested that vitamin D (VD) deficiency is related to sarcopenia, but mechanisms responsible for VD to maintain skeletal muscle are not clear. It has been reported that an overdose of dexamethasone (DEX) causes muscle atrophy and promotes the branched-chain amino acids (BCAAs) catabolism, suggesting that accelerated catabolism of the amino acids contributes to muscle atrophy. Therefore, the present study aimed to examine effects of VD deficiency on the BCAA catabolism and DEX-induced muscle atrophy in rats.We conducted 2 experiments. In Experiment 1, 9-week-old male rats were divided into two groups and either saline or DEX (600 µg/kg body weight) was intraperitoneally administered at 10:00 a.m. for consecutive 5 days. In Experiment 2, 5-week-old male rats were divided into two groups and fed either a control diet (AIN93G) or a VD-deficient diet (D18121302) for 8 weeks. At 14 weeks of age, each group of rats was divided into two subgroups, and then rats were given saline or DEX as in Experiment 1. On the final day of the experiment, rats were fasted for 6 hours and anesthetized with isoflurane, and then blood and tissues were collected.DEX administration decreased muscle weights of tibialis anterior and gastrocnemius+plantaris by 29% and by 23%, respectively, in Experiment 1, and by 18% and by 17%, respectively, in Experiment 2. Soleus muscle weight was not affected by DEX administration in either experiment. These results suggesting that the skeletal muscles consisting mainly of white muscles in younger rats are susceptible to the DEX treatment. The DEX treatment significantly elevated the concentrations of plasma insulin and BCAAs, the former suggesting insulin resistance and the latter suggesting promotion of protein degradation. The VD deficiency did not affect muscle atrophy or plasma concentrations of insulin and BCAAs, suggesting VD deficiency did not promote DEX-induced muscle atrophy or insulin resistance.

A novel method for measuring serum albumin redox state using a thiol-binding reagent.

Fuka Tabata[1], Yasuaki Wada[1], Satomi Kawakami[1], Kazuhiro Miyaji[1]

1. Morinaga Milk Industry Co., Ltd. (Japan)

Background and objectives: Albumin is the most abundant serum protein, comprising a mixture of human mercaptalbumin (HMA, reduced albumin) and nonmercaptalbumin (HNA, oxidized albumin), depending on the redox state of the cysteine residue at position 34. The redox state of serum albumin has been viewed as an oxidative stress biomarker, and recent studies have found its potential as a protein nutrition biomarker (Tabata et al., Antioxidants 2021). Serum albumin redox state has normally been measured using HPLC. However, this requires an expensive equipment and laborious technique, and is not feasible in many clinical practices. To overcome these limitations, we developed a simple method to evaluate albumin redox state by separating HMA and HNA, using a thiol-binding reagent and detecting albumin fractions in colorimetric assays.

Methods: HMA in serums of healthy adult volunteers (20 samples) were removed by reacting the free thiol group of HMA with a pyridyl disulfide-linked resin, e.g., a Cytiva Activated Thiol Sepharose 4B, or a Thermo Scientific EZ-Link HPDP-Biotin in combination with a Streptavidin Agarose Resin; HNA-containing fractions were then separated by ultrafiltration. Albumin concentrations in both serums (HMA+HNA) and the HNA-containing fractions were measured by a colorimetric method with bromocresol green (BCG) or bromocresol purple (BCP), and the ratio of HMA to total albumin (%HMA) was determined. The %HMA measured by the above method was then compared with the %HMA determined by a conventional HPLC method.

Results: Removal of HMA from the serums, i.e., the purity of HNA in the HNA-containing fraction, was confirmed by HPLC. Simple linear regression analyses indicated that %HMA by this method and the one by HPLC were correlated significantly (r = 0.614-0.910).

Conclusions: This novel and simple approach can be a valuable tool for measuring serum albumin redox state, a potential protein nutrition biomarker as well as an oxidative stress biomarker, in a variety of clinical settings.

Dietary calcium intake and obesity association according to alcohol drinking and smoking status in Japanese type 2 diabetes mellitus patients

Efrem d'Avila Ferreira[1], Mariko Hatta[1], Yasunaga Takeda[1], Chika Horikawa[1], Mizuki Takeuchi[1], Noriko Kato[2], Hiroshi Maegawa[3], Kazuya Fujihara[1], Hirohito Sone[1]

1. Niigata University (Japan), 2. Kato Clinic of Internal Medicine (Japan), 3. Shiga University of Medical Science (Japan)

Background and objectives: Many previous studies have reported an inverse association between higher dietary calcium or dairy products intake and obesity or metabolic syndrome. Even though many studies have assessed this association, the effect of cofactors on this relationship have not been fully investigated. Therefore, we aim to conduct a cross-sectional study between calcium intake and obesity as measured by the body mass index (BMI) with stratification by cofactors including alcohol drinking and smoking status in Japanese people with Type-2 diabetes.

Methods: This was a cross-sectional study which included Japanese outpatients with Type 2 diabetes (n=1567; 63.1% men; mean age 62.3 SD 11.6 years). Diet information was collected via a self-administered validated food frequency questionnaire. Height and weight were self-reported and obesity was defined as BMI >;=25kg/m2.

Results: Multivariate analysis with adjustment by life-style confounders and energy intake resulted in an inverse association between quartiles of calcium intake and obesity in all participants (OR=.426, 95% CI= .292-.621; p trend= <;.001) and in all subgroups of the stratified analysis. Inclusion of vegetable intake in the multivariate analysis resulted in no association in the alcohol drinkers and smokers subgroups, while further adjustment by a number of food groups including soybeans, milk and other dairy products or bread intake was necessary for the inverse association to disappear in all participants, non-alcohol drinkers and never smokers subgroups. The nutrient-adjusted multivariate analysis showed that phosphorous and retinol, but not vitamin D, were important confounders, as the adjustment by these micronutrients resulted in a loss of significant association between calcium with obesity.

Conclusion: Higher quartile of calcium intake was inversely associated with obesity, but more strongly in non-alcohol drinkers and never smokers subgroups. There was a lower intake of dairy products by members of alcohol-drinkers and smokers subgroups. In addition, dairy consumption increased as rice intake decreased. Future research assessing dairy products intake by fat content and obesity in adult population is recommended.

Exploring strategies to improve the surveillance of iron deficiency

Andrea J Sharma[3,4], Nicole D Ford[3], Anne M Williams[1,2]

1. University of Otago (New Zealand), 2. Emory University (USA), 3. Centers for Disease Control and Prevention (USA), 4. US Public Health Service Commissioned Corps (USA)

Background and objectives: When national population-based estimates of iron deficiency (ID) are unavailable, clinical data may be useful for surveillance of ID. Our objective was to compare clinically used iron and hematologic indictors to the WHO recommended iron indicator to assess ID among a population of adult women.

Methods: Using data from the United States' National Health and Nutrition Examination survey (2003-2006 and 2017-2018, years when all indicators measured), we evaluated the sensitivity, specificity, and area under the receiver operating characteristics (ROC) of indicators used in clinical settings (hemoglobin, Hb <;12.0 g/dL; transferrin saturation, TSAT <;15%; total iron binding capacity, TIBC >;400 µg/L; serum iron, SI <;40 µg/L; and mean corpuscular volume, MCV <;80 fl) compared to inflammation-adjusted serum ferritin (<;15 µg/L) for ID among non-pregnant women aged 20-44 years (n=2,580).

Results: Prevalence of ID based on inflammation-adjusted serum ferritin was 18.0% and ranged from 6.1% (MCV) to 17.4% (TSAT) using alternative indicators. Sensitivity was greatest for Hb (74.4%), followed by MCV (66.5%), SI (61.2%), TIBC (52.9%), and TSAT (51.2%). Specificity was greatest for TSAT (90.6%), followed by TIBC (87.4%), SI (86.5%), Hb (85.2%), and MCV (83.8%). The ROC curve was greatest for TSAT (AUC=0.84), followed by TIBC (AUC=0.81), Hb (AUC=0.81), SI (AUC=0.79), and MCV (AUC=0.76).

Conclusion: When ferritin is unavailable, other iron indicators may be suitable for surveillance of ID among non-pregnant women in the United States. This exercise could be repeated to improve the estimation of ID where clinical data are available.

Breakfast skipping habits affect dietary intake in Japanese athletes

Mika Goshozono[1], Motoko Taguchi[1]

1.Waseda University (Japan)

Background and objectives: Skipping breakfast has been reported to reduce daily energy and protein intake in healthy individuals. However, few studies have examined intake levels in athletes with breakfast skipping habits. Since athletes have higher energy expenditure than regular healthy individuals, more energy and nutrient intake are required. Therefore, if athletes skip breakfast, there is a risk of accelerating performance degradation. This study aimed to assess the nutritional intake and examine the relationship between nutritional intake and food group intakes among athletes with breakfast skipping habits.

Methods: A total of 177 male collegiate athletes from various sports (18 sports) participated in this study. Participants were classified into two groups based on the breakfast skipping habits: breakfast skipper (BS, 0–3 times) and the breakfast eater (BE, 4–7 times). Body weight and body composition were measured by bioelectrical impedance analysis. Habitual energy, nutritional, and food group intakes using the Food Frequency Questionnaire for Japanese Athletes (FFQJA) were investigated. Estimated energy requirement (EER) was obtained by multiplying athletes' resting energy expenditure estimation equation based on fat-free mass by physical activity levels.

Results: Body composition was not significantly different between the BS and the BE groups. The median difference between EER and energy intake level was significantly lower in the BS group than in the BE group (BS: -659 kcal, BE: -376 kcal, p<;0.05). The median intakes of protein, fat, calcium, iron, vitamin B2, and dietary fiber were significantly lower in the BS group than in the BE group. Furthermore, the food group intakes of soybean products and milk and dairy products were significantly lower in the BS group than in the BE group (p<;0.01, respectively). The daily intakes of soybean products and milk and dairy products were positively correlated with protein, fat, calcium, iron, vitamin B2, and dietary fiber levels.

Conclusions: This study indicated that athletes with breakfast skipping habits had lower energy, nutrients, and food group intakes. Breakfast intake that includes soybean products and milk and dairy products might improve nutritional status in athletes with breakfast skipping habits.

The relationship between “home cooking” and dietary outcomes: A scoping review of definitions and assessment methods

Xiaoyi Yuan[1], Aya Fujiwara[1], Mai Matsumoto[1], Ryoko Tajima[1], Chisa Shinsugi[1], Emiko Koshida[1], Hidemi Takimoto[1]

1. National Institutes of Biomedical Innovation, Health, and Nutrition (Japan)

Background and objectives: Epidemiological findings regarding the relationship between home cooking and dietary outcomes (e.g., dietary intake) were inconsistent. The inconsistency may be partially explained by various definitions and methods used to assess home cooking. This scoping review aimed to examine the definitions and methods used in studies assessing the relationship between home cooking and dietary outcomes.

Methods: Six databases (4 English: PubMed, Web of Science, Scopus, and ProQuest; 2 Japanese: Ichūshi and CiNii) were used to identify the relevant studies published in English or Japanese. When explanations were available in measurements used to assess home cooking, definitions were identified. Measurements for home cooking were classified based on participants' perceptions, perception-dependent (e.g., self-reported questions), or investigators' classification, perception-independent (e.g., diet records). In addition, indicators used to assess home cooking were extracted. The quality of the analyses was evaluated based on previously developed criteria that were further adapted by including home cooking measurements as a domain.

Results: Of the 40 studies (2 in Japanese) included in this review, 8 provided definitions but did not specify the extent (e.g., the number of dishes) or the level (e.g., the number of prepared ingredients or meals) of convenience foods allowed in home food preparation. Twenty-nine studies used perception-dependent methods, and 11 used perception-independent methods. All but 5 studies used single indicators, primarily the preparation frequency (n=18), to assess home cooking. Studies that used multiple indicators or perception-independent methods had high or moderate overall quality (n=21). In contrast, those using single indicators based on perception-dependent methods had low quality (n=19). The relationships between home cooking and dietary outcomes varied. Inconsistent findings were observed for fruits and vegetables in high- or moderate-quality studies, whereas consistent in low-quality studies. However, for dietary components often regarded as unhealthy (e.g., fast foods, sugar, and saturated fatty acid), consistent negative relationships were observed in high- or moderate-quality studies, whereas inconsistent in the low-quality.

Conclusions: The definitions extracted lacked clarity, and most methods may not capture the complexities of home cooking. Relationships between home cooking and dietary outcomes need to be interpreted cautiously on measurements of home cooking.

A re-evaluation of the antioxidant property of vitamin A: Retinol can enhance glutathione levels in cultured monocyte/macrophage cell lines

Rintaro Yamanishi[1], Rika Yamanishi[1]

1. Kanagawa University of Human Services (Japan)

Background and objectives: Vitamin A is often referred to as an antioxidative vitamin based on the property of pro-vitamin A carotenoids, such as β-carotene, α-carotene, and β-cryptoxanthin, to quench singlet oxygen efficiently. Unlike pro-vitamin A carotenoids, preformed vitamin A molecules, such as retinol, retinal, and retinoic acid (RA), do not have the significant quenching ability. We previously found that the supplementation of murine macrophage RAW264 culture with β-carotene increased intracellular glutathione (GSH) levels. We also demonstrated that the mRNA and protein expression levels of glutamate-cysteine-ligase [EC 6.3.2.2], the rate-limiting enzyme in GSH synthesis, were increased in RAW264 cells cultured in media supplemented with β-carotene. As GSH is a major intracellular antioxidant, we had estimated that, in addition to the singlet-oxygen quenching activity, promoting GSH synthesis may be another antioxidative ability of β-carotene as a carotenoid. However, we found that retinol also have the same effect (Food Science & Nutrition 6, 1650-1656, 2018), even though retinol is not a carotenoid. On the other hand, we found that the RA signaling pathway, which plays a role in a wide range of transcriptional activities, is not involved in the expression of glutamate-cysteine-ligase by β-carotene, and the supplementation with RA was indeed not as effective as that with retinol. Thus, we hypothesized that retinol is the molecule responsible for enhancing GSH levels in RAW264 cells. To develop this, we assessed the effect of retinol on monocyte/macrophage cell lines other than RAW264.

Methods: We investigated the effect of retinol on intracellular GSH levels using the murine macrophage cell line J774.1 and the human monocyte/macrophage cell line THP-1.

Results: We found that retinol supplementation increased GSH levels in both J774.1 and THP-1 cells in a dose-dependent manner. In contrast, the effect of RA supplementation on enhancing GSH levels was not detected in either cell line.

Conclusions: Our findings suggest that retinol supplementation may increase GSH levels in unspecified monocyte/macrophage cell lines.

Evaluation of daily salt intake using a new self-monitoring salt excretion device for monitoring salt excretion on urination

Nozomi Morikawa[1], Kotaro Yamasue[2], Osamu Tochikubo[2]

1. Jissen Women's University (Japan), 2. Yokohama City University (Japan)

Background and objectives: Sodium excretion measurement in 24-h pooled urine is the gold standard for estimating the dietary salt intake. However, collecting 24-h urine is difficult in daily life. We investigated and estimated the daily salt intake using a new self-monitoring salt excretion device during each urination. This study aimed to assess the validity of the new self-monitoring salt excretion device (new device), by comparing it with the 24-h urine collection method.

Methods: Eleven healthy female students who were studying nutrition participated in this study. The 24-h salt excretion was measured 8 days (two non-consecutive days at a 3-month interval from May 2021 to February 2022). Participants were instructed to urinate in a 500-mL measuring cup of the new device and measure their urinary salt excretion every time voiding the entire day. After each measurement, they poured all the urine from the measuring cup into the proportional sampling cup and collected a 1/50 portion of the 24-h urine. Urinary sodium concentrations were analyzed using the electrode method. The 24-h urinary sodium excretion was converted into its salt equivalent. The study protocol was approved by the ethics committee of Jissen Women's University (approval no. H2021-05).

Results: A total of 87-day measurements were included in the analysis, excluding one day of incomplete urine collection for one participant. The mean (standard deviation) 24-h urinary salt excretions derived from the 24-h urine collections and new device were 7.7±2.8 g and 7.6±2.9 g, respectively. However, no significant difference was observed between the measurement values of the two methods and found a significant positive correlation (r = 0.902; p <; 0.001). Among our participants, those who met the national intake recommendations (<;8.0 g/day) were 4 and 5 from the 24-h urine collection method and new device, respectively.

Conclusions: Despite the limited number of participants, the 24-h urinary salt excretion measured using a new self-monitoring salt excretion device is an efficient assessment method of daily salt intake compared with the 24-h urine collection.

Effect o Covid-10 health services in Guinea: Case of the vitamin a supplementation campaign

Mohamed Lamine Fofana[1], Lansana Massandouno[2], Kadiatou Sanoh[1], Abdoul Gadri Diallo[1], Mamady Daffe[3], Christophe Zoungrana[1], Fatou Berete Ndiaye[4], Romance Dissieka[5]

1.Helen Keller Intl Country Office (Guinea), 2. Indépendent Consultant (Guinea), 3. Ministry of Health and Public Hygiene. (Guinea), 4. Helen Keller Intl Regional Office (Senegal), 5. Helen Keller Intl Regional Office (Cote d'Ivoire)

Background and objectives: From July 26 to September 25, 2020, the Ministry of Health, UNICEF and Helen Keller International implemented a vitamin A supplementation (VAS) campaign in Guinea in the 38 health districts in 2 phases first phase from July 26 to August 6, 2020, in 29 districts, and from September 21 to 25, 2020 in 9 districts during the COVID-19 pandemic. Various measures were implemented to reduce the risk of COVID-19 transmission, including the development of a guide to implement VAS; the purchase and distribution of hand sanitizer and face masks; infection prevention training, and close supervision of community distributors. This study assessed the impact of COVID-19 on reported health seeking behavior and VAS coverage.

Methods: This cross-sectional study used data from a post-campaign coverage survey that was administered among caregivers of children aged 6-59 months in 30 of 38 health districts in Guinea from September 10-26, 2020. This survey used a stratified WHO (2015) cluster design. In total, 1,700 caregivers of 2,720 children were surveyed. Interviews were also conducted among 122 health workers and 138 community distributors.

Results: VAS coverage among children was 72% (85% in rural areas and 60% in urban areas). Approximately 96% of households received VAS at home through community distributors. Only 4% of households refused VAS. The main reasons for refusal were fear of contracting COVID-19, and fear of administering the COVID-19 vaccine to children. Nearly 98% of respondents reported willingness to go themselves or send a household member to a health facility for treatment if they suffered from any illness during the COVID-19 pandemic. Among the respondents, 66% reported that community distributors wore masks, 56% reported that community distributors stayed at least one meter away from others, and 60% reported that distributors washed their hands with hand sanitizer before administering vitamin A.

Conclusions: This campaign held in the context of COVID-19 achieved an average VAS coverage of 72%, below the target of 80%. Observed COVID prevention measures were lower than ideal but may be affected by recall bias.

Fluctuation of Serum 25(OH)D during the Menstrual Cycle in Young Japanese Women

Yukino Nakamura[1], Kazuhiro Uenishi[1]

1. Kagawa Nutrition University, Laboratory of Physiological Nutrition (Japan)

Background and objectives: There is a growing interest in the importance of vitamin D in gynopathy, female reproductive function, and menstruation. However, the role of vitamin D function in the female reproductive health has not yet been elucidated. Therefore, this study aimed to determine whether serum 25(OH)D levels change during the menstrual cycle of young women.

Methods: The participants included 39 healthy Japanese women aged 20–27 years. The survey period was from October to December 2018. Before the survey, the participants measured their basal body temperature for two months to estimate the follicular, ovulation, and luteal phases of their menstrual cycle. For the ovulation phase, a test kit for the prediction of ovulation day was also used, which made estimates based on the measurement of urinary LH. Blood sampling and sun exposure time surveys were conducted within the follicular, ovulatory, and luteal phases (three times in total), and physical measurements and semi-quantitative food frequency questionnaire were conducted once during the survey period.

Results: Regarding hormonal fluctuations during the menstrual cycle, LH levels were significantly higher in the ovulation phase than in the follicular and luteal phases. FSH levels were significantly lower in the luteal phase than in the follicular and ovulation phases. The estradiol levels were significantly higher in the ovulation and luteal phases than in the follicular phase. Progesterone levels changed significantly across all three phases and were highest in the luteal phase. Serum 25(OH)D also changed; it was significantly lower in the luteal phase (15.8 ± 3.7 ng / mL) than in the follicular (16.9 ± 3.5 ng / mL) and ovulation (16.5 ± 3.3 ng / mL) phases.

Conclusions: The results of this study suggest that serum 25(OH)D levels change during the menstrual cycle of young Japanese women.

Nutritional assessment of plant-based meat alternatives in Spanish Supermarkets

Lucia Rizzolo Brime[1], Yael Pujol[2], Ujué Fresán[3], Paula Jakszyn[1,2]

1.Catalan Institute of Oncology-ICO, IDIBELL (Spain), 2. Blanquerna Faculty of Health Sciences, Ramon Llull University (Spain), 3. Global Health Institute, Barcelona (ISGlobal) (Spain)

Background and Objectives: Since the classification of processed meat as carcinogenic to humans by the IARC (International Agency for Research on Cancer) in 2015, a significant increase of consumption of plant-based (PB) meat alternatives has been observed worldwide. This tendency occurs in an environment characterized by concern for health, animal welfare, as well as greater sensitivity about the emission of greenhouse gasses. In this context, the evidence on its nutritional quality is limited. Therefore, our objective is to evaluate the nutritional quality of PB-meat alternatives available in Spanish Supermarkets.

Methods: An audit undertaken in September 2020 (updated in December 2021) has been conducted from seven of most common Spanish Supermarkets. Quantitative and qualitative information were collected as well as the estimation of Health Star Rating (HSR). For each product, several data were collected: type of product, nutritional content (including: calories, carbohydrates, sugars, proteins, total fats, saturated fats, salt and fiber /100g of product) and main ingredients.

Results: A total of 151 products were analyzed and classified in 9 categories: sausages, nuggets and patties, meatballs, cold-cuts, veggie burgers, "Beyond Meat type" burgers, "chicken-type" strips, mince and seitan. These products were generally low in sugars, but high in carbohydrates, salt, total and saturated fat, as well as dietary fiber compared to meat. The most relevant vegetable protein source was soy protein (45%) followed by wheat gluten (37.75%). On the other hand, 28.48% of products presented animal protein as the main protein source, transforming them into non-vegan products. The main ingredient used in these products was egg, found mostly in the cold-cuts category (44%). These products stand out for the larger list of ingredients and additives. Moreover, a large number of technological processes used in their elaboration, transform them as ultra-processed foods (UPFs).

Conclusions: This study shows that the greater number of plant-based meat alternatives products available in Spanish Supermarkets have a variable nutritional composition depending on the product category. Further research is needed to determine if replacing meat with these UPFs in the population`s diet could be a good solution or an alternative towards healthier and more sustainable dietary patterns.

Semi-quantitative dietary assessment among children in Sissili Province, Burkina Faso shows low Vitamin A intake and high consumption of sugar sweetened beverages.

Regina Khassanova[1], Augustin N. Zeba[2], Issaka Savallé[3], Jeoffray Diendéré[4], Djeinam Touré[5], Ali Yonli[6], Kossiwavi Sawadogo AYASSOU[7], Fanny Yago-Wienne[8]

1.Helen Keller International (Burkina Faso), 2. Institut de Recherche en Science de la Santé Direction Régionale de l'Ouest (Burkina Faso), 3. Helen Keller International (Burkina Faso), 4. Institut de Recherche en Science de la Santé Direction Régionale de l'Ouest (Burkina Faso), 5. Helen Keller International (Senegal), 6. Helen Keller International (Burkina Faso), 7. Initiatives Conseil International -Santé (Burkina Faso), 8. Helen Keller International (Burkina Faso)

Background and objective: Few studies using blood tests have reported the prevalence of vitamin A deficiency (VAD) among children in areas of Burkina Faso. No studies have estimated dietary intake of vitamin A (VA) across a wide range of local foods. Study aimed to determine dietary intake of VA among young children in the province of Sissili, Burkina Faso using quantitative dietary recall. Study population: Representative sample of 524 mother-child pairs (children aged 6-23 months) from the province of Sissili in Central-Western Burkina Faso.

Methods: A cross-sectional study was conducted in two phases. Phase one, conducted in June 2020, established a list of 103 locally relevant foods. For mixed recipes, quantities of ingredients and portion sizes were calibrated using local kitchen utensils (spoons, glasses, cups, bowls, plates, etc.) as visual aids. Phase two, in July 2020, consisted of a 24-hour dietary recall of children's intake conducted with their caretakers based on the 103 foods previously listed and calibrated. Intake was estimated using the nutrient profiles of these foods.

Results: The mean daily intake of retinol was 73.1 ± 169.5 µg RE/day and average ß-Carotene intake was 804.2 ± 2018.3 µg/day for the entire population of children. Only 5% of children met the U.S. Institute of Medicine's estimate of adequate intake for VA (500 µg/day retinol activity equivalents for children 6-12 months; 300 µg/day retinol activity equivalents for children 12-23 months). Dark green leafy vegetables contributed the most RE to children's diets. Sixteen percent of children had consumed meat, and 10% had consumed dairy, while 20% consumed a sugar sweetened beverage the previous day. The average dietary diversity score, at 2.8 ± 1.2, was below the 2021 WHO and UNICEF minimum recommended 5 of 8 food groups.

Conclusions: Dietary intake of VA remains below the recommendations. Children are likely at high risk for VAD, while consumption of sweetened beverages is elevated. Micronutrient supplementation strategies remain relevant for this at-risk population. In the context of the nutrition transition, dietary interventions should address under consumption of micronutrient rich foods but also overconsumption of low nutrient and high sugar foods.

Bioavailability of the indispensable amino acids of the red kidney bean in a typical Jamaican meal using a dual stable isotope tracer method

Daniel Thomas[1], Bentley Chambers[1], Orgen Brown[1], Ryan Francis[2], Cliff Riley[2], Sarita Devi[3], Thomas Preston[4], Anura V Kurpad[3], Asha Badaloo[1]

1.University of the West Indies, Mona (Jamaica), 2. Scientific Research Council (Jamaica), 3. St. John's National Academy of Health Sciences (India), 4. Scottish Universities Environmental Research Centre (UK)

Background and objectives: Reliable knowledge of protein and indispensable amino acid (IAA) digestibility is necessary to assess protein quality which is important to inform dietary choices for maintaining good health. More recently the minimally-invasive dual stable isotope tracer (DSIT) method has been shown to reliably measure IAA digestibility at the level of the ileum, compared to the commonly used oro-faecal method which is confounded by endogenous protein sources. This study aimed to evaluate the IAA digestibility, except tryptophan, of the red kidney bean (Phaseolus vulgaris) consumed in a typical Jamaican meal, in adults, using the DSIT method and derive its digestible IAA score (DIAAS).

Methods: IAAs in red kidney beans were intrinsically labelled with deuterium by adding 2H2O in timed pulses to the irrigation water. Uniformly-labelled [13C]-spirulina (reference protein) was added to a meal-mix of labelled stewed beans with rice, and fed to 5 males and 5 female adults (25.5±5.6 years; Normal BMI) as primed/intermittent doses to achieve a steady state IAA enrichment in the plasma [Clinical trial: NCT-04118517]. Enrichment (ppm excess) of the bean 2H-IAA and 13C-IAA in the meal mix as well as their appearance in plasma was measured by mass spectrometry. For each IAA, digestibility was calculated as the ratio of plasma 2H-IAA to meal 2H-IAA divided by the ratio of plasma 13C-IAA to meal 13C-IAA, adjusted for known digestibility of reference protein and a transamination factor.

Results: Adequate 2H enrichment of IAAs in the red kidney beans was achieved (>;1000 ppm excess). Plateau enrichment, indicating a steady state of 2H and 13C, was obtained between 5-8 hours (CV <; 10%). The mean IAA digestibility (%) of red kidney beans was 79.4±0.5, with lysine and threonine having highest (85.7±1.7) and lowest (69.0±1.2) values respectively. DIAAS (%) calculated using the established adult IAA requirement pattern were greater than 75, except for methionine and cysteine, with a score of 37, being the limiting amino acids.

Conclusion: The red kidney bean is a good source of the IAAs (DIAAS >; 75) except sulphur amino acids (SAAs) indicating the importance of complementing beans with cereal-grains in plant-based diets.

A simplified estimation method for the percentage of subjects with inadequate micronutrients intake. -Secondary Analysis of National Health and Nutrition Examination Survey (NHNS) 2017 in Japan-

Akiko Kuwabara[1], Shoko Tojo[2], Akane Yasuoka[2], Taichi Inui[3], Shigeo Takenaka[1], Kiyoshi Tanaka[4]

1.Osaka Metropolitan University (Japan), 2. Osaka Prefecture University (Japan), 3. DSM Nutritional Products (Japan), 4. Kobe Gakuin University (Japan)

Background and objectives: Although overt nutritional deficiencies are rare in developed countries, epidemiological studies have revealed that even micronutrient insufficiencies, milder than deficiencies, are risks of various non-communicable diseases (NCDs). However, publicly available data on micronutrients intake assessment in the Japanese population is limited. In this study, we have studied the possible usefulness of simplified evaluation of inadequate micronutrients intake calculated from the mean and standard deviation (SD) using data from the National Health and Nutrition Examination Survey (NHNS) 2017.

Methods: NHNS 2017 data including 4,464 subjects (Males/Females: 2,072/2,392), aged 18 years and older, excluding pregnant and lactating women, were analyzed with stratification by gender and age (younger; 18-49 years vs, older; 50 years and older) for micronutrients intake status, including calcium, iron, zinc, vitamin A, vitamin B1, vitamin B2, vitamin B6, vitamin B12, folic acid, and vitamin C. Percentage of subjects with inadequate nutrients intake was calculated either by the cut-point method using the raw data (reference method) or from the sex- and age-specific mean and SD from NHNS 2017 (simplified method).

Results: In both genders, the percentage of subjects with inadequate micronutrients intakes, as assessed by the reference method, was significantly higher in the younger group than in the older group, except for zinc intakes in males. The difference between values from the two methods was larger in the older groups (13.6%) than in the younger group (approximately 7%). The ranking of nutrients according to the proportion of subjects with inadequate micronutrient intakes was in general agreement with the reference method in both gender and age. Differences were relatively smaller in calcium, vitamin A, and vitamin B1, and larger in iron, vitamin B6, and folic acid.

Conclusions: The results of the simplified method calculated from the mean and SD were not so discordant from those by the raw data-based reference method regarding the percentage of subjects with inadequate nutrient intake, although the differences were greater in the older group, which had larger inter-individual variability in nutrient intakes. Our results showed that a rough estimate can be made with mean and SD alone would be of practical value in assessing the prevalence of inadequate micronutrients intake.

Association of serum uncarboxylated osteocalcin levels with dietary vitamin K, soy products, and vegetable intake in Japanese female athletes

Tatsuya Ishizu[1], Suguru Torii[1], Motoko Taguchi[1]

1.Waseda University (Japan)

Background and Objectives: Bone strength is defined by two main aspects: bone mineral density (BMD) and bone quality. Several studies on the bone strength of athletes have reported that BMD is one of the most important factors for their bone health. However, bone quality, which accounts for approximately 30% of bone strength, has been poorly studied in Japanese female athletes. Serum uncarboxylated osteocalcin (ucOC) levels, an indicator of bone quality, may be linked to nutritional intake. Previous studies have revealed that high serum ucOC levels were associated with low vitamin K intake among elderly people. The current study aimed to understand the association of serum ucOC levels with dietary vitamin K and food group intake in Japanese female athletes.

Methods: Fifty-two female athletes (age 20.0 ± 1.2 years) participated in this study. Their nutritional profile and food group intake were investigated using 3-day dietary records. Food groups were categorized into 18 groups according to the Standard Tables of Food Composition in Japan. Blood samples were collected after overnight fasting to measure serum ucOC levels, while their body composition and BMD were estimated using dual-energy X-ray absorptiometry. Data were analyzed using Spearman's correlation coefficient.

Results: In the present study, the intake level of vitamin K was 235 ± 148 µg/d, and approximately 70% (n=36) of the participants consumed more than the adequate intake (AI) of vitamin K, based on the Dietary Reference Intakes for the Japanese female population. Correlation analysis showed significant negative association of serum ucOC levels with daily intake of vitamin K (r = -0.388, p = 0.004), soybean products (r = -0.326, p = 0.018), and vegetables (r = -0.405, p = 0.003) after adjustment for energy intake.

Conclusions: Our study revealed that serum ucOC levels are associated with dietary vitamin K intake and the consumption of vegetables and soybean products, which are good sources of vitamin K in Japanese diet. Athletes may consume more vitamin K than the general population to maintain bone health, even though most participants in this study consumed more vitamin K than AI.

A crossover study on the effects of continuous soymilk intake on lipid metabolism and glucose metabolism in Vietnamese (2nd Report) -Lipid metabolism improving effect-

Ai Yamamoto[1], Tamaki Shintomi[1], Hien Thi Thu Vu[2], Tuyen Danh Le[2], Trung The Le[3], Anh Thi Diep Nguyen[2], Hoa Anh Le[2], Makoto Sugawara[4], Ryoichi Unno[4], Miki Tomoe[1]

1.Department of Nutrition, Faculty of Home Economics, Kyushu Women's University (Japan), 2. Vietnam National Institute of Nutrition (Viet Nam), 3. Nam Dinh University of Nursing (Viet Nam), 4. MARUSAN-AI Co., Ltd. (Japan)

Background and objectives: Soy protein has been reported to lower serum LDL cholesterol and triglycerides in many meta-analyses. Unprepared soymilk is expected to have a physiological effect due to its high protein content, but there are few clinical trials on soymilk intake in Vietnam and other Asian countries targeting patients with dyslipidemia. Continuing from the first report, this study was conducted a crossover study to verify the effect of unprepared soymilk intake on improving lipid metabolism in a joint study with Vietnam National Institute of Nutrition, Nam Dinh University of Nursing, MARUSAN-AI Co., Ltd., and Kyushu Women's University.

Methods: It was conducted with the approval of the Kyushu Women's University Ethics Review Committee and the Vietnam National Institute of Nutrition Ethics Review Committee. Thirty-seven type 2 diabetic patients with LDL cholesterol borderline (3.10-3.59 mmol/L) or mild (3.60-4.10 mmol/L) dyslipidemia attending hospital in Nam Dinh City, Vietnam, were included in the analysis. The study design was a randomized crossover study of 2 groups, and only the intervention group was given 500 mL/day (250 mL x 2 times) of unadjusted soymilk (MARUSAN-AI Co., Ltd.) for 8 weeks, and the washout period was 4 weeks. The primary endpoints were LDL-C, TG and the secondary endpoints were TC, HDL-C.

Results: The amount of change in LDL-C and TG in the intervention group were significantly reduced at both the 4W-intake and 8W-intake. In addition, the amount of change in HDL-C in the intervention group were significantly increased at the 8W-intake. Furthermore, as a result of stratified analysis, it became clear that the improvement effect of LDL-C was significantly higher in the outer group of reference value than the inner group, and the improvement effect of HDL-C was significantly higher in the outer group. In addition, although no significant change in body weight was observed, the waist circumference and hip circumference of the intervention group decreased significantly the 4W-intake and 8W-intake.

Conclusions: For Vietnamese with type 2 diabetes with dyslipidemia, it became clear that the continuously intake of unprepared soymilk could decrease LDL-C and TG and increase HDL-C.

Keywords: Vietnamese, Unprepared soymilk, LDL cholesterol, Lipid metabolism

Conflicts of interests: This study was funded by MARUSAN-AI Co., Ltd.

PAB(T2)-22

A crossover study on the effects of continuous soymilk intake on lipid metabolism and glucose metabolism in Vietnamese (1st Report) - Nutrient intake status -

Tamaki Shintomi[1], Ai Yamamoto[1], Hien Thi Thu Vu[2], Tuyen Danh Le[2], Trung The Le[3], Anh Thi Diep Nguyen[2], Hoa Anh Le[2], Makoto Sugawara[4], Ryoichi Unno[4], Miki Tomoe[1]

1.Department of Nutrition, Faculty of Home Economics, Kyushu Women's University (Japan), 2. Vietnam National Institute of Nutrition (Viet Nam), 3. Nam Dinh University of Nursing (Viet Nam), 4. MARUSAN-AI Co., Ltd. (Japan)

Background and objectives: Lifestyle-related diseases are increasing in Vietnam as in developed countries, and the proportion of people who have died from hyper-LDLemia has increased by 37.3% in 10 years from 2009. The annual per capita consumption of soymilk by Vietnamese is increasing year by year. Soymilk consumed in Vietnam is a high sucrose content, therefore, it could be one of the factors that increase the risk of lifestyle-related diseases. In this study, joint research with Vietnam National Institute of Nutrition, Nam Dinh University of Nursing, MARUSAN-AI Co., Ltd., and Kyushu Women's University, we investigated the effects of unprepared soymilk intake without sucrose on nutrient intake and nutritional status in Vietnamese with type 2 diabetes with dyslipidemia.

Methods: Thirty-seven type 2 diabetic patients with LDL cholesterol borderline (3.10-3.59 mmol/L) or mild (3.60-4.10 mmol/L) dyslipidemia attending hospital in Nam Dinh City, Vietnam, were included in the analysis. The study design was a randomized crossover study of 2 groups, and only the intervention group was given 500 mL/day (250 mL x 2 times) of unprepared soymilk (MARUSAN-AI Co., Ltd.) for 8 weeks, and the washout period was 4 weeks. The test items were a 24-hour recall method and a dietary survey using the nutrition support system (Calorie Smile Vietnam version), and physical measurements (height, weight, body fat percentage), and a total of 6 surveys and measurements were performed once each period.

Results: As a result, the protein intake was significantly higher in the intervention group than in the control group in the Δ4W-intake and the Δ8W-intake. The protein content of unprepared soymilk was 4.5 g/100 mL, so the intervention group significantly increased protein intake by ingesting 500 mL daily. Sugars intake increased significantly in the control group at the Δ8W-intake, but not in the intervention group.

Conclusions: A continuous intake of unprepared soymilk significantly increased protein intake in the intervention group but did not increase sugars intake. In the future, we will investigate the effect of unprepared soymilk intake on nutritional status and verify that it will lead to the prevention of lifestyle-related diseases. [Conflict of Interest Disclosure] This study was funded by MARUSAN-AI Co., Ltd.

PAB(T2)-23

Deterioration of nutrition during hospitalization in convalescent rehabilitation ward decreases effects of rehabilitation

Kozue Okamoto[1,2], Hiromasa Inoue[2], Yoshiro Tsuji[2], Shinsuke Ishino[2], Hideyuki Morita[2], Miho Kogirima[1]

1.Doshisha Women's University (Japan), 2. Jyujyo Takeda Rehabilitation Hospital (Japan)

Background and Objectives: As appropriate nutrition management could improve rehabilitation outcomes, malnutrition among patients should be addressed as early as possible. Therefore, we have created malnutrition criteria in our hospital as a nutrition assessment method, to select malnourished patients without an interview. The criteria were composed of 5 items: 1) body mass index <; 18.5 kg/m2, 2) serum albumin ≦ 3.0 g/dL, 3) average intake rate of meal ≦ 50 %, 4) rate per week of weight loss ≧ 1 %, and 5) others (total parenteral nutrition and digestive symptom). When two or more items were satisfied, the patient is considered suffering from malnutrition. In this study, the practicality of the criteria was verified from the viewpoint of rehabilitation outcomes.

Methods: The participants were 65 years or older and hospitalized between February 2020 and November 2021, after acute-phase treatment for brain stroke. Their motor score in Functional Independence Measure (FIM-M), body weight (BW), and nutrition status were evaluated at admission and discharge. They were divided into four groups with our criteria as follows: 1) “Good” (G), not suffering from malnutrition during hospitalization; 2) “Worse” (W), suffering from malnutrition during hospitalization; 3) “Improved” (I), recovered from malnutrition at discharge; and 4) “Deteriorated” (D), increased malnutrition at discharge. During hospitalization, the benefits of FIM-M (amount of FIM-M change), efficiency of FIM-M (benefit of FIM-M divided by the length of hospital stay), and BW change were compared between these four groups.

Results: Of the 142 patients (W:M = 71:71, mean: 77.7-years-old), 97, 20, 14, and 11 were classified in the G, I, D, and W groups, respectively. The benefit and the efficiency of FIM-M in group D were significantly lower than in group G (12.8 vs. 29.3, p=0.012, and 0.17 vs. 0.39, p=0.023, respectively). BW significantly decreased during hospitalization in group D, compared to groups G and I (-5.2 kg vs. -1.6 kg and 0.18 kg, respectively, p<;0.001).

Conclusions: Our original criteria for malnutrition might be helpful in identifying patients whose benefit and efficiency of FIM-M are poor. Furthermore, scheduled BW measurements could be a valuable method to prevent rehabilitation outcomes from worsening.

Factors affecting Vitamin A Supplementation hesitancy and refusal among families with children under 5 years in two rural communities in East Cameroon

Ismael Teta[1], Moise Tao[1], Christine Pouth[2], Etienne Steve Ahanda Etong[1], Louis Chauvin Ouafeu Tambo[1], Melissa Baker[3], Fatou Ndiaye[4], Djeinam Toure[4], David Doledec[3], Jennifer Nielsen[5]

1. Helen Keller International (Cameroon), 2. Ministry of Public health (Cameroon), 3. Helen Keller International (Kenya), 4. Helen Keller International (Senegal), 5. Helen Keller International (USA)

Background and objectives: High coverage of vitamin A supplementation (VAS) is required to reduce child mortality in countries with high prevalence of vitamin A deficiency. With the support of Helen Keller Intl and UNICEF, a national VAS campaign was organized in Cameroon in November 2021. Community acceptance of vitamin A has traditionally been high. In 2021, the VAS campaign coincided with the COVID-19 vaccination campaign. We took advantage of a mop-up campaign to incorporate a study to understand VAS refusal. The objective of this study is to explore reasons for VAS hesitancy and refusal in two districts in Cameroon in 2021.

Method: The study used a cross-sectional study design with two questionnaires on VAS refusal, one for caregivers of children aged 6-59 months, and another for VAS campaign supervisors. Self-administered surveys were conducted in Batouri and Bertoua, two semi-urban and urban health districts in the Eastern Cameroon. All parents who refused VAS for their children were interviewed on their reasons. VAS campaign supervisors were interviewed on strategies to address the refusals.

Results: Overall, 339 cases of refusal were reported representing 0.5% of the 67,800 children targeted by the campaign. Refusal was higher among caregivers of children aged 6–11-months (66%). The refusal management teams successfully convinced 209 caregivers (62%) to change their mind and accept VAS. Main reasons for refusals included fear that the campaign was a pretext to administer COVID-19 vaccines (31%) and that the capsule would make the child sick (17%). Some caregivers reported that they preferred to get VAS from a health facility (11%). Other reasons for refusal included caregiver suspicion about a free health intervention (5%), perception it was not needed as their child was not sick (4%), or the belief that VAS would make their child sterile (3%). Some caregivers (11%) did not provide a reason. Among the 24 supervisors interviewed reasons for the high levels of refusal, the vast majority cited weakness in the social mobilization before the campaign.

Conclusion: The COVID-19 vaccination campaign was launched in Cameroon two weeks before the VAS campaign in November 2021. The COVID-19 vaccination was largely rejected by the Cameroonian population. Caregiver fear of the COVID-19 vaccine influenced their refusal of the VAS campaign. Stronger social mobilization and mass communication are needed to sensitize caregivers on the benefits and safety of VAS and Covid-19 vaccines.

An algorithm to assess calcium bioavailability from foods

Connie Marie Weaver[1], Meryl Wastney[2], Keith Lividini[3],[4]

1.San Diego State University (USA), 2. Metabolic-Modeling-Services (USA), 3. Research Delivery & Impact Division, Systems Transformation Group/IFPRI (USA), 4. Friedman School of Nutrition Science and Policy, Tufts University (USA)

Background and objectives: Calcium bioavailability from individual foods, beverages, and fortified foods has been determined with calcium isotopic tracers and compared to milk as a referent to adjust for physiological differences of the host. Our objective was to develop a calcium bioavailability algorithm using these data to predict calcium bioavailability in the food supply.

Methods: We modeled data from 475 observations to develop a predictive algorithm for calcium bioavailability in adults based on calcium load and oxalate and phytate loads which represent the two main inhibitors of calcium absorption.

Results: The calcium bioavailability model was optimized by minimizing the squared residuals between observed data and model-calculated values using the least-squares fitting routine in WinSAAM software. Model development affirmed the effect of calcium load on fractional calcium absorption and the potency of oxalate as an inhibitor of calcium absorption compared to phytate.

Conclusions: This algorithm will be helpful in assessing calcium availability from the food supply and for designing policies and interventions to address inadequate calcium intake for populations. It will also be useful for developing diets for individuals, research cohorts, and populations. We plan to work with an international network of scientists to apply this algorithm to countries in South Asia and Africa as test cases.

Triglyceride to high-density lipoprotein cholesterol ratio predicts body fat percentage rather than the skeletal mass index in elderly patients with diabetes mellitus.

Katsumi Iizuka[1], Takuma Ishihara[2], Yusuke Seino[1], Akemi Ito[1], Masaki Makino[1], Daisuke Yabe[2,4,3,5], Atsuchi Suzuki[1]

1.Fujita Health University (Japan), 2. Gifu University (Japan), 3. Kansai Electric Power Medical Research Institute (Japan), 4. Tokai National Higher Education and Research System (Japan), 5. Kobe University (Japan)

Background and Objectives: The triglyceride/HDL-cholesterol ratio (TG/HDLc) is significantly correlated with HOMA-R, a marker of insulin resistance. Furthermore, TG/HDLc has also been reported to be an independent marker of cardiovascular risk in obese patients. Whether TG/HDLc can be a good marker of body composition remains unclear, although decreased skeletal mass and increased body fat accumulation can lead to insulin resistance.

Methods: The subjects (>;60 years old) with diabetes mellitus were enrolled at Fujita Health University and had blood HbA1c and eGFR data and body composition results obtained from their medical records. After adjusting for age, sex, HbA1c, eGFR, and BMI (body fat percentage and SMI only), we evaluated the nonlinear association between TG/HDLc and BMI, skeletal muscle index, and body fat percentage. Furthermore, TG/HDL≧3 is known as a high-risk condition for cardiovascular disease. After dividing the subjects into high-risk (TG/HDL≧3, n=88) and low-risk (TG/HDL<;3, n=213) groups for cardiovascular disease, we examined factors contributing to the high-risk group. This study was conducted with the approval of the Fujita Health University Ethics Committee.

Results: A total of 301 subjects (164 males and 137 females) were included in this study. In nonlinear multivariate regression analysis, BMI was correlated with TG/HDLc (β=1.63, 95% CI 0.82-2.43; p<;0.001). Body fat percentage also correlated with TG/HDLc (β=2.078, 95% CI 1.047-3.11; p<;0.001), sex (β=5.90, 95% CI 4.81-6.99; p<;0.001) and BMI (β=8.22, 95% CI 7.51-8.92; p<;0.001). In contrast, SMI was significantly correlated with age, sex, and BMI but not TG/HDLc. Linearity between TG/HDLc and BMI or body fat percentage was found up to approximately 3 for TG/HDLc, 24.5 for BMI, and 27.5 for body fat percentage. Finally, logistic multivariate analysis showed that sex (odds ratio 0.42; 95% CI 0.17-0.99; p=0.049), eGFR (odds ratio 0.98; 95% CI 0.97-0.99; p=0.012) and body fat percentage (odds ratio 1.09; 95% CI 1.047-1.13; p<;0. 001) were associated with high cardiovascular risk (TG/HDL≧3).

Conclusions: In nonobese patients with diabetes mellitus, TG/HDLc is a good marker of body weight and body fat percentage. This study also confirms that men, renal dysfunction, and high body fat percentage may contribute to high cardiovascular risk.

Keywords: body fat percentage, skeletal muscle index, diabetes mellitus, Triglyceride, high-density lipoprotein cholesterol

Assessing nutrient content of locally available commercially produced complementary food products in the Philippines using WHO Europe's Nutrient Profile Model

Mary Christine Castro[1], Cherry Cristobal Maramag[1], Efi Chatzinikolaou[2], Nadine Nasser[2]

1.Nutrition Center of the Philippines (Philippines), 2. Access to Nutrition Initiative (Netherlands)

Background and objectives: About five in every 10 young children in the Philippines consumed commercially produced complementary food (CPCF) products in a national survey conducted in 2019. Sales of these products have gradually increased in the last five years. We aimed to assess the suitability of available CPCF in the Philippines targeted to children aged 6 to 36 months in terms of nutritional content.

Methods: Commercially produced complementary food products available in the National Capital Region of the Philippines were assessed using the 2019 World Health Organization Europe Region Nutrient Profile Model (WHO NPM) for CPCF. The model proposed compositional thresholds on the following key nutrients: total energy, total sugar, total fat, and sodium, among others. Products found to be locally available, whether from physical or online stores, from August 01 to 28, 2020 were included in the assessment. Product composition was ascertained based on the nutritional information on the product package.

Results: A total of 211 locally available CPCFs, the majority (98%) of which were imported, were assessed. About 37% met the WHO NPM for CPCF requirements for total energy, total sugar, total fat, and sodium levels. Among the CPCF assessed, 69% did not have added sweetening agents; 98% were below the maximum allowable total fat content, and; 78% met the allowable content for sodium. Sugar contributed between 10% to as high as 67% of the total energy content of CPCF. Aside from confectionery and sweet spreads, products with pureed or dried fruits or fruit juice as one of their ingredients have high sugar content.

Conclusions: The majority of locally available CPCF products in the Philippines were of suboptimal nutrient quality. Manufacturers are urged to reformulate their CPCF products to improve their nutritional content in line with public health guidance. Further, the use of fruits, and other sweetening agents, as an ingredient in CPCF products should be limited. The use of the WHO NPM for CPCF to assess the nutritional quality of locally available CPCF is recommended in lieu of the lack of localized NPM models to assess these products. The development of locally adapted NPM for CPCF is encouraged.

Effect of lunch with different calorie and nutrient balances on dinner-induced postprandial blood glucose variability

Mai Kuwahara[1], Hyeonki Kim[1], Akiko Furutani[1,3], Lyie Nitta[1], Keyi Xiao[1], Yui Mineshita[1], Masaki Takahashi[2], Shigenobu Shibata[1]

1.Waseda University (Japan), 2. Tokyo Institute of Technology (Japan), 3. Aikoku Gakuen Junior College (Japan)

Background and objectives: Few studies have examined the effects of missing lunch or differences in nutritional balance on blood glucose fluctuations. Therefore, the purpose of this study was to examine the effects of differences in lunch energy (Study1) and nutritional balance (Study2) on postprandial glycemic variability due to dinner.

Method: [Study1] Effects of different amounts of energy at lunch on blood glucose fluctuations. Four trials [No lunch, Low energy (200kcal), Standard (700kcal) and High (1200 kcal) energy] were conducted within the 2-week study period. The energy balance of lunch for each trial (P: 18.5%, F: 33.6%, C: 48.0%) was matched and subjects were 13 healthy men and women (male: 22.4 ± 0.7 years, n=10; female: 21.7 ± 0.3 years, n=3) [Study2] Effect of different nutritional balance at lunch on glycemic variability. Four trials (Standard, High protein(65.1%P), High fat(67.6%F), High carbohydrate(75.1%C)) were conducted within the study period of 2 weeks. Lunch energy for each trial was aligned to approximately 700 kcal, and subjects were healthy men and women (male: 24.6 ± 2.1 years, n=8; female: 23.8 ± 2.1 years, n=6). Trials were conducted at least one day apart, with breakfast-lunch and lunch-dinner intervals of at least 4 hours. Continuous Glucose Monitoring (CGM) was also used to assess blood glucose fluctuations.

Result: [Study1] The area under the curve (AUC) of blood glucose levels after dinner was significantly higher in the no-lunch and low energy trials when compared to the high energy trial (P <; 0.05). [Study2] The AUC of blood glucose levels after dinner was significantly higher in the high-fat trials in comparison with high protein trial (P <; 0.05) or high carbohydrate trial (P = 0.063). There was no correlation between blood glucose fluctuations and meal intervals of lunch/dinner, except for the low energy trial (r = 0.550, P = 0.052).

Conclusions: It was suggested that fasting and low energy diet or high fat diet intake at lunch may increase postprandial blood glucose levels after dinner.

The Price of Good Health: Save the Children leverages a Cost of the Diet to Support the Implementation Nutrition intervention in Mali

Souleymane Arouwani[1], Meghan Pollak[1], Aurelien Barriquault[1], Nael Jean-Baptiste[1], Hady Haidara[1]

1.Save the Children (Mali)

Background and objectives: The USAID-funded Albarka Activity managed by Save the Children aims to improve the health and nutrition of poor and very poor households and IYCF practices in North and Central Mali. A study was conducted to estimate households' minimum cost of a diet [CotD] based on habit and nutritive requirements. The results were used to model the impact of various interventions and identify the ones with highest impact on sustainable nutrition outcomes.

Methods: Albarka used mixed research methods [FDG, food frequency questionnaire, and market surveys] in two livelihood zones and surveyed six markets and six villages per zone. Albarka compiled a list of 106 foods and collected price and weight data in each market. Data on dietary habits including food taboos, perceptions on malnutrition, foods considered as acceptable and non-acceptable, were collected through FDG with PLW and mothers and fathers of children of under two.

Results: The cost of a nutritious diet based on eating habits for Very Poor and Poor households represents 1.5 and 2 times the cost of a diet based solely on energy needs in Timbuktu and Gao regions. The CotD found that low-cost nutritious foods are available in markets year-round as well as foods households gather in the wild at no cost. Lack of income is therefore the main barrier to a nutritious diet, and Albarka can leverage cash transfers and SBC programming to improve nutrition outcomes sustainably. A cash transfer of 42,000 CFA/month for a very poor household could cover the total cost of a food habits nutritious diet for children under two, adolescent girls, and PLW. Identified wild foods such as roselle, water lily, jujube and dates reduce the cost of the diet for lactating women.

Conclusions: The cost of a nutritionally adequate diet adapted to eating habits remains an obstacle for very poor and poor households. Community nutrition groups can support behavior change by promoting and negotiating for the adoption of recommended IYCF behaviors while also teaching caregivers how to create nutrient-rich recipes using cash transfers, leveraging locally available wild foods and eventually using their own income after transfers have finished.

Vitamin D and calcium supplementation in nursing homes - a targeted adherence-improvement intervention study

Charlotte Mortensen[1], Inge Tetens[2], Michael Kristensen[1], Anne Marie Beck[3]

1. University College Copenhagen (Denmark), 2. University of Copenhagen (Denmark), 3. Herlev Gentofte Hospital (Denmark)

Background and objectives: Despite recommendations of supplementation with vitamin D or combinations of vitamin D and calcium to nursing home residents in a variety of countries, vitamin D deficiency is still widespread in this vulnerable group. We recently showed a low adherence to the national recommendation of providing nursing home residents a daily supplement of 20 µg vitamin D and 800-1000 mg calcium. A main barrier for following the recommendation was an ambiguity of responsibility between general practitioners and nursing home staff. The objective of this study was to improve adherence to the vitamin D and calcium supplement recommendation at Danish nursing homes targeting the experienced barriers.

Methods: This was a 20-week targeted adherence-improvement intervention study conducted at two nursing homes. Inclusion criteria was an estimated initial adherence to the recommendation of <; 40 % of residents receiving both supplements. The Plan-Do-Study-act cycle (PDSA) was used as quality improvement method. An information sheet with brief and concise facts on the recommendation and its rationale was developed for the nurses to help them argue for supplementation among the residents and the general practitioners (PDSA cycle 1). Additionally, it was incorporated as part of the initial meeting with new residents that staff encouraged them to initiate supplementation (PDSA cycle 2). Percentage of residents prescribed adequate doses of vitamin D and calcium (≧ 20 µg vitamin D and ≧ 800 mg calcium) was evaluated by patient record reviews every third week during the intervention period.

Results: The two nursing homes had 109 residents. At baseline, 32.1 % (n = 35) of the residents were prescribed adequate doses of vitamin D and calcium. During the intervention period, this increased to 57.8 % (n = 63) at week 10 and to 65.1 % (n = 71) at endpoint in week 20.

Conclusions: We found that involvement of the nursing home staff and targeting experienced barriers improved adherence to the vitamin D and calcium supplement recommendation with a doubling of number of prescriptions of adequate doses of vitamin D and calcium over a 20-week period. Other strategies should be considered to improve adherence even further.

Use of generic meal images to assess dietary intakes

Cathal O'Hara[1], Eileen R. Gibney[1]

1.University College Dublin (Ireland)

Background and Objectives: Data input required for food-based methods of dietary assessment is time consuming. Individuals who track their intakes value ease of use and convenience. A meal-based approach may reduce the burden of data input and improve adherence to dietary assessment. Methods used in meal pattern research can characterise commonly consumed meals (generic meals) in given populations. The objective of this study was to determine the accuracy of generic meals for dietary intake assessment.

Methods: Generic meals were identified from the 2008-2010 Irish National Adult Nutrition Survey (NANS) using partitioning around the medoids clustering to categorise meals into groups based on similarities in their nutrient profile and food group composition. The nutrient content for each generic meal was defined as the mean nutrient content of the grouped meals. The median weight in each septile of the grouped meals were defined as the 7 standard portion sizes for that generic meal. Following derivation of the generic meals, standardised photographs were taken of the generic meals and 3 of their 7 portion sizes. The photographs were presented to participants who chose the meal images and portion sizes that most represented their dietary intakes in the preceding 24hours. Participants also completed a traditional web-based 24-h recall. Participants completed these in a randomised order. Estimates of nutrient intake arising from the meal-based method and the 24-h recall were compared using t-tests with Bonferroni adjustment. Effect sizes were calculated for the differences.

Results: The 27,336 meals consumed by the 1500 participants in NANS were aggregated to 63 generic meals. 18 participants completed the meal-based and 24-h recall methods of dietary assessment. No significant differences were observed for any of the 4 nutrients compared and all effect sizes were negligible: energy (kcal/day) (P = 0.510, Cohen's d = 0.159), protein (g/day) (P = 0.835, Cohen's d =0.050), carbohydrate (g/day) (P = 0.127, Cohen's d = 0.127), and fat (g/day) (P = 0.957, Cohen's d = 0.013).

Conclusions: Use of meal images provided accurate estimates of mean nutrient intakes. Further work is required in a larger sample comparing a greater range of nutrients and to determine this method's accuracy in classifying individuals according to nutrient-based guidelines.

Vitamin E intake and status of adolescent girls in central Mozambique – focus on seasonal variation and lactating girls

Riitta Freese[1], Liisa Korkalo[1]

1.University of Helsinki (Finland)

Background and objectives: Data on vitamin E (alpha-tocopherol, α-TF) intake and status in low-income populations is scarce. In addition to the antioxidant effects of vitamin E, it is also likely to have specific roles in pregnancy. Our aim was to describe the α-TF intake and status of adolescent girls in central Mozambique and to explore predictors of α-TF status.

Methods: A cross-sectional study was carried out among girls aged 14 to 19 years in Quelimane city (urban area) and two rural districts in January-February and May-June 2010. Dietary intake of α-TF was calculated from 24-h dietary recall data. Non-fasting serum α-TF concentrations were analysed by HPLC, and concentration <;12 µmol/l was used as the cut-off for inadequate status. α-TF:cholesterol ratios were also calculated. Urine tests and background questionnaire were used to determine pregnancy and lactation status. For pairwise comparisons, t-tests and Mann-Whitney U-tests were used. Linear multilevel regression analysis was used to evaluate the associations between independent variables (age, pregnancy, lactation, season) and serum α-TF:cholesterol ratio.

Results: Serum concentration data were available from 508 girls (32% and 68% from urban and rural areas, respectively) and of them, 54 (10.6%) girls were pregnant and 48 (9.4%) lactating. Median (IQR) α-TF intake was significantly (p<;0.001) higher in January-February than in May-June [7.9 (4.9-13.0) and 5.2 (3.0-8.6) mg/d, respectively]. Seasonal differences (p<;0.001) in the same direction were found for serum α-TF concentrations [mean (SE): 14.7 (0.23) vs. 12.0 (0.22) µmol/l] and α-TF:cholesterol ratio [4.10 (0.06) vs. 3.44 (0.07) µmol/mmol, in January-February vs. May-June, respectively]. In January-February, the main sources of α-TF were mango (46%) and dark green leafy vegetables (27%) while in May-June, the main sources were dark green leafy vegetables (38%), groundnuts (17%), and oils (16%). The overall weighed prevalence of vitamin E inadequacy was 36.7% (95% CI: 31.9-42.0%). Season and lactation status were significant predictors of α-TF:cholesterol ratio (lower in lactating girls and in May-June).

Conclusions: Seasonal differences were large and low α-TF serum concentrations prevalent in the population. Lactating adolescent mothers may be a specifically vulnerable group for vitamin E inadequacy.

Determination of problem nutrients and formulation of food-based recommendations for women and pre-school children in Sri Lanka using Optifood linear programming approach

Renuka Ruchira Silva[1], Prasani Saluja Wickramawardana[1], Chathurika Madumali[1], Joshepkumar Thamilini[1]

1.Wayamba University of Sri Lanka (Sri Lanka)

Background and objectives: Women and pre-school children in Sri Lanka are at high risk of inadequate intakes of multiple micronutrients. Understanding the deficient nutrients in the current diet are important in recommending food-based dietary guidelines. The objective of the study was to determine the "the problem nutrients" (local food supply is unlikely to provide in sufficient quality) in the diets of women and pre-school children and to formulae realistic food-based recommendations (FBRs) to optimize the nutrient intake using locally available foods.

Methods: Food consumption patterns of 1000 nationally representative sample of 2–5-year-old child and mother (women) pairs were assessed using 24h dietary recalls. By using Optifood linear programming analysis, "problem nutrients" were identified, FBRs were formulated using locally consumed foods and alternative strategies were modelled for the target groups.

Results: Dietary patterns of the women showed that calcium, thiamin, riboflavin, niacin, folate, vitamin A and iron were "absolute problem nutrients" (<;100% of RNI even when the diets are optimized), whereas niacin and vitamin A were "absolute problem nutrients" for pre-school children. Refined grains and products, milk, cooked beans and lentils, fish and eggs were identified as potential nutrient-dense food items that would fill the nutrient gaps. Adherence to the best combination of five food groups and six food subgroups recommendations would ensure the nutrient adequacy (>;65% RNI in the worst-case scenario) of women for protein, fat, vitamin C, vitamin B6, vitamin B12, and zinc and achieving >;40% of RNI for ten modelled micronutrients except for iron. Further, the best combination of seven food groups and five food subgroups recommendations would ensure the nutrient adequacy of pre-school children for protein, fat, thiamin, riboflavin, vitamin B6, folate, and vitamin B12 and achieving >;40% of RNI for ten micronutrients except for vitamin C.

Conclusions: Promotion of the two formulated sets of FBRs only by using locally available foods would not adequately address micronutrient inadequacies of women and pre-school children. Therefore, multiple micronutrient supplementation, food fortification, and targeted nutrition intervention programmes to increase the nutrient-dense foods should be prioritized in order to achieve adequate levels of micronutrients of the pre-school children and mothers.

Further Collaborators: Dr Umi Fahmida and her team of South East Asian Ministers of Education Organization Regional Centre for Food and Nutrition (SEAMEO-RECFON) supported providing training on the Optifood Linear Programming; Nutrition Society of Sri Lanka and Food & Agriculture Organization of United Nations funded the work.

Women in Punjab, India have low dietary intakes of iron, zinc, folate, and vitamin B12 and a high prevalence of micronutrient deficiencies: Implications for a trial of multiply-fortified salt

Yvonne E Goh[1,2], Mari S Manger[1,2], Mona Duggal[3], Reena Das[3], Manu Jamwal[3], Hanqi Luo[4], Nancy F Krebs[5], Rosalind S Gibson[6], Kenneth H Brown[2,7], Christine M McDonald[1,2]

1.University of California, San Francisco (USA), 2. International Zinc Nutrition Consultative Group (USA), 3. Post Graduate Institute of Medical Education & Research (India), 4. Emory University (USA), 5. University of Colorado School of Medicine (USA), 6. University of Otago (New Zealand), 7. University of California, Davis (USA)

Background and objectives: We assessed biomarkers of micronutrient (MN) status and dietary intakes among 100 non-pregnant women of reproductive age (NPWRA) in 11 communities of Punjab, India, to determine optimal levels of iron, zinc, vitamin B12, and folic acid to include in multiply-fortified salt (MFS) that will be evaluated in an upcoming trial in this area.

Methods: Fasting venous blood samples were analyzed for hemoglobin (Hb) and biomarkers of iron, zinc, vitamin B12, and folate status. One-day weighed food records were obtained from 100 NPWRA and repeated in 40, to measure usual intakes of iron, zinc, vitamin B12, folate, and discretionary salt. SIMPLE macro was used to estimate inadequate and excessive MN intakes from the baseline diet and model the optimal level of fortificants in MFS to reduce the prevalence of inadequate intakes while limiting intakes above the UL, based on Indian and US IOM Nutrient Reference Values (NRVs).

Results: The prevalence of anemia (Hb <; 12 g/dL) was 37% and of other conditions was as follows: iron deficiency (inflammation-adjusted serum ferritin <; 15 µg/L): 67%; zinc deficiency (plasma zinc <; 70 ug/dL): 34%; vitamin B12 deficiency (serum vitamin B12 <; 150 pmol/L): 23%; and folate insufficiency (RBC folate <; 748 nmol/L): 70%. There was a high prevalence of inadequate MN intakes regardless of which set of NRVs was considered. According to the Indian NRVs, the prevalences of inadequate intakes from the baseline diet were 46% for iron, 95% for zinc, 83% for vitamin B12, and 36% for folate. Mean ± SD intake of discretionary salt was 4.6 ± 1.8 g. Optimal amounts of each MN per gram of MFS were 1.34 mg iron, 1.4 mg zinc, 0.6 µg vitamin B12, and 52.4 µg folic acid. At these levels, the prevalences of inadequate intakes are expected to decline by 29 percentage points (pp) for iron; 76 pp for zinc, 81 pp for vitamin B12, and 36 pp for folate according to Indian NRVs.

Conclusions: MFS holds great potential for substantially reducing this burden of MN deficiencies among NPRWA in the study communities without imposing an unacceptable risk of excessive intakes.

County Department of Health, Kisumu (Kenya), 5. South African Medical Research Council Vaccines and Infectious Diseases Analytics Research Unit, University of the Witwatersrand, Johannesburg (South Africa), 6. Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA (USA), 7. Department of Pediatrics and Emory Global Health Institute, Emory University, Atlanta, GA (USA)

Background: The Child Health and Mortality Prevention Surveillance (CHAMPS) Network aims to elucidate the causes of under-5 mortality in sub-Saharan African and South Asia through minimally invasive tissue sampling (MITS). We investigated the potential of postmortem liver biopsies collected through MITS for reference-standard vitamin A (VA) assessment in two CHAMPS sites.

Methods: Liver samples (n=405, 19 ± 8 mg) were procured via needle biopsy, within 72 hours after death, from stillbirths and cadavers under 5 years of age. Liver VA concentrations (retinol plus retinyl esters) were quantified using ultra-performance liquid chromatography. Cutoffs of <;0.1 µmol/g, >;=0.1 to <;0.7 µmol/g, >;=0.7 to <;1.0 µmol/g, and >;=1.0 µmol/g were used to define VA deficiency (VAD), adequate VA status, high VA status, and hypervitaminosis, respectively. Prior to specimen collection, the MITS procedure involves collection of anthropometric measures, which were used to assess stunting, wasting, and underweight. We used ANOVA to test for differences in the continuous distribution of liver VA concentrations by covariates. Logistic regression was used to model the association between stunting and VAD.

Results: Of the liver samples procured, 368 (90.9%) had viable extraction efficiencies; of which 190 (51.6%) were from Kenya and 178 (48.3%) were from South Africa. The majority (42.1%) were neonates (death in the first 24 hours to 27 days) and 11.1%, 23.4%, 23.4%, were stillbirths, infants (28 days to <;12 months), and children (12-59 months), respectively. The distribution of VA spanned the continuum; 34.0% with VAD, 50.8% with adequate VA status, 6.0% with high VA, and 9.2% with hypervitaminosis. The distribution of Liver VA concentrations differed significantly by age and stunting but not by site, sex, wasting, nor underweight. After adjusting for site, sex, and age,

the odds of VAD were 3-times greater among those who were stunted than those who were not stunted (aOR=3.0; 95%CI (1.8,5.2)).

Conclusions: The VA status in stillbirths and cadavers under 5 years spanned the continuum from deficiency to excess. The odds of VAD were higher among those who were stunted.

Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA (USA)

Background: Undernutrition is a key determinant of under-5-mortality (U5M). However, current studies lack high-quality anthropometry on young children and lack comprehensive cause of death data from the highest-burden countries. The Child Health and Mortality Prevention Surveillance (CHAMPS) network assesses causes of stillbirths and U5M in sub-Saharan Africa and South Asia through standardized postmortem anthropometrics as part of the minimally invasive tissue sampling (MITS) procedure. We characterized the prevalence of undernutrition across CHAMPS sites prior to undertaking an analysis of the association between nutritional status and immediate cause of death as determined by CHAMPS adjudication panels.

Methods: We analyzed data from children 1-59 months (mo) who had MITS and cause of death determined between December 2016-March 2022 from all CHAMPS sites, including Bangladesh, Ethiopia, Kenya, Mali, Mozambique, Sierra Leone, and South Africa. Moderate-to-severe undernutrition was defined as wasting, stunting, or underweight, using z-scores <;-2 SD for weight-for-length (WLZ), length-for-age (LAZ), and weight-for-age (WAZ), derived from World Health Organization growth standards. Any undernutrition was defined as WLZ, LAZ, or WAZ<;-2. We expanded the cutoffs of biologically plausible values (>;=-10 SD) to complement this population of severely ill children and took into consideration evidence of undernutrition elsewhere in the data (clinical abstraction, verbal autopsy or photographs).

Results: MITS was performed on 1128 children 1-59 mo enrolled in CHAMPS; 52.2% were aged 1-11 mo, 24.4% were 12-23 mo, and 23.4% were 24-59 mo. Based on postmortem anthropometrics, 72% of cases had evidence of any undernutrition. The prevalence of moderate-to-severe wasting, stunting, and underweight was 51.3%, 38.8%, and 58.8%, respectively. Age-specific prevalence of moderate-to severe malnutrition among children 1-11 mo, 12-24 mo, and 24-59 mo. was 55.4%, 25.9%, 18.7% (WLZ), 52.3%, 26.9%, 20.8% (LAZ), and 57.5%, 24.1%, 18.4% (WAZ), respectively.

Conclusions: Nearly 3 in 4 children 1-59 mo who underwent MITS in the CHAMPS network sites have anthropometric evidence of undernutrition. The increased specificity of diagnoses determined through the CHAMPS adjudication process in conjunction with standardized postmortem anthropometry will allow us to develop robust estimates of cause-specific prevalence of malnutrition.

Beverage quality index (BQI): A new tool for the assessment of healthy beverage intake patterns in epidemiological studies

Maria Gorety Jacobo Cejudo[1], Renee van Laarhoven[1], Trudy Voortman[1,2], Marianne J. Geleijnse[1]

1. Wageningen University (Netherlands), 2. Erasmus MC, University Medical Center (Netherlands)

Background and objectives: Individual beverage recommendations exist, but few studies have assessed overall beverage intake quality. We set up a scoring system for the overall quality of an individual's beverage intake, which may be used in epidemiological studies.

Methods: We used data of 4365 post-myocardial infarction patients (79% male, mean age 69 years) of the Alpha Omega Cohort in the Netherlands. The intake of foods and beverages was assessed using a validated 203-item food frequency questionnaire. We constructed a beverage quality index (BQI), based on recommended intakes for coffee, tea, fruit and vegetable juice, milk, sugar-sweetened beverages (SSB), and alcohol (total ethanol). For each BQI component, patients received a score between zero (no adherence) to 10 (maximal adherence). Additional scoring took place for added sugar and

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

calories in beverages. BQIs could range from zero to 80, with higher scores indicating a healthier beverage intake pattern. Mean BQIs were compared between men and women, between obese (24% of cohort) and non-obese, and between patients with (20% of cohort) and without diabetes, using ANCOVA with adjustment for age and sex (if not used as stratification factor).

Results: Popular beverages were coffee (96% consumers; median of 375 g/d in cohort), tea (74%, 150 g/d), milk (81%; 150 g/d) and alcohol (78%; 74 g/d). Fruit and vegetable juices were less consumed (75%, 54 g/d), as were SSB (69%; 42 g/d). The BQI ranged from 7.7 to 79.2 with a mean (SD) of 47.7 (12.5). Significant differences were found between men and women (mean(SD) BQI: 46.8 (12.5) vs 51.2 (11.9), respectively, p<;0.001). Women had more favorable scores for the components SSB, alcohol, added sugars and energy from beverages than men (all p-values <;0.001). BQI also differed between obese and non-obese individuals [48.7(12.6) vs 47.4(12.4), respectively, p<;0.05], and between patients with and without diabetes [50.4(12.7) vs 47.0(12.3), respectively, p<;0.001].

Conclusions: The BQI may be a valuable tool for the assessment of overall beverage intake quality. Validation of the BQI in non-Dutch and healthy populations is needed. Whether BQI is related to morbidity and/or mortality risk warrants further investigation in epidemiological studies.

Validity of the Food Frequency Questionnaire-and the 12-day weighed food records-estimated intakes of sodium, potassium, and sodium-to-potassium ratio for screening in Japanese adults

Aoi Suzuki[1], Tomoka Matsuno[1], Ribeka Takachi[1], Junko Ishihara[2], Yuri Ishii[3], Kumiko Kito[3], Sachiko Maruya[1], Motoki Iwasaki[3], Shoichiro Tsugane[3,4], Norie Sawada[3]

National Cancer Center Institute for Cancer Control (Japan), 4. National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Background: The use of FFQs is in demand to compare dietary references; however, to date, FFQs have been widely used for ranking individuals in a population based on their dietary intake. Objective: To determine the validity of intake of sodium (salt equivalent), potassium, and sodium-to-potassium ratio (Na/K) obtained using the FFQ to detect individuals who deviated from the dietary reference intakes measured by multiple 24-hour (24-h) urinary excretion in comparison with those using the 12-day weighed food records (12-d WFR).

Methods: The study was conducted among the 235 residents of 40–74 years in five areas designated in the JPHC-NEXT Protocol Validation Study. Correlation coefficients (CCs) of the estimates from the FFQ consisting of 172 items compared with the intakes by 12-d WFR or five-times' 24-h urine excretion was calculated. Using 12-d WFR or 24-h urinary excretion as the reference standards, estimations were also analyzed using the area under the receiver-operating characteristic curve (AUC) at a point of dietary reference intakes.

Results: The CCs of the estimates by the FFQ compared with those by the 12-d WFR were mostly moderate (0.24–0.54), although the CCs compared with those by the 24-h urinary excretion were low or moderate (0.26–0.38). While, the CCs of the estimates by 12-d WFR compared with those by the 24-h urinary excretion were moderate or more (0.52–0.87). AUC values for the intakes by 12-d WFR were >;0.78 using the 24-h urine excretion as a reference standard. AUC values for salt or potassium intakes by FFQ were >;0.7 using the 12-d WFR as a reference standard, but those were ranged from 0.60–0.76, when using 24-h urine as the standards.

Conclusion: The estimation of salt equivalent and potassium intake using the FFQ to screen at a point of absolute intake may be comparable with that using the WFR, but the accuracy was not as good as compared with 24-h urinary excretion. Considerable careful attention is needed when using estimation by FFQ as an absolute intake to screen the individuals. This study was conducted on behalf of the JPHC-NEXT Protocol Validation Study Group.

Comparison of two methods for measuring consumption of unhealthy sweet and salty/fried foods among young children in Cambodia

Ngik Rem[1], Guy-Marino Hinnouho[1], Elaine Ferguson[2], Hou Kroeun[1], Sophonneary Prak[3], Chea Mary[3], Alissa M Pries[1]

1.Helen Keller International (USA), 2. London School of Hygiene and Tropical Medicine (UK), 3. Ministry of Health (Cambodia)

Background and objectives: In 2021, the World Health Organization (WHO) published updated indicators for assessing infant and young child feeding practices, including a new indicator of unhealthy food consumption. This indicator is comprised of two questions assessing 6-23 month-olds' consumption of sweet or salty/fried foods in the previous day. Such an indicator will allow measurement of shifting diet patterns indicative of increased intakes of added sugars, unhealthy fats, and salt among children. Two methods for collecting consumption data have been suggested by WHO – an open-recall 24-hour dietary recall (24HR) or a list-based 24HR. This study compared caregiver responses to these two methods for measuring consumption of unhealthy sweet and salty/fried foods.

Methods: Data were drawn from a survey among a representative sample of 501 children 15-19 months of age in rural/peri-urban Kandal province, Cambodia. Caregivers participated in an open-recall 24HR to identify all foods/beverages consumed by their child in the previous day. Half of the sample was randomly sampled (n=250) to also receive the WHO indicator questions as an abridged list-based 24HR; these caregivers were directly asked about their child's consumption of 1) sweet and 2) salty/fried foods in the previous day. Responses to the open-recall versus list-based 24HR were compared using Cohen's kappa.

Results: Among the 250 caregivers who were asked the list-based WHO indicator questions, 61.6% and 58.8% reported that their child consumed a sweet or a salty/fried food, respectively, as compared to 60.0% and 56.4% reporting these foods in the open-recall 24HR. A kappa of 0.86 for sweet foods and 0.87 for salty/fried foods were found. Among the 251 participants that did not receive the WHO indicator questions, a lower proportion reported their child consumed a sweet or salty/fried food during the 24HR, (43.8% and 47.8%, respectively), indicating that a list-based 24HR may aid memory in recalls.

Conclusions: This study found strong agreement between measurement of sugary or salty/fried food consumption using an open-recall and a list-based 24HR among caregivers in Cambodia. This WHO measure may provide reliable data on unhealthy dietary patterns among young children; however, validation studies are needed.

PAB(T2)-40

Vitamin K content of cheese, yoghurt and meat products in Australia

Eleanor Dunlop[1], Jette Jakobsen[2], Marie Bagge Jensen[2], Jayashree Arcot[3], Liang Qiao[4], Judy Cunningham[1], Lucinda J Black[1]

1.Curtin University (Australia), 2. Technical University of Denmark (Denmark), 3. University of New South Wales (Australia), 4. The Westmead Institute for Medical Research (Australia)

Background: Vitamin K is important for normal blood coagulation and may play a role in skeletal, neurological and vascular health. In the absence of a single biomarker for vitamin K status, estimates of dietary intakes are commonly used as an indicator of vitamin K status at the population level. However, the vitamin K food composition data required to estimate intakes are limited globally. As there are currently no nationally representative food composition data for vitamin K in Australian foods, we aimed to determine the vitamin K content of cheese, yoghurt and meat products purchased in Australia.

Methods: Primary samples (total n = 288) were purchased in three cities (Sydney n = 90, Melbourne n =114, Perth n = 84) over a 10-month period to account for seasonal variation. Samples were prepared as they would be consumed (cooked using common household methods where applicable), combined into 48 composite samples, frozen and transported to the Technical University of Denmark for analysis. We used a validated liquid chromatography with electrospray ionisation-tandem mass spectrometry method to measure the K vitamers, phylloquinone (PK) and menaquinones (MK) -4 to -10. Results are reported as means (± standard deviation for foods with multiple analytical samples) of duplicated or triplicated analyses.

Results: Each sample contained at least one K vitamer. PK was quantified in 28 foods with mean concentrations ranging from 0.54 µg/100 g (full-fat yoghurt) to 4.93 µg/100 g (lamb liver). MK-4 was quantified in 46 samples and predominated in all cheese products (Cheddar, feta, Mozzarella, Brie/Camembert, cream cheese, cheesecake). The greatest mean concentration of MK-4 was found in chicken leg meat at 58.16 ± 8.59 µg/100 g. MK-5 was found only in Cheddar (1.05 ± 0.30 µg/100 g) and cream (0.95 µg/100 g) cheeses, while only Cheddar cheese contained MK-8 (3.95 ± 2.19 µg/100 g). We found MK-9 in all cheese products. No samples contained quantifiable concentrations of MK-6, MK-7 or MK-10.

Conclusions: This study adds to the limited knowledge of the vitamin K composition of foods. Australia needs a comprehensive vitamin K food composition database to allow estimation of usual intakes in the Australian population.

PAB(T2)-41

Using WHO/EURO's Nutrient Profiling Model for commercially available complementary foods to assess products sold in Senegal

Ndeye Yaga Sy[1], Rosenette Kane[2], Katelyn Yuen[3], Anzélle Mulder[4], Lara Sweet[5], Alissa M Pries[6]

1.Helen Keller International (Senegal), 2. Helen Keller International (Senegal), 3. Helen Keller International (USA), 4. JB Consultancy (South Africa), 5. JB Consultancy (South Africa), 6. Helen Keller International (USA)

Background and Objectives: Some commercially produced complementary foods (CPCF) have the potential to improve nutrient intakes by providing critical micronutrients. Others are of concern due to high levels of added salt and/or sugar. WHO/EURO's CPCF nutrient profiling model (NPM) was used to assess the nutritional suitability of CPCF sold in Senegal for older infants and young children (IYC) 6-36 months of age.

Methods: In June 2021, 11 larger and 30 smaller stores were purposively sampled for purchasing CPCF in Dakar and Guédiawaye Departments, where all available CPCF were purchased. A total of 329 products were categorized according to the WHO/EURO's CPCF NPM, and the ingredient list and nutritional content provided on product labels were assessed against the NPM's category-specific nutrient/ingredients standards. CPCF were categorized as nutritionally suitable for older IYC if they achieved all category-specific nutrient/ingredients standards.

Results: Of the 329 CPCF products assessed, 76 were instant cereals, 194 purees, 49 meals and 10 snack/finger foods. Only 56 (17.0%) CPCF products passed all relevant NPM standards. This included 9.2% (n=7) of instant cereals, 21.7% (n=42) of purees, 14.3% (n=7) of meals and no snacks/finger foods. For the 'no added sugar/sweeteners' standard, 100% of meals and 81.4% (n=158) of purees met the NPM standard, while only 11.8% (n=9) of instant cereals and no snacks/finger foods met this standard. The NPM sodium standard was met by 82.9% (n=63) of instant cereals and nearly all fruit purees (97.5%, n=78). However, only one-third (n=1) of pureed meals with cheese and pureed meals with meat/fish and half (n=5) of all snacks/finger foods met the maximum sodium limit. All purees and meals and 93.4% (n=71) of instant cereals met the NPM fat standard versus 60.0% (n=6) of snacks/finger foods.

Conclusions: The majority of CPCF products sold in Senegal are nutritionally unsuitable for older IYC consumption, failing to achieve all category-specific NPM nutrient/ingredient standards. Using this NPM tool in the African context, where IYC malnutrition is prevalent, is both novel and valuable, enabling identification of CPCF suitable for promotion for IYC feeding based on their nutrient composition.

Effect of milk on the measurement of exhaled carbon monoxide in healthy Japanese non-smokers and current smokers

Kiho Miyoshi[1], Narito Kurioka[2], Sadahiro Kawazoe[1], Takashi Miyawaki[1,2]

1.Department of Food and Nutrition, Graduate School of Home and Economics, Kyoto Women's University (Japan), 2. Kyoto Association for Tobacco Control (Japan)

Background and Objectives: One of the adverse products of smoking is carbon monoxide (CO). To date, three different exhaled CO monitors are used to assess smoking status in Japan. However, the sensor in these CO monitors has a cross-sensitivity to hydrogen (H2). Therefore, if H2 is included in the expiratory gas after taking indigestible carbohydrates, such as lactose, this can produce false higher readings, causing erroneous results. This study investigates the influence of consuming milk containing lactose on measuring CO in Japanese non-smokers and smokers.

Methods: Four healthy non-smokers and three current cigarette smokers (aged 22–60 years) were recruited. After staying overnight without smoking and eating, exhaled breath of the subjects was collected by breath collection bag. After consuming 200mL milk containing lactose at 9:00 am, exhaled breath was collected every 30 min for about eight hours. Then, the exhaled H2 and CO values in each bag were measured as a reference standard by gas chromatography. Further, CO in each bag was measured using three different portable CO monitors (A, B, and C) and compared with the value of a reference standard.

Results: After consuming milk, the median concentration of exhaled H2 was significantly increased (before: 6.2 ppm, after maximum value: 23.8 ppm, p=0.03). The H2 concentration measured by gas chromatography and the differences between CO value measured by portable CO monitors and gas chromatography were correlated (A: r=0.27, p=0.01, B: r=0.77, p<;0.01, C: r=0.21, p=0.02). After consuming milk, the values shown on the three portable CO monitors increased and were significantly higher (A: p=0.02, B: p=0.02, C: p=0.04) than those before consuming milk. Furthermore, the higher values of CO measured by CO monitors compared with the reference CO were observed for at least 8 hours.

Conclusions: The concentration of H2 in participants' breath increased after consuming milk containing lactose, which influenced the measurement of exhaled CO in the portable CO monitors. Therefore, before measuring CO with CO monitors in Japanese, the effects of taking milk should be considered.

Assessment of dietary iodine intake among pregnant women from coastal and countryside areas

Debora Leticia Frizzi Silva[1], Sandra Patricia Crispim[2], Gabriele Beraldi Silva[3], Francilene Maria Azevedo[4], Aline Carare Candido[5], Carina Aparecida Pinto[6], Edimar Aparecida Filomeno Fontes[7], Mariana de Souza Macedo[8], Sylvia do Carmo Castro Franceschini[9]

1.Federal University of Vicosa (Brazil), 2. Federal University of Parana (Brazil), 3. Federal University of Parana (Brazil), 4. Federal University of Vicosa (Brazil), 5. Federal University of Vicosa (Brazil), 6. Federal University of Vicosa (Brazil), 7. Federal University of Vicosa (Brazil), 8. Federal University of Vicosa (Brazil), 9. Federal University of Vicosa (Brazil)

Background and objectives: Geographic location can compromise the iodine intake of some population groups, especially those with higher nutritional requirements (e.g., pregnant women), as location influences the iodine concentration in food and food choices. To ensure iodine intake, Brazil implements a universal salt iodization strategy. Thus, the objective is to compare the iodine intake and its prevalence of inadequacy on pregnant women living in Brazilian coastal and countryside municipalities.

Methods: Pregnant women's data from the Multicenter Study of Iodine Deficiency in Brazil is the basis of this investigation. Data collection was carried out in 11 municipalities between 2018-2020 with four of them located in Brazil's coastal region. One 24-hour recall was applied to the sample, with replicates in a subsample (18.9%), following the Multiple Pass Method assisted by a photographic manual for food portion quantification. Food consumption data were entered in the GloboDiet software and later linked to the composition data from the Table of Iodine Composition in Food. Usual intake distributions were estimated from daily intakes and adjusted for the intra-individual variability by the UCD/NCI Simulating Intake of Micronutrients for Policy Learning and Engagement macro in SAS. Moreover, the prevalence of iodine inadequacy was estimated based on the average nutrient requirement of 160 mcg/day. Coastal and countryside distributions were modeled by age, season, gestational age, education, day of the week, and recall order. Significant difference was assumed in the absence of overlap between 95% Confidence Intervals (CI).

Results: Considering food only, usual iodine intake of pregnant women was 127.7mcg (95%CI:127.6-27.9), being inadequate for 82.6% (95%CI:82.4-82.7) of the sample. In comparison to countryside women (126.2mcg;95%CI:126.0-126.4), those living in coastal regions (36.4%) showed lower mean of usual intake (123.4mcg;95%CI:123.1-123.6). Also, the prevalence of inadequate iodine intake was significantly higher among coastal pregnant women (86.5%; 95%CI:86.3-86.8 versus 80.4%; 95%CI:80.2-80.6).

Conclusions: Pregnant women living in Brazilian coastal municipalities showed higher inadequacy of iodine intake than those from countryside. This result confirms that geographic location can impact iodine intake and its prevalence of inadequacy even in a country with universal salt fortification, suggesting that policies promoting adequate intake could be planned considering this influence.

Dietary diversity and its relationship to nutrient and food group intake among Japanese pregnant women

Reina Doi[1], Minatsu Kobayashi[1], Kohei Ogawa[2], Naho Morisaki[2], Seung Chik Jwa[3], Takeo Fujiwara[4]

1.Otsuma Women's University (Japan), 2. National Center for Child Health and Development (Japan), 3. Saitama Medical University (Japan), 4. Tokyo Medical and Dental University (Japan)

Background: Dietary habits during pregnancy affect several pregnancy outcomes. In Japan, the Ministry of Health, Labour and Welfare has presented "Dietary Guidelines for Expectant and Nursing Mothers Starting Before Pregnancy," which recommend a well-balanced intake of necessary nutrients through a combination of various dishes and foods. However, most dietary surveys of Japanese pregnant women have assessed excess or deficiency of specific nutrients or food intake, and dietary assessments using dietary diversity has rarely been conducted. Therefore, this study examined the relationship between dietary assessment using dietary diversity and the intake of nutrients and food groups.

Methods: The survey was conducted between January and December 2011. A total of 194 women in the first trimester of pregnancy (8-15 weeks gestation) living in the Tokyo metropolitan area were included. The FFQ was administered to the subjects, and the number of foods consumed per day was calculated by converting the frequency of FFQ intake to a daily frequency if the answer was less than one day, such as "1-2 times a week" or "3-4 times a week. The number of foods consumed per day was used to classify the subjects into tertiles and compare nutrient intake and intake by food group.

Results: The average number of foods consumed per day calculated from the FFQ was 25.8. The average number of foods consumed per day by the highest group was 35.0, and those by the lowest group was 17.2, a difference of more than 10 points. In terms of nutrient intake, the highest group consumed more energy, protein, fat, iron, and folic acid than the lowest group, but less carbohydrate. The highest group consumed more vegetables, mushrooms, meat, and fewer cereals than the lowest group.

Conclusions: The group that consumed more foods per day was considered to have a higher intake of meat and vegetables,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

which increased the intake of nutrients such as protein and iron. While it is essential to consume various foods, the results also suggest the importance of adequate intake of cereals as a source of carbohydrates.

High Dietary Quality with Alternative Health Eating Index-Taiwan and component Is Associated with Prevent Graft Kidney Function in post Renal Transplant Recipients in Taiwan

I Hsin Lin[1,2], Te Chih Wong[3], Tuyen Van Duong[2], Shih Wei Nien[1,2], I Hsin Tseng[1], Hsu Han Wang[1], Yang Jen Chiang[1], Shwu Huey Yang[2,4]

1.Linkou Chang Gung Memorial Hospital (Taiwan), 2. Taipei Medical University (Taiwan), 3. Chinese Culture University (Taiwan), 4. Taipei Medical University Hospital (Taiwan)

Background and objectives. A successful of renal transplant is depends on the years of graft kidney function maintenance. Eating index was used to assess dietary quality and associated with several chronic diseases in global. However, an index which adapted to national population is necessary to be developed. The Alternative Healthy Eating Index-Taiwan (AHEI-T) version was modified from Alternative Healthy Eating Index-Taiwan (AHEI) based on Taiwan's dietary recommendations. The study is to investigate the association between AHEI-T and graft kidney function in renal transplant recipients (RTRs).

Methods: A total of 102 RTRs aged more than 18 years or above with a functioning allograft and without any acute rejection in the past 3 months were enrolled from September 2016 to June 2018. Laboratory data were obtained from medical record; Chronic kidney disease (CKD) was defined as an estimated glomerular filtration rate (eGFR) less than 60 mL/min/1.73 m2 according to Kidney Disease Outcomes Quality Initiative (KDOQI) guideline. Statistical analyses were performed using SAS software 9.4 version. The scores of AHEI-T and component were divided into quartiles.

Results: The RTRs with higher AHEI-T have older age, higher eGFR and higher scores of dietary fruit, vegetable, wholegrains ratio, white and red meat ratio, and nut and soybeans. Logistic regression analysis adjusted age, gender, calorie intake and comorbidity index was demonstrated that the highest quartiles of the AHEI-T had 90% (odds ratio [OR], 0.10; 95% confidence interval [CI], 0.03–0.43, p for trend <; 0.01), lower risk of CKD. The highest quartiles of wholegrains ratio, and white and red meat ratio were associated with 67% (OR, 0.33; CI, 0.13 - 0.85 p for trend <; 0.05) and 72% (OR, 0.28; CI, 0.08 - 0.97 p for trend <; 0.05) low odds of CKD, respectively. In addition, RTRs with highest quartiles of red/processed meat had 10.4 times higher risk of CKD (OR, 10.38; CI, 2.16 - 49.85, p <; 0.01).

Conclusion: High AHEI-T and the component of wholegrains ratio, white and red meat ratio were associated with CKD prevention. Red/processed meat was associated with poor graft kidney function.

PAB(T2)-46

A study on nutritional status of patients with mild cognitive impairment

Shih Wei Nien[1,2], I Hsin Lin[1,2], Hsiu Chuan Wu[1], Suh Ching Yang[2,3]

1.Linkou Chang Gung Memorial Hospital (Taiwan), 2. Taipei Medical University (Taiwan), 3. Taipei Medical University Hospital (Taiwan)

Background and objectives: Aging populations is rising by years in Taiwan. Mild cognitive impairment (MCI) has become the important health issue. Based on current knowledge, the etiology of cognitive decline is incomplete. Dietary intake may be a potential modifiable factor to delay the deterioration of disease. This study is aimed to comparison between dietary food and nutrients intake and in patients with mild cognitive impairment.

Methods: A total of 50 subjects were recruited in this cross-sectional study from July, 2019 to September, 2021. According to clinical dementia rating (CDR) and mini-mental state examination (MMSE), subjects are divided into healthy group (CDR = 0 and MMSE ≧ 26) and MCI group (CDR ≧ 0.5 and MMSE ≧ 26). Dietary data was obtained by 3-day dietary records and nutrients intake were calculated by trained dietitian. Statistical analyses were performed using statistical SAS software version 9.4. Data was expressed as mean ± standard deviation.

Results: Participants with extremely or missing dietary data were excluded (n = 10) and 40 subjects remained to analysis. The mean age and body mass index were 71.4 ± 6.6 years old and 25.0 ± 3.2 kg/m2, respectively. Subjects were divided into healthy group (n = 19) and MCI group (n = 21). Compared with healthy group, MCI group significantly have higher dietary copper and lower low fat beans, fish, eggs and meat intake. Multivariate regression analysis adjusted age and gender was showed that dietary calcium (β = 0.001, P = 0.04) and fruit (β = 0.81, P = 0.01) intake were positively associated with MMSE. Dietary copper (β = 0.001, P = 0.02) intake was positively associated with CDR. Low fat beans, fish, eggs and meat intake (β = -0.08, P = 0.01) was negatively associated with CDR.

Conclusions: MCI group have higher copper and lower low fat beans, fish, eggs and meat intake. Higher dietary calcium, fruit and low fat beans, fish, eggs and meat, and lower copper intake were associated with protective predictors of MCI. Further randomized control studies should be warranted.

Assessing the applicability of nationally-adapted sentinel food lists at the subnational level in six geographically unique food systems.

Chris Vogliano[1], Gina Kennedy[1], Veronica Varela[1], Silvia Alayon[1], Monica Woldt[1], Laura Hackl[1], Sarah Pedersen[2], Erin Milner[2], Jennifer Yourkavitch[1]

1.USAID Advancing Nutrition (USA), 2. USAID (USA)

Background and objectives: High quality diets are essential for preventing malnutrition and diet-related NCDs, yet to date there are limited ways of rapidly assessing the diet quality of populations. Since 2021, USAID Advancing Nutrition has supported The Global Diet Quality Project to develop nationally adapted sentinel food lists for adults in 53 countries and infant and young child feeding (IYCF) sentinel food lists for children 6-23 months in 92 countries. Sentinel foods refer to context-specific foods that are frequently consumed within a food group in a given population (Herforth et al. 2020). The primary objective of this study is to determine if national-level sentinel food lists adequately capture food groups reported to be consumed at subnational levels, and if not, to determine the difference in diet quality indicators such as the minimum dietary diversity score in women of reproductive age (MDD-W) and in children (MDD). Secondary objectives include identifying whether the national-level sentinel food lists more accurately capture some food groups than other food groups for women 15-49 years and/or children 6-23 months.

Methods: Using datasets from six different dietary recall studies from subnational administrative areas in Bangladesh, Benin, Columbia, Kenya, Malawi, and Nepal, we will compare responses from open recall dietary questions or weighed food records to each country's adapted sentinel food lists. Differences will be tested by comparing diet quality indicator estimations (MDD-W, MDD) for each subregion from open recall and the sentinel list using a McNemar's test for difference in paired proportions .

Results: Analysis is currently in progress. Results will show how suitable nationally-adapted sentinel food lists are for use at the subnational level to measure population-level diet quality, inclusive of any differences in capturing diet quality indicators and food group consumption.

Conclusions: This study will demonstrate the suitability of national-level sentinel food lists for use at the subnational level for the rapid measurement of diet quality for women and children in unique geographic contexts.

Keywords: Diet quality, sentinel food lists, tool validation, measurement

Conflicts of interests: USAID financially sponsored USAID Advancing Nutrition to conduct this validation study of the nationally adapted sentinel food lists

Nutrient composition of fresh produce – assessing variability between European countries for substantiating food claims

Belen Beltramo[1], Aalt Bast[1], Hanne Diliën[1], Alie de Boer[1]

1.Maastricht University (Netherlands)

Background and objectives: Food claims can help translate distant health recommendations into more accurate and easy to access messages at the point of sale. In the European region, non-prepackaged fresh produce, such as fruits and vegetables, is excluded from mandatory nutrition labelling. However, the product's nutrient content is central to comply with conditions of use of such claims. Accurate nutrient composition information is key to establishing which products contain a sufficient amount of nutrients to bear claims. National Food composition databases (FCDBs) are the main sources of the nutrient composition, yet, fresh produce composition is highly dependent on cultivar and external characteristics. This study examines the variability in nutrient content for substantiating the use of food claims in fresh produce, in particular fruits and vegetables.

Methods: We sampled and assessed the nutrient content variation in fresh fruits and vegetables from FCDBs in Germany, Belgium, and the Netherlands retrieved from EuroFIR. The analysis focused on those macronutrients and micronutrients highly affected by external conditions and object to food claims. A one-way ANOVA analysis was used to test the differences in nutrient content between countries, and multiple testing was accounted for with a post-hoc test. We also studied whether a food item would have sufficient nutrients to carry a claim in all countries.

Results: Preliminary results show that food composition does differ between countries, in some cases resulting in only some countries being able to make a claim. It was also observed that some differences are more pronounced for vitamins highly affected by external conditions.

Conclusions: This study illustrates the heterogeneity that exists between national FCDBs. The lack of nutrient composition of different cultivars between countries affects the representatives of fresh produce varieties and derived used of food claims. Therefore, more effort should be put into collecting and integrating data on cultivars, growth conditions, seasonality, and production region. Widely available and cost-efficient nutrient composition sources could economically benefit small and middle scale producers to sustain food claims on their products.

The use of Mini Nutritional Assessment for malnutrition and sarcopenia assessment in elderly home care residents in Indonesia

Bianda Aulia[1,2], Atika Anif Prameswari[2], Toto Sudargo[2]

1. University College London (UK), 2. Universitas Gadjah Mada (Indonesia)

Background and objectives: Sarcopenia increases the risk of comorbidities and mortality in older adults. It coexists with malnutrition and shares many components related to age-related declines. This study aimed to explore the use of Mini Nutritional Assessment (MNA) in assessing sarcopenia in the elderly.

Methods: A total of 84 elderly home care residents (mean age 71.3 ± 7.4 years; 30 (35.7%) male) in Yogyakarta, Indonesia were enrolled in this cross-sectional study. Nutritional assessments were performed for body mass index (BMI), body circumferences, body composition (OMRON HBF-375 bioimpedance analyzer), and grip strength. Mini Nutritional Assessment (MNA) questionnaire was used to assess malnutrition risk. Sarcopenia was defined according to the Foundation for the National Institutes of Health (FNIH) Sarcopenia Project among Asian older adults.

Results: Mean BMI was 21.2 ± 3.7 kg/m2, with 49 (58.3%) subjects being at risk of malnutrition and 18 (21.4%) categorized as malnourished according to MNA. The prevalence of sarcopenia was 13.1%, and it was higher in male and in malnourished participants (p<;0.01). Participants who were malnourished had significantly lower calf circumference (median: 28.0 vs 32.0 cm, p=0.024) and arm circumference (22.5 vs 26 cm, p=0.042), compared to those who were well-nourished, but hand-grip strength and skeletal muscle mass index-kg/m2 (SMMI) were not statistically different (p=0.27 and p=0.09, respectively). Correlations between MNA score and SMMI (rs=0.395, p<;0.001), calf circumference (rs=0.345, p=0.001), and grip strength (rs=0.237, p=0.030) were also observed. An MNA score under 9.5 gave the highest sensitivity and specificity cut-off of older people at risk of sarcopenia (AUC=0.809; p=0.001; 72.7%; 63.0%).

Conclusions: Sarcopenia was not uncommon in malnourished elderly and elderly at risk of malnutrition. MNA score correlates positively with muscle mass and strength indices, suggesting that it might be a potential tool to recognize older people with sarcopenia.

Royal jelly controls intestinal stem cell homeostasis via SIRT1/mTORC1 axis

Masaki Igarashi[1], Masaomi Miura[1], Ryosuke Isotani[1], Yoshiko Nakagawa[1], Kyoko Naruse[1], Nobuaki Okumura[2], Toshimasa Yamauchi[1]

1.The University of Tokyo Hospital (Japan), 2. Yamada Bee Company, Inc. (Japan)

Background and objectives: The homeostasis of the gut epithelium is maintained by the self-renewal and differentiation of intestinal stem cells (ISCs). As previous studies have described the aging-related deterioration of adult stem cell function, developing the interventions to increase the adult stem cell pool could be an efficient strategy to prevent the tissue decline during aging. On these backgrounds, we try to discover how royal jelly (RJ) affects the ISCs function.

Methods: Mice were administered with RJ at 500 mg/kg/day or with 10-Hydroxydecanoic acid, which is an ingredient of RJ, at 10mg/kg/day by oral gavage for more than 6 weeks. Small intestine was isolated and used for immunohistochemistry. Proliferative function of ISCs was assessed by organoid culture from isolated crypts. ISCs and Paneth cells (stem cell niche) were isolated from Lgr5-EGFP-IRES-CreERT2 mice and were co-cultured for assessing the ISC and Paneth cell function.

Results: RJ treatment of intestinal crypts (including ISCs and Paneth cells) promoted organoid formation from both young and old mice derived crypts. While RJ treatment of isolated Lgr5-positive ISCs did not promote organoid formation, Paneth cells isolated from RJ-treated mice stimulated organoid formation in co-culture with control ISCs. RJ treatment increased the number of ISCs and Paneth cells in vivo. Moreover, we found 10-Hydroxydecanoic acid, an ingrediend of RJ, mimiced the effect of RJ ex vivo and in vivo. In order to probe the mechanism of ISCs proliferation by RJ, ISCs and RJ-treated Paneth cells were co-cultured with the CAMKK inhibitor STO609, AMPK inhibitor Compound C, or the specific SIRT1 inhibitor EX527. STO609, Compound C or EX527 treatment blocked the promotion of organoid formation by RJ-treated Paneth cells. Moreover, mRNA of SIRT1 and Nampt was upregulated in RJ-treated ISCs. Finally, pS6 staining of intestine from RJ treated mice showed mTORC1 activation by RJ. These all results suggest that CaMKK-AMPK-Nampt-SIRT1-mTOCR1 pathway in ISCs mediates the effect of RJ like calorie restriction (Igarashi M et.al., Cell.2016)

Conclusions: RJ expands the ISC pools though Paneth cell activation and mimics the effect of calorie restriction on ISCs. These results indicate that RJ could modify intestinal environment via Paneth cell and ISCs activation.

Development of the mynutritionis platform for improving the nutritional status of stunting children under five in Subang Regency, west Java Province, Indonesia

Ratnayani[1], Khanifa Ghina Fauziyyah[1], Firda Nur Amelia[1]

1. Binawan University, Indonesia (Indonesia)

Background and Objective: Subang Regency is an area located in the West Java Province, Indonesia. Stunting is one of the nutritional problems of children under five in this region. In terms of food security, Subang Regency has sufficient food security. This indicates that stunting is not caused by a lack of food availability. Another factor that is suspected to be one of the causes of stunting in Subang Regency is the lack of nutritional knowledge of mother, especially about arrange foods that can meet Recommended Dietary Allowance (RDA) of their children. The Covid-19 pandemic has affected several health activities, such as the decline in Integrated Healthcare Center (Posyandu) activities to monitoring and educating children's nutrition. Based on this, a platform (website) was created that provides information about children under five nutritional status as well as how to give balance nutrition.

Methods: Prior to the creation of the platform, a Forum Group Discussion (FGD) was first conducted. The FGD was carried out with the head of the Primary Healthcare (Puskesmas), nutritionist, posyandu and village representatives, the public health and the food security office of Subang Regency for the preparation of the features contained in the platform. After agreeing on the features contained in the platform, then the creation of the platform is carried out. After the platform was created and tested, socialization was carried out to related parties.

Results: In this platform, mothers of children only need to enter data on weight and/or height and age to find out how much their children's RDA are. In addition, this platform also displays what foods can be given to meet RDA. The foodstuffs displayed on this website are foods that are available in the Subang Regency area so that people can reach them. In addition, this platform also provides several recipes for processing recommended food ingredients.

Conclusions: Therefore, with this platform, mothers of children can provide nutritious food every day. It is hoped that when this process continues, there will be an improvement in children's nutritional status, especially in reducing the incidence of stunting.

Further Collaborators: This research received a grant in the TOP 120 social project Innovillage program organized by BUMN for Indonesia and Telkom University

Double burden of malnutrition and cardiometabolic risk factors in Ecuadorian women

Melisa A. Munoz Ruiz[2], Melisa Forero-Velilla[2], Sandra Victoria Abril-Ulloa[1], Laura I. González-Zapata[3,4], Diego A. Gaitán-Charry[4]

1. University of Cuenca (Ecuador), 2. Universidad de Antioquia (Colombia), 3. Grupo de investigación Determinantes Sociales y Económicos de la Situación de Salud y Nutrición, Escuela de Nutrición y Dietética, Universidad de Antioquia (Colombia), 4. Unidad de Problemáticas de Interés en Nutrición Pública, Escuela de Nutrición y Dietética, Universidad de Antioquia (Colombia)

Background and objectives: Both sides of the double burden of malnutrition, DBM, have been associated with adverse effects on health. Anemia or iron-deficiency anemia affects physical performance and health outcomes during pregnancy and birth. Being overweight is associated with an increased risk of cardiovascular disease mortality, and a high prevalence of altered cardiometabolic risk factors, CMRF, such as blood glucose, cholesterol, triglycerides, systolic and diastolic blood pressure. However, it is not clear if DBM represents a differential risk on health that may be attributed to under and over-nutrition. The objective of the present report was to compare cardiometabolic variables between three groups of women: apparently healthy, overweight, and affected by DBM i.e. coexistence of overweight and iron deficiency.

Methods: Data from the National Survey of Health and Nutrition of Ecuador were analyzed. The analysis included 1992 women from 18 to 59 years: 664 apparently healthy, 664 overweight, 664 DBM. DBM was considered as the coexistence of overweight and iron deficiency without anemia i.e. non-anemic and low ferritin. The Kruskal Wallis test was used to evaluate the differences between groups in CMRF i.e. blood glucose, cholesterol, triglycerides, systolic, and diastolic blood pressure. In this analysis, the post hoc test was the Bonferroni test. The SPSS statistical software package version 18.0 was used to conduct the analyses.

Results: Comparing with the apparently healthy group, the women affected by DBM had higher levels of all CMRF evaluated, p-value less than 0.05 for all. However, compared with the overweight group, the women affected by DBM showed lower levels of blood glucose, cholesterol, triglycerides, p-value less than 0.05; but, diastolic and systolic blood pressure were similar, with a p-value greater than 0.05.

Conclusions: The Ecuadorian women of reproductive age affected by DBM may present differential comportment of CMRF compared with those affected by overweight.

Infant and young child feeding practices and nutritional status in urban and rural area of South Kivu, Democratic Republic of Congo: a descriptive study

Marie Amelie Nabuholo[1], Olouwafêmi Mistourath Mama[1], Adama Diouf[1], Esto Bahizire[2,3,4], Nicole Idohou-Dossou[1]

1. Laboratoire de Recherche en Nutrition et Alimentation Humaine, Universite Cheikh Anta Diop de Dakar (Senegal), 2. Center for Tropical Diseases and Global Heath, Catholic University of Bukavu, South Kivu (Democratic Republic of the Congo), 3. Center for Research in Natural Sciences of Lwiro, Bukavu (Democratic Republic of the Congo), 4. Department of Medical Microbiology, University of Nairobi, Nairobi (Kenya)

Background and objectives: The optimal infant and young child feeding practices (IYCF) are crucial to improving children's health and nutritional status. In the Democratic Republic of the Congo (DRC), 43% of preschool children were stunted (Demographic Health Survey 2019). This study aimed at assessing the feeding practices and nutritional status of children aged 6-23 months from two areas, Kadutu (urban) and Miti-Murhesa (rural), in South Kivu, eastern DRC.

Method: A descriptive cross-sectional study conducted from August to September 2021 on randomly selected 530 children aged 6 to 23 months and their mothers in Kadutu and Miti-Murhesa. Socio-demographic characteristics were collected and IYCF practices were assessed using 24-hour recall. Nutritional status was determined according to the World Health Organization 2006 standards.

Results: Median (IQR) age was 13 months (9-17, n=522) and sex ratio 1.05. Overall, 97.1% of children were ever breastfed between 0-24 months and 85.4% within the first hour of birth. However, only 60.6% of children were exclusively breastfed to 6 months. The median age of introduction of liquid, semi-solid, solid complementary food was 4, 6 and 8 months respectively. The median age for weaning was 12 months. Overall, 68.8%, 10.8%, 8.7%, 12.9% of children, received water, sugar water, tea+soy, tea+milk respectively, in addition to breastfeeding the day before the survey (n=388). In both areas, complementary feeding was poor in food of animal origin, fruits and vegetables. Most children (88.5%) consumed porridge consisting only of grain, roots, tubers (sorghum, soybeans, plantains and maize) and water. Among these children, only 42% met minimum dietary diversity, 19% a minimum meal frequency and 10% reached a minimum acceptable diet. Stunting and wasting affected 36.6% and 4.9% respectively, without any difference between urban (38.6% and 3.7%) and rural areas (34.2% and 6.6%).

Conclusion: Majority of mothers breastfeed, however many introduce complementary food very early in their child's life. The diversity of complementary foods in the study area was found to be sub-optimal and could explain at least partly this high prevalence of stunting. Upgrading nutritional composition of the cereals complementary foods should be of highest priority for improving the young child nutrition.

A method to monitor structural changes of the nutritional quality of packaged food supply over time

Marie Tassy[1], Andréas Rytz[1], Adam Drewnowski[2], Alec Lecat[1], Emma Jacquier[1], Véronique Rheiner Charles[1]

1.Nestle Research (Switzerland), 2. University of Washington (USA)

Background and objectives: Food and beverage companies reformulate their products to improve their nutritional quality, adapt to evolving consumer needs and preferences, and to follow public health policies, both local and global. More broadly, reformulation of the global packaged food supply by multiple companies has the potential to improve diet quality and global public health. This study applied a product portfolio evaluation method to two subsets of the international Mintel New Products Global Database for years 2016-2018 and 2018-2020. The present goals were to provide feasible targets for reformulation that were category specific [1] and to monitor the structural changes of the nutritional quality of the packaged food supply over time.

Methods: The three components of the product portfolio evaluation system were (1) identification of nutrients relevant to each food category, (2) assignments of products into nutritionally homogeneous sub-categories and (3) the development of feasible nutrient thresholds for "best of class" products. Nutritional categories were matched from one period to another using products launched during the year 2018, which were present in both periods of time.

Results: The category-matching process between the two periods of time resulted in three different outcomes: a single category in 2016-2018 matching a unique one in 2018-2020, multiple categories merging into one, or a single category splitting into smaller ones. The structure of categories evolved in 38% of cases. As an example, the unique 2016-2018 Pizzas category split into two categories between 2018 and 2020. The first category reflects a healthier pizza offering than the second one which gathers mostly indulgent pizzas, despite an absence of evolution of the average nutrient thresholds overall. From a qualitative perspective, the threshold remained stable for 85% products, indicating that nutrient thresholds remain relevant for most products over multiple years. Whenever nutrient thresholds were evolving, they appeared to move to nutritionally more stringent thresholds, especially for the two disqualifying nutrients sodium and sugars.

Conclusions: The present method enables one to determine category-specific nutrient thresholds applicable at one time point, and, when combined with a category-matching algorithm, to monitor the structural and qualitative changes in the manufactured food supply over time. This method can support decision making for the creation, or merging, of product categories and the evaluation of their nutrient thresholds for food formulation.

Dietary choline and betaine intakes are associated with anthropometric measures in young children from Vancouver, Canada

Alejandra M Wiedeman[1,2], Rajavel Elango[1,2], Angela M Devlin[1,2]

1.The University of British Columbia (Canada), 2. BC Children's Hospital Research Institute (Canada)

Background and objectives: Choline is the precursor for acetylcholine, phosphatidylcholine, sphingomyelin, and betaine. Little is known about dietary choline and betaine intakes during childhood and the relationship to indicators of growth (anthropometric measures). The objective of this study was to determine the relationships between anthropometric measures, and choline and betaine intakes and status in children.

Methods: Participants were from a randomized controlled trial of arachidonic acid and docosahexaenoic acid supplementation between ages 1 (1y) and 2 years (2y); or a cross-sectional study at age 5-6 years (6y). Anthropometric measures were assessed using weight, height, and BMI using the WHO Child Growth Charts z-scores stratified by sex. Dietary information was collected by three non-consecutive day food records (1y n=110; 2y n=86) or three non-consecutive day 24-hour recalls (6y n=265). Intakes were estimated using the Canadian Nutrient File and USDA database for choline. Plasma free choline and betaine concentrations were quantified using LC-MS/MS.

Results: Daily choline and betaine intakes were (mean [SD], respectively) 174 (56.2) and 45.6 (27.1) mg at 1y; 205 (67.5) and 62.5 (40.3) mg at 2y; and 249 (94.3) and 87.2 (39.9) mg at 6y. At all ages, the top sources of choline were eggs and dairy (~48%), and grain products (~62%) for betaine. Children that consumed eggs had a greater odds of meeting the Adequate Intake for choline (OR=5.60 at 1y, OR=8.14 at 2y, and OR=12.6 at 6y; all P<;0.001) than none egg consumers. Plasma free choline and betaine concentrations were (mean [SD], respectively) 10.4 (3.3) and 41.1 (15.4) µmol/L at 1y; 8.50 (2.30) and 39.0 (12.1) µmol/L at 2y; and 8.62 (2.13) and 45.3 (13.7) µmol/L at 6y. Dietary choline intake was positively associated with z-scores of weight-for-age, length/height-for-age, weight-for-length (1-2y), and BMI-for-age (6y) (all P<;0.05). Dietary betaine intake was positively associated with weight-for-age, length-for-age, weight-for-length, and BMI-for-age (all P<;0.05). Plasma betaine was inversely associated with BMI-for-age at 6y (r=-0.168; P=0.008).

Conclusions: These findings suggest that anthropometric measures are associated with choline and betaine intakes and plasma betaine in young children. The role of choline metabolism in growth and body composition during development requires further investigation.

PAB(T2)-56

Assessing nutrient intakes of Canadian children and adolescents in schools

Emily Ziraldo[1], Mavra Ahmed[1], Chelsea McPherson[1], Daniel W Sellen[1], Mary R L'Abbé[1]

1.University of Toronto (Canada)

Background and objectives: The diet quality of Canadian children is suboptimal and unhealthy diets contribute to increased prevalence of childhood overweight and obesity. The school food environment can influence children's food choices and consumption patterns thereby impacting children's health. Monitoring nutrient intakes of children and adolescents at school is critical to understanding the school food environment. The nationally representative Canadian Community Health Survey (CCHS) Nutrition 2015 provides an opportunity to investigate nutrient intakes by location of food consumption. Therefore, the objective was to examine nutrient intakes of Canadian children and adolescents in schools.

Method: Intake data from the CCHS 2015 Public Use Microdata File first 24-hour dietary recall was used to estimate intakes of energy, macronutrients, nutrients of concern (i.e., sodium, saturated fat, sugar), and micronutrients of interest (i.e., calcium, fibre, iron, potassium) for children and adolescents between 2-18 y at schools. Nutrient intakes were expressed as means and as a proportion of total daily intake and are reported by Dietary Reference Intake (DRI) group. Participants who reported no food consumption, those with invalid energy intake and breastfeeding women were excluded.

Results: Across all DRI groups, children consumed 552.3±14.3 calories at school, representing 29.2% of their daily energy intake. Males 14–18 y consumed the lowest proportion of their daily energy intake at school (24.1%±1.6) and 4–8 y consumed the highest (32.3%±1.3). For all participants, the proportion of sodium, saturated fat and sugar consumed at school was 30.6%±0.8, 27.5%±0.8 and 30.5%±0.8. Notably, 4–8 y consumed the largest proportion of their daily sodium intake (33.8%±1.6) at school and males 14-18 y had the highest mean sodium intake

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

(1010.8±104.4 mg). For sugar, 2-3 y reported the highest intakes (39.2±11.2 g) and consumed the largest proportion of their sugar intake (44.1%±12.4) at school. For all nutrients, calcium was consumed in the lowest proportion (25.2%±0.7) and fibre was the highest (31.7%±0.8).

Conclusions: Findings demonstrate that Canadian children consume 29% of their daily energy intake at school and contribute to an understanding of nutrient intakes of children while at school. This knowledge informs and supports the development of a national school food program.

Development and Validation of a semi-food frequency questionnaire (Thai semi-FFQ) for urban and semi-urban at-risk populations with metabolic syndrome

Korapat Mayurasakorn[2], Kitti Sranacharoenpong[1], Nattvara Nirdnoy[1], Apinya Surawit[2], Bonggochpass Pinsawas[2], Pichanun Mongkolsucharitkul[2], Tanyaporn Pongkunakorn[2], Sophida Suta[2]

1.Mahidol University (Thailand), 2. Faculty of Medicine Siriraj Hospital, Mahidol University (Thailand)

Background and Objectives: Semi-food frequency questionnaire (semi-FFQ) is one of the tools to assess the relationship between diet and risk of diseases. The aim of this study is to develop and validate the semi-FFQ for at-risk people of metabolic syndrome.

Methods: In the development phase, we used the single food items data from Thailand national food consumption survey in 2016 to analyze the list of food and proportionate amount. Data on Thai mixed-dish food were collected from 5 canteens at Siriraj Hospital in Thailand. The three sampling dishes from each menu were weighted for the major ingredients. The nutritive values were calculated using the Thai food composition software program. The nutrient profiling criteria (NP) was used to classify those menus. In the validation phase, participants were recruited from Siriraj-health cohort study. The reference indicator to compare with the semi-FFQ was the biochemical results of the participants.

Results: ninety-seven food items of 8 food groups and 5 serving size choices were included in the semi-FFQ. The food groups were fruits (n=18), beverage (n=10), snacks and Thai desserts (n=29), Thai mixed-dishes (n=32), egg menus (n=3), and dressing (n=5). The Thai mixed-dish were classified into 3 groups: a la carte, noodles, and rice with toppings. The content validity of semi-FFQ was evaluated by 3 nutrition specialists. The score was 0.97. The validation results were associated between three major nutrients for metabolic syndromes (sugar, fat, and sodium) and biochemical results (fasting blood glucose, lipid profiles, blood pressure and 24-hour urine sodium). Ninety-four participants were in the validation phase (54 unrequired urine collection, 40 required urine collection). Level of biochemical results of each key metabolic syndrome nutrient significantly increased with the rise of semi-FFQ estimated intakes. Correlation coefficients (r): fasting blood glucose; r=0.293 in fruits, r=0.285 in desserts. Triglyceride; r=0.252 in a la carte-dish. LDL-cholesterol; r=0.205 in rice with toppings-dish. Systolic blood pressure; r=0.272 in snacks and r=0.190 in a la carte-dish.

Conclusions: The final semi-FFQ was useful for assessing dietary food pattern of Thai populations who are at risk for non-communicable diseases.

Effects of eating and exercise patterns on energy deficiency in free-living Korean male soccer players

Sihyung Lee[1], Motoko Taguchi[1]

1.Waseda University (Japan)

Background and objectives: Excessive exercise energy expenditure (EEE) and limited energy intake (EI) in athletes result in energy deficiency, which can cause physiological impairment. To monitor the energy deficiency in athletes, the ratio between measured and predicted resting energy expenditure (REEratio) has been recommended. However, there is no study on the effects of eating and exercise patterns on the REEratio. Therefore, this study aimed to assess the 7-day EI and EEE patterns of free-living athletes and analyze their effects on the REEratio.

Methods: Eleven Korean male collegiate soccer players completed the 7-day dietary records for EI and heart rate monitoring for EEE. Body composition was measured using dual-energy x-ray absorptiometry. Measured REE was evaluated using the Douglas bag method and predicted REE was calculated using the organ-tissue prediction equation. EI and EEE patterns of the participants during the training and rest days were analyzed; further, their effects on the REEratio were analyzed using regression analysis.

Results: Mean REEratio was 0.96 ± 0.08, and 7-day EI and eating frequency were 3,308 ± 508 kcal/d and 4.8 ± 0.8 times/d, respectively; there was no significant difference between training and rest days in eating patterns (3,350 ± 458 vs. 3,203 ± 807 kcal/d, p = 0.607, 5.1 ± 0.8 vs. 4.2 ± 1.3 times/d, p = 0.062, respectively). The 7-day EEE and exercise frequency were 1,519 ± 364 kcal/d and 1.7 ± 0.5 times/d, respectively, and training day

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

exhibited significantly higher EEE and exercise frequency than rest day (2,009 ± 419 vs. 295 ± 322 kcal/d, p <;0.001, 2.2 ± 0.5 vs. 0.4 ± 0.5 times/d, p <;0.001, respectively). The regression analysis showed that the athletes with higher EI were more likely to have higher REEratio (R2= 0.54, p = 0.009), and the higher eating frequency during rest day can result in higher total EI (R2 = 0.42, p = 0.032).

Conclusions: There is high risk of energy deficiency in Korean male collegiate soccer players, and EI affects the REEratio, but EEE has no effect on the REEratio. Increased eating frequency, especially during rest days, might help prevent the decrease in the REEratio and energy deficiency in athletes.

Reliability of a web-based time-use diary (MEDAL) in assessing children's meal intakes using food photography taken by parents as reference

Kar Mun Chong[1], Airu Chia[2], Foong-Fong, Mary Chong[2], Bee Koon Poh[1], Nor Aini Jamil @A.Wahab[1], Denise Koh[1], Jyh Eiin Wong[1]

1.Universiti Kebangsaan Malaysia (Malaysia), 2. National University of Singapore (Singapore)

Background and objectives: My E-Diary for Activities and Lifestyle (MEDAL) is a web-based time-use diary developed to assess diet and movement behaviour of Asian school children. This pilot study aimed to determine the reliability of MEDAL in assessing dietary intake of Malaysian school children using food photography taken by parents as the objective measure.

Methods: A total of 28 children aged 10-11 years recorded their daily activities in MEDAL for 4 days (2 weekdays and 2 weekend days). Over the four-day period, parents took meals and snacks photos consumed by their children (before and after consumption). The reliability of child-reported food items in MEDAL was determined by comparing their MEDAL reports to food photos taken by parents and classified as matches, omissions, or intrusion.

Results: The total food photos (n=307) submitted by parents was 91.4% of the total minimum expected reports (n=336 eating occasions) for 4 days. Overall, the match, omission, and intrusion rates were 69.0%, 34.1%, and 20.1%, respectively. Carbohydrate-based items from “Breads, spreads, and cereals” and “Rice and porridge” food categories were the most accurately reported (total match rates 74.6% and 75.0%, respectively). “Snack and dessert” items were most omitted (omission rates 48.4%). “Drinks” and “Milk, cheese and yogurt” items were most intruded (intrusion rates 29.0–29.7%). Compared to boys, girls reported more matches (74.6% vs. 57.2%) and fewer omissions (25.7% vs. 52.0%) and intrusions (15.1% vs. 30.9%).

Conclusions: Children were able to report their food and drink intake in MEDAL although some items were omitted and intruded when compared to food photography taken by parents. Omission of snacks and desserts might be attributable to multitasking—like eating while watching television or studying. The result of intrusion is further limited by the fact that parents might forget to photograph the drinks. MEDAL is a promising tool to assess the dietary intake of Malaysian school children aged 10-11 years.

Contribution of organ mass on resting energy expenditure in Japanese male athletes

Nozomi Miura[1], Satomi Oshima[2], Suguru Torii[1], Motoko Taguchi[1]

1. Waseda University (Japan), 2. Nagoya University of Arts and Sciences (Japan)

Background and objectives: Estimated energy requirement is predicted by multiplying resting energy expenditure (REE) with physical activity level, and is used to determine individual energy needs. Therefore, it is important to explore the factors that influence REE. In athletes, fat-free mass (FFM) is a major determinant of REE. However, FFM is a heterogeneous compartment with a wide range of specific metabolic rates. Particularly, the brain, liver, heart, and kidneys have high metabolic rates. Few studies of organ mass on REE in athletes have been undertaken. This study aims to investigate the contribution of these organs, the components of FFM, on REE in male athletes.

Methods: A total of 31 Japanese male athletes (age, 20 ± 0.9 years) with normal levels of serum triiodothyronine were included in the study. REE was measured via indirect calorimetry using the Douglas bag technique. Body compositions were measured using dual-energy X-ray absorptiometry (DXA). Fat mass (FM), adipose tissue mass (AT), skeletal muscle mass, bone mass, and residual mass were calculated using data derived from DXA measurements. Mass of the brain, liver, and kidneys was measured by magnetic resonance imaging, and mass of the heart was estimated by echocardiography. The total mass of the brain, liver, kidneys, and heart was used as organ mass (OM) for the analysis. Multiple regression analysis was used to assess the contribution of FFM, FM, and mass of organs on the variance of REE.

Results: Total mean body weight and FFM were 76.0 ± 8.2 kg and 65.6 ± 5.7 kg, respectively. Significant correlations between REE and all body components except body fat percentage, FM, and AT were observed. In components of FFM, OM most highly correlated with REE (r=0.707, p<;0.001). OM was an independent factor of REE and explained 50.0% of the variance in REE in athletes. The relative contribution of high metabolic organs to REE appeared to be consistent regardless of the body size.

Conclusions: The OM would be the most effective predictor of REE in athletes. This information might well lead to a more

detailed understanding of individual differences in athlete's REE.

Relationship between nutritional status and nutritional interventions on length of stay and clinical outcomes of corona virus disease (COVID) 19 patients

Nurpudji Astuti Taslim[1,2], Giena Tiara Werdhianti[1], Agussalim Bukhari[1,2], Aminuddin Aminuddin[1], Suryani As'ad[1,2,3], Haerani Rasyid[1]

1.Hasanuddin University (Indonesia), 2. Wahidin Sudirohusodo General Hospital (Indonesia), 3. Muhammadiyah University of Makassar (Indonesia)

Introduction: Malnutrition in particular undernutrition and overweight/obesity, alters the immune response, increasing the risk of infection, such as influenza and coronavirus. Proper diet and good nutritional status are considered as essential elements for an optimal immune response to prevent infection. Various nutritional interventions, such as oral nutritional supplements (ONS), dietary management and counselling, have shown positive results in patient care. Nutritional status and diet modulate inflammation and immune function and influence COVID-19 outcomes. This study aims to evaluate the relationship between nutritional status and nutritional interventions with length of stay (LOS) and clinical outcomes in COVID-19 patients in Dr. Wahidin Sudirohusodo Hospital, Makassar, Indonesia.

Method: Clinical data of 1726 subjects were collected from hospital's medical record in a cohort retrospective study method between June – September 2021. Nutritional status was graded with body mass index (BMI), mid upper arm circumference (MUAC) and Subjective Global Assessment (SGA). Nutritional intervention expressed in the percentage of energy, protein, carbohydrate and fat achievement of patients in treatment. We evaluated nutritional status and nutritional interventions on length of stay and clinical outcomes in the form of mortality and conversion time from the patient's PCR swab.

Results: 1726 patients entered the inclusion criteria grouped based on the degree of disease, namely moderate, severe and critical. Assessment of nutritional status using MUAC and BMI had a significant effect on length of stay (P<;0.05), BMI and SGA had significant effect on mortality (P<;0.05). Energy achievement had a significant effect on length of stay, mortality and clinical outcomes (P<;0.05). While, the intake of protein, carbohydrates and fat had an effect on mortality (P<;0.05).

Conclusions: Nutritional Assessment status using MUAC, BMI and SGA in admitted patients can be used as a prognostic predictor of clinical outcome in moderate COVID-19 patients. Nutritional interventions, specifically intake of energy and protein affects the length of stay, mortality and conversion time of COVID-19 patients.

PAB(T2)-62

Comparison of label-declared versus laboratory-analyzed nutrient content values among commercially produced complementary foods sold in Cambodia, Indonesia and Senegal

Katelyn Joyce Yuen[1], Mary Champeny[1], Yaga Sy Ndeye[2], Senveasna Chum[3], Dian Hadihardjono[4], Eva Juniza[4], Anzélle Mulder[5], Lara Sweet[5], Jane Badham[5], Alissa M. Pries[1]

1.Helen Keller International (USA), 2. Helen Keller International (Senegal), 3. Helen Keller International (Cambodia), 4. Helen Keller International (Indonesia), 5. JB Consultancy (South Africa)

Background and objectives: Commercially produced complementary foods (CPCF) are increasingly fed to infants and young children in low- and middle-income countries (LMIC). Given this age group's unique nutritional requirements, it is essential that CPCF accurately report their nutrient content. This study assessed whether CPCF in three urban, peri-urban and rural LMIC settings contained key nutrients in the amounts declared and claimed on product labels.

Methods: A purposive sample of commonly available CPCF (instant cereals, purees/meals, and snacks/finger foods) in Khsach Kandal, Cambodia (n=11); Bandung City, Indonesia (n=11); and Dakar, Senegal (n=21) were sent for blind laboratory-measurement of total fat, saturated fat, protein, carbohydrate, sugar, sodium, calcium, iron, and zinc content. European Union (EU) guidance on nutrient-specific tolerance thresholds was used to assess the label values (LV) and laboratory-measured analytical values (AV) to characterize the accuracy of nutrient content claims and nutrient content information on CPCF labels.

Results: All 11 CPCF from Cambodia failed to meet the EU tolerance range for protein, with protein LV lower than AV. Of products declaring sugar content, half of products (n=4/8) from Indonesia and 40.0% (n=2/5) from Cambodia were noncompliant, with sugar AV higher than LV. Conversely, nearly all (91.7%, n=11/12) of the products from Senegal that declared sugar content on labels were compliant. Four products from Indonesia made a calcium claim, yet all four failed to meet the calcium tolerance range with calcium LV higher than AV. Six products from Indonesia made an iron claim, yet four were noncompliant with the iron tolerance range, half (n=2/4) of which overstated iron content. Most CPCF products (88.4%, n=38) had at least one of the analyzed nutrients missing from the label's nutrient content declaration.

Conclusion: Nutrient declarations on the labels of most CPCF assessed in this study deviated from laboratory-measured values. Caregivers rely on labels to inform them of what nutrients their child receives from a product. Without accurate nutrition information, caregivers' decision-making about young child feeding is compromised. Increased monitoring of declarations of

nutrient content and associated claims, especially for key micronutrients, is recommended to avoid misleading consumers of the true content of CPCF.

Nutritional composition of packaged foods and non-alcoholic beverages available in Senegalese supermarkets

Yassarath Mireille ONIFADE[1], Mane Helene Faye[1], Fatou Fall[1], Stefanie Vandevijvere[2], Gary Sacks[3], Olouwafemi Mistourath Mama[1], Nicole Idohou-Dossou[1], Adama Diouf[1]

1.Laboratoire de Recherche en Nutrition et Alimentation Humaine, Faculte des Sciences et Techniques, Universite Cheikh Anta Diop, Dakar (Senegal), 2. Public Health Nutrition Epidemiology and Public health, Sciensano, Brussels, Belgium (Belgium), 3. Global Obesity Centre (GLOBE), Institute for Health Transformation, Deakin University, Burwood, Victoria, Australia (Australia)

Background and objectives: The World Health Organization (WHO) recommends food companies to reformulate their products to limit the content of energy and nutrients of concern (saturated fat, added sugars, and sodium). The purpose of this study was to evaluate, for the first time, the nutritional quality of packaged foods and beverages available in supermarkets in Dakar, Senegal.

Methods: A market survey was conducted between August and September 2021 to collect data from packaged food in the two largest and most popular retailers in Dakar. Nutritional composition and promotional strategies were recorded from the packaging. The food products were divided into permitted or not permitted to be marketed to children using the WHO Nutritional Profiling Model for the African Region.

Results: Overall, 7398 packaged food products were collected and 82% of products providing some nutritional information were analyzed. Levels of nutrients of concern varied considerably across food categories and the majority of them do not meet criteria for energy, fat, total sugars. The most energy-dense foods per 100g were butter (744 kcal), snacks (530 kcal), cookies (473 kcal), confectionery (405 kcal), and breakfast cereals (386 kcal). Those with high saturated fat content were crackers (9.8g), cookies, ice cream (9.1g). Total sugars were higher in desserts (84g), breakfast cereals (73g), confectionery (71g), cookies (66g), and brioche bread (65g). The highest levels of added sugars were observed in chocolate spreads, jams, confectionery (55g), ice creams (26g). High salt content was found in the condiment sauces, including mustard (5.62g), ketchup (2g) and mayonnaise (1.25g). According to the WHO AFRO nutrient profile model, 100% of confectioneries, cakes, cookies, breakfast cereals and ice creams would be prohibited from marketing (levels of total sugars exceeding the thresholds), while 100% of chips and ketchup and 80% of cheese should not be marketed due to excessive levels of fat. Nevertheless, 31% of confectioneries and cookies and 60% of breakfast cereals were promoted on the packaging.

Conclusions: Policy regulation of packaged food should be addressed and strength to support industrial companies to limit the content of nutrient concern in the context of increasing levels of obesity and diet-related NCDs.

Relationship between the Dish Based Dietary Patterns and Metabolic Indicators

Woori Na[1], Seunghee Choi[1], Chaeryeon Kim[1], Cheongmin Sohn[1]

1.Wonkwang University (Korea)

Background and objectives: When eating, it is consumed as unit of food, not as a unit of groceries or nutrients. Therefore, this study tried to analyze relationship between their food based dietary patterns and metabolic indicators, to provide the dietary guidelines for preventing and managing metabolic disease such as diabetes, hypertension and dyslipidemia.

Methods: This study used the metabolic indicators and food intake data of men and women aged 30 to 49 in the 6th & 7th Korea National Health and Nutrition Examination Survey. Total of 10,037 persons (men 4,108, women : 5,929) were analyzed with the exception of the persons whose data are insufficient. The metabolic indicator was blood pressure, fasting glucose and serum lipid profile. For the analysis, 24-hour recall was applied for food groups, and consequently 23,174 foods were categorized into 24 food groups. After that, factor analysis was conducted in the satisfaction of over 0.3 communality of food groups. The three patterns were derived both men and women, under the conditions of KMO=0.521 in men, KMO=0.513 in women. For analysis, factor score was divided into quartiles, generalized linear model (GLM) was performed to analyze the relationship between food based dietary patterns and food based dietary patterns.

Results: The study results are as follows: Pattern 1 was grilled, beverages, seasonings, pickles, and vegetables, pattern 2 was rice, kimchi and soup, pattern 3 was dairy products, fruits, and individual foods for men. Pattern 1 was rice, kimchi, soup and food boiled down in soy sauce, pattern 2 was grilled, beverages, pickles, and stew, pattern 3 was dairy products, fruits, and individual foods for women. Both men and women showed a significant decrease in systolic blood pressure (men,Q1:119.4 mmhg, Q4:116.7 mmhg, p<;0.001; women, Q1:109.9 mmhg, Q4:107.3 mmhg, p<;0.001)and triglycerides(men,Q1:205.9 mg/dL, Q4:167.4 mg/dL, p<;0.001; women, Q1:110.4 mg/dL, Q4:98.8 mg/dL, p=0.001) in pattern 3.

Conclusions: A diet pattern with sufficient milk and fruit may help lower blood pressure and blood lipids in Korean adults aged

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

30-49 years.

Lignan intake of plant-based foods in the Netherlands and its relation with obesity indicators

Umi Kalsum Hussain Zaki[1,2], Laura Trijsburg[1], Edith Feskens[1]

1.Wageningen University and Research (Netherlands), 2. Malaysian Agricultural Research & Development Institute (Malaysia)

Background and objectives: The global burden of obesity has profound public health implications in chronic disease onset and a healthy lifespan. An exploration of food patterns that are beneficial in the primary prevention of obesity is warranted. Lignans are biologically active plant-derived compounds with a chemical structure similar to estrogen and have been associated with modulation of energy metabolism with possible effects on weight loss. Lignans may suppress adipose tissue growth, inhibit differentiation of preadipocytes, stimulate lipolysis, and induce apoptosis of existing adipocytes, thus reducing adipose tissue mass. This study aimed to assess whether lignan intake is associated with lower body mass index (BMI) and waist circumference in a Dutch population.

Methods: Data on lignan content of foods was extracted from a lignan database of Dutch plant based foods and complemented with three other references to estimate lignan intake in 1012 Dutch men and women participating in the NQ-plus prospective cohort study. The association between lignan intake and BMI and waist circumference was assessed using linear regression analysis. Three multivariate models were used to investigate the association of BMI and waist circumference with total lignan intake. Model 1 included adjustments for lifestyle variables, in model 2 adjustments were made for energy intake and nutrients, and in model 3 these adjustment were combined.

Results: The median lignan intake was 3226 µg/day (mean 4763 µg/day, SD 5386 µg/day). The median BMI was 25.2 kg/m2 (IQR 23.1 – 28.0) and waist circumference was 90.5 cm (IQR 82.7 – 99.0). Lignan intake was strongly skewed towards higher values, ranging from 40-50500 µg/day. The major sources of lignans were bread, which contributed 52%, nuts, seeds, and snacks (21%), and vegetables (12%). After adjustments lignan intake was associated with lower BMI (-0.93 kg/m2 per 1-SD of lignan intake, 95% CI: -0.91; 1.02) and with a lower waist (-0.93 cm, 95 % CI: -0.88; -1.00).

Conclusions: A higher lignan intake is significantly associated with a smaller waist circumference in Dutch adults. To what extent a high lignan intake can reduce waist circumference in obese patients or can prevent onset of abdominal obesity remains to be tested in future intervention studies.

PAB(T2)-66

Estimation of dietary iron bioavailability from total iron intake and iron status of Filipino adolescents living in a rural area

Lotte Hulsbergen[1], Lowela Padilla Mughal[1], Edith Feskens[1], Angelina dR. Felix[2], Corazon VC. Barba[2], Alida Melse-Boonstra[1]

1.Wageningen University & Research (Netherlands), 2. University of the Philippines Los Baños (Philippines)

Background and objectives: Iron reference values are essential for assessing adequacy of iron intake. Among Filipino adolescents, a large inconsistency exists between the reported prevalence of anemia (7.7%) and iron deficiency (9.6%), and their inadequacy of iron intake (87–97%), which may be related to the underestimation of iron bioavailability from the diet. We aimed to explain this discrepancy by estimating the average iron absorption required to maintain iron status with current dietary iron intake in Filipino adolescents living in a rural area as part of the Ten2Twenty project in the Philippines.

Methods: A total of 195 Filipino adolescents were included and stratified by sex (boys, n=97; girls, n=98) and menarche status (pre-menarche, n=43; post-menarche, n=55). A probabilistic model was applied using total dietary iron intake based on two non-consecutive 24h-recalls against physiological iron requirements to estimate the prevalence of iron inadequacy along a scale of 1–40% bioavailability. Subsequently, the cumulative distribution of inflammation-adjusted serum ferritin (SF) concentrations was calculated for each sub-group, providing the group-specific prevalence of iron deficiency. Iron bioavailability was estimated by matching the prevalence of iron inadequacy with the observed prevalence of iron deficiency for each group, assuming that these were equal.

Results: Overall, the prevalence of anemia was 19%. Median total iron intake and SF concentrations were 9.99 mg/d and 82.4 µg/L in boys, 9.49 mg/d and 73.7 µg/L in pre-menarche girls and 10.1mg/d and 58.4µg/L in post-menarche girls. The corresponding predicted iron bioavailability values in boys, pre-menarche girls and post-menarche girls, were 13%, 11% and 15%, respectively, which is higher than the currently assumed bioavailability value of 8.5%. The overall prevalence of iron inadequacy decreased markedly from 77% to 43% after applying the modeled bioavailability predictions.

Conclusions: We found evidence that the discrepancy between a high inadequacy of dietary iron intake and a mild prevalence of anemia can be partially explained by underestimation of the current iron bioavailability value. However, methodological uncertainties by unstable iron status due to growth and the onset of menstruation during adolescence

should be further investigated. [Conflict of Interest Disclosure] The data used for this study originated from the Ten2Twenty Philippines Project, which received support from a company that markets and sells micronutrient supplements in the form of hygienic products, which was given as part of tokens received by the study participants.

Solanum Torvum Consumption as a means of improving heamogloblin levels in pregnancy, a facility-based study of pregnant women attending antenatal services in the Cape Coast Metropolis, Ghana.

Kingsley Kwadwo Asare Pereko[1], Charles Adongo[1], Edward Ameyaw[2], Kwabena Dankwa[1], Jacob Setorlgo[1], Sebastian Shine Kwarpong[1]

1.University of Cape Coast (Ghana), 2. University of Technology (Australia)

Background and objective: Anaemia in pregnancy constitutes a significant public health and developmental concern globally. Women in West Africa and Ghana commonly use Solanum torvum as one of the means of improving the haemoglobin levels during pregnancy. This study aimed at assessing the consuption of Solanum torvum in pregnancy and haemoglobin levels of pregnant women.

Methods: This was a facility based prospective study that targeted women in their first trimester of pregnancy. Using a purposive sampling procedure, data was collected from 211 consented women on their socio-demographic characteristics, dietary diversity scores, Solanum torvum consumption patterns, and haemoglobin measures of respondents. Both descriptive and inferential analysis using probit regression and a paired sample t-test were conducted.

Results: Approximately 98.5% of the women indicated ever-using solanum torvum preparation. The predictors were essentially their background characteristics, including age, marital status and educational attainment. The differences in haemoglobin levels between phase 1 and phase 2 and those who took the special preparation of solanum and those who did not was not statistically significant.

Conclusion: The result suggest no effect of the special preparation of solanum torvum intake on heamglobin levels of pregnant women. However, its use in daily diet is recommended.

Inclusion of nutrient status performance indicators in diet optimisation modelling: a case study of dietary iron intake optimisation and recuperation from anaemia in Nigerian women

Maike van Rooijen[1], Joke C van Lemmen-Gerdessen[1], Taymara Abreu[1], Edith JM Feskens[1], Alida Melse-Boonstra[1]

1.Wageningen University & Research (Netherlands)

Background and objective: Diet optimisation models are frequently used to evaluate effects of diet modifications on adequacy of nutrient intake. So far, diet models have only used total nutrient intake performance indicators as an outcome, without taking changes in nutrient status and bioavailability into account. We aimed to evaluate the feasibility of including iron status performance indicators in diet modelling, and to use this to predict the required time span to recuperate from anaemia, thereby accounting for changes in bioavailability over time.

Methods: Data from the Nigerian Household Consumption and Expenditures Surveys (2015/2016) were used to calculate daily dietary iron intake of women of reproductive age (n=4,042). A uniform distribution of Hb concentrations was randomly applied to the sample population. Bioavailability of non-haem iron (5%) was assumed to increase by +44% in mild anaemia, +75% in moderate anaemia and +100% in severe anaemia. Linear goal programming was applied to optimise diets for iron intake in three sequential steps: 1) iron balance model, in which meeting iron requirements was set as a hard constraint; 2) iron recuperation model, in which iron intake was optimised until a Hb concentration of 12 g/dl was reached; and 3) iron status model, for calculating the number of days it would take to reach a non-anaemic state.

Results: Iron balance and recuperation diets could be formulated for 3,350 (69%) women, followed by iron status modelling. On average, it would take 55 days to reach a non-anaemic state when starting from a state of mild anaemia (n=1157), 212 days from moderate anaemia (n=722), and 396 days from severe anaemia (n=29). In the iron recuperation diets, vitamin A intake was reduced, but intake of most other nutrients increased slightly.

Conclusion: We have shown that it is feasible to include iron status performance indicators into diet modelling for optimizing iron intake, while accounting for changes in iron bioavailability over time. Nigerian women can recover from mild anaemia by increasing their dietary iron intake within a reasonable time span, but not from moderate or severe anaemia. This modelling approach can be further refined by taking dietary inhibitors and enhancers into account.

Investigation of Amino Acids and Fatty Acids Profiles of Japanese Diets Using the Food Exchange Chart for Diabetes Diet

Ayari Tsumura[1], Hisami Yamanaka Okumura[1,2], Hana Kawakami[1], Shiori Yamamoto[1], Mayu Ohura[1], Hiroshi Tatano[3], Hirokazu Ohminami[1], Masashi Masuda[1], Yutaka Taketani[1]

1.Tokushima University (Japan), 2. Doshisha Women Collage of liberal Arts (Japan), 3. The University of Shimane (Japan)

Background and objectives: Diet is an essential part of healthcare, and dietary assessment primarily uses PFC balance in the conventional way. In addition, dietary surveys have been needed objective evaluation methods that do not require interviews. We thought that food metabolomics could be utilized for this purpose. However, there are little information on reference values for basic amino acids (AA) or fatty acids (FA) metabolites. Therefore, we investigated dietary AA and FA profiles as an ideal diet of Diabetes Mellitus (DM) exchange menu for Japanese.

Methods: Eighteen AA and forty-nine FA in DM menu for 15 days. It has three types of carbohydrate rates with 60 % (HC), 55 % (MC), and 50 % (LC). From 1200 to 2000 kcal/day menus were calculated by the Japanese Food Composition Table 2020 7th, which differences in energy were corrected by dividing by 1000 kcal. AA and FA mg/1000kcal and calorie density (CD) g/kcal were compared among the three groups.

Results: AA in HC, MC, and LC were 42.9, 47.6, and 45.6 mg/1000 kcal, with no significant differences among the three groups. FA in HC, MC, and LC were 20.1, 23.7, and 28.0 mg/1000 kcal, respectively. FA of MUFA, PUFA, and n-6 PUFA in LC was significantly higher than those in HC. The 18:1 total, 16:0, and 18:2 n-6 had higher FA values in that order. The 18:1 total was accounting for 35.3 % of the total FA. The 16:0, 20:0, and 18:1 total in LC had significantly higher than those in HC, while 22:0 and 18:3 n-3 in MC had significantly higher than those in HC. CD in HC, MC, and LC were 0.82, 0.84, 0.93 kcal/g, respectively, which showed low-calorie density. There were no significant differences in CD among the three groups.

Conclusions: There were no significant differences in the 18 amino acids among the menu items, suggesting that differences occur in fatty acids. These data are useful for the ideal value of Japanese Diet and a new evaluation for meals of food metabolomics.

Comparison of blood sampling techniques for hemoglobin measurement: Results from The Demographic Health Survey Program pilot

Sorrel ML Namaste[1], Rhona Baingana[2], Eleanor Brindle[3]

1.The DHS Program, ICF (USA), 2. Makerere University (Uganda), 3. The DHS Program, PATH (USA)

Background and objectives: Standard practice for estimating anemia in population-based surveys is to use a single drop of capillary blood and measure the hemoglobin (Hb) concentration on a point-of-care device. Emerging evidence points to larger than expected differences in Hb concentration depending on the blood sample technique used. We evaluated use of different blood sources to measure Hb on a HemoCue 201+ compared to the gold standard of venous blood on a hematology analyzer.

Methods: Hb concentration from a single capillary blood drop, pooled capillary blood, and venous blood were collected in a controlled (laboratory) and field setting (DHS-8 pilot) among non-pregnant women 15-49 and children 6-59 months in Uganda. Hb concentration was measured in capillary and venous blood using a HemoCue 201+ and the venous blood was also measured on a Sysmex XN-450 hematology analyzer. Agreement was estimated using Lin's concordance correlation coefficient, Bland-Altman plots, and Deming regression. Means and prevalences were compared across groups using paired t-tests and McNemar's tests, respectively.

Results: The correlation between blood measured using a HemoCue 201+ against the gold standard was the highest for venous blood (0.89-0.97), followed by pooled capillary blood (0.81- 0.91), and single drop capillary blood (0.76-0.88). Bland-Altman plots indicated no bias for any comparators. The absolute mean difference in Hb was lower than 0.5 g/dL for all comparators. There were no differences in mean or prevalence estimates between venous blood and the gold standard except among women in the controlled setting but there were non-clinically relevant statistically significant differences in means from both types of capillary blood. This translated into a statistically significant difference in anemia estimates for pooled capillary blood among children (controlled and field setting) and women (controlled setting) compared to the gold standard.

Conclusion: Venous blood samples measured by the point-of-care HemoCue 201+ and the gold standard method were similar. While there was good agreement between capillary blood measured using the HemoCue 201+ and the gold standard, capillary Hb variability was higher than venous blood. Further work is needed to evaluate the implications of using venous versus capillary blood to measure Hb in population-based surveys.

A prudent Japanese dietary pattern is associated with a reduced risk of metabolic diseases predicted by principal component analysis of the clinical parameters related to metabolic syndrome

Toshinao Goda[1], Yuko Takeda[2], Saki Takeuchi[3], Chihiro Imai[4]

1.University of Shizuoka (Japan), 2. University of Shizuoka (Japan), 3. University of Shizuoka (Japan), 4. University of Yamanashi (Japan)

Background and objectives: Dietary quality is related with the prevalence of metabolic disorders worldwide, and its application to dietary practice is expected. In this study, we have explored a dietary pattern, the score of which is associated with reduced risks of metabolic disorders in community dwelling people in Japan.

Methods: A cross-sectional survey including 5,025 healthy Japanese men (aged 40-64 years) who participated in health checkups was conducted in Shizuoka, Japan. We analyzed their dietary habits and food intake using a brief-type self-administered diet history questionnaire (BDHQ), and the dietary patterns were identified by factor analysis. We assessed the risk of metabolic diseases using principal component (PC) analysis of the clinical parameters including body mass index, blood pressure, triacylglycerol, HDL-cholesterol, and fasting blood glucose. We compared the relationship between the score of a prudent Japanese dietary pattern and the PC1 score calculated from the parameters strongly associated with metabolic syndrome.

Results: Factor analysis of dietary habits and food intakes showed that the major factor (factor 1) accounting for their dietary pattern was closely related with the intakes of vegetables, mushroom, see weeds, soy products, potato, fruits, and fish, which suggests “a prudent Japanese dietary pattern” with a variety of food in the meals. The score of the prudent Japanese dietary pattern was associated with lower PC1 score, and it was also associated with a lower level of γ-GTP. The group of higher PC1 score showed significantly less intakes of vegetables, see weeds, soy products and potatoes, along with a lower score of the prudent Japanese dietary pattern than other groups.

Conclusions: The results of this study indicate that a prudent Japanese dietary pattern is associated with a reduced risk of metabolic diseases in community dwelling Japanese people.

Estimating minimum dietary diversity for children 6 to 23 months of age: a comparison of two dietary recall methods to an observation of dietary intake

Ingrid Weiss[1], Laura S Hackl[2], Erin Milner[1], Jennifer Yourkavitch[2], Sarah Hansen Pedersen[1]

1. USAID (USA), 2. USAID Advancing Nutrition (USA)

Background and objectives: Dietary intake in large-scale surveys is often assessed using a 24-hour dietary recall using an open, list-based, or a hybrid method involving both open and list-based dietary recalls. A recent study comparing list-based and open recall methods against weighed food records [WFR] to assess minimum dietary diversity in women of reproductive age [MDD-W] showed similar differences in accuracy; list-based and open recall methods overreported women achieving MDD-W by 16 and 10 percentage points, respectively, as compared to WFR. It is not known if minimum dietary diversity [MDD] in children 6 to 23 months calculated from different dietary recall methods is comparable or which method is most accurate. The aim of this study is to compare estimations of the MDD indicator from a list-based method and a hybrid method with an observation of dietary intake in representative samples of children 6 to 23 months of age (participants) in USAID Feed the Future Zones of Influence (geographic areas where programming is targeted) in Cambodia and Zambia.

Methods: Data in both countries will be collected in May 2022. Data for each participant will be collected over two consecutive days. On Day 1, a participants' food intake will be observed for an entire day and recorded. On Day 2, the participants' primary caregivers (respondents) will be interviewed twice (once in the morning, once in the afternoon), to recall the participants' dietary intake from Day 1 using a list-based and a hybrid method, with random order assignment. The MDD indicator will be estimated three times—based on the observation on Day 1 and the two interviews on Day 2. Observed (Day 1) or reported (Day 2) foods will be grouped into sub-food groups, which will be collapsed into eight defined food groups. MDD will be calculated as achieved when foods and beverages from at least five out of eight defined food groups were reportedly consumed (WHO and UNICEF, 2021).

Results: Preliminary results will be available in July 2022.

Conclusions: The findings will contribute evidence to optimize MDD assessment in population-based surveys.

The relationship between sex, eating disorders, stress levels, food habits, and parent's income with nutritional status of health sciences undergraduate students x university in Indonesia during pandemic Covid-19 year 2022

Sintha Fransiske Simanungkalit[1], Duma Lumbantobing Lumbantobing[1], Nur Intania Sofianita[1], Avliya Quratul Marjan[1]

1.Universitas Pembangunan Nasional Veteran Jakarta (Indonesia)

Background and objectives: Nutritional status is a condition in the human body that can be seen from food and the use of nutrients consumed in the body. The 2018 Indonesia Basic Health Survey found the prevalence of overweight in adolescents aged over 18 years has increased from year to year, namely in 2007 as much as 8.6% however in 2013 as much as 11.5% and in 2018 by 13.7% (RISKESDAS, 2018). During adolescence, there is rapid growth and development, both physically, psychologically, hormonally, and intellectually. The obvious changes are physical growth and development that will affect nutritional status. Therefore, at this age period, adolescents are vulnerable to nutritional problems. Nutritional status is a state of the body that is influenced by food intake and the use of nutrients consumed in the body. Some of the indirect causes of nutritional problems related to body image, eating disorders and stress levels. University students tend to have poor eating practices which is related to nutritional status. The aimed of this study to determine nutrition status determinants among undergraduate students X University at Jakarta in Indonesia.

Methods: We used cross sectional design. The subject of the study were 267 students aged 17-21 years old in 2022. The data for this study were anthropometric data, body image, eating disorders, stress levels, food habits, media exposure, physical activity, parental education, parental income and nutritional knowledge Fischer's exact test was used to compare the categorical variables. Statistical significance was set at p <; 0.05. We used chi square for bivariate analysis and for multivariate analysis we used logistics regression.

Results: The bivariate analysis reported a significant association between sex, eating disorders, stress levels, food habits, and parent's income with nutritional status. Based on logistic regression, the odds of having nutritional status is about 2.5 times higher among students whose the poor food habits.

Conclusions: The poor food habits are a major factor in nutritional status problems. Therefore, nutritional and public health intervention to prevent adolescent nutritional problems. Keywords: eating disorder, food habits, nutritional status, sex, stress level.

Keywords: food habits, nutritional status, stress level, sex, eating disorder

The prevalence of obesity among adolescents between the ages of 10 to 15 years at the University of Ghana basic school.

Joycelyn Lamptey[1], Husein Mohammed[1], Adwoa Sarfoa Osei Mensah[1], Fernand Palestia Intsiful[1]

1. University of Ghana, Legon (Ghana)

Background and objectives: Obesity is a medical disorder characterized by the excessive deposition or accumulation of fats in the adipose tissues to the point that health is compromised. It is one of today's most visible yet least addressed public health issues. According to the Center for Disease Control, the prevalence of obesity among adolescents has increased over time, with 20.3 percent among 6- to 11-year-olds and 21.2 percent among 12- to 19-year-olds. The objective of this study is to determine the prevalence of obesity and nutritional status of adolescents between the ages of 10 to 15 in the University of Ghana basic school.

Methods: Random and systematic sampling techniques were used in selecting seventy study participants. The background information of the parents of participants were collected. Participants' background information, anthropometric data, level of physical activity, lifestyles, eating habits, dietary intakes (food frequency and 24-hour recall) were assessed. SPSS version 26, WHO anthroplus and West African Food Composition tables were used for analysis. Descriptive and bivariate analyses were used in determining the relationships among variables used.

Results: The prevalence of underweight, normal, overweight and obesity among study participants were 11%, 4%, 15% and 10% respectively. In contrary to previous reports from the same population, the prevalence of obesity was higher in males (6%) than in females (4%). Most of the participants had moderate physical activity. Females recorded slightly higher moderate physical activity (53%) than their male counter parts (36.7%) even though this was not significant (p-value=0.422). Most of the respondents were sedentary (90%) and 10% were physically active. Out of eighteen food groups, respondents had an adequate dietary diversity score of 7.68±1.36. Only 38.6% and 27.1% of respondents were overweight and obese respectively. There was no significant relationship between obesity and physical activity (p-value =0.622). Also, there was no significant relationship between dietary diversity and physical activity (p value=0.207) and between BMI status and physical activity (p value=0.622).

Conclusions: This study revealed that the prevalence of obesity among participants was higher in males than females with percentages of 6% and 4% respectively.

Ultra-processed foods and human health: reliability and validity of a novel measure PIE score to assess processed food intake in adolescents

Maria Balhara[1]

1.Broward College (USA)

Background and objectives: This paper describes the development of a novel measure- Processed Intake Evaluation score (PIE score) for use with adolescents to measure processed food intake. Adolescent intake of ultra-processed food now comprises 67% of their diet. (Wang, et al., 2021). Due to this, there has been an interest in new approaches to assess processed food eating behavior.

Methods: To examine PIE score in comparison to controls, we collected data for 215 participants, aged 13–19 years, in Florida. PIE score was calculated for each participant to assess overall consumption of ultra-processed foods including Cookies, Candy, Chips, Chocolate, Energy drinks, Frozen desserts, Processed Meat, Protein bars, Soda, Sports drinks, Store pastries, Store smoothies, Sweetened tea or coffee, and White bread.

Results: The participants' mean age was 16.2 ± 1.1 years with 57% (n = 122) females. All a priori predictions regarding associations of PIE score with measures like subset DINE score (Roe, et al., 1994) were supported at high significance indicating good convergent validity. The median PIE score was 37.5 (scale 0-100). PIE scores were higher (p<;0.01) for participants who eat dinner watching TV (45.5 vs 33.8), eat dinner browsing smartphone (44.1 vs 33.7), don't read nutritional labels (43.0 vs 35.8), don't consider protein content (42 vs 35.1), have parents who don't put hard limits on some foods (40.4 vs 31.6), and have parents who tell participants they "must finish everything on plate" (44.2 vs 35.6). Participants linking food and emotion also had higher PIE scores (p<;0.01) if they eat food when angry (65.9 vs 36.0), sad (47.6 vs 35.34), anxious (46.7 vs 34.9), or guilty (53.9 vs 36.8).

Conclusions: The development of PIE score, designed specifically to measure processed food eating habits in adolescents, gives it an advantage over standard food-groups or nutrient-questionnaires in assessing processed food intake. The resulting instrument has a high level of internal and test-retest reliability. Understanding underlying factors leading to an unhealthy processed diet and higher PIE scores is key to addressing improper nutrition knowledge, attitudes, and health outcomes earlier through outreach programs.

Proximate analysis of rice bean (vigna umbellata) isocaloric diet for sprague-dawley rat biossay

Denniese Sy[1]*, Jade Florento*[1]*, Jeena Sandra Manrique*[1]*, Jeline Marie Corpuz*[1]*, Niña Marie Caballero*[1]*, Ernani Bullecer*[1]

1.University of the Philippines Manila (Philippines)

Background and objective: Protein intake is an essential component of adequate diet due to its physiological functions for growth and development. Alternative protein source from indigenous legumes such as the rice bean (Vigna umbellata) has potentials in alleviating food insecurity especially among families with low income in the Philippines. Hence, as part of the methods of protein efficiency ratio to evaluate the quality of dietary protein in rice bean; this study aims to determine the moisture, crude protein, crude lipid, and carbohydrate content of rice bean diet which will be used as test protein in a Sprague-Dawley Rat Biossay.

Methods: The rice bean isocaloric diet was made in accordance with the Association of the Official Analytical Chemist (AOAC) diet formulation method. The moisture content of the rice bean diet was determined through a moisture analyzer; the crude protein was determined by Kjeldahl method; the crude lipid was determined by Soxhlet method; and the carbohydrate content by difference method. All procedures of the study were reviewed by the Institutional Care Committee of the National Institutes of Health-University of the Philippines Manila in accordance with the Guidelines and Policies on Animal Care and Use.

Results: The study findings showed that the proximate analysis of the rice bean isocaloric diet were the following: moisture content was 10.99%, crude fat was 11.28%, crude protein was 9.89%, and carbohydrate content was 67.83%.

Conclusion: With reference to the composition of diet based on AOAC diet formulation, the proximate analysis of the rice bean isocaloric diet, the test protein for Sprague-Dawley rat bioassay, is within the recommended dietary level, especially the protein content which should be within 10-12% in average.

A food frequency questionnaire is a valid tool for the assessment of dietary nutrient intake of Sri Lankan pregnant women

Namalie Thakshila Adikari[1], Umapriya Thiyagarajah[1]

1.Wayamba University of Sri Lanka (Sri Lanka)

Background and objectives: Food Frequency Questionnaires have been shown to be an appropriate method for assessing diet. If FFQ can be accessible quantitatively, dietary habits, as well as dietary nutrient intake, can be assessed. This study aimed to develop and validate a Semi-Quantitative Food Frequency Questionnaire (SQFFQ) for Sri Lankan pregnant women.

Methods: Commonly consumed foods were identified by conducting focus-group discussions, and household observations including foods in home gardens. For each food item, the subjects were asked to specify their frequency of intake over a day, week, month, and year. "Never" and "rarely" were included. The portion sizes were estimated by using the portion sizes showing pictorial food albums and common household measures. One hundred four pregnant women attended the maternal clinics in Jaffna and Pannala areas were participated in the validation of the developed SQFFQ. Three-day Diet Diary (DD), including instructions to fill consumed foods with portion sizes, was used to validate the developed SQFFQ. Selected nutrients intake from the diet was collected by using developed SQFFQ and 3-day DD separately from each individual.

Results: The developed SQFFQ consisted of 113 food items. Mean daily energy and selected nutrients intake obtained from SQFFQ was higher than the 3-day DD. Pearson Correlation coefficients between energy and nutrient intake estimated using SQFFQs and 3-day DD ranged from 0.36 for protein to 0.53 for calcium. When adjusting for energy, the correlation was decreased for most of the nutrients except for fat. Cross classification analysis revealed that on average 87% of participants were classified into the same or adjacent quartile of energy, protein, calcium, and folic acid intake when comparing data obtained from SQFFQ and 3-day DD. According to Cohen's weighted kappa values, energy, protein, calcium and folic acid showed relatively fair agreement between these two dietary assessment tools.

Conclusion: The developed SFFQ has adequate validity for assessing the energy, protein, calcium, and folic acid intake of pregnant women in selected areas in Sri Lanka and it may potentially be useful in identifying women at risk for nutrient deficiency in pregnancy.

Most wheat and maize flour brands are fortified but not always with recommended iron compound and iron and zinc quantity: Findings from a market assessment in 2 states of Mexico

Svenja M Jungjohann[1], Ignacio Vazquez Larruscain[2], Kristin Sundell[3], Nusa Urbancic[4], Mduduzi NN Mbuya[3]

1.Global Alliance for Improved Nutrition (Switzerland), 2. ShareAction (UK), 3. Global Alliance for Improved Nutrition (USA), 4. Changing Markets Foundation (UK)

Background and objectives: Fortification of wheat and nixtamalized maize flour with iron, zinc, and B vitamins has been mandated in Mexico since the early 2000s, but micronutrient deficiency, particularly iron-deficiency anemia, remains high. To verify consumers benefit from flour fortification, we assessed (1) the wheat and maize flour brands available in 2 different states of Mexico and (2) the extent to which they meet national flour standards in terms of the micronutrient content and type of compound added.

Methods: We collected data in 2018 on all packaged wheat and nixtamalized maize flour brand products available in different retail outlets in a rural (Chiapas) and urban (Mexico City) state and recorded the added iron compounds indicated on the label. We collected samples of multiple batches of each identified flour brand and assessed added iron using a qualitative test (AACC Method 40-40). Fortified samples were composited by brand product, and the average iron and zinc levels quantified using the atomic absorption spectroscopy and compared to the Mexican standard.

Results: Of the 40 packaged wheat flour and 21 maize flour brands identified, 90% of the wheat and all maize flour were labelled as fortified, while 78% of the wheat and 24% of the maize flour indicated the addition of a recommended iron compound (ferrous salts). A qualitative iron test confirmed fortification of 93% of the wheat and of the 86% maize flour brands and quantitative tests showed 68% of wheat and 67% of maize flour brands met mandated minimum iron and zinc content, but 60% of wheat and only 10% of maize flour brands met the standard levels using a recommended iron compound.

Conclusions: Most packaged flour products are fortified but the effectiveness of the flour fortification program may be compromised due to several producers using iron compounds with lower bioavailability (electrolytic iron) than those recommended by the Mexican standard or international WHO guidelines and the average iron and zinc content of many products not meeting the standard minimum. These study results were used in an elaborate advocacy campaign to influence the government to conduct robust monitoring and enforcement of the Mexican Official Standard NOM-247-SSA1-2008 and hold industry accountable.

PAB(T2)-79

Elderly dietary index in relation with frailty in free-living elderly of Tehran, Iran

Arezoo Rezazadeh[1], Samaneh Jafaripour[1], Mahshid Rezaei[1], Nasrin Omidvar[1], Hassan Eini-Zinab[1]

1.National Nutrition and Food Technology Research Institute, Faculty of Nutrition Sciences and Food Technology, Shahid Behehshti University of Medical Sciences, Tehran, Iran (Iran)

Background and objectives: Frailty is a common clinical syndrome in elderly that carries an increased risk for poor health outcomes including falls, incident disability, hospitalization, and mortality. Frailty is strongly correlated with the dietary intake status. This study aimed to investigate the relation of elderly dietary index (EDI) with frailty phenotype in free-living elderly of Tehran, Iran.

Methods: In this cross-sectional study, 334 elderly (157 women and 177men) aged ≧60 years living in Tehran city were selected using a systematic cluster sampling method. Dietary intake was measured by a validated 168-item semi-quantitative food frequency questionnaire. EDI was calculated by scoring nine components (including questions on the frequency consumption of meat, fish, fruits, vegetables, grains, legumes, olive oil, and the type of bread and dairy products) according to the Modified MyPyramid for Older Adults and selected features of the traditional Mediterranean diet. Fertility was measured using the five indicators suggested by Fried et al., including: 1) slow walking speed 2) muscle weakness (assessed by a hand-dynamometer) 3)fatigue 4)low physical activity, and 5)unintentional weight loss. Total score of 1 or 2 indicated moderate risk for adverse outcomes (prefrailty) and scores of 3–5 indicated frailty Logistic regression was used to investigated the chance of prefrailty/frailty across tertiles of EDI score.

Results: Mean±SD of participants` age was 71.2±7.35 years. EDI score was 29.2±2.2 and was not significantly different between men and women. About half [169(50.6%)] and a quarter of [85(25.4%)] participants were prefrail and frail, respectively. The prevalence of frailty was higher in ages ≧75 years and was higher in women compared to men [51 (32.5%) vs 34 (19.2%)](p-value<;0.05). Also, the frequency of low muscle strength was significantly higher in women than men [58 (36.9%) v.s 8(4.5%)] (p-value<;0.001). After adjusting for confounders, those at the highest tertile of EDI score had lower chance of being prefrail or frail (OR=0.76; 95%CI=0.63-0.91). Across components of EDI, higher legumes score was related with the lower chance of prefrail/frailty (OR=0.69; 95%CI=0.40-0.84).

Conclusion: Higher diet quality of free-living elderly can be a protective factor against prefrailty and frailty. Also, higher intake of plant protein sources was preservative.

The impact of recipe disaggregation in the dietary surveys: results from a national food consumption survey in Saint Kitts and Nevis

Sandra Patricia Crispim[1], Vanessa Cardozo Mendes Elias[1], Isabella Francis-Granderson[3], Latoya Matthew-Duncan[4], Fransen Jean[5], Victoria Padula de Quadros[2], Agnieszka Balcerzak[2], Rita Ferreira De Sousa[2], Sharon D Hutchinson[3], Bridget Holmes[2]

1.Federal University of Parana (Brazil), 2. Food and Agriculture Organization (Italy), 3. University of West Indies (Trinidad and Tobago), 4. Ministry of Health of Saint Kitts and Nevis (Saint Christopher and Nevis), 5. Food and Agriculture Organization (Barbados)

Background and objectives: When assessing dietary intakes, individuals may report the consumption of single foods and beverages but also complex dishes or recipes. Although seen as necessary, it is not always the case that recipe disaggregation is performed in dietary surveys, and currently, no standardised methodology is available. This can potentially impact the amounts of reported food items and food grouping, and ultimately influence the dietary indicator of interest. The aim of the investigation was to assess the impact of recipe disaggregation in the recent national dietary survey in Saint Kitts and Nevis and provide recommendations for future assessments.

Methods: Data collected in the first National Food Consumption survey in Saint Kitts and Nevis (2020) was used. A total of 1004 individuals provided information on their food intake obtained using 24-hour dietary recalls (24HDR) and 440 recipes were reported. Recipes were reported in single ingredients at the stage of data collection (n=65) but in most cases, a standard recipe without disaggregation was provided by the respondent (n=375). A simple and pragmatic recipe methodology was developed whereby only those recipes reported more than once during the study or those consumed in large amounts (defined as >;=500 grams) would be disaggregated. The procedure of recipe disaggregation comprised nine steps, including identification of recipes, ingredients, quantities, conversion factors, presence of apparent fluid, among others.

Results: 78 standard recipes were disaggregated (21% of recipes). These recipes contributed to 15.2 percent of the total energy intake of the population while the remaining non-disaggregated dishes (n=297) contributed to 12.5 percent. The proportion of consumers across the different food groups increased dramatically for some food groups after recipe disaggregation, with the most remarkable difference for fats (6.9% before and 44.5% after), pulses (18.6% before and 49.2% after), and vegetables (49.9% before and 76.6% after). Consequently, the reported intakes were also impacted across the food groups.

Conclusions: Recipes are an important source of food group intakes and their disaggregation should be carefully considered in dietary assessments. The methodology used in this investigation will be further refined in order to provide guidance for future surveys.

Validation of Hemocue method for anemia detection and development of a new cut-off to detect anemia in children

Mustafa Mahfuz Mahfuz[1], Md. Ashraful Alam[1], Tahmeed Ahmed[1]

1. icddr,b (Bangladesh)

Background: Assessment of Hemoglobin (Hb) by Hemocue has been used widely as a convenient method for anemia screening at population-level surveys. Previous studies showed poor agreement between Hemocue and the direct cyanmethaemoglobin (DCM) method - the diagnostic gold standard for Hb assessment resulting in underestimation of anemia prevalence by Hemocue. This study aims to validate Hemocue with the direct cyanmethaemoglobin method and to develop a new cut-off to detect anemia by Hemocue in children.

Methods: This study used Hb data of children under 5 years from an urban slum of Dhaka, Bangladesh. The study used both the Hemocue and the DCM method for Hb assessment using venous blood samples. Hb levels were compared between the assay methods and sensitivity and specificity of Hemocue were calculated. The optimal cut-off of anemia for children by Hemocue method was estimated based on Youden's index in receiver operating characteristic (ROC) analysis and it was validated by Train/Test method, where data set was split into two: training dataset (70%) and testing dataset (30%).

Results: The mean Hb concentrations for 1216 venous blood samples estimated by Hemocue and the DCM were 11.80 ± 1.50 g/dL and 10.97 ± 1.38 g/dL, respectively. Using the cut-off of <; 11 g/dL for anemia, anemia prevalence was significantly higher in DCM method (DCM vs. Hemocue, 48.6% vs. 28.3%; p<;0.05). Considering DCM as the gold standard, the sensitivity and specificity of Hemocue method were 53% and 95%, respectively. ROC analysis has identified an optimal cut-off of 11.7 g/dL for anemia in children which has an area under the curve (AUC): 85%, sensitivity: 76%, and specificity: 82%. In the test/train method, by using the new cutoff of 11.7 g/dL identified from the training data set, the testing data set showed the prevalence of anemia is 45.3% with a sensitivity of 74.6% and specificity of 80%. Conclusion Hemocue method has low sensitivity to detect anemia resulting in a grossly underestimated anemia burden. A new cut-off of 11.7 g/dL to detect anemia in children <;5 years can be used for the Hemocue.

Determinants of malnutrition among children aged 6-59 months in the Buea health district, Cameroon

Tambe Betrand Ayuk[1,2], Andinwoh Betterdel Ngassa[1], Henry Dilonga Meriki[1], Dapi Leonie Nzefa[3], Xikombisso G Mbhenyane[2]

1.University of Buea (Cameroon), 2. Stellenbosch University (South Africa), 3. Linnaeus University (Sweden)

Background: Malnutrition is a major cause of morbidity and mortality in children under-five. According to the 2011 Demographic and Health Survey, 5.6% of Cameroonian children are malnourished, with 1.9% of them being severely malnourished. This burden varies across the country, and is most felt in areas plagued with ongoing humanitarian crisis, such as the Southwest region. Data on the burden of malnutrition in the Southwest region is sparse. As such, we set out to determine the prevalence and risk factors of malnutrition among children under-five.

Methods: This was a community based cross-sectional study. Children under-five-carer pairs were sampled from households. Households surveyed were selected using a multistage randomized cluster sampling method. Dietary diversity and household food insecurity were assessed using standardized questionnaires. Characteristics associated with malnutrition were obtained using multivariate logistic regression, adjusting for potential confounders.

Results: A total of 321 children (52.3% female) with a mean age of 33.6 ± 16.5 months, and their carers (94.6% female, mean age 30.1 ± 7.7 years) were retained for the analysis. Of the 321 children, 65.1% had a diverse diet with dietary diversity Score more than 4). The prevalence of household food insecurity was 73.9% (10.0% mild, 38.3% moderate, and 25.6% severe). The prevalence of stunting, underweight and wasting were 26.5% 1.6% and 3.7% respectively. Not schooling (OR: 2.33, 95% CI: 1.13 – 4.82); drinking water from inappropriate sources (OR: 2.32, 95% CI: 1.30 – 4.15) and a Dietary Diversity Score <; 4 (OR: 2.59, 95% CI: 1.46 – 4.61) were associated with increased risk of stunting. Children of the male sex were more likely to be wasted (OR: 5.34, 95% CI: 1.09 – 26.14).

Conclusion: Household food insecurity is high in the Buea Health District. Poor dietary diversity and inappropriate drinking water were potentially modifiable, risk factors of malnutrition identified, highlighting the need to develop and strengthen existing interventions aimed at: improving access to safe drinking water within the study area; educating carers of children on the importance of dietary diversity, water, sanitation and hygiene for the proper growth and development of their children.

Alterations of antioxidant enzyme activities vitamin A and E status in type 2 diabetic Thai patients

Natnicha Promyos[1], Pornpimol Panprathip Phienluphon[1], Naruemon Wechjakwen[2], Jirayu Lainampetch[1], Karunee Kwanbunjan[1]

1.Mahidol University (Thailand), 2. Nakhonratchasima Rajabhat University (Thailand)

Background and objectives: Type 2 diabetes (T2D) is one of the metabolic disorders causing 4.2 million deaths worldwide. There are several controversies and limited information about antioxidant defenses and diabetes. In general, increasing production of free radicals and decreasing in antioxidant defense system were considered to cause high blood glucose levels by resisting of insulin hormone in the pancreas. Some studies reported that high levels of antioxidant enzymes were detected in T2D patients. However, few studies have focused on antioxidant vitamins. Therefore, the aim of this study was to investigate the associations of antioxidant enzyme activity including superoxide dismutase (SOD) and catalase (CAT), and vitamin levels consisting of vitamin A and vitamin E in T2D Thai patients.

Methods: The T2D (n=48) and nondiabetic participants (n=56) were included in this study. Blood samples of all participants were determined for SOD, CAT, vitamin A and vitamin E levels.

Results: The results presented that both SOD and CAT antioxidant enzyme activities in T2D group were significantly lower than the control group [odds ratio (OR), 4.31; 95% confidence interval (CI), 1.14-16.30 and OR, 3.57; 95% CI, 1.14-11.18, respectively]. However, there was no significantly statistical difference on vitamin A and vitamin E levels between two groups. Considering of correlation, there was a moderate positive correlation of vitamin A with vitamin E in T2D participants (r = 0.385; p <; 0.01), whereas there was no association between activities of antioxidant enzymes and antioxidant vitamins levels in this group. Similar in control group, the SOD and vitamin A levels showed a weak positive correlation (r = 0.273; p <; 0.05), but there was no correlation of the other parameters presented in this group.

Conclusions: The results suggested that the reduction of antioxidant enzymes activities such as SOD and CAT provides the useful information on prediction of the risk of T2D progression and various complications. These enzymes could be used as the possible parameter to indicate oxidative stress status/ level relating to diabetes. Nevertheless, the data on vitamin A and vitamin E status was not remarkable for this study.

Improving calcium status of women: a study of bio-availability of calcium from slaked lime fortified rice

Nurun Nahar Naila[1], Subhasiah Das[1], Khandaker Afsana Mim[3], Rahvia Alam[1], Jaime Westcott[2], Julie Long[2], Nancy Krebs[2], Md Munirul Islam[1], Tahmeed Ahmed[1,4]

1. icddr,b (Bangladesh), 2. University of Collorado, Denver (USA), 3. University of Nevada (USA), 4. University of Washington (USA)

Background and Objectives: Fortification of rice with slaked lime is an acceptable and inexpensive way to combat Ca deficiency. However, bioavailability of calcium after intake of slaked lime fortified rice is yet to be investigated. Our objective was to measure the fractional absorption of Ca (FAC) from slaked lime fortified cooked rice.

Methods: We conducted an experimental study using stable isotopes of Ca to measure fractional absorption of Ca during a single morning test meal containing rice fortified with slaked lime. Participants (n=22) were given slaked lime fortified rice three times a day for 4 days. On the morning of the 5th day, the participants were served with the exact amount of rice as previous 4 days at the breakfast test meal with an accurately measured amount of 44Ca stable isotope tracer followed by an intravenous injection of 42Ca. Urine was collected over the next 24 h in 3 consecutive 8-h pools. FAC was measured from the ratio of each administered tracer to 44Ca and 42Ca by using ICP-MS.

Results: The mean dietary Ca from 24-h was 879.5 ± 152.9 µg/g with a coefficient of variance (CV) of 17.2%. Although Ca absorption efficiency decreases during high calcium intake, FAC from test meal using third 8- hr urine pool was 68.8 (CV of 15.15) mg. We found 45.8 (13.06) mg and 70.0 (16.02) mg FAC from the test meal using the first and second 8-h pools.

Conclusions: We showed that one-fifth of daily calcium recommendation could be met by ingesting ~200 mg cooked slake fortified rice.

Evaluation of the test meals and hospital meals by using two mobile food records

Chihiro Ushiroda[1], Takuma Ishihara[2], Mayuka Watanabe[3], Akemi Ito[3], Atsushi Suzuki[1,3], Eiichi Saitoh[1], Hitomi Sasaki[1,3], Katsumi Iizuka[1]

1.Fujita Health University (Japan), 2. Gifu University Hospital (Japan), 3. Fujita Health University Hospital (Japan)

Background and objectives: Mobile food records are currently being used with obese and diabetic patients. There have been papers comparing mobile food records with daily dietary interviews; however, there have been no reports quantitatively assessing actual intake. Here, to test the accuracy of mobile food records, we evaluated the nutritional composition of test meals (ramen noodle soup cup and fruit juice) and hospital meals (Japanese set meal) by using two different mobile food records.

Methods: Eighteen healthy subjects (2 males and 16 females) were enrolled. We used the test meals and hospital meals with the valid information of nutrient contents. We evaluated nutrient contents of these meals by two food record applications, Asken® (Asken Corporation, Tokyo, Japan) and Calomeal® (Life Log Technology, Inc, Tokyo, Japan) over 5 days. A linear mixed model was used to evaluate the effect of meal type, time, age (<;45, >;45 years) on the nutritional composition. Finally, the coefficient of variation (CV) between each parameter was compared using Mann-Whitney U test.

Results: For the test meals, the values measured by two applications were close to the valid values included in the test meals. On the other hand, for the hospital meals, the values measured by the two applications were approximately 1.5 times higher than the valid values in the diet. Furthermore, the mixed model analysis showed that total energy, carbohydrates, and salt were significantly overestimated in the hospital meals. Protein tended to be overestimated, while lipids did not change significantly. Furthermore, total energy and lipids were significantly higher with increasing date. No association with age was observed. Comparison of CVs for each nutrient in the hospital meals indicated that lipids were significantly higher.

Conclusions: In this study, dietary record application of the test meals was very accurate. However, total energy and nutrients of hospital meals may have been overestimated because hospital meals are designed to limit total energy, especially salt and lipids.

Effect of ingestion of cake with resistant starch on preference and postprandial blood glucose levels

Masako Yokotsuka[1], Atsuko Anada[1], Kotomi Okuyama[1], Akari Shigekawa[1], Mayuko Shimada[1], Honoka Tawatari[1], Miyu Chonan[1]

1. Showa Women's University (Japan)

Background and objectives: Prevention of diabetes through daily eating habits is important. Adequate intake of dietary fiber is said to reduce the risk of diabetes. Resistant starch (RS) has a physiological effect similar to that of dietary fiber, such as an effect of suppressing an increase in blood glucose. RS2 has a high amylose content and is used in foods for the purpose of increasing the intake of dietary fiber. Therefore, the performers focused on baked confectionery, which is often taken as a snack in their diet, and measured the GI value of baked confectionery containing RS2. It was examined whether the blood glucose level after ingestion suppresses the increase in the postprandial blood glucose level of healthy subjects as compared with the baked confectionery using normal wheat flour. The preference was examined by a sensory test.

Methods: As the sample, a cake containing 100% wheat flour, a cake containing 60% cornstarch, and a cake containing RS2-containing cornstarch (obtained from J-OIL MILLS,Inc.) were used. The subjects were 15 adults (20 to 22 years old). The test was performed by a randomized crossover method. The subjects ingested a cake was the weight of the dough containing 50 g of carbohydrate. Blood glucose levels were measured before, 15, 30, 45, 60, 90, 120, 150, and 180 min after ingestion. The amount of RS was measured and a sensory test was performed.

Results: As for the increase in postprandial blood glucose level, since the blood glucose increase curve of RS2-containing cornstarch was gentler than that of wheat flour and corn, it is considered that the increase in blood glucose level was suppressed by RS contained in RS2-containing cornstarch. No change in the amount of RS was observed before and after baking. In the sensory evaluation, the average score of RS2-containing cornstarch was lower than that of wheat flour in the items of "fluffy feeling", "moist feeling", and "comprehensive evaluation".

Conclusions: It was confirmed that the cake containing RS2-containing cornstarch had the effect of suppressing the increase in blood glucose level as compared with the cake containing wheat flour and cornstarch.

Iron deficiency in pregnancy: A secondary data analysis from Vancouver, Canada Kelsey

M Cochrane[1,2], Jennifer A Hutcheon[1,2], Crystal D Karakochuk[1,2]

1. University of British Columbia (Canada), 2. BC Children's Hospital Research Institute (Canada)

Background and objectives: Pregnant women are particularly vulnerable to iron deficiency, given increased requirements to support growth of the uteroplacental organs and fetus. As such, public health guidelines recommend supplementation with an iron-containing prenatal multivitamin throughout pregnancy to meet recommendations of 27 mg elemental iron daily. However, whether supplementation with standard prenatal multivitamins is sufficient to prevent maternal iron deficiency as pregnancy progresses is unclear, as needs increase substantially with advancing gestation. Maternal iron deficiency and anemia are most prevalent in the third trimester, and may result in symptoms of fatigue, hair loss, and irritability (often dismissed as normal symptoms of pregnancy) and have been associated with impaired neonatal growth and neurocognitive development. This study aimed to assess iron status in early and late pregnancy among 60 pregnant women receiving 27 mg/day elemental iron as part of a randomized trial in Vancouver, Canada.

Methods: Study visits were conducted at 8-21 (baseline) and 24-38 (endline) weeks' gestation. Venous blood specimens were collected for a complete blood count and measurement of iron and inflammatory biomarkers. Iron deficiency was defined as inflammation-corrected ferritin <;30 µg/L. Quantile regression was used to explore predictors of endline ferritin concentrations, including ethnicity, education, income, and baseline ferritin.

Results: Overall, n=60 and n=54 women participated in baseline and endline visits, respectively. Rates of iron deficiency at baseline and endline were: n=22 (41%) and n=44 (81%). Ethnicity was the only significant modifier of endline ferritin, with higher concentrations in those of South, East, and Southeast Asian ethnicity compared to European (β=10.4 µg/L, 95% CI=0.3-20.5).

Conclusion: Iron deficiency remains a significant and largely neglected concern among Canadian women during pregnancy. Pregnant women may believe that they are meeting their iron needs throughout gestation by consuming a standard prenatal multivitamin. However, this study provides further evidence that women may require additional or more bioavailable iron to support needs into later pregnancy. Our findings support that the assessment of iron status should be incorporated into routine perinatal clinical practice guidelines to ensure iron deficiency is addressed and that optimal status is maintained throughout all of pregnancy.

Eating behaviour and its association with anthropometric indicators among secondary schoolteachers in Selangor, Malaysia

Nurul Balquis Azlan[1], Sarina Sariman[1], Sasveni Subramaniam[1], Sairah Abdul Karim[1]

1.Management and Science University (Malaysia)

Background and objectives: Over the years, the escalating rates of overweight and obesity is becoming a global concern. Malaysian schoolteachers are shown to be vulnerable as their overweight and obesity prevalence surpassed the 2019 National Health and Morbidity Survey (NHMS) which was 30.4% and 19.7%, respectively. Thus, this study aims to evaluate eating behaviour and its association with anthropometric indicators of schoolteachers, representing the working adults' population in Malaysia.

Methods: A cross-sectional study was conducted among 101 schoolteachers from four secondary schools in Selangor, Malaysia, recruited through stratified sampling method. A structured questionnaire consists of socio-demographic characteristics and Dutch Eating Behaviour Questionnaire (DEBQ) was used to obtain the schoolteachers' characteristics. Body mass index (BMI) was determined according to measured height and weight, while waist circumference (WC) was obtained using Lufkin tape W606PD, respectively.

Results: Most of the respondents were female (74.3%), from Malay ethnicity (87.1%), were married (79.2%), with mean age of 40.63 ± 9.39 years and had moderate eating behaviour across all DEBQ subscales. Most of the teachers experienced moderate emotional eating (50.5%), external eating (70.3%) and restrained eating (69.3%) behaviours. The prevalence of overweight and obese were 22.8% and 50.5%, with 23.8% of the teachers having normal weight and a smaller percentage (3.0%) were underweight. Male teachers had higher WC (90.1 ± 13.0cm) as compared to female teachers (86.8 ± 10.4cm). Only emotional eating and restrained eating were significantly associated with BMI, with similar patterns observed with WC of the teachers (p<;0.05).

Conclusions: The schoolteachers in this study experienced varying levels of emotional, external, and restrained eating behaviour and were associated with their anthropometric indicators. Intervention to promote healthy eating behaviour could be conducted to improve overall health and wellbeing, especially among these working adults' population.

PAB(T2)-89

Increased PTH secretion and Ca absorption rate due to fish bone intake in rats

Ga-Hyun Joe[1], Kazuki Fujimoto[1], Hirofumi Takeda[2], Hiroki Saeki[1]

1.Hokkaido University (Japan), 2. Hokkaido Research Organization (Japan)

Background and objective: Fish-bone, a typical waste in the seafood industry, is a rich in minerals and has high-nutritional value as a potential source of Ca. In this study, we investigated the effects of Alaskan pollock bone, one of the world's largest fish species, on nutritional value and Ca metabolism regulation.

Methods: Alaskan pollock fillets with or without bone (APP-B, APP) were retort-treated and powdered. Ca content of APP-B was 6.16%, which was 58 times higher than that of APP. Male Crl:CD (SD) rats (4 weeks old) were fed four types of experimental diets with different Ca (Total 0.5%) and protein (Total 16.66%) sources for 30 days. (1) Control (AIN-93G): 0.5% CaCO3, 16.66% casein, (2) CaCO3/Casein/APP: 0.49% CaCO3, 10.07% casein, 0.01% Ca and 6.59% protein from APP, (3) Bone Ca/Casein/APP-B: 10.07% casein, 0.5% Ca and 6.59% protein from APP-B, and (4) CaCO3/APP only: 0.48% CaCO3, 0.02% Ca and 16.66% protein from APP. The Ca absorption rate was estimated by measuring the amount of Ca in feces on day 28 of ingestion by ICP-OES analysis. After 30-day ingestion, the aorta plasma was collected to measure plasma Ca, bone formation, and resorption markers (Gla-OC, Glu-OC). Also, we investigated the parathyroid hormone (PTH) in plasma, which modulates blood Ca concentration and participate in bone formation and Ca absorption.

Results: (1) The Ca absorption rate was significantly increased in the APP-B group, indicating that the fish-bone Ca has better absorption characteristics rather than CaCO3. (2) There was no significant difference in plasma Gla-OC and Glu-OC among the four groups, suggesting no marked difference in Ca metabolism between APP-B and CaCO3. These results are consistent with those of herring bone (Fish. Sci., 87, 739, 2021). In addition, (3) PTH secretion increased significantly in the APP-B although no significant differences among the experimental groups in the plasma Ca. Therefore, these results indicate that increased PTH secretion would induce Ca absorption by APP-B.

Conclusion: The ingestion of APP-B stimulates PTH secretion, which induced Ca absorption. Thus, APP-B is the health-beneficial material efficiently absorbed into the body and contributes to maintaining the homeostasis of bone metabolism.

Association of zinc and iron status in low-income women of reproductive age in Bangladesh

S M Tafsir Hasan[1], Mahfuzur Rahman[1], Zannatun Nyma[1], Syada Munia Hoque[2], Enamul Haque[1], Aminul Islam[1], Ibrahim Saiyed[2], Russell Reinke[2], Tahmeed Ahmed[1]

1.icddr,b (formerly International Centre for Diarrhoeal Disease Research, Bangladesh) (Bangladesh), 2. International Rice Research Institute (Philippines)

Background and objectives: Co-occurrence of zinc and iron deficiencies has been reported in low and middle-income countries, possibly because zinc and iron nutriture share many common dietary sources, bioavailability inhibitors and enhancers, and metabolic pathways. However, literature is limited as to the quantification of the relationship between the indices of zinc and iron nutriture. This study aimed to determine the relationship between zinc and iron status in low-income women of reproductive age in Bangladesh.

Methods: We analyzed data from 1308 non-pregnant, non-lactating women of reproductive age, who participated in a cross-sectional survey conducted in 2021 in purposively selected 10 poverty-stricken rural Mouzas in northern Bangladesh, 3 urban slums in Dhaka, and a readymade garment (RMG) factory in Narayanganj. Concentrations of zinc and ferritin in serum were measured by atomic absorption spectrometry and electrochemiluminescence immunoassay and adjusted for inflammation (CRP and AGP). Zinc deficiency was defined as serum zinc <;66 mcg/dL for blood samples collected in the morning and <;59 mcg/dL for samples obtained in the afternoon. Iron deficiency was defined as serum ferritin <;15 mcg/L.

Results: The study population comprised 458 rural, 351 slum-dwelling, and 499 RMG-worker women. The mean (SD) age and BMI of the women were 28.9 (8.1) years and 22.9 (4.2) kg/m2, respectively. The median (IQR) concentration of serum zinc and ferritin were 62 (57, 68) mcg/dL, and 40.5 (21.7, 71.4) mcg/L, respectively. Of the women, 629 (48.1%) had zinc deficiency, while 195 (14.9%) had iron deficiency. In a multivariable linear regression model with clustered standard errors, adjusted for age, BMI, and blood sample collection time, each log unit increase in serum ferritin concentration was associated with a 0.017 log unit increase in serum zinc concentration (95% CI: 0.005, 0.028; P = 0.009). In a multivariable logistic regression model adjusted for the same covariates, iron deficiency was associated with increased odds of zinc deficiency (OR 1.4, 95% CI: 1.2, 1.6; P <; 0.001).

Conclusions: Depleted iron stores are associated with an increased prevalence of zinc deficiency in low-income women of reproductive age in Bangladesh. Further analyses are required to understand the underlying mechanisms responsible for the association.

PAB(T2)-91

Nutritional status of pre-liver transplant patients and predictors of new-onset diabetes after the transplantation

Dao Thi Hao[1], Nguyen Thu Ha[1], Nguyen Thi Huong[1]

1.108 Military Central Hospital (Viet Nam)

Background and objectives: Malnutrition before Liver transplantation may increase the risk of complications and affect the success post-operation. New-onset diabetes after liver transplantation (NODAT) is the most common complication in liver recipients and reduces their quality of life. The main objective of the study was to assess nutritional status before liver transplantation and to identify the predictors of new-onset diabetes after liver transplantation (NODAT).

Methods: The retrospective study on 108 adult patients from July 2017 to December 2021 (91.7% male and age 53.6±10.7) has been assigned to the transplantation at the Department of Hepatobiliary Surgery at 108 Military Central Hospital. Eight patients with diabetes before the transplantation were excluded. The nutritional status before liver transplantation was assessed by SGA, BMI, NRI, and biomedical tests. The physician diagnoses the NODAT. Binary regression is used to identify the predictors of NODAT.

Results: The results showed that SGA-C:45.0 %; SGA-B:35.0%; while the risk of malnutrition index showed NRI severe: 10.0%; NRI moderate 43.0%; NRI mild 10.0%. Prevalence of overweight (BMI>;25): 22.0%; low albumin (<;35g/l): 48.0%; anaemia 62%; and 55% had NODAT. Binary regression found age (OR 1.09, 95%CI 1.04 – 1.14), anaemia (OR 0.43, 95%CI 0.19 - 0.99), and blood glucose (OR 1.21, 95%CI 1.01 – 1.47) before the liver transplantation were independent risk factors of NODAT.

Conclusion: The rate of malnutrition risk before the liver operation is very high. Age, anemia, and blood glucose are predictors of NODAT in liver recipients. The caring strategy to improve these factors may reduce the risk of NODAT and enhance the patient's quality of life.

Prevalence of concurrent stunting and wasting among under- five children in Nepal and its association with micronutrients deficiencies.

Suresh Mehata[1], Ranju Kumari Mehta[2]

1.Ministry of Health, Province 1, Nepal. (Nepal), 2. Little Buddha College of Health Sciences, Nepal. (Nepal)

Backgrounds and objectives: Micronutrients deficiencies and concurrent stunting and wasting (WaSt) have been prevalent in Nepal especially among the marginalized groups. This study assessed the prevalence and factors associated with the WaSt.

Methods: This study uses data from Nepal Micronutrients survey 2016, a nationally representative cross-sectional study. A total of 4309 households were interviewed using cluster sampling. This analysis used 1462 for the children in analysis with response rate of 85%. Background variables and hemoglobin, ferritin, C-reactive protein (CRP), Retinol Binding Protein (RBP), and Alpha-1 acid glycoprotein (AGP), RBC folate, serum zinc were assessed. The STATA 15 was used to analyze the data. The sample weight was used in order to obtain the national estimates. Multivariate logistic regression was used to assess the factors associated with WaSt considering the complex survey design.

Results: the study revealed the prevalence WaSt was 6% (4.0-7.9) and the odds of WaSt were higher among Terai dwellers compared to Hill dwellers (AOR: 2.84; 95%CI: 1.29-6.25). The odds of WaSt inversely associated with the wealth quintiles, compared to those of bottom quintile the odds of stunting was significantly lower among fourth and richest quintile (p<;0.05). No significant association was observed with age, sex, place of residence, anemia, iron, zinc and folate deficiency, CRP, AGP, ferritin and RBP status with WaSt. The prevalence of stunting or wasting 42% was (37.8-46.7). The odds stunting or wasting increase with increase in age (p<;0.05). The stunting or wasting was significantly lower among female child (AOR: 0.71; 95%CI:0.56-0.89) compared to male counterparts. The stunting or wasting inversely associated with the wealth quintiles (p<;0.05). No significant association was observed with place of residence, ecological zones, anemia, iron, zinc and folate deficiency, CRP, AGP, ferritin and RBP status with either stunting or wasting.

Conclusions: prevalence of WaSt and either stunting or wasting were high among under-five children in Nepal and more prevalent among those who were poor and resides in Terai reasons. Early detection and appropriate treatment of WaSt would be instrumental for child survival. Also, no significant association was observed WaSt and either stunting or wasting and micronutrients status.

Fruit and vegetable consumption in urban and rural settings in Ethiopia

Seifu Hagos Gebreyesus[1], Samson Gebremedhin[1], Kaleab Baye[1], Fikadu Reta[2], Alemtsehay Sergawi[3], Meseret Zelalem[4]

1.Addis Ababa University (Ethiopia), 2. Hawassa University (Ethiopia), 3. Federal Ministry of Agriculture (Ethiopia), 4. Federal Ministry of Health (Ethiopia)

Background and objectives: Though overweight including obesity has multiple behavioural, environmental and genetic risk factors, a low intake of fruits and vegetables is an important risk factor for NCD. We aimed to examine the frequency and adequacy of fruit and vegetables consumptions in the context of

NCD prevention in rural and urban settings in Ethiopia.

Methods: We conducted a community-based comparative survey in urban and in a typical rural setting in Ethiopia. We collected data from a representative sample of 1,152 adults. Fruit and vegetable consumption was assessed based on two different approaches; Quantitatively using 24-hr recall method and qualitatively via the 2017 Behavioural Risk Factor Surveillance System (BRFSS) approach. Respondents were asked consumption of 22 common fruits and vegetables over the previous day. Finally, the intakes were dichotomized into adequate (<; 400g/day) or inadequate (>;=400 g/day).

Results: The study included 1,140 adults and assessed the frequency of consumption of different food groups over the preceding 30 days. In the urban setting, 33.4% and 10.4%; and in rural setting 31.7 and 1.0% of adults consumed whole fruit and 100% fruit juice once per week or more frequently, respectively. Based on frequency of consumption of once per week or more, the most frequently consumed vegetables groups in the urban setting are starchy staples (75.2%), carrots (64.5%), green leafy vegetables (60.9%) and cruciferous (53.4%). On the other hand, in the rural setting green leafy vegetables (92.0%) were the predominating ones. In addition, the median (IQR) total fruit and vegetable intake was 124.0 (15.5-262.3) g/day in the urban setting and 201 (99.6-397.0) g/day in rural setting (p<;0.001). Proportion who consumed 400 g or more were 11.8% in The urban setting and 24.6% in rural setting (p<;0.001). Estimation based on the BRFSS approach suggested 99.7% in urban and 65.2% of the study participants in the rural setting have very low levels of fruit and vegetable intakes (p<;0.001).

Conclusions: Although the WHO/FAO recommend taking 400 or more grams of fruits and vegetables for improving overall health and reducing the risk of certain NCDs, our study showed a very low intake of fruit and vegetables.

PAB(T2)-94

Intake of sugar including fructose recorded using a dietary questionnaire in Japanese adults

Keiichiro Sugimoto[1], Yuta Takahashi[2], Saori Murakami[2], Toshihiro Kakinuma[2], Toshikazu Yamanouchi[3]

1.Nagaoka Co., Ltd. (Japan), 2. ORTHOMEDICO Inc. (Japan), 3. Kashiwa-Tanaka Hospital (Japan)

Background and objectives: Excessive consumption of sugars (sucrose, fructose, and glucose) is considered a cause of visceral fat accumulation and metabolic syndrome. Few reports on sugar intake in Japan have been published because a comprehensive database on sugar composition was lacking until the publication of a carbohydrate table. “Calorie and Nutrition Diary” (CAND) is a simplified method that allows people who are unfamiliar with recording meals to provide easy answers*. This work was aimed at determining the sugar intake of Japanese adults with a preference for sweet foods and beverages, a habit of snacking, and mild obesity (body mass index [BMI] of ≧23 to <;30).

Methods: In a clinical study for the evaluation of the antiobesity effect of a plant extract (UMIN000042469), participants noted their daily food intake for 3 consecutive days before examination using CAND version 1.0. The examination was conducted at screening and 4, 8, and 12 weeks after the start of intervention in 2021. The intake of the dietary components was defined according to the Standard Tables of Food Composition in Japan 2015 (Seventh Revised Edition) and calculated from the CAND data.

Results: Among the participants, 190 who met the eligibility criteria (91 male and 99 female participants; age, 47.1 ± 10.5 years [mean ± SD]; BMI, 25.7 ± 1.8) participated in the intervention study. Their daily intakes of energy, sucrose, fructose, and glucose for 12 days were 2,690.4 ± 900.1 kcal/day, 45.6 ± 21.8 g/day, 18.8 ± 12.5 g/day, and 18.2 ± 10.3 g/day, respectively. The total sugar intake was approximately 82.7 g/day. Since the participants' daily energy requirement was approximately 1,930 kcal/day, as calculated using the Long method, the total sugar intake was higher than that recommended by the World Health Organization (WHO; less than 10% of energy intake, approximately 50 g/day).

Conclusion: Our results indicate that the sugar intake of a part of the Japanese population exceeds the amount recommended by the WHO.

Decreased sugar intake due to the increment of conflict-like behavior in consummatory successive negative contrast paradigm: lick microstructure analysis in rats

Jilada Chongmankhong[1], Keisuke Shinohara[1], Yasunobu Yasoshima[1]

1. Osaka University (Japan)

Background and objectives: After exposing rats to 32% sucrose for 10 trials but suddenly downshifting the sucrose to 4%, rats will show less intake and number of licks when compared to control animals that have always been exposed to 4% sucrose. This phenomenon is known as the consummatory successive negative contrast effect (cSNC) and is one of the appropriate models presenting how prior taste experience influences food choice. In this study, while focusing on rats' approaching and licking pattern of sucrose solution, we aim to investigate how prior taste experience and its interaction with metabolic needs shape the decision making process in feeding behavior and how this may change over time, using the cSNC

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

model and adopting lick microstructure analysis to measure rats' hedonic state throughout the experiment.

Methods: Rats were assigned to either food-deprived or non-deprived conditions. In each condition, rats were presented with 32% (downshift group) or 4% (unshift control group) sucrose in the 5-minute 10 preshift trials and were all given 4% sucrose in the later 12 postshift trials.

Results: Non-deprived downshift group showed a prolonged suppression of 4% sucrose intake, along with decreased number of licking bursts, an index of motivation level, and the number of access to the drinking spout (entries). Interestingly, deprived animals showed an increase in the number of licking bursts and entries after sucrose downshift. This may be due to the increase in hesitation-like behavior of approaching the drinking spout without ingesting (entry-conflicts), which may have resulted from a conflict between devalued palatability of sucrose stimulus and homeostatic needs to compensate for caloric loss after the downshift of sucrose solution.

Conclusion: From our results, we can conclude that although approaching behavior toward taste stimulus is affected by animals' motivation level, which is modulated by their metabolic needs, actual ingestive behavior may be controlled by factors such as evaluation of tastant. In the evaluation process, the rewarding nature of a taste stimulus may depend not only on its concentration but also on animals' prior taste experience. Such experiences shape subjective evaluation of taste stimulus, influencing the decision making process in feeding behavior.

Assessment of the availability of dietary choline-related compounds in vitro and in vivo

Yuto Yoshinaga[1], Chiharu Sibamiya[1], Yutaka Miura[1]

1.Tokyo University of Agriculture and Technology (Japan)

Background and objectives: Choline is a vitamin-like nutrient responsible for various physiological functions, including synthesis of cell membrane phospholipids and acetylcholine. Although choline plays an important role in the body, there are several choline-related compounds in food, and the availability of these choline-related compounds in the body remain unknown. In this study, we used mouse melanoma B16F10 as cancer cells, human dermal fibroblast NHDF and rat skeletal myoblast L6 as normal cells to evaluate the cellular availability of choline-related compounds and also examined the absorption efficiency of choline-related compounds from the intestinal tract in rats.

Methods: The WST-8 method was used to examine the proliferative ability of cells cultured in a choline-deficient medium added by each choline-related compound. For in vivo studies, rats fasted for 16 hours were orally administered GPC or PC, and after a fixed time (0h ,1h ,2h ,4h ,6h), blood was collected from the portal vein, superior mesenteric vein, inferior vena cava and abdominal aorta. LC-MS and LC-MS/MS were used to measure choline-related compounds in cells and serum.

Results: The proliferative capacity of B16F10, NHDF, and L6 was suppressed by choline deficiency, and the addition of Pcho and Cho tended to recover their proliferations, while the addition of GPC showed little effect. In B16F10, the addition of Cho significantly increased the amount of Cho, GPC and lipophilic choline in the cells. In L6, the addition of Pcho and Cho tends to increase the total amount of soluble choline and lipophilic choline. In rats treated with GPC, the concentration of GPC in the portal vein and superior mesenteric vein was maximal after 4 hours, and the amounts of Pcho and Bet also tended to increase slightly.

Conclusions: Choline-related compounds are available as a source of choline in cultured cells, but their availability varies. GPC is absorbed mainly from the small intestine as GPC after approximately 4 hours. The results of the PC-treated rats are currently under investigation and will be reported as well.

Keywords: Choline, Choline-related compounds, B16F10, L6, intestine

Anaemia status and associated factors of anaemia among adolescent girls, pregnant and lactating women in Southern Bangladesh

Gulshan Ara[1], Anika Bushra Boitchi[1], Riad Imam Mahmud[2], Kazal Ahidul Islam[2], Hafizur Rahman[2], Samira Dilruba Ali[1], Zhahirul Islam[1], Tahmeed Ahmed[1]

1. International Centre for Diarrhoeal Disease and Research Bangladesh (icddr,b) (Bangladesh), 2. Max Foundation, Bangladesh (Bangladesh)

Background and objective: Children and women in reproductive years are more susceptible to micronutrient deficiency, particularly anemia. Although iron deficiency is the primary cause of anemia, other factors, such as inadequate dietary intake, micronutrient inadequacy, socio-demographics, and WASH behaviors, may also be involved. The purpose of the study was to evaluate the current anaemia status among adolescent girls (AG), pregnant women (PW), and lactating mothers (LW), as well as the associated factors with anaemia in this population.

Method: In the South-coastal districts of Bangladesh, a cross-sectional survey was carried out utilizing multi-stage cluster-random sampling techniques. AG (10–19 years), PW, and LW were the study population. Local NGOs provided WASH-Nutrition intervention to the participants. WASH initiatives and nutrition education were part of the intervention. There were 375 women in each group, and 400 AG in the sample. Data on socio-demographics, dietary variety, and WASH indicators were gathered. Anaemia was measured by assessing the hemoglobin

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

concentration of capillary blood of the participants. Multiple logistic regression was used to assess the factors associated with anemia.

Results: The average age of women was 24 years and 15.2 years for AG. Half of the PW, 46% of the LW and 37% of the AG were anaemic. Only around 20% of the participants consumed food from more than 5 food groups which suggest poor dietary diversity. Risk of anaemia was 4 times higher among PW who did not wash their hands at least during three critical times compared to those who had proper handwashing practice (AOR: 4.08, 95% CI: 1.7, 9.6, p<;0.001). PW from wealthy quintiles had less risk of anaemia compared to poorest quintile. Middle-aged LW had a higher risk of anaemia compared to younger mothers (AOR: 1.3, 95% CI: 1.1, 1.5, p<;0.005). LW from the middle wealth quintile had less risk compared to the poorest.

Conclusion: The high prevalence of anemia was noticed among all survey participants who needed to get urgent attention. Improved handwashing practice and better asset quintiles reduced the risk of anaemia among women. Nutrition-sensitive or specific intervention is required to improve the dietary diversity among this vulnerable group.

The association between health behaviors and Korean Diet Score (KDS) as an index for the balanced diets: KNHANES (2015-2019)

Jieun Shin[1], Seonyoung Kim[2], Jihyun Kim[3,4], Sangduk Yoon[5], Dajeong Son[5], Narae Kim[5], Sowon Jung[5], Myoungsook Lee[3,5]

1.Konyang University (Korea), 2. Konyang University College of Medicine (Korea), 3. Research Institute of Obesity Sciences (Korea), 4. Institute of Traditional Korean Food (Korea), 5. Sungshin Women's University (Korea)

Background and objectives: In the previous study, we created the Korean Diet Score (KDS) as the index to evaluate the balanced diets or the dietary diversity based on the "Food Balance Wheel" with six classified food categories developed by the Korean Nutrition Society. Furthermore, in this study, the association between health behaviors like "Alamada 7 health habits" and KDS was evaluated, and it will be applied in the "Chronic Diseases Prevention with Health Behaviors-related Quality of Life".

Methods: Based on Korean National Health and Nutrition Examination Survey (2015-2019), healthy adults over 19 years old (n=11,498, men; 3,867 women; 5,258) were our subjects, excluding pregnant/lactating women, under-or overfeeding, patients, and missing data of health behaviors. We used the complex weighted samples with CDC guidelines and ANOVA to analyze health behaviors on KDS and multivariate analysis with extra factors, such as marriage, economics, and education, etc, using the statistic SW, SAS ver. 9.4 (SAS institute Inc, Cary, NC, USA).

Results: KDS was significantly high in adults with health behaviors such as non-smoking, non-skip breakfast, and self-control in eating out without gender differences (p<;0.05). In an older person, KDS was significantly associated with health behaviors such as non-smoking, nondrinking, normal weight, non-skip breakfast in men, but it was high in women with non-skip breakfast behaviors only (p<;0.05). As results of multivariate analysis, nondrinking (β=0.74) and non-skip breakfast (β=1.13) in adult men, normal weight (β=0.71) and non-skip breakfast (β=1.13) in adult women were significantly related to KDS. The self-control in eating out (β=-0.74) habit had an effect of lowering KDS in older men, non-skip breakfast (β=2.87) habit increased KDS in older women.

Conclusions: We found that various health behaviors were significantly associated KDS index with gender differences. KDS, an index to evaluate the balanced diets or dietary diversity, might be recommended as a predicted indicator to evaluate the effects of health behaviors in the Korean Health action plan to prevent chronic diseases.

PAB(T2)-99

Characteristics of physical growth in lean girls at the end of adolescence

Saki Yamanaka[1], Rieko Sato[1], Kazuhiro Uenishi[1], Hiromi Ishida[1]

1.Kagawa Nutrition University (Japan)

Background and objectives: In Japan, the proportion of lean young women (Body Mass Index [BMI] under 18.5kg/m2) is higher than in other developed countries. The leanness in adolescence might be the reason for leanness in young women. This study aimed to examine the characteristics of physical growth of lean adolescents retrospectively at the end of adolescents.

Methods: This study included 838 girls who entered combined junior high and senior high school in Tokyo from 2005 to 2014; we call them “all subjects”. Data on height, weight, body fat percentage, and bone status were collected from 12 to 17 years old. We also extracted underweight girls (degree of obesity for Japanese children under -15%) at the age of 17 years from all subjects (“underweight group”). Anthropometric data, physical activity and dietary intake from underweight group questionnaire survey were compared to all subjects each school year from 12 years old to 17 years old. We also used a growth chart to assess physical growth.

Results: The annual growth of weight at the age of 16 to 17 years in the underweight group declined by -0.5kg on average, whereas there was an increase of +0.5kg in all subjects. Also, the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

bone status of the underweight group was significantly lower than all subjects. The average energy intake of the underweight group was not significantly lower than all subjects. When we assessed the physical growth using a growth chart, we could clearly see the difference of constitutional leanness and unhealthy leanness.

Conclusions: The characteristics of physical growth from 12 to 17 years old of lean adolescents at the age of 17 years had severe patterns; they are constitutionally lean or remarkably lost weight at the end of adolescence. The latter girls might have a risk of unhealthy leanness, which may cause diseases such as anorexia nervosa.

Production and nutritional evaluation of biscuits made from blends of unripe plantain flour, tiger nut flour, ginger, dates and moringa leaves

Abimbola Eniola Ogundele[1], Aderonke Mosuro[1], Elizabeth Oluwafolakemi Aleru[1], Queen Oluwatoyin Adeniji[1]

1. Lead City University (Nigeria)

Background and objectives: Snacks are a small portion of food generally eaten between meals. They come in a variety of forms such as biscuits and cookies most of which contains "empty and excess calories contributing to overweight and obesity. This study determined the proximate and micronutrient content of biscuits produced from blends of unripe plantain flour, tiger nut flour, ginger, dates and moringa leaves.

Methods: This experimental study involved the production and nutritional analysis of biscuits made from two (2) blends of composite flour [unripe plantain flour (UPF) and tiger nut flour (TNF)] and a constant mix of other ingredients in ratio 20 (moringa leaves:5%, ginger:5% and dates:10%). Samples A, B, C were mixed in the ratio 80:0:20, 40:40:20, 0:80:20. Sample D (UPF:30%, TNF:30%, Ginger:25%, moringa leaves:5%, dates:10%) and E (UPF:30%, TNF:30%, coconut:20%, moringa leaves:5%, ginger:5% and dates:10%). The control sample was a blend of whole wheat:80% and the constant mix of other ingredients in ratio 20. Proximate and micronutrients composition were determined according to AOAC methods. Data was analyzed using SPSS version 25.0 and ANOVA was used to test for mean differences with the level of significance set at 5%.

Results: Sample B had the highest moisture content (22.33%) and sample A the least (11.66%). The ash and fat content were highest in Sample D and C (2.20%, 24.33%) respectively while the least fat content was 16.33% in sample E. The crude fiber and carbohydrate content were highest in Sample B (1.78%, 68.65%) while Sample C had the highest protein content (10.21%). Energy content was highest in Sample A (478K/Cal) and least in sample B (361k/Cal). The control sample (wheat) had the least mineral content (310.31mg, 1.25mg, 242.15mg) while the highest was in Sample D (331.51mg), B (1.30mg) and A (261.20mg) for Ca, Zn and Fe respectively.

Conclusion: The composite blend of ingredients is more nutrient dense than the control sample. This study thus recommends that consumption of biscuits made from the blend of UPF and TNF with other ingredients as a healthy snack for children to prevent non communicable diseases in later adult years.

Maternal perceived stress, HIV status, and feeding styles are predictors of infant dietary intake in Ghana

Anna Lartey[2], Prerana Adhikari[1], Grace S Marquis[1]

1. McGill University (Canada), 2. University of Ghana (Ghana)

Background: Indicators of poor maternal mental health have been associated with non-responsive feeding styles that affect dietary intake in infants

Objective: To examine the association between maternal mental health indicators and (i) infant dietary intake and (ii) infant feeding behaviors within a 2003 to 2008 longitudinal observational cohort study (the Research to Improve Infant Nutrition and Growth [RIING] project).

Method: A random sample of one third of the RIING cohort (19 HIV positive [HIV-P], 29 HIV negative [HIV-N], and 24 HIV unknown [HIV-U]) and their infants was selected for an in-home 24-hr weighed dietary study at 9 mo postpartum. Maternal depressive symptoms and perceived stress scores had been measured at 6 mo using the Edinburgh Postnatal Depression Scale (EPDS) and Perceived Stress Scale (PSS), respectively. All foods and liquids including human milk were weighed to determine energy and nutrient intake values. Each feeding session was observed, and the feeding style was recorded.

Results: Multiple linear regression showed that maternal perceived stress was negatively associated with total food (-12.4 g, 95% CI: -21.0 to -3.8), energy (-19.5 kcal, 95% CI: -33.8 to -5.2), and fat (-0.7 g, 95% CI: -1.4 to -0.1) intake in infants. An HIV-P status was associated with a lower intake of fat (-6.3 g, 95% CI: -11.1 to -1.5) and vitamin A (-293.9 µg, 95% CI: -529.9 to -57.8) compared to HIV-N. Maternal mental health indicators were not associated with feeding style. However, a positive feeding style was associated with a higher intake of fat (4.8 g, 95% CI: 0.3 to 9.2) and vitamin A (245.3 µg, 95% CI: 28.2 to 462.5) compared to a passive feeding style.

Conclusion: Interventions to improve infant dietary intake should prioritize maternal mental health and promote positive feeding styles among caregivers.

Is iodine deficiency associated with stunted children in South Sulawesi, Indonesia?

Abdul Razak Thaha[1], Abdul Salam[1], Saifuddin Sirajuddin[1], Akmal Novrian Syahruddin[2], Sabaria Manti Battung[1], Muh Rizal[1], Nur Ainin Alfi[1], Musfira Muksin[1]

1. Hasanuddin University (Indonesia), 2. Institute of Health Sciences Tamalatea (Indonesia)

Background and objectives: Stunting and Iodine Deficiency Disorder (IDD) is a serious public nutrition problem, especially in developing countries. Both conditions affect altered linear growth, developmental delays, brain damage, hearing and learning disorders. This study aimed to assess the relationship between stunting and IDD in the areas of goiter endemic.

Methods: A cross-sectional study was conducted in Buntu Batu District, Enrekang Regency. A total of 100 children aged 0-23 months participated in this study. Data were collected through an interview-administrated questionnaire, anthropometric and urinary iodine measurement, and also iodine concentration assessment in household salt. Data were analyzed using the chi-square test.

Results: The prevalence of stunted children was 48%, which the highest proportion was in the 12-17 month age group (72.4%) and among males (55%). A 43% of mothers had median urinary iodine excretion (UIE) <100ug/L, whereas only 3.7% of mothers met the iodine Recommended Dietary Allowance. The coverage of salt iodization that had >30 ppm was only 16%. Bivariate analysis showed a relationship between the lack of iodine content in household salt (p=0.045), maternal UIE (p=0.030), and stunting.

Conclusions: The iodine deficiency was likely to contribute to stunting. Efforts are needed to improve and monitor the iodine salt program, especially in areas with IDD.

Keyword: Iodine Deficiency Disorder, Salt Iodization, Stunting, Urinary Iodine Excretion

Increases in Omega-3 Index after krill oil supplementation compared to predicted increases from triglyceride-based omega-3 fatty acid supplements

Welma Stonehouse[1], Bianca Benassi-Evans[1], Kaylee Azzopardi[2], Kristina Gorgievska[2,3], William Harris[4], Lieke Scheepers[5], Graeme Jones[5]

1. Commonwealth Scientific Industrial Research Organisation (CSIRO) (Australia), 2. H&H Group (Australia), 3. Dairy Australia (Australia), 4. Fatty Acid Research Institute (USA), 5. University of Tasmania (Australia)

Background and objectives: The omega-3 index (O3I) is a recognised biomarker for omega-3 fatty acids (FA) eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Achieving an O3I target of >8% has been associated with improved health outcomes. Krill oil (KO) provides EPA+DHA in phospholipid-form as opposed to triglyceride (TG)-form in fish oil, and this may facilitate absorption and result in greater O3I levels.

Objective: To compare increases in O3I with KO supplementation to predicted increases for TG-based omega-3 FA supplements.

Methods: Data were derived from two 6-month double-blind randomized placebo-controlled multicenter trials investigating effects of KO in adults with clinically diagnosed knee osteoarthritis (Study 1: 4g/day KO [0.88g/day EPA+DHA], inclusion criteria <0.5 g/day EPA+DHA intake; Study 2: 2g/day KO [0.44g/day EPA+DHA], no exclusion based on EPA+DHA intake). Superba BOOST KO and mixed vegetable oil placebos were used in both studies. O3I was assessed from finger prick dried blood spots using gas chromatography at baseline, 3- and 6-months follow-up. Predicted changes were calculated using the Walker et al equation including baseline O3I and assuming 0.88g/day or 0.44g/day EPA+DHA TG-based doses. As the prediction equation is based on ~3-month supplementation, baseline to 3-month changes in KO-consuming groups were compared to TG-based predicted changes using linear mixed models including O3I-change (actual vs. predicted) and O3I-change*study interaction.

Results: O3I increased with KO from baseline to 3-months (Study 1: 5.97±1.27% to 8.86±1.52% [n=108]; Study 2: 6.54±1.60% to 7.79±1.51% [n=98]) while remaining constant in placebo groups (n=103 Study 1, n=92 Study 2). O3I-change differed between studies (O3I-change*study interaction, P=0.003). Increases in O3I with KO in Study 1 was greater than TG-based predicted changes (mean[95%CI]: 2.89[2.61, 3.17]% vs. 2.41[2.36, 2.46]%, mean difference 0.48[0.20, 0.76]%, P=0.001) while no differences were seen in Study 2 (1.26[0.96, 1.55]% vs. 1.40[1.35, 1.45]%, mean difference -0.14[-0.43, 0.15], P=0.33). Compliance were >80%.

Conclusion: O3I increased on average 0.5% more after consuming 0.88g/day EPA+DHA from KO vs. predicted change from the same dose triglyceride-based EPA+DHA, while no differences were seen with the lower dose (0.44g/day EPA+DHA). Differences in O3I between KO vs. predicted TG-based omega-3 FA supplements may become more evident at higher dosages.

Protecting the First 1000 Days in Conflict-Affected Myanmar: Lessons Learned from Family MUAC Pilot

Swe Linn Maung[2], Hnin Julia Weatherson[1]

1. Save the Children, UK (UK), 2. Save the Children, Maynmar (Myanmar)

Background and objectives: An estimated 290,000 children under the age of five are expected to suffer from acute malnutrition in Myanmar in 2022 – among them a staggering 49,000 children (17%) suffer from Severe Acute Malnutrition. Exacerbated by the collapse of the health system first during Covid-19 and then crumbling further after the military takeover, coverage of therapeutic and supplementary feeding programs diminished significantly. Resulting in only 1 in every 5 children being reached with Infant and Young Child Feeding in Emergency interventions to mitigate malnutrition. A recent Save the Children (SC) study reported Global Acute Malnutrition rate as 22.3% in Rakhine and 11.9% in Kachin and Norther Shan. To fill a vital need in the absence of a functioning health system, SC piloted Family/Mother MUAC (Mid-Upper Arm Circumference) approach in fragile and conflict-affected Myanmar. Family MUAC is a community screening method which empowers families to screen their own children for acute malnutrition using color-coded MUAC tapes, requiring neither literacy nor numeracy skills.

Methods: Operational research of the Family MUAC approach in four implementation areas to determine feasibility in fragile and conflict affected settings

Results: SC capacitated over 4500 mothers and caregivers of children 6-59 months with the Family MUAC approach. Community volunteers validated the accuracy MUAC measurements by mothers monthly and found 99% of mothers conducted the screening correctly. Surprisingly, during Covid-19 lockdown, families sustained the screenings despite many other activities being suspended. As a result, 46 children suffering from acute malnutrition were detected by families and referred to treatment.

Conclusions: SC learned that Family MUAC is a feasible approach to detect children suffering from malnutrition early as possible in fragile and conflicted-affected areas. Moreover, community capacity strengthening is a viable and vital avenue in remote areas inaccessible by health staff. Given the limited health service access in these complex settings, SC found treatment centers unavailable nor functional in many areas. This poses a profound risk and challenge in ensuring timely, appropriate referral, exacerbated by the deteriorating health system. In response, SC ensured remote support through calls to provide and/or secure appropriate treatment for children.

"Test, Treat and Talk" (T-3) Anemia Camps: An innovative model to strengthen anemia control in India

Kapil Yadav[1], Shashi Kant[1], Vani Sethi[1], Kashish Vohra[1], Surbhi Gupta[1], Sila Deb[2]

1. All India Institute of Medical Sciences (India), 2. Ministry of Health and Family Welfare (MoHFW) (India)

Background and objectives Anemia is a serious public health problem in India with more than half of the under-five children, adolescent girls, women of reproductive age, pregnant and lactating women being anemic. India had launched Anemia Mukt Bharat (AMB) strategy in 2018, to address the high burden of anemia with a target for a 3% annual reduction in burden among selected vulnerable groups. Diagnosis and community awareness was one of the key focus areas for the AMB program and was a key challenge for the program. we share an innovative approach to integrating diagnostic, therapeutic, and Social and Behaviour Change Communication (SBCC).

Methods Under the T3 strategy, the participants attending the camps were tested for anemia using digital hemoglobinometers, treated with iron-folic acid (IFA) tablets, and delivered a talk on a diet rich in iron. Medical schools, academic institutions, and partner agencies supported the ministry of Health in conducting the T3 camps.

Results The pilot of T3 camps was conducted in the year 2018- 19 during nutrition (September 2018- 19) and Pradhan Mantri Surakshit Matritva Abhiyan (PMSMA) days in 2019. The prevalence of anemia varied from 39.2% to 48.4% in people screened during these camps. Around 100 such camps were held with a median footfall of roughly 400 participants in each camp. Subsequently, T3 camps were incorporated as one of the activities of the AMB program with human resources, Standard Operating Procedure (SOP), and a budget is provided. Presently, T3 camps are being scaled up across India. The future strategy is to sustain these T3 camps as an integral component of the AMB program. The four-year experience of piloting, scaling up and subsequent consolidation of T3 camp has proven highly beneficial for the AMB program.

Conclusions Test, treat, and Talk (T3) camps have proven to be a valuable innovation for high-level advocacy, demand generation, awareness generation, and Social and Behaviour Change Communication (SBCC). Similar integrated camps may be incorporated into other public health programs.

Validity and reliability of the malay version of 3-minute nutrition screening-paediatric (paediatric 3-minns)

Pei Sien Yeo[1], Christopher Chiong Meng Boey[2], Hazreen Abdul Majid[2]

1. Kuala Lumpur Hospital (Malaysia), 2. University of Malaya (Malaysia)

Background and objectives: Most of the malnutrition screening tools are developed in the English language, there is limited study in validating their translated versions. The aim of this study is to validate the Malay version of 3-Minute Nutrition Screening-Paediatric (Paediatric 3-MinNS) to determine its reliability and validity for use among hospitalized children.

Methods: The Paediatric 3-MinNS was translated to Malay version. The translation was performed using methods: 1) Forward translation from English version to Malay version by two bilingual translators, 2) Synthesis of forward translation, 3) Back translation from Malay version to English version and synthesis of back translation. The translated items were reviewed by three clinical expects for clarity and comprehensiveness of the tool. The face validity was performed among 14 health care providers to verify the understanding of the items. The reliability was evaluated through inter-rater agreement in 30 participants. The Screening Tool for the Assessment of Malnutrition in Paediatrics (STAMP) and anthropometric measurements were used as the reference methods for criterion validity.

Results: The inter-rater reliability (kappa estimation, κ) of Paediatric 3-MinNS between two different staff nurses was 0.814, while the inter-rater reliability (κ) of Paediatric 3-MinNS between a research dietitian and staff nurse was 0.377. The Paediatric 3-MinNS identified 26.1% of 165 participants as being at high malnutrition risk, whereas STAMP identified 27.9%. The sensitivity and specificity of Paediatric 3-MinNS compared with the STAMP were 82.5% and 46.7%, respectively. The sensitivity of the Paediatric 3-MinNS at detecting participants with severe acute malnutrition (weight-for-height z-score of less than -3) was 73.2%, and the specificity was 33.3%. While the sensitivity of the Paediatric 3-MinNS at detecting participants who were severe chronic malnutrition (height-for-age z-score of less than -3) was 75.3% and 33.3%, respectively.

Conclusion: The inter-rater agreement between a research dietitian and staff nurses, and between two different staff nurses were shown to be fair to substantial in this study. The Paediatric 3-MinNS was comparable with other validated nutritional screening tool in diagnostic performance.

PAB(T2)-107
Osteosarcopenic obesity and vitamin D status

Maria Georgieva Nikolova[1], Lalka Rangelova[2]

1. Medical University - Sofia (Bulgaria), 2. Natinal Center of Public Health and Analyses (Bulgaria)

Background and objectives: Low levels of serum vitamin D have been associated with osteosarcopenic obesity (OSO). We assessed the correlations of plasma 25(OH) vitamin D levels with indices of body composition examined by bioelectrical impedance: FM, FM, FFM, TBW and by DXA with an emphasis on lean and bone mass; appendicular lean mass (ALM) as well as on indices such as android/gynoid fat; appendicular lean mass index (ALMI); fat-mass indexes (FMI); fat-free mass indexes (FFMI) and the ALM-to-BMI index.

Methods: 264 adult subjects participated (109 men and 155 women) - aged 20-60 years. Body composition was recorded by bioelectrical impedance (Tanita BC 420 MA, Tanita Inc., Japan) and by Fan-beam dual-energy X-ray (Lunar Prodigy Pro bone densitometer with software version 12.30). The FMI, FFMI, ALMI and ALM-to-BMI index were calculated. Vitamin D was measured by electro-hemi-luminescent detection as 25(OH)D Total (ECLIA, Elecsys 2010 analyzer, Roche Diagnostics).

Results: Serum 25(OH)vitamin D is tightly correlated to FM, % FM and %TBW but not to FFM or TBW. In men the FFM, the FFMI, the TBW and the bone mass were not correlated to vitamin D, while in women they were. In men, visceral obesity ($p < 0.001$) and a lower ALMI were significantly more common ($p < 0.05$). The serum 25(OH)D level was correlated significantly only to the whole body bone mineral content (BMC); ALMI and the ALM-to-BMI index, underlining a predominant role for lean and fat-free mass. People with vitamin D deficiency have significantly lower average levels of the ALM-to-BMI index and fat mass in the hands (Reg. Arms-Lean) compared to those with vitamin D insufficiency.

Conclusions: Serum 25 (OH) D correlates slightly proportionally to moderately with: total bone mineral content and indicators of the risk of sarcopenia - ALMI and the ALM-to-BMI ratio.

Keyword: vitamin D, sarcopenia, obesity

Conflict of Interest Disclosure: No conflict of interest.

Association of dietary fish and n-3 unsaturated fatty acid consumption with diabetic nephropathy from a district hospital in Northern Taiwan

Sing-Chung Li[1], Shih-Ping Lin[1,2], Chiao-Ming Chen[3], Kang-Ling Wang[4], Kun-Lin Wu[5,2]

1. Taipei Medical University (Taiwan), 2. Taoyuan Armed Forces General Hospital (Taiwan), 3. Shih Chien University (Taiwan), 4. Taipei Veterans General Hospital (Taiwan), 5. Tri-Service General Hospital (Taiwan)

Background and objectives: Nephropathy caused by diabetes mellitus (DM) is the main cause of end-stage renal disease (ESRD). To understand the association of dietary intake with renal function indicators among patients with diabetic nephropathy (DN), this cross-sectional study was conducted at the dietetic consultation clinic of the Taoyuan Armed Forces General Hospital in Taiwan.

Methods: In total, 317 participants were recruited for this study. Patients with DM who had a urinary albumin–creatinine ratio (UACR) of ≧30 mg/g were defined as having DN. The anthropometric characteristics, blood biochemistry, and renal function of the participants were examined. Furthermore, a semiquantitative 28 food frequency questionnaire (SQFFQ) was administered to investigate the dietary content of the participants and compare the dietary intake of participants with DM.

Results: The result indicated that participants in the DN group were older, were more likely to have a history of diabetes, and had poorer glycemic control and renal function relative to the those in the DM group, Logistic regression models revealed that high fat marine fishes had the lowest odds ratio (OR) compared with other fishes (OR: 0.868; 95% CI: 0.781-0.965, p =0.009). Shellfish, soybean products and skim milk also provided better protective effect to decrease the risk of DN. A further analysis of polyunsaturated fatty acids revealed that total n-3 PUFAs significantly reduced DN risk, while Σn-6 PUFAs did not, especially EPA (OR: 0.821; 95% CI: 0.688-0.979, p = 0.029) and DHA (OR: 0.903; 95% CI: 0.823-0.992, p = 0.033) regardless of whether the variables were adjusted.

Conclusions: Our findings suggest that a diet that incorporates high-fat fish, shellfish, soybean products and a lower Σn-6/Σn-3 ratio can mitigate DN risk.

Inadequacy of multiple micronutrients is widespread and spatially varied in Malawi

Gareth Osman[1], Kevin Tang[2], Liberty Mlambo[3], Lucia Segovia De La Revilla[2], Edward J.M. Joy[2], Alexander A. Kalimbira[1], Louise Ander[3]

1. Lilongwe University of Agriculture and Natural Resources (Malawi), 2. London School of Hygiene & Tropical Medicine (UK), 3. University of Nottingham (UK)

Background and objectives: In resource-constrained countries, routine assessment of micronutrient deficiencies (MNDs) is limited to a few "priority" micronutrients including vitamin A, zinc, iron and iodine. We estimated deficiency risks for 17 micronutrients due to inadequate dietary intakes in Malawi, estimated from household consumption and expenditure survey data.

Methods: Household food consumption data from Malawi's 2019/20 Fifth Integrated Household Survey were matched with food composition data from Malawi, Kenya, Lesotho and West Africa, using approaches developed in the Micronutrient Action Policy Support (MAPS) project. Estimated intakes were compared against Harmonised Average Requirement values. Apparent intake of micronutrients was individualized using the Adult Female Equivalent (AFE) approach. Nutrient density of diets was estimated as the ratio of dietary micronutrient:energy supply. Data were transformed and analysed in RStudio (v.4.1.3) to estimate prevalence of inadequate intakes for vitamins A, B1, B2, B3, B6, B9, B12, C and E, and calcium (Ca), magnesium, zinc (Zn), selenium (Se), copper, sodium, potassium and iron (Fe). Micronutrients with ≧50% prevalence of inadequate apparent intake or micronutrient density were further analysed by estimating their median apparent intakes per AFE per day and estimating spatial variation in the prevalence of inadequate apparent intake at district-level.

Results: The prevalence of inadequate apparent intake or micronutrient density exceeded 50% for nine micronutrients: vitamins B2, B3, B12, C, and E, and Ca, Fe, Se and Zn. Among these, only Se showed notable variation in inadequacy when estimated by the apparent intake and nutrient density metrics. The poorest populations had the lowest median apparent intake of the nine shortfall micronutrients. Cereals were the dominant source of vitamins B2 and B3, and Fe, Se and Zn. Vitamin B2 had the highest prevalence of inadequacy, reflecting low apparent consumption of animal source foods. Spatially, districts in central Malawi had a higher prevalence of inadequacy than those in the northern and southern regions.

Conclusions: Inadequate apparent intake of multiple micronutrients, including vitamins B2, B3, B12, C and E, and Ca, Fe, Se and Zn, are prevalent in Malawi. Inclusion of a wider set of micronutrients in routine public health surveillance is warranted.

Examining and comparing the validity and reproducibility of scales to determine vegetable variety

Kaya Ominami[1], Osamu Kushida[1]

1. University of Shizuoka (Japan)

Background and objectives: Previous studies have reported that vegetable variety reduces the risk for non-communicable diseases independently of the consumed amount. Because vegetable variety has been assessed by using an existing food frequency questionnaire (FFQ) in numerous studies, it is important to study whether the scales extracted from each FFQ can determine actual vegetable variety. Therefore, this study aimed to examine and compare the validity and reproducibility of several scales.

Methods: Twenty-three nutrition students in Japan were asked about their vegetable intake over the past month using a self-administered questionnaire between July and August 2021. Four patterns of the scales were used: 1) a single question "How many vegetables do you eat per day?" (Single), 2) nine subgroups of vegetables included in a brief-type self-administered dietary history questionnaire (Group), 3) 19 items of vegetables included in a self-administered dietary history questionnaire (Item-1), and 4) 20 items of vegetables from the "Ranking of vegetable consumers in Japan" which was analyzed based on the report on the National Health and Nutrition Survey Japan (Item-2). Vegetable variety was defined as "number of types consumed" for Single, "total score for each vegetable subgroup with one point for consumption at least once a week" for Group, and "total score for each item with one point for consumption at least once every two weeks" for Item-1 and Item-2, respectively. Scale validity was assessed by correlation with the number of vegetable items extracted from semi-weighed dietary records for seven consecutive days, and reproducibility was assessed by test-retest reliability.

Results: Regarding the correlation between vegetable variety based on dietary records for seven consecutive days and the four scales, no significant correlation was found between Single and Group (ρ = 0.28, 0.22), and a significant correlation was confirmed between Item-1 and Item-2 (ρ = 0.51, 0. 44). Reproducibility showed a significant correlation in Group (ρ = 0.45) and a strong correlation in Item-1 and Item-2 (ρ = 0.73, 0.75).

Conclusions: The scales for vegetable items had good validity and reproducibility and may determine actual vegetable variety when compared to the scales for a single question or vegetable subgroups.

A scoping review of the availability of geospatial information in food composition databases in sub-Saharan Africa

Lucia Segovia de la Revilla[1], Elaine Ferguson[1], Claire Dooley[1], Edward Joy[1]

1. London School of Hygiene & Tropical Medicine (UK)

Background and objectives: Food composition data are valuable to identify and characterise dietary micronutrient status, and inform interventions to alleviate deficiencies. Food composition varies spatially with potentially large effects on dietary micronutrient intake and risks of deficiency, particularly in contexts like in some regions of sub-Saharan Africa (SSA) where dietary diversity is low and food systems are highly localised. However, geographic information is seldom included in food composition tables and databases (FCTs/FCDBs). The objective of this review was to identify published FCTs/FCDBs for use in dietary assessment of calcium, iron, iodine, zinc and selenium in sub-Saharan Africa and to assess the geographic information accompanying current food composition data.

Methods: We conducted a scoping review following the PRISMA guidelines (PRISMA-ScR) and reviewed four databases and other online resources to identify published FCTs/FCDBs in sub-Saharan Africa. Data and metadata were collected to identify the geographic location of the mineral micronutrient values reported for commonly-consumed foods in each FCT/FCDB.

Results: From the 19 FCTs/FCDBs for SSA included for review, >60% of the referenced nutrient values were imputed or borrowed from other FCTs/FCDBs. Twelve FCTs/FCDBs reported the use of analytical values, of which 72% referenced published studies and other publications. Five FCTs/FCDBs reported sampling and analysis of foods as part of the data compilation, whereas only two reported georeferenced information (i.e., coordinates of the sampling location). We attempted to allocate geographic information (e.g., country of origin, sampling location) to each data entry (mineral value per selected food entry) however this was often impossible due to the data structures employed in FCTs/FCDBs, for example where multiple references were provided for a single food item entry.

Conclusions: The majority of datapoints in FCTs/FCDBs for use in sub-Saharan Africa report secondary data with a lack of clear information on geographic origin. There is a need to employ new data structures and improved metadata processes to adequately capture and report geographic information in FCTs/FCDBs, and ensure these are ready to accommodate a new generation of spatially-resolved food composition data.

Nutrition status and Pressure injury among Covid-19 patients in critical care division: case study in pandemic- Phase I

Yooyadmak[1], Varanporn Panasittivana[1], Kingkarn Klinungkab[1]

1. Mahidol University (Thailand)

Background and objectives: The COVID-19 pandemic was the global health crisis and the greatest challenge of our time. It effects to patients and health care worker by changes in care, cost of admitted, mental health status and leading to complication such as pressure injury (PI). The aim of this research was to report the incidence and related factors of PI among Covid-19 patients in Critical care division at Phase I pandemic in a part of Thailand.

Methods: This a retrospective study was analyzed the descriptive statistics such as mean, standard deviation and chi-square test were used to statistically analyze the associated of PI in 18 patients. All subject were confirmed COVID-19 who admitted in Critical care division in Ramathibodi Chakri Naruebodindra Hospital in Samut Prakan province from 1 January - 31 July 2020. All data were include from the Hospital Information System (HIS) that included patient in formation such nutrition status, Braden score, length of stay in ICU, status in ICU, endotracheal intubation, on vasopressor and sedative drug.

Results: The results revealed that the incidence of PI in Covid-19 patients were 5 in 18 patients (27.78%). The factors i.e. the nutritional status (p=0.004), the Braden score (p=0.008), length of ICU stay (p=0.036), endotracheal intubation (p=0.002), on vasopressor (p=0.002) and sedative drug (p=0.002) were associated with PI.

Conclusions: This results suggest that the PI in the critical care unit was important. Therefore, critically ill patients should be treated accordingly to prevent complications.

Behaviours and Visceral Adiposity among Malaysians' Adults.

Mazuin Kamarul Zaman[1], Ardinie Atikah Azlan[1], Nur Islami Mohd Fahmi Teng[1]

1. Universiti Teknologi MARA (Malaysia)

Background and objectives: Chrononutrition, or timing of dietary intake has emerged as novel strategy to improve health outcomes due to its association with weight regulation. A recent tool was developed to assess multiple components of chrononutrition behaviours. The aim of this study was to explore relationship between chrononutrition behaviours and visceral adiposity.

Methods: Community-based cross-sectional survey was conducted to collect data on the adult population in Malaysia. A pre-tested structured questionnaire, Chrononutrition Profile Questionnaire (CPQ), was translated to Malay for assessment of chrononutrition behaviours. Six domains studied were breakfast skipping, largest meal, evening eating, evening latency, night eating and eating window. Responses were scored based on domains in CPQ. Waist circumference (WC) was used as a surrogate marker for visceral adiposity. Spearman correlation was used to test for associations of variables of interest using SPSS version 28. Statistical significance was set at 0.05.

Results: A total of 275 adults participated in this study. Median WC of male and female is 83.8 and 78.7 cm respectively. Median for breakfast skipping was two days per week and the largest meal reported was lunch. Meal latency ranged from 0 to 13.5 hours. Median for night-time snacking was three days per week. Significant negative correlation was found between breakfast skipping and night eating and WC (rs= -0.126, p= 0.040) and (rs= -0.185, p= 0.002) respectively. Evening eating, latency and window as well as largest meal were not correlated with WC.

Conclusions: Our results showed altered chrononutrition behaviours among adults. Chorononutrition behaviours were mainly not correlated or exhibited low correlation with visceral adiposity. Further studies are warranted to investigate protective mechanism of chrononutrition toward fat metabolism.

PAB(T2)-114
A path to 'FAIR' Food Composition Data

Lucia Segovia de la Revilla[1,2], Thomas Codd[1], Fernanda Grande[3], Ana Moltedo[3], Louise Ander[1,4], Bridget Holmes[3]

1. School of Biosciences, University of Nottingham (UK), 2. Department of Population Health, London School of Hygiene & Tropical Medicine (UK), 3. Food and Agriculture Organization of the United Nations (Italy), 4. Centre for Environmental Geochemistry, British Geological Survey (UK)

Background and objectives: Food composition tables/databases (FCTs) are essential to assess population nutrient intake and inadequacy prevalence. Challenges in preparing and using FCTs include the lack of standardization in formats, food names, descriptions, and grouping; also food components (e.g. analytical methods, units, denominators). This impacts data reproducibility, interoperability and re-usability. Our objectives are to (1) apply open science approaches to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

generate human-readable and consistently formatted FCTs, and (2) openly share FCT processing scripts for re-use or adaptation. We thus aim to provide a first attempt to generate a 'FAIR' (findable, accessible, interoperable, reusable) FCT that will exemplify how this approach can be used.

Methods: A single global food composition table was previously developed to ensure consistent assessment of nutrient availability data for the FAO Supply Utilization Accounts. This work further focused on fish and aquatic products collated from thirteen previously selected FCTs. Items were evaluated and allocated standard fish codes and categories (e.g., FAO ISSCAAP, FAO ICS) food components to the FAO/ INFOODS components tagnames (Tagnames). Composition data with varying formats were imported, harmonised?, and combined, before being exported into a standard format. All the steps used scripts and functions created in 'R' software, in RStudio.

Results: Tagnames were provided in six FCTs, for the rest manual identification and renaming was needed which resulted in seventy-seven Tagnames covering available food components and nutrients. Sixteen Tagnames required recalculation (e.g., energy) or a combination of different tagnames, e.g. values for fat content were computed using mixed solvent extraction (FAT), continuous extraction (FATCE) or unknown (FAT-) analytical method values. Similarly, the content of vitamin B6 was obtained either from calculated by summation (VITB6C), analysed (VITB6A) or unknown origin (VITB6-).

Conclusions: Efficient and shared scripts for processing FCTs makes their re-use more readily accessible and traceable, exemplified here by a new fisheries micronutrient FCT drawing on data from thirteen distinct original FCTs. This approach can be extended to other nutrients, geographical regions? or food items to support users worldwide.

Nutritional status and dietary intake of ethnic minority students at boarding junior high schools in the region northern mountains in Vietnam

Duong Thi Thuy Truong[1], Trang Thi Huyen Tran[1], Van Thi Hong Tran[1]

1. Thai Nguyen University of Medicine and Pharmacy, Vietnam (Viet Nam)

Background: The nutritional status of students, including those of lower secondary school age, has also become a prominent public health issue that needs to be addressed in the current period. Currently, Vietnam is facing a double burden of nutrition. Besides the high prevalence of malnutrition in children and chronic energy deficiency in adults, the rate of overweight and obesity is increasing, leading to to change the pattern of morbidity and mortality.

Methods: A cross-sectional study was conducted from September 2019 to March 2020 in six mountainous areas of Northern Vietnam among 3172 ethnic minority school-aged children. The nutritional status of students was assessed according to the 2006 WHO Z-score classification for students aged 10 to 19 years. Use the food weight method to collected data on the actual total energy, nutrient composition in the dietary intake.

Results: The rate of undernutrition (BMI/age) of ethnic minority students was 5.3%. The rate of stunting (height/age) among ethnic minority students was quite high at 14.4%. The rate of zinc deficiency in students accounted for 66.7%. The rate of students with anemia accounted for 10.7% and the serum ferritin decreased compared to the prescribed threshold of 15.3%. The overall overweight and obesity rate (BMI/age) of ethnic minority students was 8.5%, of which the rate of overweight was 7.0% and obesity was 1.5%. Student's dietary intake was not balanced and reasonable.

Conclusion: It is necessary to strengthen nutrition interventions that are reasonable and appropriate to the socio-economic conditions of each locality in order to tackle the double burden of malnutrition among ethnic minority children.

PAB(T2)-116
National asessment of anemia and some micronutrient deficiencies among 6-59 month-old children in Vietnam

Nga Thuy Tran[1], Van Khanh Tran[1], Tu Song Nguyen[1], Tuyen Danh Le[1]

1. National Institute of Nutrition (Viet Nam)

Background and objectives: Assessing micronutrient status in children may also have the benefit of addressing the problems of micronutrient deficiencies with a unified programmatic approach on a public health scale. This study was conducted to assess the prevalence of anemia and deficiencies of vitamin A, iron and zinc in 5367 children 6-59 months of age representative for urban, rural and mountainous areas in Vietnam in 2019.

Methods: Hemoglobin concentrations were measured using HemoCue. Plasma ferritin was measured by enzyme linked immunosorbent assay. Plasma retinol concentrations were determined by high-performance liquid chromatography. Zinc was analyzed using a flame atomic absorption spectrophotometer using trace element-free procedures. Definitions of anemia, iron deficiency anemia, iron and zinc deficiencies are classified by the World Health Organization and the International Zinc Nutrition Consultative Group.

Results: Results showed that the prevalence of anemia among children aged 6-59 months was 19.6%, classified as mild

level of public health significant problem. The prevalences of anemia among children living in urban, rural and mountainous areas were, 17.9, 18.1 and 26.1%, respectively. The prevalence of pre-clinical vitamin A deficiency in children aged 6-59 months was 9.5%, classified as mild level of public health significant problem. Prevalence of serum zinc deficiency in children was 58.0% classified as severe level of the public health significant problem. The prevalences of zinc deficiency among children living in urban, rural and mountainous areas were, 49.6, 58.4 and 70.1%, respectively. 26.3% children had iron deficiency. 12.3% children had iron deficiency anemia.

Conclusions: Anemia and micronutrient deficiencies are common in Vietnamese 6-59 month-old children in urban, rural and mountainous areas. Implementing the most effective solutions to fight against micronutrient deficiencies and anemia in order to improve the micronutrient status of the groups at risk of micronutrient deficiencies in community is essential.

PAB(T2)-117
Underweight and bodyweight prediction equations using neck, calf and mid-upper arm circumferences in Malawian adult patients

Limbikira Wasambo[1]

1. University of Agriculture and Natural Resources (Malawi)

Background: Bodyweight is necessary in all the four steps of nutrition care process; assessment, diagnosing, nutrition intervention, and monitoring and evaluating of nutrition outcomes.

Problem statement: In Malawian public hospitals, unavailability of bed-scales in public hospitals to obtain weight in non-ambulatory patients deter the provision of dietetics services. Hence an urgent need to develop cutoff points and equations from measurements of body parameters that can be used to predict weight status.

Objectives: The study aimed at i) establishing the cut-off point of Mid-upper arm circumference (MUAC) equivalent to body mass index (BMI) <18.5 kg/m^2 in Malawian adult patients; ii) developing bodyweight prediction equations using neck, calf and MUAC in Malawian adult patients.

Methods: Anthropometric data of patients were collected using non-stretchable measuring tapes and Seca scale at Kamuzu Central and Mzuzu Central Hospitals through a cross-sectional study. Pearson correlations were conducted on the following variables weight, height, BMI, sex, age and neck, calf and mid-upper arm circumferences using SPSS version 24. Receiver operating curve in MedCalc version 20 was used to develop MUAC cutoffs for predicting underweight, and multilinear regression analysis was used to develop the equations.

Results: 513 subjects (56.1% females) participated. MUAC <22.4 cm correlated (r = 0.789) with BMI of <18.5 kg/m^2 in both gender, and simplified formulas of weight = (0.9*MUAC [cm] – height [m]) x height (m) x height (m) (for males) and (0.925*MUAC [cm] – height [m]) x height (m) x height (m) (for females) were developed.

Conclusion: In Malawian adult patients, MUAC cutoff point of <24.4 cm predicted underweight status than the current 23 cm for females and 24 cm for males. A height and MUAC based weight estimation equation is proposed for non-ambulatory Malawian adult patients where chair-scales are not available. Therefore, there is a need to validate the derived equation and the MUAC cutoff point for underweight with large population in Malawi.

PAB(T2)-118
Comparative study on the proximate analysis and nutritional composition of sweet potato (Ipomoea batatas) bread and wheat bread.

Taibat Motunrayo Oduneye[2], *Emmanuel Aanuoluwapo Oyebamiji*[1,2], *Jubilee Amajuoritse Ajemigbitse*[2]

1. University College Hospital Ibadan Oyo State Nigeria (South Africa), 2. University College Hospital,Ibadan (Nigeria)

Background and Objectives: Bread is one of the foods most consumed by individuals in the world. According to a study done by Bakery, Biscuit, and Pasta magazine in 2015, consumption of bread increased by 1.3% to 9.4M tones in Nigeria, rising for the fifth consecutive year after two years of decline. Overall, consumption saw a relatively flat trend pattern. The most prominent rate of growth was recorded in 2012 when the consumption volume increased by 2.4% year-to-year. Over the period under review, consumption attained the peak volume in 2015 and is likely to see gradual growth shortly. Sweet potato (Ipomoea batatas [L.] Lam) is a dicotyledonous plant belonging to the family Convolvulaceae. The plant bears white and purple sympetalous flowers and has large nutritious storage roots. Chronic diseases are the major cause of death and disability worldwide. In Nigeria, chronic diseases are projected to account for 24% of all deaths. At least 80% of premature heart disease, stroke, and type 2 diabetes, and 40% of cancer could be prevented through a healthy diet, regular physical activity. (W.H.O, 2015). Bread provides over half of the caloric intake of the world's population including a high proportion of the intake of carbohydrates, proteins, minerals, and vitamins. The aim of this project is to assess the nutritional composition of sweet potato bread compared to wheat bread.

Method: The sweet potato bread used to make the bread was sourced and bought at Bodija Market, Ibadan, Oyo state. Other ingredients including yeast, flour, sugar, butter, milk were

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

also bought at Bodija Market. The wheat bread was obtained at FoodCo, Bodija, Ibadan, Oyo State.

Result: Results of the proximate composition of the wheat bread, the highest proximate content was carbohydrate (56.13g/100g), followed by crude protein (9.22g/100g) while the least was crude fibre (0.31g/100g) followed by crude fat (1.57g/100g), while proximate composition of the Sweet Potato bread shows, carbohydrate (55.50g/100g), followed by crude protein (11.12g/100g) while the least was crude fibre (0.17g/100g) followed by crude fat (2.05g/100g).

Conclusion: The formation from both wheat and potatoes flour are a good source of nutrients that can be eaten by diabetes patients.

Keyword: Potatoes Flour, Wheat Flour, Diabetes, Non-commendable diseases

PAB(T2)-119
The effects of vitamin micronutrient beverage (VCRESC) on oxidation stress marker and values in healthy subjects

Akihiko Nakagawa[1], Kayo Yamamoto[1], Kingo Takeshita[1], Rituko Kimura[1]

1. Kanazawa medical University (Japan)

Background and objectives: 'Healthy Japan 21' outlines the need to consume more than 350g of vegetables per day to reach the recommended daily intake of vitamins. The goal of this research was to examine how a nutritional dietary supplement would affect vitamin values in a healthy subject.

Method: Twenty healthy subjects, (without history of disease) (n=20) consumed hospital vitamin supplement drinks (VCRESC 125ml) for the period of one month. Blood samples were taken before commencement of the study and again after the one month period. Subjects were not given any nutritional guidance and were encouraged to continue their usual daily diets.

Results: Blood vitamin B1, vitamin C significantly increased ($p < 0.01$). However, in both before and after consumption of supplements, blood vitamin C showed a lower value than the standard recommended range. Folic acid, Vitamin B6 and B12 involved in the metabolism of homocusteine (Hcy) showed correlation with Hcy and decreased significantly ($p < 0.01$). Antioxidant capacity test, urinary 8-iso-prostaglandin F2alpha (8-iso-PGF2alpha) and 8-OHdG showed significantly lower values ($p < 0.01$). Urinary 8-iso-PGF2alpha, 8-OHdG in urine showed a correlation ($p < 0.05$), CoQ10 oxidation quotient significantly decreased ($p < 0.01$). . With these results, there is a possibility that a healthy person may have insufficient intake of vitamins and minerals.

Conclusion: Through the long-term intake of a vitamin supplement drink, an overall antioxidant capacity improvement can be observed. However, if the original diet is unbalanced, it is possible that some nutrient scores will not improve.

Vitamin and mineral supplements are valuable to healthy persons, and will require further research on their uses in dietary management.

Evaluation of the effect of Moringa Oleifera in the prevention of low birth weight in Bamako en 2021

Djeneba Coulibaly[1,2], Yara Koreïssi Dembele[3], Fatou Diawara[1,2], Ousmane Boubacar Toure[4], Akory Ag Iknane[1,2,4], Rokia Sanogo[1,2]

1. Université des Sciences des Techniques et des Technologies de Bamako (USTTB) (Mali), 2. Institut National de Santé Publique (INSP) (Mali), 3. Institut d'Economie Rurale (Mali), 4. Organisation Mondiale de la Santé (OMS) (Mali)

Infant mortality remains high and worrying in developing countries, however the prevention of low birth weight could be one of the strategies that can contribute to the reduction of neonatal mortality. It is in this context that the present study on the use of Moringa Oleifera leaves in the prevention of low birth weight in Bamako was carried out.

An experimental study with three dynamic cohorts concerning 129 malnourished pregnant women under 7 months seen in prenatal consultation in three health centers of Bamako was conducted. They were divided between three supplementation protocols for nutritional recovery (protocol 1 based on enriched flour, protocol 2 based on Moringa powder and protocol 3 based on enriched flour plus Moringa powder). Newborn parameters were collected to compare the effectiveness of the three protocols. The ANOVA test was performed to compare the effect of protocols and logistic regression to identify factors associated with low birth weight with a significance level set at 5%. The study had the approval of the scientific and technical committee and the ethics committee of the National Institute for Public Health Research.

The majority of pregnant women were between 20 and 34 years old (65.89%). For 40.31% of the women in the study, no level of education was observed. Only 2.33% of women had made four prenatal consultations. The same percentage of women were on Vitablé (Group 1) and Moringa (Group 2) i.e. 34.88% and 30.23% were on Vitablé and Moringa (Group 3). The majority of births took place in a health center with 88.37% and 15.5% of newborns weighed less than 2500g. The male sex predominated with 54.26%. Vaginal delivery was 96.12%. It emerged from the multiple regression analysis that the age of the women and the presence of complications were significantly associated with the occurrence of low birth weight with respectively p=0.01 and 0.004. The mean birth weight did not differ significantly according to the protocol received (p=0.65).

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Locally available foods are avenues for sustainable solutions to combat maternal and child malnutrition and improve birth weight.

A simple and sensitive method for estimation of serum zinc using fluorophore

Puneeta Singh Yaduvanshi[1], Raghu Pullakhandum[1]

1. ICMR-National Institute of Nutrition (India)

Introduction: The essentiality of Zinc (II) in biological functions is associated with the regulation of gene expression, DNA synthesis and apoptosis and nutritional deficiency of this vital element leads to gastrointestinal problems, neurological disorders, growth impairment and immunodeficiency. The problems of zinc insufficiency are well known, still, we lack conventional and widely applicable markers for human zinc status. In the absence of better options, serum zinc is the best marker for zinc status to date. Assessment of cellular zinc pool in humans is mostly done by atomic absorption spectroscopy and by radioactive zinc. The fixed pool of zinc which is non-exchangeable and tightly bound to cellular proteins is difficult to analyze from these methods. Furthermore, the amount of sample used for analysis makes them less likeable indicators. Applications of fluorophores as Zn^{2+} identification tools have emerged as popular biological techniques. Zinquin, a Zn^{2+} specific fluorophore, binds to loose bound labile pool of zinc with a negligible affinity for other cellular trace elements and has been used for tissue studies. Zinquin has the potential to define the relationship between the distribution of labile Zn and the major iZn-binding protein, metallothionein. In this study, we have developed a simple Zinquin-based method for the quantification of serum zinc.

Materials and methods: Standard graph of Zn^{2+} against Zinquin was plotted at Ex/Em=364/490. Interferences of other trace elements such as Ca^{2+}, Fe^{2+}, Mg^{2+} and Cu^{2+} were also tested. Human serum samples (n=20) were treated with 4% Trichloroacetic acid in 1:1 ratio and protein was precipitated. Sample Zn^{2+} (n=80) was estimated and the concentration was quantified. Bland-Altman difference plot was used to compare data obtained from Atomic absorption spectroscopy and Zinquin method for the validation of the method.

Result: Dose-dependent titration of Zinc with Zinquin showed an inflection till it reaches equimolar concentration. (r^2=0.996). Evaluation of different metal ions with Zinquin revealed negligible interference on the binding affinity of Zn^{2+} and Zinquin. Measurements of Zinc in human serum samples were evaluated. Bland-Altman plot validates the degree of agreement of the method.

Conclusion: The developed Zinquin-based method is a simple and sensitive method for the quantification of serum zinc.

Assessing the association between occupational stress levels and the dietary intake and nutritional status of drivers on the University of Ghana campus

Junita Owusu[1], Barbara Boamah[1], Mercy Atakora[1], Husein Mohammed[1]

1. University of Ghana (Ghana)

Background: Work stress has been highlighted as a common occupational concern due to the pressure and increased demand for labour. Studies have shown that employee productivity and performance are heavily influenced by their dietary intake and nutritional state. Higher levels of stress have been linked to poorer eating habits, increased body weight, and thus, inadequate nutrition. This study aimed to determine the influence of occupational stress on the dietary intake and nutritional status of University Ghana drivers.

Methodology: The study was cross-sectional and involved 80 drivers from the University of Ghana, Legon campus. Semi-structured questionnaires were used to assess their occupational stress and the drivers' performance. A 7-day food frequency questionnaire was used to assess their dietary intake. Their anthropometric measurements (height and weight) were also assessed. Data were analyzed using SPSS version 26.0.

Results: 12.5% of the participants were obese, 38.8% were overweight and only 2.5% were underweight. Almost all the drivers (97.5%) had higher dietary diversity scores and only 28.7% of the drivers recorded high occupational stress. There was no association between dietary intake and occupational stress (p = 0.05). However, there was a statistically significant relationship between occupational stress and the nutritional status (BMI) of the drivers (p < = 0.02).

Conclusion: The drivers generally had adequate dietary intake and lower occupational stress. There was a significant relationship between occupational stress and nutritional status. This relationship was however not seen between occupational stress and dietary intake.

Keyword: Occupational Stress, Nutritional Status, Dietary Intake

Conflict of Interest Disclosure: The authors have no conflict of interest to report.

Measuring sodium intake from discretionary salt in New Zealand using the lithium-tagged salt method.

Nan Xin Wang[1], Rachael Mira McLean[1], Claire Cameron[1], Sheila Skeaff[1]

1. University of Otago (New Zealand)

Background and objective: A high sodium intake is associated with high blood pressure and cardiovascular disease. The amount of sodium from discretionary salt (added in the home or at the table) varies globally, and is unknown in New Zealand. The aim of this study was to estimate the proportion of total sodium intake from discretionary salt in adults using the lithium-tagged salt method.

Methods: Healthy males and females, who regularly consume home-cooked meals, use salt during cooking or at the table, are neither pregnant nor lactating, and aged 18–40 years living in Dunedin, New Zealand, were recruited into the study. Over a nine-day period, participants were asked to collect a baseline 24-hour urine sample (Day 1) to establish their normal lithium output. Discretionary salt was replaced with lithium-tagged salt for seven days. Another two 24–hour urine samples were collected between Day 6 and Day 8. Urinary sodium and lithium were analysed using the Ion–Selective Electrode method and the Inductively Coupled Plasma Mass Spectrometry method, respectively. All statistical analysis were conducted using Stata 17.0.

Results: Of the 116 participants recruited into the study, 109 participants collected complete 24–hour urine samples and were included in the analysis. The median urinary sodium excretion was 3222 mg/24 hours (25th, 75th percentile: 2516, 3969). We found that the median (25th, 75th percentile) estimated sodium intake from discretionary salt was 13% (7, 22) of total sodium intake or 366 mg/24 hours (186, 705).

Conclusions: In a group of healthy adults aged 18-40 years, we found that discretionary salt contributed to 13% of total sodium intake, similar to the United Kingdom and Denmark. Our finding confirms other studies finding that total sodium intake is high (above 2000 mg/day). A range of sodium reduction strategies is recommended. For example, food reformulation to reduce the amount of sodium added to processed foods, front of pack labelling to inform consumers of products high in sodium and public campaigns to promote the purchase of lower sodium products or use less discretionary salt.

Keyword: Sodium, Discretionary salt, New Zealand, Lithium-tagged salt, 24-hour urine

PAB(T2)-124
The serum vitamin D status of medical staffs and the effectiveness of high-dose vitamin D intervention

Xiaoyin Huang[1], Peirong Li[1], Shungsheng Tsou[1]

1. Tungs' Taichung MetroHarbor Hospital (Taiwan)

Background and objectives: Vitamin D is a fat-soluble vitamin, it involved in skeletal and extra-skeletal health. According to the survey in Taiwan, 25.9% of Taiwanese were vitamin D deficiency (<20 ng/mL). More studies indicated that vitamin D insufficient could increase the risk of upper respiratory tract infection. Medical staffs often work indoor and night shifts, they would easily to become a group of deficiencies if without proper vitamin D intake. The purpose of this study was to investigate the concentration of 25(OH)D and the impact of high-dose vitamin D intervention in medical staffs.

Methods: This study performed from April 2021 to September 2021, included medical staffs from Tungs' Hospital. If participants' 25(OH)D concentration above 20 ng/mL were assigned to normal group, those below 20 ng/mL were assigned to intervention group. Intervention group required daily intake high-dose vitamin D3 supplements (4000IU) for one month, and follow up again after one month without vitamin D3 intervention. All participants were taken blood sample. They were also surveyed using questionnaires with adverse effects of high-dose supplement and frequency of respiratory tract infections at the beginning, and those of intervention group at the end of the supplement and after one month without supplement.

Results: Total numbers of participants were 68, of which 55.9% had vitamin D deficiency. The mean baseline 25(OH)D level for all participants was 20.49±8.93 ng/mL, which was 14.91±3.33 ng/mL in intervention group and 27.57±8.79 ng/mL in normal group. In intervention group, the mean 25(OH)D levels increased significantly to 34.73±8.16 ng/mL (p<0.05), and which reduced to 28.81±6.79 ng/mL after one month without supplement. According to the questionnaire, short-time high-dose vitamin D3 intervention did not cause acute adverse effect. The frequency of respiratory tract infections decreased from 0.34±0.81 to 0.14±0.42 times/person per month, but it was no statistical difference (p = 0.22).

Conclusions: Our study showed that the prevalence of vitamin D deficiency was higher among medical staffs than in Taiwan (55.9% vs. 25.9%). For vitamin D deficient person, short-time high-dose vitamin D3 intervention could significantly increase 25(OH)D levels and not cause acute adverse effect. However, the relationship with respiratory tract infections would need further study.

Keyword: vitamin D, vitamin D deficiency, medical staff, high-dose vitamin D3 supplementation

How accurate are self-reported anthropometrics among Japanese? A scoping review

Tomoko Aoyama[1], Xiaoyi Yuan[1], Mai Matsumoto[1], Emiko Okada[1], Ryoko Tajima[1], Chika Okada[1], Hidemi Takimoto[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Background and objectives: Weight and height are frequent measures in nutritional surveillance to assess the population prevalence of obesity. The recent COVID-19 outbreak has increased the need for using self-reported anthropometrics. Its accuracy has often been discussed in the context of assessing overweight/obesity (body mass index, BMI >25.0 kg/m^2). Although previous reviews reported underestimation of obesity prevalence by self-report, little is known about its accuracy in populations where underweight (BMI <18.5 kg/m^2) is also a public issue. Therefore, we aimed to conduct a scoping review on the accuracy of self-reported versus measured anthropometrics in Japan where obesity and underweight problems coexist.

Methods: A literature search was conducted using CiNii Research and PubMed. Studies published in English or Japanese between January 1990 and April 2022 were screened. We included studies conducted in Japan comparing self-reported and measured values of height, weight, and/or BMI. Study design and major outcomes based on observations (e.g., men and women) in each study were extracted and tabulated.

Results: A total of 17 publications (11 in English, 115 total observations) were included in this review, conducted in nationwide cohort settings (n = 4), local communities (n = 4), workplaces (n = 3), and educational institutions (n = 6). The participants' ages (10–91 years) and sample sizes (<100–<30,000) varied across studies. All the studies included the mean differences between self-reported and measured values, showing that the overall tendency for height to be overreported (20/35 observations), weight to be underreported (24/33 observations), and BMI to be underestimated (27/31 observations). Twelve observations included the percentage of misclassification when using BMI based on self-report; 0–40% of overweight/obese and 0–32% of underweight were misclassified to the normal BMI category (18.5–24.9 kg/m^2), while 0–5% and 0–10% of normal BMI was misclassified to the overweight/obesity and underweight, respectively. Four observations showed that weight was more commonly underreported in overweight/obese, but was overreported among underweight people.

Conclusions: Both underweight and overweight/obese individuals are prone to inaccurate reporting, which can underestimate the prevalence of underweight and overweight/obesity. This should be considered in nutritional surveillance using self-reported anthropometrics

Keyword: self-reported, weight, height, body mass index, accuracy

Intra- and Interindividual variability in postprandial blood Amino Acid kinetics in healthy young adults after ingestion of a good and a moderate digestible protein source

Marco Mensink[1], Els Oosterink[1], Nikkie van der Wielen[1], Ron Wehrens[1], Jurriaan Mes[1], Esser Diederik[1]

1. Wageningen University & Research (Netherlands)

Background and objectives. Measuring postprandial blood amino acids levels is a relatively easy method used to characterize the quality of a protein source. However considerable individual variation in postprandial amino acid kinetics can be expected due to, amongst others, differences in an individual's digestion and absorption capacity. Therefore, this study aimed to quantify the variation in postprandial AA profiles *between* and *within* individuals after consumption of a good (whey) and moderate (lucerne) digestible protein source.

Methods. In this randomised, cross-over, double-blind trial 18 healthy adults consumed a 20 g protein drink on five occasions. Three times an identical lucerne drink and two times whey, in random order. Blood was collected before and up-to five hours after protein consumption. Blood amino acid kinetics of free amino acids were calculated as Area Under the Curve (AUC), maximum peak height, and time to peak, using an AA response package in R.

Results. On average, lucerne was associated with ~50% lower postprandial AA AUC, a lower peak height and a delayed time to peak compared to whey. However substantial variation *between individuals* was observed, with AUC for whey being 2.1 times higher for the highest versus the lowest subject for total AA (TAA) and 1.7 times for essential AA (TEAA). For lucerne these differences were 3.1 and 2.4 times respectively. Also substantial *within individuals* ('day-to-day') variation was seen, with intra-individual variation being lower than inter-individual variation for whey, but both being of a similar magnitude for lucerne. Finally, there was little-to-no correlation between the response (AUC) on the two proteins sources (r<0.20); in other words those with a high AUC for one protein source were not necessarily those with a high AUC for the other protein source.

Conclusions. Postprandial AA levels after ingestion of 20 gram protein showed substantial variation *between* individuals, as well as *within* individuals. This appeared to be larger for a moderate digestible protein, i.e. lucerne, compared to whey. These results indicate that individual variation in protein uptake kinetics should not be neglected and insights in this variation is warranted to support future optimized protein intake advice to prevent deficiency.

Prognostic Nutritional Index at admission As Predictor of Body Weight Loss and Swallowing Dysfunction at discharge in Older Adults Inpatients

Yoko Hokotachi[1,2], Ayako Tsunou[3,2], Hiroyo Miyata[4,2], Teruyoshi Amagai[5,2]

1. Takarazuka-Daiichi Hospital (Japan), 2. Mukogawa Women's University (Japan), 3. Kitauwa Hospital (Japan), 4. Kindai University Hospital (Japan), 5. Jikei University of Health Care Sciences (Japan)

Background: Older adult inpatients, diagnosing sarcopenia or frailty is determining procedures of mortality or outcomes, partly because body composition assessments measured by radiological modality such as computed tomography (CT), magnetic resonance imaging (MRI), ultrasonography (US), or dual-energy X-ray absorptiometry (DEXA) that must interfere social distances in COVID-19 circumstances.

Hypotheses: Under such conditions, we hypothesized that: 1) prognostic nutritional index (PNI) is predictor of body weight (BW) change during hospitalization in older adult inpatients (pts) ≧ 65 years old. 2) BW loss is associated with muscle depletion not only in legs but also swallowing muscles.

Aims: To test our hypothesis that pts who showed BW loss at discharge must have impairment of swallowing capacity and poor outcome and that these pts must be predicted by low PNI score and to be target of nutritional interventions at admission, we have conducted this study.

Methods: Participants was sequentially recruited to all inpatients. The exclusion criteria were: shorter stay in hospital. To measure swallowing capacities in recruited pts, Functional Oral Intake Scale (FIOS) and International Dysphagia Diet Standardization Initiative Functional Diet Scale (IDDSI-FDS) for scaling diet textures objectively were applied.

Results: The recruited pts counted 95 cases. Body size and CCI of two groups were similar. PNI score at admission in group with BW loss was significantly smaller than in without group (39.0 vs. 43.6, p=0.040). BW loss group had swallowing dysfunction shown by FIOS and IDDS scores. The cutoff value of PNI among participants to predict BW loss at discharge was 40 determined by ROC curve analysis.

Conclusions: PNI as surrogate biomarker seems to predict BW loss at discharge and swallowing dysfunction in older adult inpatients ≧ 65 years. The cutoff value of PNI was determined 40.

Correlation between energy and vitamin A intakes and their dietary factors among Rwandans

Hiroka Sato[1], Noriko Sudo[1], Sayaka Nagao-Sato[1], Ayumi Yanagisawa[1], Yukiko Amitani[1], Yuko Caballero[2], Makiko Sekiyama[3], Takuya Matsuoka[4], Takayo Sasaki[4], Hirotaka Matsuda[5]

1. Ochanomizu University (Japan), 2. Utsunomiya University (Japan), 3. National Institute for Environmental Studies (Japan), 4. World Vision Japan (Japan), 5. Tokyo University of Agriculture (Japan)

Background and objectives: Vitamin A is present in different types of food. In industrialized nations, the major sources of vitamin A are animal foods, which are also high in energy. However, as diets in developing countries are plant-based and they rarely eat animal foods, energy and vitamin A intakes may not be positively correlated. In this study, we examined the correlation between energy and vitamin A and the background food consumption patterns observed among Rwandan villagers.

Methods: Energy and vitamin A intakes were calculated using 147 one-day weighed food records (WFRs) collected from 14–70-year-old 36 males and 59 females in rural eastern Rwanda.

Results: No significant correlation between energy and vitamin A intakes was observed for either sex. Matooke green banana was the largest contributor to vitamin A and energy intakes, accounting for about half of all intakes in both sexes. It was consumed in the largest amount among the participants. Because of its high vitamin A content, sweet potato was the second largest contributor to vitamin A, but its contribution to energy intake was only 6.0% for males and 4.9% for females. They barely consumed retinol sources, and milk's contributions to both energy and vitamin A intakes were around 2%.

Conclusions: Although a significant correlation between vitamin A and energy intakes was unobserved, matooke green banana, which is neither an animal food nor a vitamin A-rich food, was consumed much and was the main contributor of both vitamin A and energy intakes among Rwandans.

Keyword: correlation, energy, Rwanda, vitamin A, weighed food record

Select nutritional problems among adolescent girls in an urban resettlement colony, New Delhi- a mixed method cross-sectional study

Archismita Santra[1], Sanjay Kumar Rai[2], Puneet Misra[2], Kapil Yadav[2], Kiran Goswami[2], Gurdeep Kaur[2]

1. All India Institute of Medical Sciences, Raipur (India), 2. All India Institute of Medical Sciences New Delhi (India)

Background and objectives: In India, 39.7% of adolescent girls are thin by WHO-BMI criterion and 59.1% girls are anaemic while about 5.4% girls are overweight according to NFHS-5. CNNS-2021 however shows 18.9% adolescent girls to be thin and 4.7% to be overweight / obese by WHO BMI-for-age. Several studies have been done regarding nutritional status of adolescent girls over the years which have reported wide range of prevalence of malnutrition. We assessed the prevalence of malnutrition and anemia amongst adolescent girls, and association of malnutrition with various socio-demographic factors and other variables.

Methods: 426 adolescent girls were selected using simple random sampling from the MIS of CCM, AIIMS, New Delhi. Semi-structured questionnaire was administered among 386 of them. Height, weight, MUAC, haemoglobin (by HemocueHb301) were measured. 24 hour dietary recall was done among 386 girls and food frequency questionnaire was also administered among 94 participants. For qualitative study four FGDs were conducted among Anganwadi workers, mothers and adolescent girls.

Results: By WHO BMI-for-age criteria, 18.9% (95%CI 15.1-23.2) were underweight and 10.6 % (95%CI 7.7-14.1) overweight and 3.9% (95%CI 2.2-6.3) were obese among 386 girls. With WHO-BMI as an indicator, the prevalence of thinness was 51.8% (95%CI 46.9 – 56.9), overweight was 10.6% (95%CI 5.7 – 11.5) and obesity was 1.0% (95%CI 0.2 – 2.6). Prevalence of anemia was 64.2% (95% CI 59.2-69.0); 29.8% (95% CI 25.3-34.6) mild, 32.6% (95% CI 28.0-37.6) moderate and 1.8% (95% CI 1.0-3.7) severe. BMI-for-age strongly correlated with MUAC-for-age (r=0.7). MUAC-for-age was significantly associated with calorie consumption (p = 0.004). 73% and 68% girls respectively consumed aerated drinks and chips weekly. On multivariable logistic regression, having low birth weight (OR 2.2, 95%CI 1.2-4.2, p value 0.02) and calorie deficiency (OR 6.0, 95%CI 1.7-21.8) were significantly associated with under-nutrition by BMI-for-age z scores. Anemics had 70% lower odds of having over-nutrition (OR 0.3, 95%CI 0.2-0.6, p value 0.001). Qualitative analysis revealed that the main reason behind malnutrition is perception about own body image and preference for fast foods.

Conclusion: Malnutrition and anaemia continued to be the major public health challenges amongst adolescent girls in urban resettlement population.

Serum undercarboxylated osteocalcin levels in stunted and non-stunted Filipino children and the association with growth

Imelda Angeles Agdeppa[1], Cristina Garcia Malabad[1], Ma. Lynell Valdeabella Maniego[1], Meng Thiam Lim[2], Dieu Huynh[2]

1. Food and Nutrition Research Institute (Philippines), 2. Abbott Nutrition Research and Development (Singapore)

Background and objectives: Vitamin K is a cofactor to γ-glutamyl carboxylase, an enzyme that carboxylates (activates) osteocalcin. Carboxylated osteocalcin binds to calcium and transports it into the bone, thus facilitating mineralization. High circulating levels of undercarboxylated osteocalcin (ucOC) may indicate vitamin K inadequacy. There is currently a lack of data on the serum content of ucOC in Asian children. This study determined the serum ucOC levels among children in the Philippines, and its association with linear growth.

Methods: Data and serum samples of stunted (n= 174) and non-stunted (n=176) children aged 1 to <5 years from the 2019 Expanded National Nutrition Survey were utilized. Weight and height were measured using standard techniques. Dietary intake was collected using a 2-day non-consecutive 24-hour food recall. Usual energy and nutrient intakes were estimated using PC-Software for Intake Distribution Estimation (PC-SIDE) Program. Socio-economic and demographic data were collected via interview-administered questionnaires. Serum ucOC content was measured using enzyme-linked immunosorbent assay (ELISA) kits. Multiple linear regression analyses were conducted to determine the association of serum level of ucOC with linear growth, as indicated by height-for-age z-scores (HAZ).

Results: The overall median serum concentration of ucOC was 18.9 ng/ml. Median serum ucOC was higher in stunted children compared to non-stunted children (26.9 ng/ml vs. 16.4 ng/ml, p = 0.0379). Intakes of protein, phosphorus, and calcium that promote bone development were significantly higher ($p<0.05$) among non-stunted than stunted children. In the energy-adjusted multiple linear regression model, serum levels of ucOC were found to be significantly associated with HAZ. An increase of 0.37 HAZ (p=0.04) was observed at the lowest tertile of serum ucOC (1.1 – 13.8 ng/ml). Dietary iron intake, hemoglobin values, wealth index, and mother's work status were also significantly associated with HAZ.

Conclusion: The higher serum ucOC concentration seen among stunted kids suggests that these children may not consume sufficient vitamin K to support optimal bone development. As vitamin K is known to be a key nutrient for bone health, ensuring an adequate intake of this vitamin along with other bone-building nutrients should not be overlooked, especially during childhood.

Keyword: stunting, linear growth, children, Philippines

Sources of dietary vitamin D and determinants for vitamin D status during pregnancy in the Norwegian Mother, Father and Child Cohort Study

Anna Amberntsson[1], Linnea Bärebring[1], Anna Winkvist[1], Lauren Lissner[1], Helle Margrete Meltzer[2], Anne Lise Brantsæter[2], Eleni Papadopoulou[2], Hanna Augustin[1]

1. University of Gothenburg (Sweden), 2. Norwegian Institute of Public Health (Norway)

Background and objectives: The determinants of plasma 25-hydroxyvitamin D [25OHD] differ between countries due to differences in latitude, cultural habits, and fortification and supplement policies. There is a need to better understand the contribution of dietary vitamin D intake as determinant of 25OHD in pregnant women in Norway. The aims of this study were to (1) describe the sources of dietary vitamin D, and (2) investigate determinants of 25OHD, in pregnant women in Norway.

Methods: This study is based on data of 2960 women participating in The Norwegian Environmental Biobank, a sub-study within the Norwegian Mother, Father and Child Cohort Study. Total vitamin D intake (foods and supplements) was estimated from a food frequency questionnaire in gestational week 22. Plasma 25OHD in gestational week 18 was analyzed by chemiluminescent microparticle immunoassay. Other covariates were collected by questionnaires in gestational weeks 15 and 30. Multivariable linear regression analysis investigated the determinants of 25OHD, and restricted cubic splines predicted response in 25OHD by total vitamin D intake in a linear regression.

Results: Median (interquartile range) vitamin D intake was 3.1 (2.1-4.3) µg/day from foods, and 5.2 (2.6-10.0) µg/day from supplements. Major sources of vitamin D were supplements (66%), fish (14%), and fortified margarine (10%). Intake of supplements and margarine, but not fish, differed between women with different 25OHD concentrations. Significant determinants of 25OHD were higher total vitamin D intake, lower energy intake, summer season, high income country of origin, higher education, lower pre-pregnancy BMI, higher age, lower c-reactive protein, solarium use and non-smoking during pregnancy. Together, these variables explained 24% of the variation in 25OHD. From October to May, a total vitamin D intake >8-10 µg/day seemed sufficient for most to reach 25OHD >50 nmol/L. From June to September, 25OHD was sufficient regardless of vitamin D intake.

Conclusions: Vitamin D supplements and fortified margarine are important contributors to total vitamin D intake and to maintain sufficient concentrations of plasma 25OHD, especially during the winter, in pregnant women in Norway. The available determinants explained 24% of the variation in 25OHD.

Nutrient intake and nutritional inadequacy of Khasi tribal children (1 to 9 years old) of West Khasi Hills, Meghalaya, Northeast India.

Ananthan Rajendran[1], Daniella Anne Laitiam Chyne[2], Subhash Kalpuri[3], Sreedhar Mudavath[4], T Longvah[5]

1. ICMR-National Institute of Nutrition (India), 2. St Aloysius College (India), 3. ICMR-National Institute of Nutrition (India), 4. ICMR-National Institute of Nutrition (India), 5. ICMR-National Institute of Nutrition (India)

Background and objective: Around 104 million indigenous tribal people reside in India. Their food intake is usually influenced by their peculiar habitat, with large seasonal variations depending on availability and accessibility. As the indigenous people of Northeast India have not been thoroughly investigated on their ecosystem in relation to nutritional status, we investigated the prevalence of nutritional status and nutrient inadequacy of the Khasi tribe of Meghalaya who are the fifteenth largest tribe in India.

Methods: Sample size was calculated by a random sampling procedure using 42% prevalence of stunting, with 5% precision and 95% confidence interval. Out of 1109 households included for the study, 499 children were estimated to cover for this study. Household food and nutrient intake conducted in the subsamples of 25% households where, 24-hour recall method used to record food intake and the nutrients. Dietary adequacy and Estimated Energy Requirements (EER) using appropriate methods. Probability of adequacy (PA) of 11 micronutrients were calculated using estimated average requirements (EARs).

Results: Median intake of macronutrients protein, fat, carbohydrates and fiber significantly increased across the age group. Protein intake in 1–3 years age group found significantly higher in girls (32.52 g/day) than boys (28.98 g/day). No significant difference observed on the median intake of fat, fiber, vitamins between boys and girls. The median intakes of vitamins such as among boys and girls of 1–3, 4–6 and 7–9 years was not significantly different. However, significant median intake difference of iron and zinc observed between boys and girls. The daily median energy intakes among the age groups of 1–3, 4–6 and 7–9 was 1291, 1481, and 1762 kcal/day respectively. The lowest PA was observed for micronutrients in both the genders and no significant difference of MPA between the gender.

Conclusions: This study is vastly explorative and has generated many components that need future and interventional research related to food and nutrition. Nutritional status in terms of probability adequacy have studied in Khasi tribes of Meghalaya and found low. Similar studies also can be conducted other tribal population of India to understand their nutritional status.

Barriers influencing effective and efficient vitamin A supplementation (VAS) during the Maternal and Child Health Nutrition Action Week (SASNIM) in Cameroon

Ndjebayi Ongla Marco Alex[1], Ulrich Brice Saha[2], Ngnie Ismael Teta[1], M Melissa Baker[1]

1. Helen Keller International (Cameroon), 2. University of Bamenda (Cameroon)

Background and objective: During the bi-annual Maternal and Child Health Nutrition Action Weeks (SASNIM) in 2021, coverage of Vitamin A Supplementation (VAS) among children aged 6-59 months, fell below the national target of 80%. In this study, we used a bottleneck analysis approach to identify the barriers to effective and efficient delivery of VAS through SASNIM.

Methodology: This study was conducted in the Centre, Littoral, East, Adamawa, North and Far-North regions of Cameroon, using a descriptive mixed-methods design. Sources of information were grey literature (~80 planning, financial and implementation-related documents), semi-structured interviews (125) with key stakeholders from the central, regional, district, health and community levels, and focus group discussions (18) with community distributors, and caregivers of children aged 6-59 months. A quantitative survey was conducted among 3616 caregivers of children aged 6-59 months.

Results: Only 67.7% of target children aged 6-59 months received VAS in the first semester SASNIM in May 2022. The main bottlenecks identified in the SASNIM were inefficiencies in coordination and micro-planning. The dependence on partner funding impacts the governments' ability to plan and coordinate the SASNIM, as funding is generally received late which causes inefficiencies in program management and delays the operationalization of critical activities such as leveraging appropriate communications resources and having sufficient community sensitization prior to the SASNIM. Inefficiencies in micro-planning including inaccuracies in target population estimation, late arrival of supplies and vitamin A capsules, and delayed training and availability of data collection tools, which can result in overlooked critical populations, misallocation of staff and supplies, and poor data management and improperly calculated coverage estimates.

Conclusion: Key stakeholders in Cameroon will explore the bottlenecks further and identify possible remedial approaches for coordination, micro-planning, procurement of supplies, data collection training and tool preparation, and take the necessary steps to test proposed interventions to overcome the bottlenecks identified.

PAB(T2)-134
Reportsof Dietary Supplement Product Use and Nutrient Intakes Among Dietary Supplement Users Varies by Dietary Assessment Method

Alexandra Elizabeth Cowan[1], Janet A Tooze[2], Regan L Bailey[1]

1. Texas A&M University (USA), 2. Wake Forest University School of Medicine (Uruguay)

Background and Objectives: Reliable dietary assessment instruments for assessing total nutrient intake (i.e., foods/beverages + dietary supplements (DS)) are critical for nutrition monitoring; yet different tools vary in their robustness for assessing dietary intake, and much is unknown about how these tools perform when measuring DS intake. The Interactive Diet and Activity Tracking in AARP (IDATA) cohort study was designed to evaluate the validity of 24-hr dietary recall (24HR) and Diet History Questionnaire (DHQ) II data, inclusive of DS. This study aimed to compare DS data reported on ≧2 24HRs and the DHQII from the IDATA study among U.S. adults (50-74y; n=795).

Methods: DS information was collected over 12 months among IDATA participants who completed ≦6 Automated Self-Administered 24HRs (ASA24s) and 2 DHQIIs which queried information on DS usage, frequency, and amounts taken. Prevalence of DS use, mean calcium and vitamin D intakes, and intakes per consumption day from DS (by source and sex) among DS users were compared between the 2nd DHQ II and the average of ≧2 ASA24s using paired t-tests; significance was set at $p<0.0083$.

Results: Most U.S. adult DS users who participated in IDATA reported DS use on the DHQ (84%) and on ≧2 ASA24s (84%). Among the DS products reported on ≧2 ASA24s and the DHQII, agreement between the methods ranged from slight ($\kappa=0.06$; multivitamin) to substantial ($\kappa=0.70$; calcium and vitamin D). Mean calcium intake primarily originated from the diet and calcium and vitamin D DS, but intakes were not significantly different between methods for either sex. For vitamin D, a large proportion of intake originated from DS (i.e., single vitamin D) and intake varied significantly between the DHQ (8.9-9.5 mcg/d) and ≧2 ASA24s (18.7-24.9 mcg/d), regardless of sex ($p<0.0001$). Mean consumption day intakes for vitamin D were significantly higher on ≧2 ASA24s (24-45 mcg/d) than on the DHQII (11.6-14.1 mcg/d) for both sexes ($p<0.0001$).

Conclusions: Currently, the best method for measuring intake from DS is unclear. The comparability of 24HRs and FFQs in estimating the prevalence of use of and nutrient intakes from DS varies by nutrient, source, and DS product types consumed.

Thiamine diphosphate predicts erythrocyte transketolase activation coefficient among young hospitalized children with suspected thiamine deficiency, their mothers and a community-based comparison group in northern Lao PDR

Sonja Y Hess[1], Taryn J Smith[1], Kerry Jones[2], Charles D Arnold[1], Dalaphone Sitthideth[3], Xiuping Tan[1], Kenneth H Brown[1], Sengchanh Kounnavong[3]

1. University of California Davis (USA), 2. University of Cambridge (UK), 3. Lao Tropical and Public Health Institute (Laos)

Background and objectives: The correlation among different biomarkers of thiamine status and their relationship with clinical signs of thiamine deficiency disorders (TDD) remain uncertain. The present analyses explore correlations between two biochemical indicators of thiamine status among young children and their mothers in Lao PDR.

Methods: Hospitalized children (ages 21 days – <18 months) were eligible, if they presented with symptoms suggestive of TDD. Children were enrolled in a community-based comparison group, frequency-matched by age, sex and residence. Mothers of enrolled children were eligible for participation. From children and women, venous whole blood thiamine diphosphate (ThDP) was determined by HPLC, and erythrocyte transketolase activation coefficient (ETKac) was assessed by UV spectrophotometer in washed erythrocytes. Associations between biomarkers were assessed using Spearman correlations, and a ThDP cutoff corresponding to ETKac >1.25 was explored using area under the receiver operating characteristic curve (AUROC), with optimal cut-offs selected via the closest-to-(0,1) corner cut-point approach.

Results: Thiamine biomarkers were available for 626 children (mean±SD age 4.5±3.4 months; 58.9% male) and 655 women (24.7±6.4 years). Median (IQR) ThDP and ETKac were 79.8 (48.2, 144.0) nmol/L and 1.21 (1.06, 1.42), respectively, among the 395 hospital children, and 64.7 (50.0, 87.8) nmol/L and 1.22 (1.12, 1.37) among community children. ThDP and ETKac were 71.0 (55.5, 88.1) nmol/L and 1.29 (1.17, 1.43) among mothers of hospitalized children, and 73.6 (54.6, 94.6) nmol/L and 1.23 (1.15, 1.30) among community mothers. ThDP and ETKac were well correlated in hospital (r=-0.84) and community children (r=-0.64), and less strongly in their mothers in the hospital (r=-0.51) and community (r=-0.19) cohorts. Among all children, ThDP was strongly predictive of an ETKac cutoff of >1.25 with an AUROC of 0.88; a ThDP cutoff of 67 nmol/L had a sensitivity of 0.80 and specificity of 0.81. Among all women, ThDP predicted the ETKac cutoff of >1.25 with an AUROC of 0.67 with a proposed ThDP cutoff of 74 nmol/L (sensitivity 0.67; specificity 0.62).

Conclusions: Whole blood ThDP was predictive of ETKac in young children and their mothers. Assessment of ThDP by HPLC is simpler than measuring ETKac, so may be more useful for population assessment.

Application of a Questionnaire Analysis to Identify the Correlation between Dietary Habits and Covid-19 Diagnoses

Hsiao Chih Wu[1], Xin Yu Cai[1]

1. Pingtung Christian Hospital, Pingtung (Taiwan)

Background and objectives: In the past few years, Covid-19 has spread globally. Meanwhile, it is understood that dietary habits play an important role in human immunity. Therefore, it is hoped that by conducting a questionnaire analysis on dietary habits, a correlation between nutrients and Covid-19 diagnoses can be identified.

Methods: From June to August, 2022, the nutrition clinic recruited 30 participants who were Covid-19 positive and 30 who were negative. The participants were asked to fill in an online dietary questionnaire to analyze their dietary habits over the previous month. The results of the systematic analysis include the proportion of three main nutrients (carbohydrates, lipids, and proteins), the minerals calcium, phosphorus, iron, magnesium, and zinc, and vitamins A, D, E, B-complex, and C. The survey results were compared using the Student's *t* test and Pearson Correlation analysis.

Results: During the study period, data were collected from a total of 60 people, including 31 females and 29 males, with an average age of 54.7±17.6. The results show that the dietary intake of vitamin B2, B6 and the protein/body weight ratios of the Covid-19 positive participants was significantly lower than that of the negative participants (*P*><0.05). In the correlation analysis, protein/body weight ratios had a significant positive correlation with phosphorus, iron, zinc, vitamin D, E and B complex vitamins. Vitamin B2 and B6 had a significant positive correlation with magnesium, zinc, vitamin D, E, and C.

Conclusions: Adequate intake of protein and foods rich in B-complex is very important. They can effectively improve the human immune system and are expected to reduce the diagnosis rate of Covid-19.

Keyword: Covid-19, Protein, Vitamin B-complex

PAB(T2)-137

Correlation of nutritional status with *Clostridium difficile* infection in inpatients: A four-year (2017-2021) retrospective study

Chu-Hsuan Hsia[1,2], Hsiu-Yueh Su [2], Yi-Wen Chien[1]

1. Taipei Medical University (Taiwan), 2. Taipei Medical University Hospital (Taiwan)

Background and objectives: *Clostridium difficile* infection (CDI) is increasingly common in health-care facilities, and represents 10-25% of antibiotic-associated diarrhea (AAD). Few studies performed that CDI is significant cause of nosocomial diarrhea in Taiwan. The awareness of CDI is increasing recently, but due to the lack of prognosis and risk factors may lead to misdiagnosis. Moreover, limited studies discussed about the association between nutrition status and CDI incidence. Therefore, an retrospective study was conducted to analyze the association of CDI incidence and the possible related risk factors.

Methods: Adult patients (age > 18 yr.) that has detected *C. difficile* toxin in fecal samples in between January 1, 2017 to December 31, 2020 was recruited for this study. The following data were collected through the Taipei Medical University Hospital database, including demographic data (age, gender, height, weight and length of hospital stay), historic data (comorbidities, nutrition status, intensive care units admit, nutrition route and nutritional intake) and laboratory data. The association between CDI and ICU admission and comorbidities was analyzed using spearman correlation, nutrition intake between patients with or without ICU admission was analyzed using unpaired *t*-test.

Results: Among 2616 stool samples were detected, a total 188 cases were identified as CDI. The total incidence rate was 7.1%. The mean age was 69.1± 17.2 yr. 24.5% cases were admitted to ICU prior development of CDI. The mean score of nutrition risk screen score 2002 (NRS 2002) were 3.2 ± 1.7. The length of hospital days was 33 ± 32.5 days. The length of hospital stays was found modestly correlated with age (r=0.14, p <0.05), ICU admit prior development of CDI (r=0.25, p <0.01) and having pulmonary disease (r=0.16, p<0.05). There was no found of correlation between nutrition status and the length of hospital stay. Patients without ICU admission history showed significantly higher calorie and protein intake percentages than those with ICU admission.

Conclusions: Incidence rate of CDI was found positively correlated to admission of ICU, the length of hospital stay, and aged. CDI patients was found to have moderate nutrition risk, though the correlation with the length of hospital stay was not found, but actual calorie and protein intake was affected by ICU admission.

PAB(T2)-138

Development of a comprehensive food composition database for Australian-grown horticultural commodities

Lucinda J Black[1,4], Judy Cunningham[1], Paul Adorno[2], Stuart Johnson[3], Eleanor Dunlop[1]

1. Curtin University (Australia), 2. National Measurement Institute (Australia), 3. Ingredients by Design (Australia), 4. Curtin Health Innovation Research Institute (CHIRI) (Australia)

Background and objectives: The Australian agricultural industry supplies a wide range of horticultural commodities to domestic and international markets. Food composition data can be used to highlight the nutritional content of plant foods; however, many of the relevant data reported in the Australian Food Composition Database (AFCD) were generated up to 30 or more years ago, and may not be representative of produce currently available. Hence, we aimed to develop a comprehensive, nationally representative, food composition database for Australian-grown fruit, vegetable, and nut commodities.

Methods: Data gaps in existing AFCD data (missing/outdated data) were determined for 92 commodities identified as priority commodities by industry stakeholders. Samples were purchased at the peak of their growing season across Sydney, Melbourne and Perth between June 2021 and May 2022, and prepared as they would be consumed (e.g., trimmed, peeled, de-seeded). All nutrients were measured at the National Measurement Institute of Australia (NMI), with the exception of dietary fibre, starch, vitamin B7 and folate, which were measured by specialist laboratories in Australia. Raw samples were analysed, with the exception of chestnuts, which were baked, and mushrooms and eggplant for which cooked and raw samples were analysed. For other foods that may be consumed cooked, nutrient concentrations were estimated using weight change and nutrient retention factors. Vitamin C was measured in individual samples in most cases; for other nutrient components, a composite sample of each commodity was analysed.

Results: A total of 932 primary samples were purchased (6-19 samples per commodity) and analysed as 349 individual samples for vitamin C and as 102 composite samples for other components. The database covers up to 148 nutrient components in 151 raw and cooked food entries (fruit/vegetables n=147; nuts n=4).

Conclusions: This study has provided new composition data for Australian horticultural commodities that are representative of current growing practices, climatic conditions, preferred varieties, and analytical methods. The data will be incorporated into future releases of the freely available AFCD. The data will allow industry stakeholders to identify and promote commodities for their nutrient content, and will provide a valuable resource for health professionals, research and the general public.

Increasing the knowledge base on aquatic foods: Expanding and updating the FAO/INFOODS Global Food Composition Database for Fish and Shellfish

Doris Rittenschober[1], Fernanda Grande[1], Sitilitha Masangwi[2], Yuko Nanjo[3], Molly Brynne Ahern[1], Fabio Consalez[1], Marian Kjellevold[4], Christina Hicks[2], Philippa Cohen[5], Bridget Anna Holmes[1]

1. Food and Agricultural Organization of the United Nations (FAO) (Italy), 2. University of Lancaster, Lancaster Environment Centre, Lancaster University, Lancaster, UK (UK), 3. Ministry of Agriculture, Fisheries, Forestry, Japan (Japan), 4. Institute of Marine Research, Bergen, Norway (Norway), 5. Worldfish, Penang, Malaysia (Malaysia)

Background and objectives: quatic foods — animals, plants and algae harvested from freshwater and marine environments — supply protein to over 3.2 billion people, are a key source of essential micronutrients for many urban, rural and indigenous communities. Despite their contribution to food systems globally, aquatic foods are underrepresented in discussions about how to feed the world's population sustainably. Accurate food composition data for aquatic foods are needed, not only to estimate their contribution to the nutrient intakes of individuals and populations, but also for the development of food-based dietary guidelines and for labelling purposes. The FAO/INFOODS (International Network of Food Data Systems) Global Food Composition Database for Fish and Shellfish (uFiSh), published in 2016, is openly available in Excel and helps address this data gap. Considering that since its publication new analytical data is available in the literature, an update and expansion of the uFish is necessary.

Methods: As part of a wider collaborative effort to increase the knowledge base on aquatic foods, a comprehensive literature search is being performed to compile analytical data published since 2016. The compilation and documentation will follow FAO/INFOODS standards and guidelines. In addition, the database, which is currently limited in coverage to mainly fillet and raw fish, crustaceans and molluscs, will be extended to include other fish and aquatic products, for example, sea urchin, roe, sea plants such as water spinach, algae, seaweed, and aquatic animals such as sea snails, and sea cucumbers. Other complementary databases, such as FishBase and FishNutrients, will be updated as part of this collaboration.

Results: Results from the identification, evaluation and validation of new sources of data will be presented.

Conclusions: The update and expansion of uFish will increase the quality and quantity of accurate and available food composition data on aquatic foods globally. Such data can also enable countries and researchers to incorporate more of these data in national and regional FCT/FCDBs, allow better calculation of nutrient intakes from aquatic foods, and integration of aquatic foods into programmes and policies. This collaborative initiative paves the way for novel approaches to improve data availability globally.

Nutritional status and cardiometabolic health among adolescents: findings from Harare, Zimbabwe.

Ashleigh Pencil[1], Tonderayi Matthew Matsungo[2], Nobuko Hongu[1], Naomi Hayami[1]

1. Osaka Metropolitan University (Japan), 2. University of Zimbabwe (Zimbabwe)

Background and Objectives: Overweight and obesity among adolescents is a global public health concern, especially in lower- and middle- income countries where it co-exists with undernutrition due to rapidly changing dietary habits, poor nutrition knowledge and reduced physical activity. Overweight/obesity is complicated by cardiometabolic indices (CMI) characterized by high total cholesterol (TC), fasting glucose (FG), waist/hip ratio (WHR), and blood pressure (BP). In Zimbabwe, screening for cardiometabolic risk (CMR) is not prioritized especially among adolescents. This study assessed the prevalence of obesity, cardiometabolic risk factors, and participants characteristics associated with CMI.

Method: The study was done among high school adolescents in Harare, Zimbabwe. Three hundred and twenty students aged 14-19 years consented to participate in the study. Questionnaires on sociodemographic characteristics, dietary habits, and physical activity were self-administered. Blood pressure (BP), height, weight, and waist circumference were measured, and finger prick blood sampling was done for FG and TC. Waist circumference and height was used calculate WHR. Body mass indices were determined as the weight per square of their heights. The results were analysed on IBM SPSS version 26 at $p \leqq 0.05$ significance level. Binary logistics regression analysis was done to identify predictors for CMR and CMI.

Results: The prevalence of obesity was (17.5%), (75%) among girls and (21.4%) among boys and (3.6%) preferred not to say. The prevalence of CMR was 225(70.3%), girls (60.4%) and boys (38.6%). CMI were clustered with high proportions among 14-16year olds and girls. WHR was higher among boys (55.0%) and TC was higher among girls (71.3%). Family size (i.e., numbers of siblings) was a significant predictor for CMR (OR=0.511). Gender (0R=1.815) and inadequate knowledge for malnutrition related diseases (OR=1.812) predicted high TC. Gender (OR=0.598) predicted high BP. Gender (OR=0.452) and skipping meals (OR=3.179) predicted high WHR, and place of residents (i.e., uptown or downtown) predicted high FG (OR=3.937).

Conclusion: Results suggest the co-existence of obesity and CMR among Zimbabwean adolescents. There is an urgent need to develop gender sensitive, family and culture-oriented nutrition intervention programmes in strategic locations, to improve and control obesity, CMR and CMI.

Keyword: Zimbabwe, Adolescents, Cardiometabolic risk, Cardiometabolic indices, Overweight/obesity

PAB(T2)-141

Pregnancy Physical Activity Questionnaire (PPAQ) is a Sensitive Tool for Predicting Percentage Body Fat in Pregnant Women: Findings from Indonesia

Mifa Nurfadilah[1], Min Kyaw Htet[1], Nur Lailatuz Zahra[1], Tiffany Cornelia Angelin[1], Umi Fahmida[1]

1. Southeast Asian Ministers of Education Organization Regional Center for Food and Nutrition (SEAMEO RECFON) (Indonesia)

Background and objectives: High percentage body fat (%F) is associated with preeclampsia which is risk factor for preterm deliveries and perinatal mortalities. Studies have shown that sedentary activity is associated with higher %F. Therefore, it is important to estimate accurately the physical activity of pregnant mothers using the appropriate tool. In this study, two different tools were used to assess the level of physical activity and its association with the %F of pregnant Indonesian women in the second and third trimesters.

Method: This cross-sectional study is part of a larger observational cohort study in East Lombok Regency, West Nusa Tenggara Province, Indonesia, entitled "UKRI GCRF Action Against Stunting Hub (AASH)". Andhra Pradesh Child and Parent's Study - Physical Activity Questionnaire (APCAPS-PAQ) and Pregnancy Physical Activity Questionnaire (PPAQ) were used to estimate the physical activity (MET-h/week) of 702 pregnant women during T2 and T3 respectively. Percentage body fat was assessed using Siri's equation with body Density estimated by Durnin and Womersley equation using triceps, biceps, and sub-scapular skinfolds. Student's T-test was used to examine the mean difference of %F between women with sufficient vs insufficient physical activity (≧50 vs <50 MET-h/week total activity, respectively) as well as between the women who achieved the physical activity level (≧7.5 vs <7.5 MET-h/week) recommended by Centers for Disease Control and Prevention's (CDC).

Results: Majority (73.5%) of pregnant women were housewives. Women in the third trimester of pregnancy were more inactive (44.6 MET-h/week) than in the second trimester (66.5 MET-h/week). The highest amount of energy (26.7 and 26.8 MET-h/week) was spent on household activities in both trimesters. There was a significant difference in %F of women based on sufficiency of physical activity level measured by PPAQ (52.9% vs 53.8%, p <0.012). On the other hand, there was no difference in %F based on sufficient physical activity level measured by APCAPS-PAQ (52.5% vs 52.6%, p= 0.805).

Conclusions: PPAQ demonstrates the ability to differentiate %F of pregnant women based on physical activity levels. PPAQ is recommended to assess physical activity level in pregnant women and to support health promotion messages to encourage adequate physical activity during pregnancy.

PAB(T2)-142

Nutritional and hydration strategies during 160 km ultramarathon race between hypoglycemic and normoglycemic runners

Naho Inamura[1], Shiori Yoshida[2], Hirokazu Taniguchi[2], Kengo Ishihara[1]

1. Ryukoku Univ (Japan), 2. Kyoto Prefectural University (Japan)

Background and objectives: Ultramarathon race is a sporting event that is growing in popularity. Nutritional demand in an ultramarathon race is physiologically enormous, and it should not be surprising that the energy intake of runners cannot reach energy expenditure. Hypoglycemia is an often-observed phenomenon even in runners ultimately finish. While many factors can contribute to this phenomenon, this paper investigated the relationship between running performance and nutritional strategies, which play a large role in maintaining normal glycemia.

Methods: Twenty-two ultramarathon runners took part in the study. The glucose profile was monitored continuously throughout the race, which was divided into nine segments by timing gates. Running speed was monitored by GPS throughout the race and standardized to the average of the top five finishers for each gender. Food and drink intake during the race were recorded, and carbohydrate, protein, fat, water, and sodium intake were calculated.

Results: Hypoglycemia was observed in 3 runners, and disturbance of glycemia was observed in 8 runners. Nutrient intake varied widely among individuals, and what was sufficient to maintain blood glucose in one runner could cause a disturbance in glycemia in another runner. Energy and nutrient intakes for each runner are in the state under calculation and will be reported in the poster presentation.

Conclusion: The present study demonstrates that continuous glucose monitoring could be practical to guarantee optimal carbohydrate intake for each ultramarathon runner to compensate for individual differences in nutritional and metabolic characteristics.

Assessment of anemia and other micronutrient deficiencies among 0.5–11-year-old children in 2020-2021: results from SEANUTS II Vietnam

Tuyen Danh Le[1], Van Khanh Tran[2], Son Duy Nguyen[3], Hoa Anh Le[4], Tu Song Nguyen[5]Ilse Khouw[6], Nga Thuy Tran[7]

1. National Institute of Nutrition (Viet Nam), 2. National Institute of Nutrition (Viet Nam), 3. National Institute of Nutrition (Viet Nam), 4. National Institute of Nutrition (Viet Nam), 5. National Institute of Nutrition (Viet Nam), 6. FrieslandCampina (Netherlands), 7. National Institute of Nutrition (Viet Nam)

Background and objectives: Despite being important for a healthy growth and development, not much information is available on the micronutrient status of children. The 2nd South East Asian Nutrition Surveys (SEANUTS II) is a cross-sectional survey conducted in Indonesian, Malaysian, Thai, and Vietnamese children. SEANUTS II aims to get an in-depth understanding of the nutritional status, dietary intake, and lifestyle behaviors in children between 0.5-12.9 years old. The objective of this study is to assess the prevalence of anemia and deficiencies of vitamin A, vitamin D, iron, and zinc in Vietnamese children.

Methods: 4001 children aged 0.5–11.9 years old in a nationally-representative sample were recruited from September 2020 to April 2021. Blood samples were collected from 1054 children. Hemoglobin levels were measured via HemoCue, ferritin and C-reactive protein via immunoturbidimetric method, retinol and vitamin D via LC/MS/MS, and zinc using flame atomic absorption spectrophotometry.

Results: Weighted results showed that overall, 12.0% the children had anemia which can be classified as mild level of public health issue. More rural children had anemia compared to their urban counterparts (13.9% versus 9.1% resp.). Especially children <1 year old were affected with anemia (38.6%), which can be classified as moderate level of public health issue. The prevalence of sub-clinical vitamin A deficiency in children aged 4-11.9 years old was 6.2%, classified as mild level of public health problem. The prevalence of vitamin D deficiency (25(OH)D<25 nmol/L) and insufficiency (25(OH)D between 25–49.9 nmol/L) being 0.69% and 31.1% in children, resp. Prevalence of serum zinc deficiency was 60.8%, classified as severe level of public health problem. Less than 1% of the children had low iron stores (corrected for inflammation).

Conclusions: Anemia and micronutrient deficiencies are common in Vietnamese children. Implementing effective solutions to fight against anemia and micronutrient deficiencies to improve the micronutrient status of the groups at risk is essential.

Ingredient statements as a tool for better understanding of use of packaged foods in the U.S.

Jaspreet Kaur Ahuja[1], Ying Li[1], Pamela R Pehrsson[1], James Harnly[1]

1. Beltsville Human Nutrition Research Center (USA)

Background and objectives: Highly-processed foods have been linked to negative health outcomes, though the mechanisms are not still fully understood. Ingredients such as added sweeteners, intense flavorings, and chemical additives are some of the proposed mechanisms. Recently a new system, IngID was developed for parsing and systematic reporting of ingredients, including a thesaurus of over 30,000 uniquely listed ingredients. The objective of this report is to assess its capabilities and limitations, using sweeteners - nutritive and non-nutritive to illustrate.

Methods: We identified over 300 uniquely-listed sweetener-type ingredients associated with over 75 different types of sweeteners in selected sweet bakery products and sweetened beverages (top-sources of added sugars in the U.S. diets) categories, and broadly grouped them by calorie content. We quantified occurrence of different types of sweeteners, and proportion of foods containing them across categories, number of sweeteners used in each product and their co-occurrence. Tracking use of different sweeteners is of interest due to their differential effects on the body.

Results: Sucrose, dextrose, and high fructose corn syrup are among the top listed sweeteners, all nutritive; their extent of use varies by category. Use of multiple sweeteners in a product is common. Non-nutritive sweeteners are used in 2% of cookies and pastry products, but much more common in beverages. The most common types are acesulfame potassium, aspartame, and sucralose. Weighting by volume of point-of-sales data and amounts of sweeteners used in each product may potentially impact the list; however, these data are not publicly available. Similarly, we are unable to assess per-capita intakes of total or specific type of sweeteners, as such details are not available in the food composition databases used for national dietary surveys.

Conclusions: IngID provides tools to help improve our understanding of packaged foods, not possible before. It can contribute to improved food composition databases, dietary assessment tools, and study of interaction of ingredients. However, more publicly available databases/tools are needed for better understanding of dietary intakes of different ingredients and eventually diet-health-disease relationships.

Changes in child dietary practices in food secure and insecure areas during COVID pandemic in Nepal

Debendra Prasad Adhikari[2], Ramesh Prasad Adhikari[1], Kristine Dandanell Garn[1], Pooja Pandey[1]

1. Helen Keller International, Nepal (Nepal), 2. U.S. Agency for International

Background: Global evidence suggests a strong association between food insecurity and malnutrition. The COVID-19 pandemic has exacerbated the challenges faced by vulnerable communities. The objective of this study was to explore the association between food insecurity and infant and young child feeding practices in both food secure and insecure areas of Nepal during the COVID-19 pandemic.

Methods: We used data from a cross-sectional rapid assessment survey on child nutrition collected via mobile phones in January 2022 supported by USAID. Respondents included 23,471 randomly selected mothers with children less than 24 months from 117 food insecure and 272 food secure (total 389) of Nepal's 753 municipalities. The three outcome variables were exclusive breastfeeding among children 0-6 months, minimum acceptable diet among children 6-24 months, and minimum dietary diversity (5 or more out of 8 food groups) among children 6-24 months. The primary exposure variable was the impact of the COVID-19 pandemic on household food security based on mothers reporting experiencing limitations in their food consumption due to the COVID-19 pandemic. We applied a logistic regression model adjusted for socio-economic confounders for food secure and insecure areas, respectively, to test the association between households reported food security status with the three child feeding outcomes.

Results: Among surveyed households, approximately 27% faced food insecurity due to COVID-19. In the adjusted models, we found that reporting experiencing food insecurity was inversely associated with exclusive breastfeeding of children less than 6 months (OR=0.72, CI: 0.55 to 0.94), children 6-23 months meeting the minimum dietary diversity (OR=0.75, CI: 0.65 to 0.85), and children 6-23 months meeting the minimum acceptable diet (OR=0.79, CI: 0.69 to 0.90) in the food insecure areas. However, in food secure areas, this association was only significant for exclusive breastfeeding among children less than 6 months (OR=0.64, CI: 0.54 to 0.75).

Conclusion: The findings of the analysis suggest that existing vulnerabilities are exaggerated during crises like pandemics with unequal consequences on child dietary practices. Future efforts should focus on improving food security and resilience of households in food insecure areas to minimize the impact of future crisis on child nutrition.

PAB(T2)-146
Anemia and determinants of hemoglobin concentration in women of reproductive age in Senegal: results of a national cross sectional survey

Ndeye Fatou Ndiaye[1,2], Nicole Idohou Dossou[2], Adama Diouf[2]

1. Institut de Technologie Alimentaire (Senegal), 2. Laboratoire de Recherche en Nutrition et Alimentation Humaine (Senegal)

Background and objectives: Anemia is a major public health problem, particularly in developing countries, and has adverse effects on the health of women. Generally, the causes of anemia are related to nutritional deficiencies, infectious diseases or hemoglobin disorders. This study aimed to determine the national prevalence of anemia and the determinants of hemoglobin concentration among the women of reproductive age (15-49 years).

Methods: A national cross-sectional study was conducted and data were collected from 1012 women. Biomarkers measurement including hemoglobin, plasma ferritin, plasma folates, C-reactive protein and alpha-1 acid glycoprotein were measured. Clinical health data were also collected. Plasma ferritin was adjusted for inflammation. Association between hemoglobin concentration and adjusted plasma ferritin, plasma folates, and physiological status (pregnant, breastfeeding, and nonpregnant/nonbreastfeeding) of women was measured using multivariate linear regression models.

Results: The prevalence of anemia was 47.6% among women and was significantly different between physiological status of women ($p < 0.001$). In a bivariate analyses, low adjusted plasma ferritin ($p < 0.001$), low plasma folates ($p < 0.007$), and being pregnant women ($p < 0.001$) were negatively related to hemoglobin concentration. These significant variables were included in a multivariate model. Even though, low plasma folates were associated with low hemoglobin concentration in the bivariate analysis, it did not become significant in the multivariate analysis nevertheless the model predict 29% of variance of women's hemoglobin concentration.

Conlusion: Such covariates underpin rates of low hemoglobin concentration among Senegalese women. Our results are not consistent with those reported by Al Khatib et al (2006) in a Lebanese study establishing a strong association between anemia, iron deficiency and folate deficiency. These authors have shown that anemia not related to iron deficiency is mainly explained by folate deficiency in women of childbearing age. Policies and programs should be design specifically to target vulnerable who bear the burden of anemia.

Al Khatib L, Obeid O, Sibai AM, Batal M, Adra N, Hwalla N. Folate deficiency is associated with nutritional anaemia in Lebanese women of childbearing age. Public Health Nutr 2006; 9 (7): 921-927

Relationship Between Balanced Meals, Energy, and Nutrient Intake in Female University Students

Hiroko Moriwaki[1], Namie Tsumura[2]

1. Prefectural University of Hiroshima (Japan), 2. Hiroshima Sanyo Women's College (Japan)

Background and objectives: The Basic Plan for Shokuiku (Food and Nutrition Education/Promotion) by the Japanese government aims to increase the percentage of Japanese who eat at least two balanced meals daily. Each balanced meal includes a grain dish, a fish or meat dish, and a vegetable dish, and should be eaten almost every day. However, in recent years, the number of young people practicing this eating habit is decreasing. We aimed to examine the relationship between balanced meals, energy, and nutrient intake in young female university students.

Methods: From 2016 to 2018, we conducted a 3-day diet survey using a weighing method and a questionnaire for third-year female University students during the months of June. Of 102 participants, we excluded those who did not respond to the survey (n=8). Data from the remaining 94 participants were analyzed with a recovery rate of 92.1%. A balanced meal was defined in accordance with the Japanese Food Guide Spinning Top. Participants who consumed at least 1 serving from each meal category were considered to have consumed balanced meals. Participants were classified into two groups based on what they ate during the 3-day survey period. The "high" and "low" groups comprised those who had at least four and less than four balanced meals during the 3-day survey period, respectively. Twenty-three items were examined by the weighing method, including energy, proteins, lipids, cholesterol, carbohydrates, dietary fibers, 10 vitamins, and 7 minerals.

Results: First, the median numbers of meals consumed during the 3-day period were seven grain dishes, six fish and meat dishes, five vegetable dishes, and four balanced meals. Second, compared with the "low" group, the daily intake of 22 out of the 23 items, excluding vitamin A were higher in the "high" group. Lastly, compared with the "low" group, a smaller number of participants in the "high" group answered that they "want to lie down," "cannot keep up with work," or "feel tired."

Conclusions: Findings from this study suggest that to help young people eat balanced meals, it is necessary to develop a program that encourages them to eat side dishes more frequently.

PAB(T3)-2
Age and gender differences in the relationships among self-rated health, dietary habits, and preventive behavior for lifestyle diseases in Japanese 30-50s.

Yoko Ishii[1], Haruka Ishii[2]

1. The University of Nagano (Japan), 2. Toyama Prefectural Central Hospital (Japan)

Background and objectives: Self-rated health is correlated with objective health indicators, and has been shown to be an independent contributor to mortality and morbidity. To investigate the association between self-rated health and dietary habits, we performed a secondary analysis of the data in the 'Survey of Public Awareness for Nutrition and Food Education' conducted by the Cabinet Office.

Methods: Targeting 30-59 years old, "interest in food education", "basic knowledge about food safety", "mind for a healthy diet", "subjective economic status", "time to spare", "self-rated health" and "preventive behavior for lifestyle diseases" were extracted, and covariance structure analysis was performed by age and gender variations.

Results: Dietary factors had a positive effect on "self-rated health" in each age group, but the effect was more pronounced in women than in men. In women, the positive effects of "subjective economic status" and "time to spare" on "preventive behavior for lifestyle diseases" were more pronounced than in men. The interfactorial correlation for dietary factors was significant in women of all ages, and was more significant in men of 40s and 50s than 30s.

Conclusions: It was suggested that more appropriate health-guidance and health-promotion supports were needed according to the age and gender of the subjects.

Keyword: self-rated health, prevention of lifestyle diseases, dietary habits, health literacy, nutrition and food education

PAB(T3)-3
Diet and quality of sleep in pandemic in adults from 20 to 30 years.

Sofia Carolina Mandujano[1], Marisol Andrea Mosto[1], Wendy Cuya[1]

1. San Ignacio de Loyola University (Peru)

Background and objectives: The pandemic brought with it changes that impacted the quality of sleep and eating patterns around the world. Different processes such as food intake participate in the regulation of sleep, which may suggest a relationship between food and sleep. The objective is to evaluate the relationship between the quality of sleep and diet in times of pandemic in the population of 20 to 30 years of Peru.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: A cross-sectional study was carried out with 105 adults, between 20 and 30 years of age. The Pittsburgh Sleep Quality Index (PSQI) was used to measure the subjective quality of sleep and a survey called the "Healthy Eating Assessment" of the Canadian government, which identifies eating patterns. Both surveys were carried out in Google Forms, they were distributed through social networks and the results were transferred to Excel. For the statistical analysis, the STATA 12.1 program, pairwise correlation, was used to correlate the surveys and their components with the level of significance taken as $p < 0.05$.

Results: A significant relationship was found between a better quality of sleep and diet in the study; In addition, there was no positive correlation with the consumption of sugary drinks and sweets, which resulted in a worse quality of sleep with higher consumption. On the other hand, dairy products, including milk, sugar-free yogurt, and low-fat cheese, had a higher significance (P=0.0007) possibly due to their tryptophan content related to a better quality of sleep. Finally, sleep components such as subjective quality (P=0.0131) and sleep duration (P=0.0288) also obtained a strong significance regarding a good diet.

Conclusions: There is a good relationship between sleep quality and diet. The intake of dairy products, probably due to the content of tryptophan, is related to better sleep results. No positive correlation was found between the consumption of sugary drinks and sweets with sleep quality.

Keyword: Sleep quality, Tryptophan, Diet quality

PAB(T3)-4
A study on leftover food waste resulting from school lunch menu-related factors

Kiyo Nakagiri[1], Suni Lee[2], Runa Mikami[3], Takemi Otsuki[4], Takayo Kawakami[3]

1. Graduate School of Health and Welfare Science, Okayama Prefectural University (Japan), 2. Department of Hygiene, Kawasaki Medical School (Japan), 3. Department of Nutritional Science, Faculty of Health and Welfare Science, Okayama prefectural University (Japan), 4. Shinjo Village National Health Insurance Clinic (Japan)

Background and objectives: Japanese school lunches provide excellent teaching material and are known to have good nutrient balance. Traditional Japanese food and dishes made with a variety of local products are served. However, the amount of leftover food is large. This study aimed to identify factors related to leftover food from school lunches.

Methods: Amounts of leftover food from school lunches provided at A primary school in Okayama Prefecture from April 2020 to March 2021 (n=187) were used for the analysis. Principal component analysis was performed on the usage of each food group in provided menus to classify school lunch menu features. The leftover rate of staple foods, milk and three side dishes which were served in cans were analyzed using Kruskal-Wallis tests.

Results: Two main factors were extracted for the provided menus: i) type of food group of Japanese style dishes consisting of rice, seaweed, small fish; and ii) type of food group of main dishes, either fish/shellfish or meat. The two factors were categorized into four groups. The leftover rate of Japanese-style fish dishes was significantly higher than that of Western meat dishes in all cans. Comparing the leftover rate of cans between semesters, the rate of leftover staple foods and side dishes decreased in the third semester compared to the first semester. The rate of leftover milk, on the other hand, increased in the third semester.

Conclusions: We confirmed that the menus were provided in accordance with the school lunch policy of the local government. The leftover rate of Japanese dishes with fish tended to be higher than that of Western dishes with meat. In addition, the amount of leftover food, including staple foods and side dishes, decreased in the third semester compared to the first semester. This might indicate dietary education effects throughout the year, increased daily intake by children as they grow and seasonal effects. The findings suggest that leftovers can be controlled through dietary education and ingenuity in the combination of ingredients and dishes.

Keyword: leftover, school lunch, Japanese dishes

PAB(T3)-5
Moderate to vigorous physical activity in daily life of Japanese children with Down syndrome is shorter than that of normal children

Erika Yamanaka[1,2], Kanzo Okazaki[3], Takayo Inayama[4], Ichiro Kita[1], Michio Kojima[5], Kazunori Ohkawara[6]

1. Tokyo Metropolitan University (Japan), 2. General Incorporated Association H & H (Japan), 3. Tohoku Gakuin University (Japan), 4. The University of Nagano (Japan), 5. University of Tsukuba (Japan), 6. University of Electro-Communications (Japan)

Background and objectives: The World Health Organization (WHO) recommends at least 60 minutes of moderate to vigorous physical activity (MVPA) for children with and without disabilities. Children with Down syndrome (DS), many of whom have congenital heart diseases, have physical characteristics such as muscle hypotonia. They may also have characteristics that differ from those of normal children (NC) in terms of physical activity intensity and duration as well as ambulation. This study aimed to compare the time characteristics of physical activity considering both ambulatory and non-ambulatory states between children with DS and NC.

Methods: Participants included 69 fourth- to sixth-grade children with DS and 68 NC attending elementary schools in Japan. The physical characteristics recorded were age, height, weight, and body mass index. Physical activity was recorded as follows: Sedentary behavior (PA < 1.6 MET) time, Light physical activity (1.6 MET ≦ PA < 3.0 MET) time, Moderate physical

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

activity (3.0 MET ≦ PA < 6.0 MET) time, Vigorous physical activity (6.0 MET ≦ PA) time, and MVPA (3.0 MET ≦ PA) time. Walking and non-walking conditions and the number of steps were analyzed as well. Student's t-test and Welch's t-test or the Mann–Whitney test was used for analysis.

Results: Children with DS had a longer MVPA time in non-ambulation than NC (27.7 vs. 24.1 min/day; p=0.035). The total MVPA time was shorter (DS: 53.1 min/day, NC: 65.0 min/day; p=0.003) owing to the shorter MVPA ambulation time (DS: 25.5 min/day, NC: 40.9 min/day; p<0.001). Thirty-three percent of the children performed > 60 minutes/day of MVPA as recommended by the WHO.

Conclusions: Children with DS were able to maintain the same amount of non-ambulatory MVPA time as NC. It is hoped that children with DS will achieve the WHO-recommended MVPA time of 60 minutes with the promotion of ambulatory activities through play and other activities.

PAB(T3)-6
Evaluation of physical condition in long-distance runners by using blood test and dietary surveys

Shiori Nakanishi[1], Haruhi Tagami[1], Miku Yokoyama[1], Kayoko Yamazaki[1], Kensuke Takezawa[2], Naoko Komenami[1]

1. Kyoto Women's University (Japan), 2. Setsunan University (Japan)

Background and objectives: Physical condition, including exercise anemia, affects the competition performance of athletes. It has been reported that low serum ferritin affects endurance performance and increases the risk of injury. Ferritin levels are reflective of iron stores, which are used for enzyme synthesis involved in energy production. This study aimed to evaluate physical condition in terms of serum ferritin level and dietary intake with the aim of improving competition performance and preventing injuries in long-distance runners.

Methods: The participants were 21 male long-distance runners at OE University. Before training, we measured body weight and body composition and evaluated the blood test data and dietary intake. This research was conducted from April to November in 2021.

Results: Body weight did not significantly differ between June–July and October–November, but body fat percentage in June–July was lower than that in October–November. The proportion of participants with a BMI <18.5 was 17.6% in June–July and 23.5% in October–November. The median serum iron levels of runners were within the normal range, but 31.3% of runners in June–July and 25.0% of those in August–September were below the normal range. Median hemoglobin levels were within the normal range, but 12.5% of runners in April–September and 25.0% of those in October–November were below the normal range. Median ferritin levels were within the normal range, but the proportion of runners below the normal range increased from June to September (37.5%) and then decreased in October–November. The median MCHC level was below the normal range in June–July, and 56.3% of runners were below the normal range in June–July. In the dietary survey, the percentage of participants who consumed all staple foods, main dishes, and side dishes was 36.8% for breakfast, 26.3% for lunch, and 57.8% for dinner. Only 37.0% of runners had pre- and post-game meals.

Conclusions: The results suggested that long-distance runners have lower serum ferritin and serum iron levels in the summer. Nutritional support may be necessary to ensure that runners have a balanced breakfast and lunch as well as pre-game meals.

Keyword: Nutrition, Exercise anemia, Long-distance runner

PAB(T3)-7
Pasta Intake in the Elderly:Results of an Eating Survey of Residents of a Long-Term Care Health Facility and Community-dwelling Elderly who Attend a Day Care Rehabilitation Center

Yuka Tachibana[1], Asuka Sueyoshi[1], Masami Maeno[2], Yui Okuno[1], Momoko Kasuya[1], Naoko Komenami[1]

1. Kyoto Women's University (Japan), 2. Nukumorinosato (Japan)

Background and objectives: Japan is a super-aging society and the population of elderly people aged 65 and over is growing rapidly every year. According to the National Health and Nutrition Survey of 2016, the intake of pasta as a proportion of total food intake decreases with age. In this study, we conducted an eating survey to investigate the preference for pasta in elderly people in Japan.

Methods: The study participants were 34 residents of a long-term care health facility in Kyoto City (age 88.4±5.2 years) and 105 community-dwelling elderly people who attend a day care rehabilitation center at the same facility (age 82.4±9.1 years). From April to November 2018, pasta or rice and fried *udon* noodles were served as staple meals at the long-term care health facility, and eating surveys were conducted using the weighing method. In addition, we created a mackerel tomato pasta dish for the community-dwelling elderly participants, served this dish along with side dishes, and conducted eating surveys.

Results: According to the results of the eating surveys (conducted 10 times), 262 meals (81.9%) were completely consumed, and 58 meals (18.1%) were incompletely consumed (i.e., there were leftovers). Pasta intake rates were the same as rice intake rates, regardless of the type of pasta, the sauce used, or the season during which the dish was served. For participants on a soft diet, the leftover rate for pasta was higher, and there was a significant relationship between the meal type and leftover rate. In the first trial, the intake rate of the mackerel tomato

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

pasta dish was low, but this was improved by devising a cooking method for the pasta sauce.

Conclusions: The results suggest that elderly people requiring support care prefer pasta and that serving pasta might improve the variety and diversity of their diet.

Keyword: Elderly, Pasta intake, Eating survey of meals

PAB(T3)-8

'Got to eat right, because I live alone': Dietary practices among Japanese older women participating in a community walking program with nutrition lessons

Nobuko Hongu[1], Rino Onishi[1], Ryosuke Haruna[1], Tatsuo Doi[2], Taeko Tsuji[3], Atsuko Fujii[4], Hitoshi Watanabe[1]

1. Osaka Metropolitan University (Japan), 2. Dynamic Sports Medicine Institute (Japan), 3. Mukogawa Women's University (Japan), 4. Izumisano City Health Promotion Division (Japan)

Background and objectives: Japan has the highest aging rate worldwide. In 2021, 29% of the total population were adults aged 65 years or older. Globally, it is estimated that by 2050 one in six people will be 65 years of age or older. There is emerging research interest on active and healthy aging, specifically, physiological, and psychosocial factors that may play a role in nutrition and food choice of older adults. This study explored the integrated role of nutrition and physical activity for active, healthy aging. We examined dietary practices and perceptions of food choice among older Japanese women who participated in a community walking program (June ~ July 2021).

Methods: The community walking program offered a dietary assessment and three 15-minutes group nutrition lessons for the participants. Dietary intake was assessed by a food frequency questionnaire (Eiyo-Kun FFQg). Body weight and height were measured at a community center when the walking program started. Demographic information was collected by the questionnaire. After the program ended, one-on-one semi-structured interviews were conducted with nine participants who had completed the walking program. Interview questions focused on eliciting a better understanding of how the walking program impacted participants' dietary practices.

Results: Participants' mean age was 72 years and the body mass index was ranging between 18.0 and 25.1 kg/m^2. Four women were living alone. All participants met the reference values of all macro- and micronutrient intakes. This qualitative evaluation helped to obtain a richer understanding of community participants' reasons for wanting to be healthy as they age, and the benefits of the program on participants' experience of motivation to have healthier food choices (i.e., food acquisition, preparation, and cooking). Interestingly, women living alone helped motivated themselves to be healthy by providing a sense of 'got to eat right, so I will be healthy and strong.'

Conclusions: This study provides insight into active, healthy older participants' experiences of community walking program with short nutrition lessons. Further research in a broader population of older adults is mandated to determine the efficacy of integrated role of nutrition and physical activity using community walking programs.

Keyword: Healthy aging, Nutrition, Physical activity, Dietary practices, Japanese older women

Effects of supplementary intake of milk protein in combination with resistance exercise training on lean body mass in female university students

Takuya Karasawa[1,2], Chieko Oie[1], Shinichi Okamura[1], Kentaro Nakamura[3], Atsushi Kanda[3], Shin Terada[2], Michiyo Kimura[1]

1. Takasaki University of Health and Welfare (Japan), 2. The University of Tokyo (Japan), 3. Meiji Co., Ltd (Japan)

Background and objectives: Increasing lean body mass (LBM) during youth is important to prevent sarcopenia and locomotive syndrome in their future. This study investigated the effects of the supplementary intake of milk protein in combination with resistance exercise training on LBM in female university students.

Methods: Thirty female university students (BMI: 19.8±2.0 kg/m^2) were recruited and asked to perform bodyweight-based and elastic tubing-based resistance exercises 4 days a week for 12 weeks. During the training period, subjects were instructed to consume cookies containing either 10 g of milk protein (MP: n=15) or isoenergetic carbohydrate (CON: n=15) daily. At 1 week before and 12th week of the interventions, subjects were required to complete 3-day food diary to determine their daily macronutrient intake. Body composition and muscle thickness were respectively measured by bioelectrical impedance analysis and B-mode ultrasound imaging before and after the interventions.

Results: Twenty-one subjects (CON: n=9; MP: n=12) successfully completed the 12-week nutritional and training interventions. Because of an unexpected increase in dietary protein intake during the interventions in the CON group, protein as well as energy intakes during the interventions did not differ between the two groups ($p<0.05$). LBM, lower-limb muscle mass, and quadriceps muscle thickness were significantly increased with training in the MP group, but not in the CON group, with the increases in the MP group being greater than those in the CON group ($p<0.05$).

Conclusions: Our results suggest that the supplementary intake of milk protein during resistance exercise training may be an effective nutritional strategy to increase LBM in young. Given that the MP and CON groups had similar protein intakes during

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

the interventions, such an increase in LBM in the MP group may be attributed to the quality rather than quantity of milk protein.

Keyword: milk protein, resistance exercise training, female, university students, lean body mass

PAB(T3)-10
Eating habits and lifestyle-related salty taste preference in early childhood

Kayoko Yamazaki[1], Yuriko Haito[2], Naoko Komenami[3]

1. Osaka Christian College (Japan), 2. Shiga Junior College (Japan), 3. Kyoto Women's University (Japan)

Background and objectives: Reducing salt intake is an important dietary issue in Japan. The purpose of this study was to investigate salty taste preference of everyday foods in young children and to examine whether it is affected by eating habits and lifestyle.

Methods: This study was carried out from December 2018 to February 2019 at kindergartens located in Osaka and Shiga prefectures, Japan. A total of 176 children aged 4-6 years participated in a salty taste preference test. The children tasted bonito broth with two different salt concentrations (0.8% and 1.2% NaCl: CON and SAL, respectively) and were asked which one they preferred. In addition, their parents were asked to complete a self-administered questionnaire covering basic items such as their child's physical characteristics, as well as items on their child's food intake frequency (15 questions), awareness of the child's diet (11 questions), and problems with meal preparation and the child's meals (13 questions).

Results: CON was preferred by 89 children (35 boys, 54 girls) while SAL was preferred by 54 (31 boys, 23 girls). The remaining 33 children (22 boys, 11 girls) did not answer clearly and were excluded. SAL was preferred by a significantly higher percentage of boys than girls. Height and weight were significantly lower in the SAL group than in the CON group. Childcare hours in kindergarten, frequency of attending kindergarten on Saturdays, and frequency of school lunch were significantly lower in the SAL group than in the CON group. The percentages of parents responding to “My child prefers sweet drinks and sweets” and “My child won't eat food that isn't strongly seasoned” were significantly higher in the SAL group than in the CON group.

Conclusions: These results suggest that gender and eating habits including school lunch are related to children's salty taste preference. It is necessary to support parents of kindergarteners in improving the eating habits of children who prefer salty foods.

Keyword: Salty taste preference, Early childhood, School lunch, Eating habits, Questionnaire survey

PAB(T3)-11
More underweight men and overweight women? A cross-sectional study in older adults experiencing food insecurity in Gasabo district, Kigali, Rwanda

Theogene Habumugisha[1], Jutta Dierkes[2,3], Inger Elisabeth Måren[4], Matthias Carl Walter Kaiser[5], Ingunn Marie Stadskleiv Engebretsen[1]

1. Centre for International Health, Department of Global Public Health and Primary Care, University of Bergen (Norway), 2. Centre for Nutrition, Department of Clinical Medicine, University of Bergen (Norway), 3. Department of Medical Biochemistry and Pharmacology, Haukeland University Hospital (Norway), 4. Department of Biological Sciences, University of Bergen (Norway), 5. Centre for the Study of Sciences and Humanities (SVT), University of Bergen (Norway)

Background: In an aging global population, improving nutrition status of older adults can contribute to healthy aging. There is a lack of data on older adults' nutrition status living in urban settings in low- and middle-income countries.

Objective: To assess the prevalence of malnutrition and associated factors among older adults aged 55 years and older in Gasabo district, Kigali, Rwanda.

Method: This cross-sectional survey was conducted between November 2021 and February 2022. Trained nutritionists collected socio-demographic data and captured anthropometric measurements. The Food Insecurity Experience Scale (score ranging from 0-8) was used to capture moderate and high food insecurity (cut-offs >3). Poverty was assessed using Rwanda's wealth categories, locally known as UBUDEHE categories (ranging from 1-4), where the lowest 2 categories are defined as poor. Cut-offs were <18.5 kg/m^2 for underweight and >24.9 to <30 and ≧ 30 kg/m^2 for overweight and for obesity, respectively. We present descriptive statistics and findings from multivariable logistic regression analysis with nutrition status (underweight vs others) as the dependent variable and age, sex, family size, wealth index, education level, and food insecurity as independent variables. Data were analyzed using STATA (version 17.0). Ethical approval was obtained in Rwanda and Norway, and local authorities provided the permission to conduct the study.

Results: Older adults (N=417) with an average (SD) age of 66.9 (8.9) years, mostly women n=314 (72.3%) were enrolled. Among women, n= 37 (11.7%) were underweight, whereas n=153 (48.7%) were overweight or obese. For men, the corresponding numbers were n=37 (36%) and 13 (12.6%). Food insecurity was high, n=297 (71%). We found that sex (Adj OR=7.2; 95% CI: 3.4, 15.4) and poverty (Adj OR=2.8; 95% CI: 1.2, 6.5) were associated with underweight after adjusting for age, family size, education level, and food insecurity.

Conclusion: There was a disparity in nutrition status where more men were underweight, and more women were overweight. Food insecurity was high among older adults, but poverty was associated with being underweight. Therefore, policy interventions should target improving the economic situation of older adults.

Dietary Patterns and Predicted 10-year Cardiovascular Disease Risk in a Multiethnic Asian Population

Yu Qi Lee[1], Clare Whitton[2], Nithya Neelakantan[1], Rob M van Dam[1,3], Mary Chong[1,4]

1. National University of Singapore (Singapore), 2. Curtin University (Australia), 3. George Washington University (USA), 4. Agency for Science, Technology, and Research (Singapore)

Background and objectives: Studies examining associations between dietary patterns and Framingham risk score (FRS) and predicted 10-year cardiovascular diseases (CVD) risk in an Asian population are lacking. This study aimed to identify *a posteriori* dietary patterns across three major ethnic groups in Singapore and ascertain their associations with locally modified FRS and predicted 10-year CVD risk.

Methods: This cross-sectional study included 8594 Singapore residents (aged 21–75 years) from the Singapore Multi-Ethnic Cohort. Data on sociodemographic and lifestyle factors were collected via questionnaires. Food consumption was assessed using a validated Food Frequency Questionnaire. Dietary patterns were identified using principal component analysis and associations with CVD risk factors, FRS and high predicted CVD risk (>=10%) were analysed using multiple linear and logistic regression.

Results: Four dietary patterns emerged. The 'processed food and sugar-sweetened beverages' pattern was significantly associated with higher FRS (B*eta*: 0.13; 95% CI: 0.04, 0.23), while the 'ethnic breads, legumes and nuts' (B*eta*: -0.13; 95% CI: -0.22, -0.04) and 'whole grains, fruit and dairy' (B*eta*: -0.17; 95% CI: -0.24, -0.10) patterns were significantly associated with lower FRS. The 'meat and vegetables' pattern was not significantly associated with FRS. Only the 'whole grains, fruit and dairy' pattern was inversely associated with high predicted CVD risk.

Conclusions: Adherence to the 'ethnic breads, legumes and nuts' and 'whole grains, fruit and dairy' patterns was associated with a lower predicted CVD risk, and an inverse association for the 'processed food and sugar-sweetened beverages' pattern in an Asian population. These findings can inform the development of culturally sensitive dietary interventions to prevent CVD.

Administration of human milk oligosaccharides during the early postnatal period ameliorates the behavioral alteration of offspring in a mouse model of perturbed maternal gut microbiota

Shiro Tochitani[1,2,3], Satoshi Koizumi[4], Takamitsu Tsukahara[5], Ryo Inoue[6], Takane Katayama[7]

1. Suzuka University of Medical Science (Japan), 2. Hamamatsu University School of Medicine (Japan), 3. Chiba University (Japan), 4. Kyowa Hakko Bio Co., Ltd. (Japan), 5. Kyoto Institute of Nutrition & Pathology (Japan), 6. Setsunan University (Japan), 7. Kyoto University (Japan)

Background and objectives: The infants are colonized by the microbes they encounter in their environment, especially those vertically transmitted from their mothers. We have developed an animal model in which maternal gut microbiota is perturbed by exposure to non−absorbable antibiotics during the prenatal period (perturbed maternal gut microbiota model, PMGM model; Tochitani, 2016). The analyses on the PMGM model showed that the perturbation of maternal gut microbiota affected the postnatal brain development of offspring and caused an alteration in offspring behavior. In this study, we explored if the transmission of the perturbed maternal gut microbiota to the offspring is the cause of behavioral alteration of offspring by intervening the offspring gut microbiota with oligosaccharides.

Methods: We performed an intervention study by applying a mixture of oligosaccharides (2'-fucosyllactose, 3'-sialyllactose, 6'-sialyllactose) on P5−14 to the offspring of the PMGM model.

Results: Administration of oligosaccharides during the early postnatal period induced an alteration in the gut microbiota profiles in the offspring of the PMGM model and attenuated the spatial preference for the peripheral area in the unfamiliar field, which is a characteristic behavior of the offspring of the PMGM model.

Conclusions: 10 day-long intervention using a cocktail of oligosaccharides induced an alteration in the gut microbiota, which led to moderate normalization of offspring behavior. This result suggests that the offspring exhibit a behavioral alteration in the PMGM model, at least in part, because they have inherited the perturbed gut microbiota from their dams. This result also implies that human milk oligosaccharides administration can be utilized for dietary intervention on the gut microbiota of infants who have inherited the perturbed maternal gut microbiota.

Provision of Meals to Toddlers at Nursery Schools (2) Focusing on Cooperation between Cooks and Childcare Workers

Tomomi Ainuki[1], Mariko Ikeya[2], Haruko Sakai[1]

1. Tokyo Kasei Gakuin University (Japan), 2. Wayo Women's University (Japan)

Background and objectives: Following on from Report (1), Report (2) covers our study on the cooperation between the cooks and childcare workers in the provision of meals to toddlers aged approximately 18 to 36 months.

Methods: We adopted the same method used in Report (1). With regard to cooperation between cooks and childcare workers, cooks were asked to answer a question "Is information being shared with childcare workers on how children eat?" by selecting a response on a scale from 1 to 10 where 1 is "No sharing at all" through to 10 "Sharing a lot." Their answers were categorized into three groups based on the distribution, namely Low Group (LG) (1~5) 117 persons (25.9%), Middle Group (MG) (6, 7) 135 persons (29.9%) and High Group (HG) (8~10) 200 persons (44.2%), which were then analyzed using the chi-square test and the Kruskal-Wallis test.

Results: In terms of years of service, many belonging to the HG had worked for longer ($p=0.03$) than those in the other groups and were certified nutritionists ($p=0.01$). Those in the HG had a good understanding of the eating behavior of toddlers both at nursery schools ($p<0.01$) and in their homes ($p<0.01$). They also evaluated the reasons why meals had been, where applicable, unsuitable for children in a particular age bracket ($p<0.01$). Additionally, those in the HG were able to incorporate their understanding of eating behavior in the provision of meals ($p<0.01$). They prepared meals with attention to the size of servings which would help children to eat without adult assistance ($p<0.01$) and scored highly for clearly conveying to childcare workers the rationale underlying the methods used to cook the meals provided ($p<0.01$).

Conclusions: In the provision of meals to toddlers aged approximately 18 to 36 months, this study demonstrated the importance of sharing information between cooks and childcare workers on how children eat.

Provision of Meals to Toddlers at Nursery Schools (1) Focusing on Main Dietary Constituents

Mariko Ikeya[1], Tomomi Ainuki[2], Haruko Sakai[2]

1. Wayo Women`s University (Japan), 2. Tokyo Kasei Gakuin University (Japan)

Background and objectives: Few reports are available in Japan on the provision of meals at nursery schools to toddlers aged approximately 18 to 36 months, that is, children who have passed the weaning stage. Accordingly, the objective of this study was to obtain fundamental data on the provision of meals to children in that age bracket. Report (1) covers the analysis focusing on the main dietary constituents.

Methods: In October 2021, we sent a questionnaire to 776 nursery schools belonging to the Chiba Prefecture Child-Care Association, specifying the subject of survey as one person representing either nutritionists or cooks. Major contents of the survey comprised 1) whether meals in the post-weaning period are different from those for children aged three years or older, 2) where different, what steps are taken to devise and prepare meals appropriate for children aged between 18 and 36 months, and 3) whether steps are taken to process 22 food items which are difficult to chew and swallow.

Results and Conclusions: We collected answers from 490 nursery schools, which represents a response rate of 63.1%. The respondents' length of service at nursery schools was 9.8±10.3 years on average. Those certified as nutritionists accounted for 58.3%, and as national registered dietitians, 27.2%. Nursery schools that served meals to children aged three years or older that were different from meals in the immediate post-weaning period constituted 66.1%. Ranked in numerical order of number of responses, meals for older children were different in terms of quantity, hardness, cooking method, types of foodstuff and stickiness. Of 22 food items which are difficult to chew and swallow, those for which 80% or more of respondents devised ways to prepare these foods included root crops, green vegetables, brassicas, mushrooms, apple, seaweed such as *wakame* (*Undaria pinnatifida*) and *hijiki* (*Hizikia fusiforme*), dried Japanese white radish strips, *abra-age* (deep-fried tofu) and tomatoes and beans with skin. These findings suggest that these foodstuffs require special attention when provided as part of a post-weaning diet.

Effect of Integrated Maternal Nutrition Interventions on Birth Weight – a retrospective quasi-experimental study

Alemayehu Gebremariam Agena[1], Michael Fissehaye Habtu[2], Cyprien Munyanshongore[2], Maryse Umugwaneza[2], Monica Monchama[3]

1. Catholic Relief Services (CRS) (Rwanda), 2. University of Rwanda, College of Medicine and Health Sciences, School of Public Health (Rwanda), 3. University of Mount Kenya, School of Health Sciences, Department of Public Health (Rwanda)

Background: Maternal malnutrition during pregnancy is the main determinant of LBW. Appropriate nutrition interventions during pregnancy are key to improve maternal nutrition and birthweight of their newborns. USAID/Rwanda's flagship nutrition project, Gikuriro, promoted intakes of healthy and balanced diet among pregnant women. Households with pregnant women were targeted with nutrition sensitive interventions including promotion of bio-intensive agriculture, Savings and microcredits, and improved WASH services. This study compares birth weight of children born to mothers exposed to these interventions with controls from non-intervention districts.

Methods and Materials: Applying a quasi-experimental study design, quantitative data was collected from women who delivered in public health facilities across two intervention districts (Kayonza and Kicukiro) and two control districts (Gisagara and Gasabo) using standardized tools and between November 2020-June 2021. Sample size was estimated at 1144 (572 mother-newborn pairs for each study group). Trained nurses conducted weight measurements for the newborns and their mothers (MUAC) within 24hours after delivery and maternal hemoglobin was assessed using results from routine labor admission tests. Maternal BMI during the first trimester were extracted from antenatal care records. Data analysis was conducted using SPSS version 25.

Results: LBW was significantly higher among control(10.3%) compared to intervention group (3.4%) ($p < 0.001$). Similarly, maternal anemia was significantly higher among control (23.7%) than intervention group (10.5%). Furthermore, the proportion of maternal MUAC less than 23cm was higher among control group (14.5%) compared to intervention group (3.4%; $p < 0.001$). More women in the control group had low BMI in the first trimester (5.5%) compared to the intervention group (1.8%) ($p=0.010$). The proportion of women consuming less than 3 meals per day was significantly higher in the control group compared to the intervention group (28.4% vs 14.0%; $p<0.001$) and the proportion of women eating less than 5 food groups was higher in the control group than intervention group (25.7% vs 18.3%; $p=0.003$). The mean birth weight was 3.22kg in the intervention group against 2.99kg in the control group. This difference was significant with average 219 grams increase among intervention group ($p<0.001$).

Discussion and Conclusion: Findings from this study revealed that babies born to pregnant women who participated in the integrated nutrition interventions had better birth weight outcomes with an average 219g increase compared to those without exposures. Similarly, mean maternal hemoglobin, MUAC, BMI, and dietary diversity scores were significantly higher among the intervention group compared to controls. We can conclude that integrated nutritional interventions including nutrition education/counseling, agricultural promotion, savings and microcredit schemes, and improved access to WASH services can significantly improve birth weight.

Amorphous calcium carbonate can delay bone loss in postmenopausal women by regulating bone turnover markers

Yu-Shan Lee[1], Ling-wen Hsu[1], Chun-Kai Chen[2], Chian-Her Lee[3], Yi-wen Chien[1]

1. Taipei Medical University (Taiwan), 2. National Taiwan Ocean University (Taiwan), 3. Taipei Medical University Hospital (Taiwan)

Background and objectives: The organic matter in the bone structure is protein, and the inorganic matter is composed of a variety of mineral salt deposits. Therefore, if the amount of certain nutrients in the diet is inappropriate, it will affect the balance of bone metabolism and cause bone loss.

Methods: This study was to use human clinical trials to evaluate the changes in bone quality of UIC amorphous calcium carbonate to achieve the assessment of osteoporotic function. In this experiment, 35 postmenopausal women were recruited to conduct a randomized double-blind clinical trial of bone mineral density measurement. They were divided into experimental group and control group, and they were treated with UIC amorphous calcium carbonate or placebo for 6 months.

Results: The results found that after the intervention of amorphous calcium carbonate, the bone density in the greater trochanter and the total bone density is statistically better than the placebo group. The bone turnover markers, bone alkaline phosphatase (BAP) and procollagen-I N-terminal propeptide (P1NP) of osteoblasts, are significantly better than the placebo group ($p < 0.05$).

Conclusions: Consuming UIC amorphous calcium carbonate may "Benefit to delay bone loss."

Keyword: amorphous calcium, osteoporosis, menopause, bone density, osteoblast indicators

Conflict of Interest Disclosure: N/A

Anthropometric assessment of relationship between dietary intake status of mothers and children: Similarity between dietary intake of mothers and children in overweight group is weak

Kaoru Ikiuo[1], Shigetaka Sugihara[1], Yoko Suzuki[1], Yukie Yanagisawa[1]

1. Graduate School of Human Ecology Wayo Women's University (Japan)

Background and objectives: The purpose of this study is to examine the relationship between the dietary intake status of mothers and children to determine specific methods of nutrition and dietary guidance based on an anthropometric assessment.

Methods: 146 pairs of 3- to 5-year-old children and their mothers from nursery schools in Ward A, Tokyo, were included in the study; 52 pairs with available results of the mother-child survey were included in the analysis. The survey items were nutrition, food intake, and height and weight measurements. The children were divided into three groups based on their BMI percentile: standard body weight group (25–75 percentile), underweight group (0–25 percentile), and overweight group (75–100 percentile). This study was approved by the review board of Wayo Women's University.

Results: There was no significant difference in the intake status of the children in terms of nutrients and food groups among the three groups. There was no significant difference in the intake of carbohydrates %E and lipids %E of the mothers among the three groups. Analysis of the association between the dietary intake of mothers and children showed a significant positive correlation in the standard body weight and underweight groups for the total energy intake; however, there was no correlation in the overweight group. The standard body weight group had a significant positive correlation for the intake of vegetable protein %E, potassium, magnesium, iron, vitamin D, vitamin C, dietary fiber, and salt equivalent; by contrast, the overweight group had no significant correlation. Notably, the overweight group had a significant positive correlation for the intake of cereals. All three groups had a positive correlation for the intake of green and yellow vegetables.

Conclusions: There was no significant difference in the intake of nutrients and food groups among the three groups of children. Analysis of the relationship between the dietary intake of mothers and children indicated a strong similarity in the standard body weight group but not in the overweight group. It is important to focus on the difference between the eating habits of mothers and children for nutrition guidance, particularly in the overweight group.

Keyword: anthropometric assessment, mothers, children, dietary intake status

PAB(T3)-19

Comparative profile of free fatty acids and the metabolites between different species and search for the critical enzymes to the lipid composition

Saya Maruoka[1], Yuki Nagasaki[1], Erika Kawai[1], Miho Oosumi[1], Izumi Tsukayama[1], Yoshimi Miki[2], Makoto Murakami[2], Kei Yamamoto[3], Toshiko Suzuki-Yamamoto[1]

1. Okayama Prefectural University (Japan), 2. The University of Tokyo (Japan), 3. Tokushima University (Japan)

Background and objectives: On the basis of developmental origins of health and disease (DOHaD) theory, the milk quality during early infancy has obvious significance on the future health. In this study, we focused the profile of free fatty acids (FFAs) and the metabolites in ingested milk, because FAAs are high bioavailability lipids and lipid mediators, the metabolites from polyunsaturated fatty acids (PUFAs), are important for homeostasis or disease risks. Firstly, lipidomic profiles of human, cow and mouse milk were compared. Secondly, expression changes of the related enzymes were analyzed serially during the development of mouse mammary gland to identify the critical ones determining lipid composition.

Method: The lipid components were extracted from human, cow, and mouse milk using modified Bligh and Dyer method. Lipidomic analysis of the components was performed by liquid chromatography-electrospray ionization-mass spectrometry (LC-ESI-MS). Gene expression during the development of mouse mammary gland was measured by real-time PCR.

Result: Human milk had more abundant free fatty acids, and especially PUFAs compared with cow milk. The ration of ω3 PUFA (eicosapentaenoic acid: EPA and docosahexaenoic acid: DHA) to ω6 PUFA (arachidonic acid: ARA) in human milk was 1:1 but that in cow milk was 1:4. And human milk had more ω3 PUFA metabolites, however, cow milk had far ω6 PUFA metabolites. Additionally, EPA-derived 18-hydroxyeicosapentaenoic acid (18-HEPE), one of the specialized pro-resolving lipid mediators, was detected highly in human milk, but not in cow milk. Comparison of the lipidomic analysis indicated that the profile of mouse milk was similar to that of human milk. Among phospholipases involving in FFAs release and synthases of lipid mediators of PUFA metabolites, some correlated enzymes with the development of mammary gland were identified.

Conclusion: The present lipidomic analysis suggested that component balance of PUFAs and lipid mediators in human milk was superior in development of healthy body and avoidance of future disease risks. Some of phospholipases and lipid mediator synthases may be involved in the balance of milk lipid composition.

Thoughts about Body Shape and Eating Habits Influencing Adolescents' Body Perception Using the Health Behavior of School-age Children Questionnaire in Niigata Prefecture, Japan

Hiriomi Inaba[1], Fumi Hoshino[1], Kousuke Takano[1], Ryouka Shibuya[1], Yuuna Tsurumaki[1], Nao Watanabe[1], Misaki Kaiwa[1,2] , Kazuo Ishigami[1]

1. Niigata University of Health and Welfare (Japan), 2. Sagami Women's University (Japan)

Background and objectives: In Japan, a significant proportion of young women are underweight (body mass index < 18.5kg / 5 kg/m^2). Underweight pregnant women are more likely to have children with low birth weight and subsequent lifestyle-related disorders. Adolescence is a crucial period for attaining maximum bone mass, and excessive dieting during this period may have a deleterious effect on bone health. Another concern in Japan is the recent increase in underweight adolescent boys. This study aimed to clarify the characteristics of adolescent boys and girls' attitudes, who live in Japan's major cities, toward their bodies and eating habits when they believe that they are "fat". Adolescents in this survey were aged 15–18 years, the same age range as Japanese high school students.

Methods: A cross-sectional survey was conducted on 1,343 boys and girls from the Niigata Prefecture, Japan, in September 2021. The questionnaire was adapted from a World Health Organization survey on the health behavior of school-age children. This study complied with the Helsinki Declaration and was approved by the institutional review boards of the Niigata University of Health and Welfare (no. 18594-210412). For statistical analysis, R software version 4.0.2 was used. The Student's t-test, Chi-square test, and binomial logistic regression analysis were used, with the objective variable being "I think my body is fat and p-values < 0.05 considered as significant.

Results: The proportion of Japanese adolescents who perceived themselves to be overweight was significantly higher in girls (60.2%) than in boys (27.8%) (p < 0.001). Five items were selected for girls, including "I dislike my body" (p < 0.001). However, eating habits had no effect on their sense of being overweight. For boys, five items were selected, including "on a diet" (p = 0.002) and "breakfast intake" (p = 0.047).

Conclusion: This study suggests that while adolescent girls in the Niigata Prefecture have a high rate of distorted body-shape perception it was unrelated to their eating behavior, while adolescent boys' beliefs that they were obese was related to their eating behavior. Therefore, we infer that measures for adolescents who misjudge their body shape vary by gender.

Keyword: Adolescents, Perception, Underweight, Thin, Breakfast

Lifestyle, physique and bone mass of female college students who have a habit of skipping food

Miki Matsuzaki Otsu[1], Akiko Koike[2], Hiroko Hattori[3], Yuko Iimura[1], Katsuhiko Sumiyoshi[1], Shinji Saito[1]

1. Tokiwa University (Japan), 2. Tokai Gakuen University (Japan), 3. Aichi Gakuin University (Japan)

Objectives: A previous study of bone mass and lifestyle of female university students, it was reported that those who had a habit of skipping meals in junior high school tended to have low bone mass. Therefore, this study additionally examined dietary habits, physique, and bone mass of female university students who currently have a habit of skipping meals.

Methods: Physique, body composition, and bone mass (ultrasound method) were measured in 211 female university students (average age 19.6 ± 0.5 years). A questionnaire survey on past and present lifestyles, awareness of changes in dietary intake, and a food intake frequency survey on nutritional intake status were completed by the subjects.

Results: Findings showed 42 subjects (19.9%) did not eat three meals a day more than three times a week (meal-skipping group). Comparison of the meal-skipping versus the non-meal-skipping subjects demonstrated that there was a significant frequency of skipping meals observed in elementary school (19.0%, p <0.01), junior high school (28.6%, p <0.01), and high school (45.2%, p <0.001). Furthermore, there were 5 subjects found to have skipped meals starting from elementary school until the present. Comparisons of physique, body composition, and bone mass found no differences between the meal-skipping and non-meal-skipping groups. In terms of nutritional intake, vitamin D was low (p <0.01), while the percentage of fat energy was high (p <0.05) in the meal-skipping group. Nutritional intake classification by food group showed that the meal-skipping group had low intakes of algae, fishes and shellfishes (p <0.01, p <0.001), while there were high intakes of milk, confectioneries, and beverages (each p <0.05). When asked about any dietary issues, some of the respondents did indicate an awareness of a problem with their own diet (73.8%, p<0.01) in the meal-skipping group.

Conclusión: There was no difference in the physique, body composition and bone mass associated with the current eating habits of female university students. These results suggest that the reason why the vitamin D intake was low, and the percentage of fat energy was high in the meal-skipping group may be related to the intake of fishes and shellfishes, confectioneries, and beverages.

Adoptin of healthy baby toolkit in feeding children in fragile environments of Uganda

Frederick Grant[1], Norman Kwikiriza[1], Joyce Nakumbi[3], Mathew Muyinda[1], Joyce Maru[2], Simon Heck[2]

1. International Potato Centre (CIP) (Uganda), 2. International Potato Centre (CIP) (Kenya), 3. University of Massachusetts (USA)

Background and objectives: A major constraint to achieving nutrition outcomes in programs that target households with young children and/or women of reproductive age is inadequate use of OFSP and other locally available nutritious diets for household level consumption. The Development and Delivery of Bio-fortified Crops at Scale (DDBIO) project, implemented by International Potato Centre (CIP) and partners, scaled out the use of an innovative feeding toolkit, Healthy Baby Toolkit/HBT, to improve child diets to enhance outcomes beyond the broader nutrition promotion activities among caregivers of children under 5yr attending community-based monthly nutrition trainings (healthy living clubs). The objectives of this study are to evaluate the early adoption of the HBT in feeding children (6-23 mos) of caregivers attending the healthy living clubs and assess the association between participation in nutrition trainings and the adoption of the HBT.

Method: In this community-based cross-sectional survey in Eastern and Northern Uganda, a total of 233 participants were randomly sampled from caregivers attending monthly nutrition trainings organised by CIP in Uganda for a period of 8 trainings.

Results: Findings indicate a high understanding of the important concepts in proper feeding of children 6-23 mos. Caregivers utilized the HBT supplied to them to feed their children with nutritious and diverse foods including OFSP enriched porridge. In addition, they were willing to buy the HBTs at 1 USD in case the ones supplied to them got lost or old. There was a significant positive association between caregiver nutrition knowledge and willingness to pay for the HBTs.

Conclusion: The adoption and willingness to pay for the HBT implies that the technology can be scaled out to entrepreneurs if the relevant user information about the HBT and relevant nutritional information accompany the HBT.

Recommendation: The study recommends scaling up of the HBT technology by government and development partners to communities and recommends nutritional trainings to be prioritized in the communities through focused training of the VHTs.

Development and validation of a prediction model for identifying the risk of inadequate protein intake in community-dwelling older adults

Yuri Yokoyama[1], Yu Nofuji[1], Takumi Abe[1], Satoshi Seino[1], Takahiro Yoshizaki[2], Yoshinori Fujiwara[1]

1. Tokyo Metropolitan Institute of Gerontology (Japan), 2. Toyo University (Japan)

Objective: Adequate protein intake is important to prevent frailty in older adults, but several older adults do not meet the required intake levels. Raising awareness of inadequate protein intake could lead to behavioral changes. However, typical dietary assessment methods may be burdensome for older adults, and few easy tools to identify inadequate protein intake are available. Therefore, we aimed to develop and validate a prediction model for identifying the risk of inadequate protein intake in Japanese community-dwelling older adults using a simple question on frequency of the intake of specific foods.

Methods: We used data of 2,174 older adults from the 2013 National Health and Nutrition Survey to develop the prediction model and data of 1,949 older adults of the 2017 National Health and Nutrition Survey for external validation. Protein intake was assessed from 1-day dietary records using a semi-weighted method. We used multivariable logistic regression with stepwise backward elimination to identify predictive variables for inadequate protein intake (<1.2 g/kg-bodyweight/day). Candidate variables were sex, age, body weight, food intake frequency (rice, bread, noodles, meats, fish, eggs, soybeans, green/yellow vegetables, and other vegetables) and meal frequency. Discrimination and calibration were assessed by area under the receiver operating characteristics curve (AUC) and the Hosmer–Lemeshow test, respectively.

Results: In the development and validation groups, 40.3% and 39.8% of older adults had a protein intake <1.2 g/kg-bodyweight/day, respectively. The developed model for predicting inadequate protein intake included sex, age, body weight, intake frequency of specific foods (rice, meats, fish, eggs, and soybeans), and meal frequency. In the development group, the AUC of the model was 0.73. The P-value for the Hosmer–Lemeshow test in the model was more than 0.05. For external validity, the AUC was 0.72 in the validation group.

Conclusions: Our results showed that the developed model could identify for inadequate protein intake in Japanese community-dwelling older adults. This prediction model comprising nine items could easily and quickly identify older adults at high risk of inadequate protein intake and is expected to be widely used in public health settings.

Keyword: protein, prediction model, older adults

Assessment of functional food *Dioscorea japónica* paste as a thickened liquid for elderly with dysphagia

Yuka Konoike[1,2], Izumi Tsukayama[1], Mei Oji[3], Takayo Kawakami[1], Kayoko Ishii[2], Toshiko Suzuki-Yamamoto[1]

1. Okayama Prefectural University (Japan), 2. Fukuyama University (Japan), 3. Kurashiki Sakuyo University (Japan)

Background and objectives: Reduced swallowing function leads to malnutrition and deterioration of the quality of life in the elderly. In an aging society, the novel concept of dysphagia diet is essential in order to prevent diseases and maintain nutrition intake. Previously, we report that the inhibition of proinflammatory lipid mediator synthesis by *Dioscorea japonica (D. japónica)*, a wild yam, is effective in preventing chronic inflammation. Additionally, the paste of *D. japónica* has conformable physical properties, and is rheologically confirmed to be useful thickened liquid for dysphagia patients. The present study focused on the unique physical properties of *D. japonica* paste, and evaluated its stability and usefulness as a thickened liquid in a condition close to cooking.

Method: Freeze-dried *D. japonica* powder were used to prepare the paste as a thickened liquid and xanthan gum, and commercially available thickened liquids were used for comparison. Viscosities of the thickened liquids were measured using a cone and plate viscometer under the following setting: temperature of 20°C and shear rate of 50^{s-1}. Changes in viscosity of the thickened liquids were measured under various conditions of temperature, pH, NaCl addition and α-amylase addition.

Result: The viscosity of *D. japonica* paste was stable in NaCl addition, and was similar as that of the other thickened liquids in α-amylase addition. The viscosity of *D. japonica* paste was relatively stable on change in pH, but it was slightly unstable on change in temperature. *D. japonica* showed high versatility because the viscosity of *D. japonica* paste could be easily adjusted by modifying its blending amount and temperature.

Conclusion: The present study demonstrated that *D. japonica* paste had an excellent suitability and the usefulness as a thickened liquid compared with commercial thickened liquids. Therefore *D. japonica* paste will be a novel type of thickened liquid with adequate food functionality for the prevention of proinflammatory lipid mediators-related diseases.

Relationship between living arrangements and nutritional intake of community-dwelling older people in the 2019 Tarumizu study

Kayoko Imamura[1,2], Sachiko Aburada[1,3], Hisami Manabe[1,2], Hajime Suzuki[4], Takuya Yoshimura[4], Toshihiro Takenaka[5], Takuro Kubozono[4], Mitsuru Ohishi[4]

1. Kagoshima Dietetic Association (Japan), 2. Kagoshima Immaculate Heart University (Japan), 3. Kagoshima Kouseiren Hospital (Japan), 4. Kagoshima University Graduate School of Medical and Dental Sciences (Japan), 5. Tarumizu Chuo Hospital (Japan)

Background and objectives: Extending healthy life expectancy is important for the older, and this requires that they have proper nutritional intake. However, the dietary habits of the older are predicted to be influenced by their living arrangements. Therefore, the purpose of this study was to clarify the relationship between living arrangements and nutritional intake among community-dwelling older people.

Methods: The Tarumizu study was initiated in 2017 as a community-based health assessment survey jointly conducted by Tarumizu City and Kagoshima University. Energy and nutrient intakes were assessed through a dietary survey using a simplified Brief-type self-administered Dietary History Questionnaire (BDHQ). In this study, we compared those who lived alone and those who did not live alone, i.e., those who lived with their families, each gender, among those aged 65 years and older living in Tarumizu City, Kagoshima Prefecture, who participated in the study in 2019.

Results: The participants consisted of 47 men living alone and 208 not living alone and 140 women living alone and 295 not living alone. Energy intake did not differ by household for either sex, with men living alone: 2016±621 kcal, not living alone: 2174±602 kcal, and women living alone: 1774±555 kcal, not living alone: 1816±486 kcal. Energy-producing nutrient intake did not differ depending on the household for protein and fat intake, while carbohydrate intake tended to be higher among men who did not live alone (271.1±84.6 g) than those who lived alone (247.8±79.3 g) (p=0.08). In terms of vitamin and mineral intake, potassium and vitamin C intake was higher in men who did not live alone than in those who did live alone. For women, retinol, vitamin B_2, and vitamin B_{12} intake was higher among those who "lived alone" than among those who "did not live alone.

Conclusions: In conclusion, we found that nutritional intake varied by living arrangement. In particular, differences by gender were observed, with better nutritional intake for men living with family and women in a single household.

Effect of fetal carbohydrate restriction on intestinal flora in mice

Fuyuka Murase[1], Kouhei Yamaguchi[1], Wataru Machida[1], Chisato Hara[1], Ayaka Ozawa[1], Yukari Egashira[1], Shizuka Hirai[1]

1. Chiba University (Japan)

Background and objectives: In recent years, many young women in Japan have a desire to lose weight. There is concern that undernutrition in women of childbearing age increases the rate of premature birth and low birth weight babies, and that such children will have an increased risk of developing obesity and metabolic syndrome in the future. It has been reported that the intestinal microbiota regulates the host energy metabolism. Furthermore, it has also been reported that the maternal intestinal flora influences the formation of that of the offspring. In a previous study, we found that total nutritional restriction in late pregnancy in mice exacerbates obesity, glucose and lipid metabolism, while carbohydrate restriction ameliorates obesity and glucose metabolism in the offspring. In this study, we investigated the changes in the intestinal flora caused by carbohydrate restriction during the fetal period.

Methods: Eight-week-old male and female C57BL/6J mice were mated. In late pregnancy, female mice were fed with a standard diet (control group) or a carbohydrate-restricted diet (carbohydrate-restricted group) and gave birth to offspring. After giving birth, all groups of dams were given a standard diet. Feces were collected from the offspring immediately after weaning, and intestinal flora were analyzed by 16S rRNA sequencing.

Results: Principal coordinate analysis revealed that the intestinal flora of the control and carbohydrate-restricted groups formed different clusters. Analysis of intestinal flora composition at the genus level showed an increase in *Prevotella Bacteroides* (*PB*) ratio, reported to be associated with weight loss, in the carbohydrate-restricted group. In addition, the carbohydrate-restricted group induced changes in intestinal flora, including a decrease in *Clostridium* spp. and *Escherichia* spp. and an increase in *Anaerotruncus* spp.

Conclusion: Prenatal carbohydrate restriction caused the changes in the intestinal flora, such as an increase in *PB* ratio, which may contribute to the improvement of obesity and glucose metabolism in high-fat diet-fed mice.

Keyword: carbohydrate restriction during pregnancy, intestinal flora, obesity, metabolic syndrome

Adjusting prenatal iron supplementation to women's needs in early pregnancy to improve maternal iron status in late pregnancy

Lucía Iglesias-Vázquez[1,2], Núria Aranda[1,2], Estefanía Aparicio[1,2], Josep Basora[1,2,3], Victoria Arija[1,2,3]

1. Universitat Rovira i Virgili (Spain), 2. Institut d'Investigació Sanitaria Pere Virgili (IISPV) (Spain), 3. Jordi Gol University Institute for Primary Care Research (Spain)

Background and objective: Inadequate iron status (deficit and excess) during pregnancy has been associated with problems in maternal–fetal health. The present analyses aimed to assess whether different doses of prenatal iron supplements, adapted to women's needs in early pregnancy, help to improve maternal iron status in late pregnancy.

Methods: The ECLIPSES study involved 791 women recruited before gestational week 12. Participants were randomized into two groups according to their hemoglobin (Hb) levels: group 1 when Hb=110-130 g/L, and group 2 when Hb>130 g/L. Women received 20 vs. 40 mg/day or 40 vs. 80 mg/day of iron, respectively. Iron deficiency (ID) in the first and third trimester was defined as serum ferritin (SF)<15 µg/mL, anemia as Hb<110 g/L, and iron deficiency anemia (IDA) as SF<15 µg/mL and Hb<110 g/L. Extensive maternal information was recorded and considered as potential confounders: clinical, biochemical, and genetic information, as well as sociodemographic and lifestyle characteristics.

Results: In women in group 1, taking 80 mg/day protected against ID in the overall sample. In addition, taking 80 mg/day increased Hb levels at the end of pregnancy in women with baseline ID, showing an additional benefit against anemia and IDA. In group 2 participants, taking 20 mg/day protected against hemoconcentration in those without baseline ID, while 40 mg/day improved final SF levels in women with baseline ID. Genetic alterations in the HFE gene may predispose to hemoconcentration.

Conclusions: Maternal iron supplementation should be adapted to both circulating and stored iron in early pregnancy. Other factors such as genetics should be considered in clinical practice in women with elevated Hb levels.

Keyword: Iron supplementation, Serum ferritin, Hemoglobin, Pregnancy

Re-examination of hemoglobin cut-offs defining anemia in school-age children and adolescents aged 5-19y

Mica J. Jenkins[1,2], Maria Elena D. Jefferds[1], Lucas K. Gosdin[1], Anne M. Williams[3], Melissa F. Young[2], Parminder S. Suchdev[1,2], Andrea J. Sharma[1], Zuguo Mei[1], O. Yaw Addo[1,2]

1. Centers for Disease Control and Prevention (USA), 2. Emory University (USA), 3. University of Otago (New Zealand)

Background and objectives: Current WHO hemoglobin (Hb) thresholds for anemia (115 g/L for children 5–11y, 120 g/L for children 12–14y and non-pregnant women 15y and older, and 130 g/L for men 15y and older) are used to inform and evaluate public health programs but were not derived using data representing diverse geographies. Our objectives were to use multi-country data on children 5–19y to determine the appropriateness of pooling Hb thresholds across countries and compare the 5th percentile for Hb, adjusted for elevation and smoking, to current thresholds for anemia.

Methods: We analyzed data from 36,967 apparently healthy (no inflammation or malaria) children aged 5–19y without iron or vitamin A deficiencies from 15 countries collected between 2006–2019: Azerbaijan, Bangladesh, Colombia, Ecuador, Ghana, Georgia, Guatemala, Laos, Liberia, Malawi, Mexico, Nepal, Great Britain, the United States, and Vietnam. A minimum sample size of 100 per age-sex category was required for the calculation of percentiles. Linear quantile mixed models with country as random effect were used to examine the intra-cluster (country) correlation coefficient (ICC) at the 5th percentile. Univariate ranking and meta-analysis were used to generate pooled 5th percentile estimates for each age-sex category.

Results: An ICC of 6% indicated that 94% of the variance around the 5th percentile was due to participant-level heterogeneity. Pooled 5th percentile Hb estimates were: children 5–11y (9 countries: 114.5 g/L, 95% CI: 111.1–118.0), children 12–14y (10 countries: 118.5 g/L, 115.3–121.7), girls 12–14y (10 countries: 117.1 g/L, 113.5–120.7), boys 12–14y (7 countries: 121.5 g/L, 117.5–125.4), girls 15–19y (13 countries: 114.2 g/L, 110.2–118.2), and boys 15–19y (3 countries: 126.8 g/L, 109.5–144.1).

Conclusion: Among healthy children 5–19y from diverse countries, current WHO Hb thresholds for identifying anemia aligned with 5th percentiles in all groups except girls 15–19y, for whom a lower threshold may be considered. A comparative analysis with women 20–49y will inform whether a change in thresholds is warranted for girls 15–19y. Given limited data on boys 15–19y, information on this demographic from additional countries is needed.

Keyword: hemoglobin thresholds, anemia, school-age children, adolescents

PAB(T3)-29

Relationship between changes in body mass index and eating habits of children aged 1.5–3 years.

Yasuko Sakaida[1,6], Rie Amamoto[2], Akiko Iwahashi[3,6], Yoko Tsujimoto[4], Kimiko Hirotsu[5], Tomoe Fukumura[6], Katsushi Yoshita[6]

1. University of Nagasaki (Japan), 2. Seinan Jo Gakuin University (Japan), 3. Tezukayama University (Japan), 4. Chubu University (Japan), 5. Graduate School of Health and Welfare, Yamaguchi Prefectural University (Japan), 6. Graduate School of Human Life Science, Osaka City University (Japan)

Background and objectives: An early adiposity rebound (AR) is associated with an increased risk of childhood obesity. This study assessed maternal and childhood lifestyle and dietary factors for increase in the body mass index (BMI) of children aged 1.5–3 years.

Methods: All participants were born between February 2015 and February 2016. Questionnaires were collected during the children's routine check-up at 4 months, 1.5 years, and 3 years of age in City A, Fukuoka, Japan. A total of 354 children who had undergone all the check-ups and whose data at the three check-ups were available and linked were included into the study. To compare the children and mothers' lifestyles, eating habits, and the children's degree of obesity, the participants were divided into two groups: the increased BMI group (BMI+, n=100) and the decreased BMI group (BMI-, n=254).

Results: The BMI+ group had a lower BMI at 4 months and 1.5 years of age than the BMI- group, but had a higher BMI when aged 3 years. When their children were aged 3 years, mothers in the BMI+ group had a significantly higher weight and BMI. Moreover, many mothers had a low subjective economic status when their children were aged 1.5 years. The snack (e.g., chips) intake of the BMI+ group at 1.5 years of age was higher than that of the BMI- group. The odds ratio of the BMI+ group to the BMI- group was 2.262 (95% confidence intervals: 1.373–3.724) for frequency of milk and dairy intake for mothers of children aged 1.5 years, and 1.955 (1.092–3.501) for that of frequency of children's snack food intake. An overall analysis showed that the BMI- group had a significantly higher proportion of children at 1.5 years of age with a degree of obesity of +15 or higher than the BMI+ group. However, it was higher in the BMI+ group at 3 years of age.

Conclusions: Snack intake in children might be associated with early AR and the transition to childhood obesity in children with early AR initiation. Therefore, dietary guidance is important from early childhood.

Keyword: adiposity rebound, childhood obesity, child health check-up, eating habits, snack

PAB(T3)-30
Creating an Enabling Environment for Baby-Friendly Hospital Initiative: Two Country Case Study of Malawi and the Kyrgyz Republic

Janet Guta[1], Nazgul Abazbekova[2], Kanji Nyambo[3], Malia Uyehara[4,5], Charlotte Block[4,6], Alyssa Klein[4,5], Jeniece Alvey[7], Altrena Mukuria-Ashe[4,8]

1. Ministry of Health (Malawi), 2. USAID Advancing Nutrition (Kyrgyz Republic), 3. Independent Consultant (Malawi), 4. USAID Advancing Nutrition (USA), 5. John Snow Inc. Research & Training Institute (USA), 6. NCBA CLUSA (USA), 7. Public Health Institute/USAID Global Health Professionals (USA), 8. Save the Children (USA)

Background and objectives: In 2018, WHO and UNICEF made major changes to the implementation guidance of the Baby-Friendly Hospital Initiative (BFHI) to facilitate the integration of the Ten Steps of successful breastfeeding into the standards of prenatal, maternity, early postpartum, and newborn care. Since the inception of BFHI in 1991, improved hospital practices resulting from its implementation proved to be effective in increasing rates of initiation and exclusive breastfeeding and in some countries, breastfeeding duration, too. To motivate hospitals to maintain the practices, they were granted a baby-friendly designation. With a paradigm shift away from external certification, public recognition, and dependence on in-service training, creating an enabling environment is required to institutionalize BFHI. The objective of this paper is to share country experiences with establishing an enabling environment for BFHI in Malawi and the Kyrgyz Republic.

Methods: We conducted a qualitative study of BFHI with in-depth interviews of 85 key informants of policy makers, stakeholders, managers and service providers from both countries. Using ATLAS.ti, we analyzed texts from interviews and documents using deductive codes informed by the research questions and inductive codes based on the data from each country.

Results: These countries reported they learned that an enabling environment for BFHI, including a strong policy environment, a cadre of well-trained trainers and managers, clear responsibilities for BFHI at all levels, an understanding of motivations at the individual and systems level to make incentives effective, and that quality improvement approaches can be employed to monitor and improve delivery of breastfeeding counseling and support. Pre-service training in breastfeeding support and counseling was not fully established.

Conclusions: Despite financial and human resource constraints, countries are deeply committed to BFHI. They have national and local policy guidance and implementation structures that support institutionalizing BFHI. They have trained national level trainers and managers. However, they continue to struggle to create a fully strong enabling environment and require some external support. The transition to full integration of BFHI into the standards of care requires a multi-sectoral approach to include health, education, and finance sectors at national and local levels.

Improving breastfeeding behaviours through traditional birth attendant support: A case study of Alive and Thrive, Nigeria

Carolyn O'Donnell[1], Karina Lopez[1], Adaeze Oramalu[1], Awotunde Williams[1]

1. Save the Children (USA)

Background: In Kaduna and Lagos, Nigeria, 21% of pregnant women access services at health facilities while 39% seek care from traditional birth attendants [TBA] as a more patient-centered and inexpensive option. [1,2] Rates of early initiation [EI] and exclusive breastfeeding [EBF] remain persistently low at 32.8% and 29% (NDHS, 2018), due largely to inadequate knowledge and lack of family support for breastfeeding. The preference for TBA services makes them crucial to the effort to improve breastfeeding behaviors. Therefore, Alive and Thrive [A&T], funded by the Bill and Melinda Gates Foundation, partnered with local health authorities (LGA) to increase knowledge and improve interpersonal communication [IPC] skills of TBAs in order to improve infant and young child feeding [IYCF] practices in Kaduna and Lagos.

Method: Local authorities selected 1,554 TBAs in 26 LGAs across Lagos and Kaduna to participate in A&T's capacity strengthening program. They received training and coaching on appropriate IYCF practices and IPC for effective counseling during antenatal care and home visits, as well as hands-on support for EI and EBF, emphasizing the benefits for mother and baby and supporting women in labor to breastfeed immediately upon delivery. A&T assessed progress via routine monitoring during supportive supervision visits and through health facility records of EBF and EI.

Results: Program monitoring data showed that 460,290 pregnant and lactating women received improved counselling during the program and that the rate of EI was higher than the national rate of 32.8%. In Lagos, of the 6,355 newborns delivered with the support of A&T trained TBAs, 6,110 (96%) were put to the breast within one hour of delivery while in Kaduna the result was 28,398 of 30,045 newborns (95%). TBA testimonials noted that they would promote EI with patients as it resulted in good outcomes for the baby and better outcomes for them as practitioners.

Conclusion: TBAs are essential change agents and frontline workers whose strengthened capacity can significantly impact breastfeeding behaviors in their communities.

Exploring the alcohol intake in community-dwellin older adults living in Auckland, New Zealan

Kathryn Louise Beck[1], Sheenal Shivani Chand[1], Karen Mumme[1], Andy Towers[1], Pamela Ruth von Hurst[1], Cathryn Anne Conlon[1]

1. Massey University (New Zealand)

Background and objectives: In a period of global ageing evidence suggests older adults are now drinking more than ever. There is limited evidence regarding types of alcohol consumed and adherence to alcohol consumption guidelines in older New Zealand adults. This study explored alcohol intake patterns in community-dwelling older adults (65-74 years) living in Auckland, New Zealand.

Methods: This study was a sub-study of the REACH (Researching Eating, Activity and Cognitive Health) study. Older adults aged 65 to 74 years living in Auckland completed demographic and dietary questionnaires, including questions specific to alcohol intake.

Results: Participants (n=371) included 64% females and were mainly of New Zealand European ethnicity (94%). Most (81%) consumed alcohol, 15% never drank and 4% used to drink alcohol. Most participants consumed alcohol within the New Zealand Ministry of Health daily (99%), weekly (96%) and per occasion (96%) guidelines, and 84% had two or more alcohol-free days per week. The most common types of alcoholic beverages consumed were beer (0.9±2.1 (mean±SD) standard drinks per week), red wine (1.7±3.1) and white wine (1.8±3.6). Males consumed more standard drinks per week (6.4±7.4) than females (4.3±5.6). For those who consumed alcohol, drinking occurrence was at least weekly. Men were more likely to consume beer (59% males; 7% females) and red wine (49% males; 31% females), while females were more likely to consume white wine at least weekly (45% females; 32% males). Multiple linear regression analysis found 'sex' (being male) and 'index of multiple deprivation score' (less deprived) were positively associated with maximum standard drinks per occasion. 'Age', 'education' and 'living situation' were not associated with maximum standard drinks per occasion in older adults.

Conclusions: Over 80% of older New Zealanders consumed alcohol, with men more likely to consume beer and red wine, and less likely to consume white wine. Most older consumers drank within the New Zealand Ministry of Health guidelines. Being male and having a lower level of deprivation were positively associated with maximum number of drinks consumed per occasion. Further research is needed in a more representative sample of older New Zealand adults to confirm these findings.

Documentation and Evaluation of the Adequacy of Complementary Foods Used by Mothers/Caregivers in the Southeast Geo-political Zone, Nigeria

Henrietta Nkechi Ene-Obong[1], Millicent Ifeoma Ogbaji[2]

1. University of Calabar, Calabar (Nigeria), 2. University of Nigeria Teaching Hospital, Enugu (Nigeria)

Background and Objective: High prevalence of childhood malnutrition in Nigeria has been attributed to suboptimal infant and young child feeding (IYCF) practices; therefore, this study aims to document and evaluate the adequacy of complementary foods used by mothers/caregivers in Southeastern Nigeria.

Methods: A cross-sectional survey involving 1200 households was carried out in three States, in Southeast, Nigeria. Multistage sampling technique was used to select households with mothers/caregivers and children aged 6-24 months from each State. Ethical approval and informed consent were duly obtained. Focus group discussions and semi-structured questionnaire were used to elicited information on IYCF practices and recipes of complementary foods used by mothers/caregivers. These recipes were standardized, prepared, and chemically analyzed and in some cases calculated for their proximate, β-carotene, vitamins A and C, folate, minerals (calcium, iron, zinc and iodine) and anti-nutrients (phytate and tannin) composition using standard methods. Phytate: zinc molar ratio was used to determine the bioavailability of zinc. The nutrient composition the cereal paps, complementary foods and food supplements were presented as means ± SD per 100g samples, while the amount of nutrient supplied by the complementary foods as consumed were compared with standards recommended for complementary foods for infants 6-8 months, 9-11 months, and 12-24 months.

Results: Cereal paps were the most widely used complementary food but enriched/supplemented with home-processed single foods (soybean flour or unripe plantain flour) or various flour blends made from soybean, crayfish/dry prawn/dry fish, green plantain, groundnut, and sugar. Commercial/institutional complementary food made of soybean, ground nut and wheat was encountered. The supplements were high in protein (24.4 - 44.7%), fat (8.1-17.6%) and energy (1731-2219 KJ/414-531 Kcal/100g dry weight). Unripe plantain flour was the least in protein (6.8%), fat (1.2%) and energy (1412 KJ/357 Kcal/100g). The phytate: zinc molar ratios were high (>15). When these supplements were incorporated into cereal pap as consumed by the children, they were found to be adequate in energy, protein, and vitamin A but deficient in all the minerals analyzed.

Conclusion: Home-made complementary foods in their present condition cannot meet many of the mineral needs of IYC unless supplemented with fruits and vegetables powders.

Keyword: Complementary foods, supplements, Nutrient composition, Adequacy, Nigeria

Gestational weight gain and perinatal outcomes in Western Brazilian Amazon

Paola Soledad Mosquera[1], Maíra Barreto Malta[2], Ana Alice de Araújo Damasceno[3], Paulo Augusto Ribeiro Neves[4], Alicia Matijasevich[5], Marly Augusto Cardoso[6]

1. Sao Paulo University (Brazil), 2. Sao Paulo University (Brazil), 3. Sao Paulo University (Brazil), 4. Sao Paulo University, Pelotas University (Brazil), 5. Sao Paulo University (Brazil), 6. Sao Paulo University (Brazil)

Background and objective: Maternal undernutrition and excess weight during gestation are highly prevalent in low- and middle-income countries and are associated with adverse obstetric outcomes and poor offspring health. However, GWG is a potentially modifiable exposure factor. Thus, the study objective was to investigate the association between gestational weight gain (GWG) and perinatal outcomes in Amazonian postpartum women.

Methods: Data of mother-child pairs (n=1305) participants in the Maternal and Child Health and Nutrition in Acre (MINA-Brazil) birth cohort study was used. The exposure of interest was GWG, which was classified as insufficient, adequate, or excessive according to the Institute of Medicine guidelines. Poisson and linear regression analyses were performed to evaluate the associations between GWG and birthweight (BW) z-scores, low birthweight (LBW), macrosomia, small for gestational age (SGA), large for gestational age (LGA), preterm birth, caesarean delivery, maternal hemoglobin, and gestational anaemia. The level of significance was set at P < 0.05.

Results: Inadequate GWG accounted for 64.7% of pregnancies, with similar rates (32%) of insufficient and excessive weight gain. Compared with adequate GWG, excessive GWG was associated with 0.41 higher mean new-born BW Z-score (95%CI 0.29, 0.53), increased risk of macrosomia (adjusted relative risk [RR]: 1.68; 95%CI 1.02, 2.76), LGA (RR: 2.16; 95%CI 1.56, 3.01), cesarean delivery (RR: 1.26; 95%CI 1.11, 1.43), and lower risk of LBW (RR: 0.44; 95%CI 0.27, 0.73) and SGA (RR: 0.38; 95%CI 0.21, 0.68). Women gaining insufficient GWG presented a mean new-born BW z-score 0.16 lower (95%CI -0.29, -0.04) than those who gained adequate weight.

Conclusions: In this population, the inadequacy of gestational weight remains an important health concern since most women ended their pregnancies with inadequate weight. Insufficient and excessive GWG were associated with adverse perinatal outcomes, highlighting the need for actions to promote adequate gestational weight gain in the Amazon population. Antenatal care visits should be maximized for monitoring weight gain, along with relevant counselling about healthy eating and physically activity to support appropriate GWG.

Keyword: Gestational weight gain, Institute of Medicine, Perinatal outcomes

Conflict of Interest Disclosure: Nothing to declare

Further Collaborators: The MINA-Brazil Study was supported by the São Paulo Research Foundation (FAPESP, grant number 2016/00270-6) and I received scholarships from the Coordination for the Improvement of Higher Education Personnel (CAPES, grant number 372666/2019-00).

PAB(T3)-35
A questionnaire survey on eating habits of Japanese infants and children

Mamoru Kimura[1], Takayuki Watanabe[1], Masaaki Kunou[1], Michiko Matsunaga[3], Keisuke Hagihara[2], Masako Myowa[3]

1. Kewpie Corporation (Japan), 2. Osaka University (Japan), 3. Kyoto University (Japan)

Background and Objects: Although eating habits from infancy to childhood are thought to be essential for life-long health, little data have been provided to support the view. We conducted a questionnaire survey on diet and related everyday problems in Japanese infants and children.

Methods: We have constructed the large-scale database (n > 1300 pairs) on the gut microbiome, physical and mental condition, and cognitive development of children aged 0–4 years and their mothers through 103 children's parks and kindergartens in Japan. The questionnaire on the eating habits of children included the frequency of intake of 24 foods within a week, food preferences, health status, and the issues related to sleeping, bowel, and eating habits. Additionally, cognitive development was evaluated using the BRIEF-P scale. For statistical analysis, we used nonparametric methods.

Results: Children with no health problems (46%) consumed significantly more vegetables, mushrooms, fruits, beans, and eggs than those with health problems ($p < 0.05$). Particularly, children with a high incidence of cold (24%) and fever (13%) ate fewer vegetables and mushrooms than those with a low incidence ($p < 0.05$). Importantly, after 18 months of age, the dislike for vegetables more than doubled (38%) than the previous age (17%). “Making (42%)” and “feeding (23%)” were the most common issues relating to parenting stress. Many dietary problems were also observed, such as “the amount of food eaten is not constant (27%)” and “unbalanced diet (35%).” Finally, the children (3-4 years) at risks of cognitive development (10%) consumed fewer deeply colored vegetables than those at no risk ($Z = -2.28$, $p = 0.27$).

Conclusions: The intake of vegetables and fruits is related to the health maintenance and cognitive development of Japanese infants and children. However, since the number of infants disliking vegetables has remarkably increased from the end of infancy, effective strategies for motivating infants for consuming vegetables are required. This may also assist in reducing parenting stress.

Keyword: questionnaire survey, eating habits, Japanese, infants, children

Maternal dietary quality assessed by Nutrient-Rich Food Index 9.3 and attitude towards dietary habits in a Japanese single-center birth cohort

Noriko Sato[1,4], Chihiro Imai[2], Hidemi Takimoto[3], Naoyuki Miyasaka[4]

1. Japan Women's University (Japan), 2. University of Yamanashi (Japan), 3. National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 4. Tokyo Medical and Dental University (Japan)

Background and objectives: The maternal diet can potentially influence the life-course health of the child. Using the Nutrient-Rich Food Index 9.3 (NRF9.3), we previously assessed the overall dietary quality of pregnant women during mid-gestation in an urban area of Japan. The NRF9.3 score was inversely correlated with the Dietary Inflammatory Index score, which reflects the inflammatory capacity of the diet. Vegetables and fruits were the food groups chiefly associated with high dietary quality assessed by NRF9.3, consistent with the results of other studies that analyzed dietary patterns in food-based manner. This study investigated how the mother's attitude towards dietary habits affects NRF 9.3 score.

Methods: Data were derived from 108 participants in the Birth Cohort-Gene and ENvironment Interaction Study of Tokyo Medical and Dental University (BC-GENIST). Information on satisfaction with the current diet, perceived body-size image, supplement intake status, foods that are actively consumed or avoided, educational attainment, and economic status was collected via a self-administered lifestyle questionnaire. The level of satisfaction with the current diet was assessed using the following five categories: “very satisfied”, ”satisfied”, “neutral”, ”dissatisfied”, and “very dissatisfied”. The level of perceived body-size image was assessed as the following: “very lean”, ”underweight”, “normal”, ”overweight”, and “obese”. Descriptive statistics and linear test for trend or t-test were performed to compare NRF9.3 scores across categories of each variable.

Results: Higher NRF 9.3 scores were observed with higher levels of dietary satisfaction and leaner body image. These associations remained after adjustment for maternal age, pre-pregnancy body mass index, educational attainment, and economic status ($p = 0.032$ and 0.0046, respectively). Supplement intake status was not associated with NRF 9.3. The participants actively consuming vegetables had significantly higher NRF9.3 ($p = 0.014$).

Conclusions: There was a significant positive association between satisfaction with dietary life and NRF 9.3, suggesting that dietary satisfaction, as well as nutritional value, is important for improving overall dietary quality. It was also indicated that an awareness of active vegetable intake contributes to an increase in overall dietary quality.

Effect of malted-rice amazake intake on defecation and nutritional status of hospitalized or institutionalized elderly

Miki Doi[1], Rikako Inoue[2], A. Yasmin Syauki[1], Suzumi Kageyama[1], Haruka Sakaue[1], Hiroe Ohara[3], Kazunori Takemoto[3], Kozo Tanabe[4], Kaori Harano[2], Yasuyuki Irie[2]

1. Graduate School of Okayama Prefectural University (Japan), 2. Okayama Prefectural University (Japan), 3. Silver center Kouraku (Japan), 4. Mizushima Daiichi Hospital (Japan)

Background and objectives: Approximately 20% of the late elderly are malnutrition, and one in nine persons over 80 years of age complains of constipation. In the elderly, constipation can easily lead to abdominal pain, vomiting, anorexia, inflammation, etc., thus highly likely to lead to malnutrition. Therefore, it is important to take remedial measures focusing on defecation and nutritional status. This study examined the effects of malted-rice amazake intake on defecation and the nutritional status of hospitalized elderly patients and institutionalized residents.

Methods: The subjects were 27 elderly (86.2±7.5 years old) who were hospitalized or admitted to a hospital or a nursing home. The schedule consisted of daily intake of malted-rice amazake for the first 6 weeks and no amazake intake for the second 6 weeks. Body composition, blood biochemical test, nutrient intake, defecation, and prescribed medications surveys were performed before the intervention (0w), after the intervention (6w), and after 6 weeks of intervention (12w).

Results: The BMI significantly increased after amazake intake. There was also an increasing trend in albumin from 3.3 ± 0.4 g/dL (0w) to 3.4 ± 0.5 g/dL (6w), while significant increases in lipid and vitamin D were observed for nutrient intake other than amazake. The subjects were divided into Constipated Group (CG: n=12) and Non-Constipated Group (NCG: n=15) according to 0w's score of CAS (Constipation Assessment Scale). The CG improved the constipation symptoms from 0w to 12w, showing an increasing trend in BMI. In the grouping by GNRI (Geriatric Nutritional Risk Index), there was a trend of increasing BMI from 0w to 12w in the no nutritional disability risk (GNRI>98) or mild nutritional disability risk (92<GNRI<98) group (n=6). There was no significant change in the severely malnourished risk (GNRI < 82) group (n=8).

Conclusions: Consumption of malted-rice amazake by hospitalized or institutionalized elderly for 6 weeks suggested the possibility of improving constipation symptoms and nutritional status. The effects of amazake consumption may differ depending on the subject's condition prior to the intervention.

Breastfeeding Practices and Head Circumference in the First Two Years of Life: a Systematic Review

Isabel Giacomini Marques[1], Lucas Damasio Faggiani[1], Paola Soledad Mosquera[1], Marly Augusto Cardoso[1]

1. University of Sao Paulo (Brazil)

Background and objectives: After birth, the human skull and brain undergo intense connectivity and transformation. Such changes occur at a greater speed, mainly during the first years of life, and an accelerated head circumference (HC) increase reflects this process. Breastfeeding (BF) plays a pivotal role in early brain development owing to its nutritional composition and emotional mother-infant interaction and bonding, but its effects on HC remain uncertain. This systematic review aimed to gather observational studies that investigated the association between BF practices and HC in children up to two years of age in different populations.

Methods: A search protocol was developed beforehand and registered in the International Prospective Register of Systematic Reviews (ID 252891). The systematic review was conducted using the PubMed, Latin American and Caribbean Literature in Health Sciences (Lilacs), Web of Science and Scopus databases. We selected observational studies published in any language from January 01, 2010 to November 19, 2021, from different populations that investigated the association between BF practice and HC among healthy children <2 years old. Titles and abstracts were screened independently by two evaluators.

Results: From the 4229 articles identified, 24 were included in this review: 6 cross-sectional, 17 longitudinal, and 1 case-control. The definition of the variables for BF varied across studies; reporting its practice, and its frequency, duration, and offering route. Regarding HC, the authors analyzed the mean differences, abnormal values (z-score above + 2SD or below -2SD according to the World Health Organization, WHO, growth standards, 2007) and longitudinal growth parameters.

Conclusions: The findings of this review suggest that BF may have a positive relationship with HC at the beginning of life. Cross-sectional studies provide some support that exclusive BF may play a protective role against abnormal HC values in vulnerable contexts. However, when HC is considered as a continuous variable, the positive association with BF is not clear, regardless of the regional economy of the population under study. More robust evidence using BF standardized assessment and WHO growth standards (2007) and in low-income countries are required.

Dietary intake of picky eaters associated with sensory profiles among college students

Sayaka Nagao-Sato[1], Yui Kawasaki[1], Rie Akamatsu[1], Yoko Fujiwara[1]

1. Ochanomizu University (Japan)

Background and objectives: Picky eating (PE) affects eating behavior and unhealthy dietary intake among children and adults. Sensory sensitivity is associated with PE; however, it is not well-known whether sensory profiles are associated with PE in adulthood. The aim of this study was to examine the association between PE, sensory profile, and dietary intake among college students, who are in an important period of emerging adulthood.

Methods: This cross-sectional study used data from 112 Japanese undergraduates at a women's university in 2018. Self-administrated questionnaires were utilized to assess sociodemographic characteristics (age, BMI, household size, weekly frequencies of hobby activities and part-time jobs), self-rated PE, sensory profile, self-rated health, and frequency of balanced meals containing staple food, protein-rich dishes, and vegetable-rich dishes. Self-rated PE was assessed as three levels: always/often, sometimes, and rarely PEs. The 60-item "Adolescent/Adults Sensory Profile" was used to assess four quadrant scores: low registration, sensory seeking, sensory sensitivity, and sensory avoiding. Dietary quality was assessed based on food frequency questionnaires. The Kruskal-Wallis test and Pearson's chi-square test were used to compare the sociodemographic characteristics, self-rated health, and sensory profiles by perceived PE levels.

Results: Of 112 participants, 25 (22.5%), 45 (40.5%), and 41 (36.9%) participants were reported having always/often, sometimes, and rarely PE, respectively. Sociodemographic characteristics and self-rated health did not differ by PE levels. Higher scores of sensory sensitivity and sensory avoiding quadrants were observed among students having "always/often PE" (p=0.049 for sensory sensitivity; p=0.032 for sensory avoiding). Frequencies of balanced meals tended to be higher among participants in "rarely PE" (p=0.0055). Participants who reported "rarely PE" consumed more green and yellow vegetables, other vegetables, folate, and vitamin K, compared to those who reported "always/often PE" (96 vs. 51 g/day for green and yellow vegetables; 140 vs. 70 g/day for other vegetables; 291 vs. 214 µg/day for folate; 259 vs. 217 µg/day for vitamin K; p<0.05, respectively).

Conclusions: Sensory sensitivity and sensory avoiding quadrants were associated with PE, which leads to less vegetable consumption among college students. Strategies

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

considered in sensory profiles could be useful for reducing PE among college students.

Keyword: Picky eating, Sensory profile, College students

Food choice patterns of Japanese college female soccer players and effects on hepatic dysfunction markers

Yuka Kurosaka[1], Sawako Wakui[1], Yu Shimasaki[1], Kumiko Minato[2], Hisashi Naito[1], Shuichi Machida[1]

1. Juntendo University (Japan), 2. Wayo Women's University (Japan)

Background and objectives: The daily dietary intake of athletes can affect their health, performance, and recovery from fatigue. Since only a limited of athletes receive individualized nutritional support, it is important to obtain information on the characteristics of the diet and problem. It leads to the ability to provide group guidance divided according to dietary characteristics may be possible even in situations where individual guidance is difficult. The purpose of this study was to investigate the characteristics of food choice patterns in female soccer players and to determine the associated effects on blood properties.

Methods: We measured the dietary intake, body composition, and blood parameters of 26 participants aged 18–22 years belonging to the Japanese women's university soccer team. Food intake was assessed using a validated food frequency questionnaire. The nutrition data were used to calculate the energy intake based on "Six Basic Food Groups" in Japan. The cluster analysis was performed using the percentage of energy intake of each food? group relative to the total. The results were compared between the clusters.

Results: Eleven participants were assigned to Cluster 1 and 15 participants, to Cluster 2. Cluster 1 had a significantly high intake of food groups that were rich in protein than Cluster 2. Cluster 2 had a significantly higher intake of food groups that were rich in carbohydrates and in fat than Cluster 1. There were no significant differences in the height, weight, BMI, and body fat percentage between the groups. Lean body mass and skeletal muscle mass were significantly higher in Cluster 2 than in Cluster 1. LDL-cholesterol ($p<0.05$), γ-GT ($p<0.01$), and ALT ($p<0.05$) blood levels were significantly higher in Cluster 1 than in Cluster 2, and abnormal values were found in 63% of Cluster 1, but they were all within the normal range in Cluster 2.

Conclusions: Food choice patterns of female soccer players could be categorized into two major groups according to the intake of carbohydrate and fat- and protein-rich foods; this may have an effect on the hepatic dysfunction markers. It may be possible to provide effective guidance to athletes in the group setting by classifying the characteristics of food selection.

Adult Mortality in Rural Bangladesh: A Retrospective Cohort Analysis of 80,000 Mothers and Fathers

Masako Horino[1], Keith P West[1,2], Hasmot Ali[1,2], Saijuddin Shaikh[2], Abu Ahmed Shamim[2,3], Rezwanul Haque[1], Lee S-F Wu[1], Alain Labrique[1,2], Towfida Sidiqqua[1], Parul Christian[1,2]

1. Center for Human Nutrition, Department of International Health and Sight and Life Global Research Institute, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD USA. (USA), 2. The JiVitA Maternal and Child Nutrition Research Project, Rangpur, Bangladesh. (Bangladesh), 3. James P Grant School of Public Health, BRAC University, Dhaka, Bangladesh. (Bangladesh)

Background and objectives: Little is known about the epidemiology and nutritional influences of adult mortality in rural South Asia. We estimated age-sex rates and causes of adult death in a multidecadal cohort of parents of reproductive aged women in rural Bangladesh.

Methods: We collected data on parents from 43,859 women ≤48 yr of age recruited into an antenatal micronutrient supplementation trial (2008-12), inquiring about their age, major illnesses, body type and vital status and, if deceased, age, year, antecedent morbidity and their understood causes of death. If unknown, age-at-death was imputed by applying coefficients associated with predictive socio-economic characteristics obtained from daughter respondents who did report parental age at death. We derived Kaplan-Meier parental survival curves, proportionate mortality by cause and risk ratios (RR) of death by reported parental phenotype (chronically thin, overweight or neither).

Results: Vital data were missing for 6583 (15%) fathers and 3533 (8%) mothers. Among remaining 37,273 fathers 30,360 were [median (IQR)] 55 (50-62) years of age and 6,913 (18.5%) had died at a median (IQR) age of 59 (51-65). Among remaining 40,326 mothers, 94% were 47 (42-52) years of age and 2,418 (6%) had died by a median (IQR) age of 47 (40-55). Daughters reported ~30% and ~18.5% of all fathers and mothers being thin for a long time and overweight, respectively. Compared to a normal body type, RRs for death were 1.24 and 1.44 for chronically thin, and 1.79 and 1.52 for overweight, fathers and mothers, respectively (all lower 95% CLs>1.15). Among fathers and mothers, chronic thinness (beyond the last year of life) posed higher risk of death from TB (RR=2.60, 4.12) and cancer (RR=1.8, 2.1). Reported overweight was associated with higher risks of death from heart attack/stroke (RR=2.60, 2.30) and sudden death unrelated to injury (RR=2.25, 1.51), with all lower 95% CL≥1.25.

Conclusions: In this middle-aged cohort of rural Bangladeshi men and women, among whom 18% and 6%, were deceased, chronic thinness and being overweight versus being neither were associated with ~1 ¼ to 2-fold higher risks of death, especially related to TB and cancer, and heart attack, stroke or sudden death, respectively.

The amount of iron eluted from iron balls in aqueous solutions

Yoshiko Higuchi[1], Ikiko Kinoshita[2], Yasue Hosoyamada[3], Masako Yamada[1]

1. Tokyo Kasei Gakuin University (Japan), 2. Kyoritsu Women's University (Japan), 3. Chiba Prefectural University of Health Sciences (Japan)

Background and objectives: Anemia is a serious public health issue worldwide, and iron deficiency anemia is the most common type of anemia. Several studies have reported that blood hemoglobin levels increase when eating food cooked in an iron pot. However, iron pots are typically susceptible to rust and difficult to maintain. Japanese Nambu ironware is characterized by its resistance to rust. Various cooking utensils are made from Nambu iron, one of which are iron balls for cook. The aim of the current study was to ascertain the amount of iron eluted from Nambu iron balls in various aqueous solutions.

Methods: An aqueous solution (distilled water, a 1% salt solution, a 1% vinegar solution, a 10% vinegar solution, or a 10% tomato puree solution) was added to a glass pot and heated. Once the temperature of the liquid was confirmed to have reached 85°C, an iron ball was placed in the pot and heated for 5, 10, or 15 min. The iron ball was removed, and then distilled water in the same amount that had evaporated was added. This aqueous solution served as the sample solution. Iron was measured using 1,10-phenanthroline absorption spectrometry. The total acidity of the aqueous solution before heating was determined.

Results: The amount of iron eluted was greatest in a 10% vinegar solution at all heating times and was significantly greater than the amount of iron eluted in other aqueous solutions (p<0.01). A large amount of iron was eluted in a 10% tomato puree solution, followed by a 1% vinegar solution. The heating time and the amount of iron eluted were correlated for all of the aqueous solutions except distilled water (p<0.01). The total acidity and the amount of iron eluted were correlated for the 1% vinegar solution, the 10% vinegar solution, and the 10% tomato puree solution (p<0.01).

Conclusions: The current results revealed that the amount of iron eluted from an iron ball increased as a highly acidic aqueous solution was heated for longer. These findings suggest that use of iron balls to cook high acidic dishes may increase iron intake to a certain extent.

Diet quality, drivers of food choices and self-efficacy among 15-19 years old adolescent girls and boys from low-income households in Dhaka city of Bangladesh: a cross-sectional survey

Mahsina Syeda Akter[1], Harriette M Snoek[1], Sabrina Rasheed[2], Edith JM Feskens[1], Elise F Talsma[1]

1. Wageningen University and Research (Netherlands), 2. icddr,b (Bangladesh)

Background and objectives: Adolescents' diets in low- and middle-income countries (LMICs) are shifting towards unhealthy energy-dense and nutrient-poor foods; particularly for adolescents living in urban areas. In LMICs, including Bangladesh, little is known about behavioural determinants related to diet quality, particularly food choice motives (FCM) and self-efficacy of healthy eating (individuals' belief in their ability to engage in healthy eating). This study aimed to evaluate which behavioural determinants are associated with diet quality among adolescents from low-income families in Dhaka city, Bangladesh.

Methods: A cross-sectional survey was conducted during October 2020 among adolescents aged 15-19 years old (n=299, 48% girls) selected from low-income households of urban and peri-urban parts in Dhaka metropolitan areas. The dietary diversity (DD) was assessed with the Minimum Dietary Diversity for Women score and adherence to the global diet recommendations was assessed with Global Dietary Recommendations (GDR) score, GDR-Healthy for 'healthy' foods and GDR-Limit for 'unhealthy' foods consumption. General linear modelling was performed to explore associations between diet quality and behavioural determinants (separately for DD, GDR-Healthy and GDR-Limit scores).

Results: The mean diversity score was 4.9 (SD=1.6) out of 10, and 60% of adolescents achieved minimum dietary diversity cut-off of consuming more than 5 food groups. The average GDR-Healthy score was 2.7 (SD=1.5) out of 9 food groups, and the GDR-Limit score was 1.6 (SD=1.5) out of 8 food groups. The most important FCM was safety, followed by healthiness of the food, taste, price, convenience and local or seasonal. The mean score of self-efficacy of healthy eating was 3.5 (SD=0.8) out of 5. Adolescents who had high self-efficacy scores, who valued FCM 'local or seasonal' more and 'price' less, had a better dietary diversity and higher intake of both healthy and unhealthy foods. These associations varied substantially by gender.

Conclusions: This study showed the relations between motivations, self-efficacy and diet quality of adolescents in urban Bangladesh. Interventions addressing self-efficacy and motivations related to food affordability and food being local or seasonal could contribute to increasing consumption of diverse and healthy foods, especially in combination with interventions in the food environment to increase availability of healthy options.

Unhealthy commercial food and beverage consumption among children 12-35.9 months of age in Guédiawaye Department, Senegal

Anna Vanderkooy[1], Elaine L. Ferguson[4], Maty Diagne Camara[3], Ndèye Yaga Sy[1], Rosenette Kane[1], Aminata Mbodji[1], Alissa M. Pries[2]

1. Helen Keller International (Senegal), 2. Helen Keller International (USA), 3. Ministère de la Santé et de l'Action Sociale (Senegal), 4. London School of Hygiene & Tropical Medicine (UK)

Background and objectives: A nutritious diet is important for young child development and can inform healthy lifelong dietary preferences. High consumption of unhealthy commercial foods and beverages (UCFB) - which are energy-dense and nutrient-poor - is therefore cause for concern. Growing evidence from Africa indicates UCFB consumption among young children is prevalent, but little is known about the degree or factors associated with such consumption patterns. This study aimed to assess UCFB consumption among children 12-35.9 months in peri-urban Dakar, Senegal and explored associations with socio-demographic characteristics.

Methods: A cross-sectional survey was conducted in November-December 2021 among a representative sample of 726 primary caregivers of children aged 12-35.9-months in Guédiawaye Department. A UCFB consumption score (min-max=0-24) was derived from a seven-day food frequency questionnaire including eight UCFB categories (biscuits/cookies; chips/puffs; crackers/salty popcorn; cake/donuts; candy/sweets/lollipops/chocolate; soft drinks; sweet milk/chocolate drinks (excluding breastmilk substitutes); and juice/fruit-flavored drinks) and four consumption levels (0=0 days; 1=1-3 days; 2=4-6 days; and 3=7 days).

Results: The mean number of the eight UCFB categories consumed at least once in the previous week was 4.0 (standard deviation=1.5; min-max=0-8). The most reported categories were biscuits/cookies and chips/puffs (83.9% and 82.0% of children respectively). Mean±SD UCFB consumption score was 6.4±3.3 (min-max=0-21). In an adjusted multivariate model, being an older child (24.0-35.9 months) and household food insecurity in the previous month were positively and significantly ($p<0.05$) associated with UCFB score. The most common reasons caregivers cited for feeding UCFB to their young child centered around palatability and child preference: given as a treat/gift (46.6%); child asked for it (40.2%); child likes it (31.3%); someone else was eating it so gave to child/child asked for it (28.9%); to calm child (28.5%). Caregivers rarely cited price/affordability (0.5%), accessibility (1.8%), or health/nutrition reasons (1.1%).

Conclusions: While not specifically made for young children, UCFB are commonly consumed among young children in Guédiawaye Department. Measuring and addressing UCFB consumption - and promoting nutritious, desirable, and palatable alternatives where this consumption is high - should be a program and policy priority to protect young child health and nutrition.

Physical Activity and Body Mass Index in Relation to Semen Quality

Katarzyna Eufemia Przybylowicz[1], Jakub Morze[1], Anna Danielewicz[1]

1. University of Warmia and Mazury in Olsztyn, Poland (Poland)

Background and objectives: Infertility is a global social issue, and reproductive health is a priority in global health. In the context of increasing rates of overweight and obesity in young adult men, and the increasing numbers of men seeking help for fertility problems, it is important to understand whether physical activity (PA) could help with the management of reproductive health problems. This work aimed to study the relationship between physical activity (PA) and semen quality.

Methods: A cross-sectional study was carried out among 207 men aged 20–55. Physical activity was evaluated by the International Physical Activity Questionnaire. Semen parameters were assessed via computer-aided semen analysis (CASA). Body mass index (BMI) was calculated as the ratio of body weight and squared height, and evaluated according to the WHO cut-off points.

Results: In the association between PA and, vigorous PA in men with normal BMI resulted in both positive and negative effects that were weaker than those in men with high BMI. Among men with low BMI, moderate PA was weakly but positively associated with semen quality.

Conclusions: There is emerging evidence that PA intervention may be as effective as other commonly used clinical intervention strategies for improving reproductive health outcomes. Our preliminary findings suggest that PA may be an affordable and feasible alternative or complementary therapy to fertility treatments. However, our findings need to be confirmed by further prospective observational and clinical studies

Project financially supported by Minister of Education and Science in the range of the program entitled "Regional Initiative of Excellence" for the years 2019-2022, Project No. 010/RID/2018/19, amount of funding 12.000.000 PLN

Characteristics of dietary practices, eating behaviors, and health awareness in Japanese middle-aged adults with no history of lifestyle diseases

Etsuko Kibayashi[1], Makiko Nakade[2,3], Ayumi Morooka[4]

1. Sonoda Women's University (Japan), 2. University of Hyogo (Japan), 3. Research Institute for Food and Nutritional Sciences (Japan), 4. Hyogo Prefectural Government (Japan)

Background and objectives: The percentage of adults who develop lifestyle diseases increases sharply at 40 to 59 years of age. This suggests that examining the eating behaviors and health awareness of adults in this age group who have no history of lifestyle diseases may provide a clue to effective primary prevention. We therefore aimed to identify the characteristics of dietary practices, eating behaviors, and health awareness in adults of this age with no history of lifestyle diseases that are linked strongly to diet.

Methods: The subjects were 577 respondents to the 2016 Hyogo Diet Survey, aged 40 to 59 years, in Japan. The chi-square test was used to compare six dietary practices for lifestyle disease prevention and improvement (control energy intake, restrict salt intake, control fat intake, control sugar intake, eat a lot of vegetables, and eat fruits), as well as eating behaviors (eating breakfast regularly, having a well-balanced meal at least twice daily) and health awareness (use of nutrition facts labels, regular exercise, healthy weight maintenance), between subjects with and without a history of lifestyle diseases. A binomial logistic regression analysis was then performed, adjusting for sex, age, family composition, and BMI.

Results: The analysis showed significantly higher odds ratios for "control energy intake" at 1.64 (95% confidence interval: 1.12–2.41) and "control fat intake" at 1.53 (1.04–2.25) among the six dietary practices for lifestyle disease prevention and improvement in subjects with no history of lifestyle diseases. In terms of health awareness, significantly higher odds ratios were observed for "use of nutrition facts labels" at 1.53 (1.04–2.24) and "regular exercise" at 1.48 (1.03–2.15) in subjects with no history of lifestyle diseases.

Conclusions: Middle-aged adults with no history of lifestyle diseases were characterized by dietary practices such as controlling energy and fat, as well as having enhanced health awareness, including using nutrition facts labels and engaging in exercise.

Keyword: middle age, history of lifestyle diseases, lifestyle disease prevention, eating behavior, health awareness

In vitro estimates of the impact of whole grain and pulses addition on the iron absorption from complementary food

Magalie Sabatier[1], Andreas Rytz[1], Carmen Tudorica[1], Yassaman Shahkhalili-Dulloo[1], Katherine Macé[1], Raymond Glahn[2]

1. Nestlé Institute of Health Sciences (Switzerland), 2. USDA ARS Cornell University (USA)

Background: Iron deficiency is highly prevalent in preschool children. Fortified complementary food based on refined flour has been reported to provide bioavailable iron and to be efficient in reducing the risk of iron deficiency anemia. The partial replacement of refined flour and dairy proteins by whole grain and pulse flours in food may improve the metabolic response. However, both sources contain inhibitors, which may impair iron absorption.

The objective was to assess the iron bioavailability from complementary cereals, using the *in vitro* simulated digestion coupled with the Caco-2 cell model, and test recipes containing 16% whole grain (Wg) and 16 % Wg plus 19% legumes i.e., red lentils (WgRL), yellow lentils (WgYL), yellow pea (WgYP) chickpea (WgCH) compared to a recipe based on refined flour (RF). The evaluation was done 1) without added iron, and with and without ascorbic acid (AA), and 2) with added iron (8,5 mg/ 100g) and AA (molar ratio AA:Fe of 2:1).

Results: The addition of AA in recipes without added iron significantly increased the iron uptake of the intrinsic iron from all recipes in a range of 2,1 to 3,8-fold (p<0,002). The highest and lowest iron uptakes were observed in the WgCH and the WgYL recipes, respectively. The addition of iron and AA increased the *in vitro* absorption from all the recipes by 4 to 24-fold (p< 0,0003, and p<0,003 for WgCH). When compared to RF, the iron uptake from Wg was slightly lower, the addition of WgYL, and WgRL tended to increase the iron absorption, while WgYP and WgCH decreased it. Nevertheless, none of these results were statistically different except for WgCH (p<0.03). When comparing the iron absorption from the mixed recipes to that from Wg, the same trends were observed, and did not reach statistical significance.

Conclusion: Combined iron and AA fortification of all tested complementary cereals significantly increased their *in vitro* iron bioavailability. The addition of Wg and, Wg plus legumes was found to have limited impact on iron uptake when added with AA, except for the recipe with chickpea. This effect could be mitigated by decreasing addition levels in the formulation.

Dietary habits and metabolic syndrome among Japanese employees

Kanae Konishi[1], Kanako Nakagawa[1], Saki Mihara[1], Yasuaki Saijo[2], Shintaro Yanagimoto[3], Fumihiro Sata[4]

1. Showa Woman's University (Japan), 2. Asahikawa Medical University (Japan), 3. University of Tokyo (Japan), 4. Chuo University (Japan)

Background and objectives: According to the 2019 National Health and Nutrition Survey, the prevalence of metabolic syndrome (MetS) and pre-MetS in Japan is 17.8% and 14.1%, respectively, and has been increasing in recent years. Therefore, this study aimed to investigate the relationship between food intake frequency and the development of MetS in Japanese employees. In addition, we aimed to examine differences in this association by age and sex.

Methods: The participants of this study were 12,542 employees at the University of Tokyo (6,402 men and 6,140 women) who underwent annual health check-ups in 2017. A self-administered questionnaire survey was conducted on lifestyle, dietary habits, and food intake frequency of the 13 food groups. Using data measured during physical and blood examinations, the participants were divided into two groups (MetS or non-MetS) according to abdominal obesity and other components of MetS risks such as hypertension, dyslipidemia, and diabetes mellitus.

Results: The prevalence of MetS was 13.8% for males and 2.6% for females. Among the participants with MetS, 8.9% of males and 2.0% of females were younger than 40 years of age, indicating that males are more likely to develop MetS at a younger age.

Among men, the odds ratios (ORs) for MetS among those who did not eat breakfast compared with those who did was 1.43 (95% confidence interval [CI]: 1.16–1.75), and the ORs for MetS among those who ate out three or more times a week compared with those who ate out less than once a week was 1.35 (95% CI: 1.01–1.83). In addition, for men, the ORs increased with increasing frequency of rice (at breakfast), eggs, and sweetened beverages, while the ORs decreased with increasing frequency of beans, milk, and sweets. For women, the trend was similar to men for added-sugar beverages and sweets.

Conclusions: Our study showed that the higher consumption of milk and legumes works to prevent MetS, while the higher consumption of rice (at breakfast), eggs, sweetened beverages, and salty snacks works to develop MetS. Particularly in men, prevention from a young age should include eating breakfast and eating out less often.

Associations between stress biomarkers and diet among Finnish preschoolers

Kaija Nissinen[1,2], Leena Koivusilta[3], Liisa Korkalo[1], Henna Vepsäläinen[1], Elviira Lehto[1], Reetta Lehto[4], Maijaliisa Erkkola[1], Eva Roos[4,5], Nina Sajaniemi[6], Katri Sääksjärvi[1,7]

1. University of Helsinki (Finland), 2. Seinäjoki University of Applied Sciences (Finland), 3. University of Turku (Finland), 4. Folkhälsan Research Center (Finland), 5. Uppsala University (Sweden), 6. University of Eastern Finland (Finland), 7. Finnish institute for health and welfare (Finland)

Background and objectives: Stress has been shown to associate with adverse health behaviors – also with higher consumption of highly palatable foods high in sugar, fat and/or salt. We examined the association between stress related biomarkers (salivary cortisol and alpha-amylase) and selected dietary variables among 3–6-year-old children.

Methods: We used a sub-sample (n=268) of children from cross-sectional data collected 2015–2016 in the DAGIS study in Finland. On one weekend day, the parents collected five saliva samples from the participating child. On the same day they kept of a food record of the child's food consumption. The following dietary variables were selected for analysis: sugary everyday foods (g/MJ), sugary treats (g/MJ), sugary beverages (g/MJ), all sugary foods (sum of the 3 previous categories (g/MJ), vegetables (g/d), fruits and berries (g/d), fat (g/MJ), added sugar (g/MJ), and energy (MJ). sCort concentrations were assayed using an enzyme immunoassay and sAA activity using a kinetic enzyme assay. Area under curve with respect to the ground for salivary cortisol (AUCg of sCort) and alpha-amylase (AUCg of sAA), and the diurnal slopes of sCort and sAA were calculated. Associations between AUCgs and diurnal slopes for sCort and sAA with diet were examined by logistic regression adjusted for age, gender, and the time difference between the first and last saliva sample collected.

Results: Belonging to the highest third of AUCg of sAA was associated with an increased likelihood of high consumption of all sugary food and with sugary beverages. Negative diurnal slope of sAA was related to a decreased likelihood of high consumption of sugary treats. Children with a slightly negative slope of sCort had an increased likelihood of low fruit and berries consumption. No associations were observed between AUCg of sCort and dietary variables.

Conclusions: We found an association between less optimal diurnal levels of sAA and higher sugary food consumption. Furthermore, less optimal diurnal slope of SCort associated with lower consumption of fruit and berries. Our findings support the metabolic-brain-negative feedback pathway theory according to which children may drift towards highly palatable, sugary foods when stress biomarker levels are higher.

Iron bioaccessibility, absorption and efficacy from reformulated infant cereals in young children

Nicholas P. Hays[1], Magalie Sabatier[2]

1. Nestle Product Technology Center - Nutrition (Switzerland), 2. Nestlé Institute of Health Sciences (Switzerland)

Background: Based on 2011 global estimates, 43% of preschool children were anemic, with the highest burden in Africa and South Asia. The etiology of anemia varies and is complex, and recent estimates suggest that 25% is associated with iron deficiency (ID). ID arises when physiological requirements are not met, and iron fortification is generally regarded as the most cost-effective and sustainable long-term approach to decrease its prevalence. To this end, we evaluated the impact of iron fortification of infant cereals (IC) made with refined flours on the prevalence of anemia or iron deficiency anemia (IDA) in young children.

Objective and results: We show that daily consumption of multi-micronutrient fortified ICs including iron for 6 months significantly improved iron status and reduced the risk of IDA in intervention trials conducted in Cameroon, Ghana, and India, involving children aged 6–59 months and using robust biomarkers and clinical outcome measures. However, whole grains are preferred to refined flours, and legumes could be a more favorable source of protein vs. milk but both contain inhibitors of iron absorption. Thus, the impact of IC reformulation, with these two ingredients, on iron absorption was evaluated with *in vitro* simulated digestion coupled with the Caco-2 cell model. The results from recipes with flour from lentils and whole grains suggested some improvement of the iron uptake by the cells, whereas with chickpeas and whole grains flour the iron uptake was impaired compared with that from IC based on refined flour. Finally, these recipes were compared for their impact on iron absorption in children (6 to 14 months) with ID and/or IDA using the erythrocyte incorporation of labelled iron 14 days post consumption of these ICs in a clinical study. The results showed that in the presence of ascorbic acid, iron absorption of reformulated ICs was not significantly different than from IC based on refined grain, with significant contributions to the requirement for absorbed iron (i.e., 33 to 57% with one serving).

Conclusion: Therefore, the efficacy of ICs containing pulses, whole grain, and ascorbic acid is expected to be similar to that from IC based on refined flours.

Empowering pregnant women to improve diet quality: Results from a randomized controlled trial among pregnant women in the Netherlands

Renske Mirjam van Lonkhuijzen[1], Jeanne H.M. de Vries[1], Annemarie Wagemakers[1]

1. Wageningen University & Research (Netherlands)

Background and objectives: A healthy diet during pregnancy is crucial for the health of both mother and child, but pregnant women often do not meet the nutritional requirements. Empowering pregnant women is a process to increase their power or control. Growing evidence shows that empowerment interventions can lead to improved health outcomes. However, empowerment has been rarely used in nutritional interventions. Empowering pregnant women to improve their diet quality could play a significant role in improving maternal nutrition. Based on research and input from pregnant women, midwives, and dieticians, we developed Power 4 a Healthy Pregnancy (P4HP) – an intervention facilitating four additional consultations for the pregnant women to discuss nutrition from an empowerment perspective. Three consultations with a midwife, and one with a dietician. Our objective is to evaluate P4HP on diet quality, empowerment levels, and three health-related factors: Sense of Coherence (SOC), Self-Rated Health, and Quality of Life.

Methods: A cluster randomized controlled trial started January 2022 in 14 Dutch midwifery practices – 7 intervention and 7 control. Each practice recruits 25 pregnant women, resulting in a total of 350 participants. Women in the intervention group follow P4HP in addition to their usual birth care. Measurements are carried out at the beginning and end of pregnancy. Diet quality is assessed using the Dutch Healthy Diet index 2015, validated with 24h dietary recall and FFQ data, specifically adapted for pregnancy. Empowerment is assessed using the Pregnancy-Related Empowerment Scale, SOC using a three-item SOC questionnaire, Self-Rated Health using a General Self-Rated Health question, and Quality of Life using a Visual Analogue Scale. Results will be analyzed using Linear Mixed Models as this allows to analyze the treatment effect of clustered data.

Results: We hypothesize that four additional consultations for the pregnant women to discuss nutrition from an empowerment perspective with both a midwife and a dietician will lead to improvements in diet quality, empowerment levels, and health-related factors among the intervention group compared to the control group.

Conclusions: Our findings will present new knowledge about the possibilities of empowerment in nutrition promotion. We expect to present our preliminary results during the congress.

Individual but together - the key to success? Value of the personalized nutrition approach to weight loss programs using the example of ProSeni

Isabell Englert[1], Laura Hoffmann[1], Kathrin Kohlenberg-Müller[1]

1. Fulda, University of applied Sciences (Germany)

Introduction and objectives: Weight loss in old age in overweight women is significant for maintaining health, but studies show large interindividual differences in weight loss, which diminishes the benefit for individuals. The ProSeni study demonstrates the success of a personalized nutrition approach to weight loss in older overweight women.

Methods: 54 postmenopausal overweight women were participated in a 12-week weight-loss study (-750 kcal from total energy expenditure), followed by a 6-months follow-up phase. A personalized nutrition approach was used, with participants receiving a total of 51 individualized daily meal plans based on a detailed diet history with their preferences and aversions. In addition, there were four group training sessions that focussed on participation and empowerment during intervention time. Participants had to keep food diaries for two 7-day periods and fill out food checklists on all other days. Continuous face-to-face conversations and telephone calls were recorded in key point form.

Results: 46 women completed the study and 29 were followed up (t_2). Weight loss was - 5.8 ± 3.0 kg at post-intervention and - 4.9 ± 5.4 kg (both $p < 0.001$) at t_2, respectively. A higher energy deficit was associated with a higher loss of fat-free mass kg ($r = -0.51$; $p<0.001$). The appreciative and individualized approach ensured good access to the women, which underscores the validity of the study results. This demonstrated the strong correlation of the energy deficit recorded within the food diaries and the real weight loss ($r=0.9$, $p < 0.001$).

Conclusion: The approach of personalized nutrition is very elaborate but effective in terms of weight loss in postmenopausal overweight women. It is also important to communicate a slow and sustainable weight loss in order to maintain fat-free mass and counteract sarcopenia.

Light breakfast increases appetite before lunch but may not increase energy intake in Japanese healthy female young subjects.

Sae Sasabe[1], Yuna Abe[1], Rina Abe[1], Miho Izumida[1], Wakana Imazeki[1], Madoka Iwano[1], Hinako Uchida[1]

1. Shukutoku University (Japan)

Background and Objective Breakfast is the most easily missed meal of the day and tends to be quick and easy. Skipping breakfast at a young is a growing problem that is associated with over-and under- nutritional intake in Japan. The objective of this study was to determine if there was a beneficial effect of a light breakfast on daily nutritional intake, appetite, and physical activity.

Methods: This intervention study recruited 12 healthy female undergraduates aged 19-23 years who were habitual breakfast eaters. They were instructed to eat a prescribed breakfast of skip (0 kcal only water), light (120-240 kcal), medium (360-480 kcal), and full (600-720 kcal) and allowed to consume freely any subsequent lunch, dinner, or snack. Energy and macronutrient intake were evaluated by their photographic food records. Appetite before lunch and dinner on the day of the prescribed breakfast was measured using a visual analog scale (VAS). The amount of physical activity (resting time, activity time, and step count) was measured during the day using a 3-axis accelerometer.

Results: When comparing the four groups according to prescribed breakfast energy intake: skip, light, medium, and full, the daily energy intake was 1,270 kcal/day, 1,524 kcal/day, 1,598 kcal/day, 1,884 kcal/day respectively. Only full breakfast days showed a significant difference compared skip days. There was no significant difference in energy intake at lunch, dinner, or snacks even though appetite VAS before lunch was significantly higher on skip and light breakfast days than on full breakfast days. The daily resting time on medium and full breakfast days was significantly shorter than on skip breakfast days but did not significantly shorten on light breakfast days.

Conclusions: Our results suggest that energy intake at breakfast may affect daily energy intake. Light breakfast (120-240 kcal) increases appetite before lunch as on skip breakfast day but did not increase daily energy intake in young females who habitually eat breakfast.

PAB(T3)-54
Prevalence of gastrointestinal symptoms in presumed healthy infants: a cross-sectional study in China

Yvonne Meijer-Krommenhoek[1], Jinjing Zhong[2], Yiling Deng[2], Kui Xie[2], Junlan Ma[2], Zhixu Wang[3], Lucie van der Zee[1], Jieshu Wu[3], Yanmei Hou[2], Linde van Lee[1]

1. Ausnutria B.V. (Netherlands), 2. Hyproca Nutrition China (China), 3. Nanjing Medical University (China)

Background and objective: Studies show that the prevalence of gastrointestinal (GI) symptoms, as assessed by the cow's milk-related symptom score (CoMiSS™), is low (median 3.0) in presumed healthy European infants. To our knowledge, no previous studies have been conducted on the prevalence of GI symptoms as assessed by the CoMiSS in presumed healthy Chinese infants. This cross-sectional study observed the GI comfort in Chinese infants under 6 months old.

Methods: A short online questionnaire was sent to parents of infants under 6 months old exclusively consuming human milk (HM) or infant formula (IF) via WeChat, with an aimed total of 1200 respondents. Questionnaires included the CoMiSS, range 0-33 points, and the infant gastrointestinal symptoms questionnaire (IGSQ), range 13-65 points. In both questionnaires higher scores indicate more GI discomfort. Moreover, the abbreviated WHO quality of life questionnaire (WHOQOL-BREF), ranging to 0 (worst) to 100 (best), and the baby eating behaviour questionnaire (BEBQ), subscales ranging from 1-5 points, were administered. Descriptives and general linear models were computed using SAS.

Results: Preliminary data consisted of questionnaires of 390 infants, of which questionnaires with incomplete data was excluded (n=70). We observed that prevalence of GI symptoms was low with a mean CoMiSS of 2.2 (SD 2.4) and a mean IGSQ of 18.8 (SD 5.7). Only 5% of the study population had a higher COMISS than 6, indicating mild GI discomfort. No statistically significant differences in CoMiSS or IGSQ were observed between infants that consumed HM or IF. The mean WHOQOL was generally high [69.9 (SD 13.8)] and was not significantly different between HM-fed and GMF-fed infants. The BEBQ domains general appetite and enjoyment of food were high (4.1 SD 0.9; 4.1 SD 0.7; respectively) whereas scores were low for the domain satiety responsiveness (2.4 SD 0.6) and slowness in eating (2.4 SD 0.7). All BEBQ domains appeared similar among groups.

Conclusion: Prevalence of gastrointestinal symptoms as assessed by CoMiSS and IGSQ is low in presumed healthy Chinese infants and comparable to previously reported prevalence in presumed healthy European infants. Data of another 800 infants are expected in June 2022.

Keyword: infant nutrition, gastro-intestinal symptoms, infant formula, CoMiSS, China

PAB(T3)-55
The Influence of Maternal Diet on the Breast Milk Composition and Clinical Health Outcomes in Infants; a sub-study within the PRIMA Birth Cohort

Anneke H. Hellinga[1], Arthur H. van Stigt[1], Elske M. Brouwer-Brolsma[2], Edith J.M. Feskens[2], Jeanette Leusen[1], Belinda van't Land[1,3], Aletta D. Kraneveld[4], Louis Bont[1,5,6]

1. University Medical Center Utrecht (Netherlands), 2. Wageningen University & Research (Netherlands), 3. Danone Nutricia Research B.V. (Netherlands), 4. Utrecht University (Netherlands), 5. Wilhelmina Children's Hospital (Netherlands), 6. ReSViNET foundation (Netherlands)

Background and objectives: Breastfeeding provides the optimal nutrition for infants to ensure a healthy development. Many components in breastmilk contribute to a variety of health outcomes for infants, including significant protection against respiratory tract infections. There are strong indications that the composition of breastmilk is influenced by the maternal diet. We aim to explore whether maternal diet affects levels of breastmilk components which play a role in the protection against respiratory tract infections in early life. To our knowledge, we are the first to study the influence of maternal diet on the composition of breastmilk, coupled to the risk of developing respiratory infections.

Methods: The objective is pursued with a nested sub-study within the PRIMA (Protecting against Respiratory tract Infections through human Milk Analysis) birth cohort of 1000 mother-infant pairs. We aim to recruit 250 mother-infant pairs in the surroundings of Utrecht, the Netherlands. Breastmilk samples are collected at 1 and 3 month(s) postpartum. Both the long-term and short-term influence of the maternal diet on these samples are assessed with a food frequency questionnaire and 24h dietary recall, coupled to each of the sampling moments. Infants are followed up to their first birthday for both parent- and physician reported respiratory tract infections. In addition, feces and saliva samples of the infant at 3 months of age are collected in order to link breastmilk composition to microbiota composition and antibody repertoire, respectively.

Results: The first step is to analyze dietary intake of lactating mothers at different stages of lactation. Dietary assessment of the second and fourth month postpartum, by means of food frequency questionnaires, allows to evaluate whether the maternal diet changes over lactation time, and if this is influenced by factors such as status of breastfeeding, pre-pregnancy BMI and whether the mother has returned to work or not. This is a first step towards dietary advice for lactating women in order to optimize the breastmilk quality for their infant.

Conclusions: To conclude, this nested sub-study will give insights of the potential of maternal diet in order to improve the protection of infants against respiratory tract infections with breastmilk.

Health and nutrition assessment is useful for the community dwelling elderly receiving meal delivery service in Japan

Yukiko Oe[1], Sanami Kouyama[1,3], Yukari Momose[1], Erika Yamada[1], Yoshie Kamiji[1], Toshinao Goda[2]

1. Institute of Health Longevity Science and Nutrition (Japan), 2. School of Food and Nutritional Sciences, The University of Shizuoka (Japan), 3. Graduate School of Humanities and Sciences, Ochanomizu University (Japan)

Background and objectives: In super-aged society in Japan, nutritionally sound meal delivery service is crucial for the community dwelling elderly at risk of undernutrition. In this study, we conducted a health and nutrition survey for 1,107 Japanese elderly people aged 65 years or older (605 men and 502 women) who appointed to receive a meal delivery service supervised by dietitians, in order to investigate possible eating function-related factors associated with undernutrition.

Methods: Mini-Nutritional Assessment –Short Form (MNA-SF) and a questionnaire for health/nutrition status including eating function, subjective health, and frequency of going-out were used to assess health and nutrition status of the subjects, who lived in four cities in Kanagawa and Shizuoka prefectures in Japan.

Results: A major age group of the subjects was 80 years or older (46 % of male and 57% of female), and 14% of male and 24% of female possessed certification of needed long-term care. MNA-SF showed that 42% of men and 53% of women were either "at risk of undernutrition" or "undernutrition". By the criteria of lower BMI less than 20.0, 21% of men and 36% of women were categorized in at risk of undernutrition. The nutrition scores based on MNA-SF were significantly associated with the years of meal delivery service in men, and the scores were associated with lack of misswallowing, lack of dry mouth, ability to bite with the back teeth, subjective health status, and frequency of going-out in both mae and female.

Conclusions: Health and Nutrition assessment is usefull to identify the personal needs of community dwelling elderly who require a meal delivery service seeking prevention of frail and undernutrition.

Keyword: community dwelling elderly, meal delivery service, undernutrition, eating function, frail

PAB(T3)-57

Association between a-priori and a-posteriori dietary patterns and depressive symptoms in community-dwelling older adults: results from the cross-sectional NutBrain Study.

Federica Prinelli[1], Silvia Conti[2], Elena Perdixi[2], Nithiya Jesuthasan[1], Alfredo Costa[2], Matteo Cotta Ramusino[2], Sara Bernini[2]

1. Italian National Research Council - CNR (Italy), 2. IRCCS Mondino Foundation (Italy)

Background and objectives: An emerging body of evidence has suggested that diet plays an important role in mental disorders like depression, but more research in older people is still necessary. This study aims to investigate the association between *a*-priori and *a*-posteriori dietary patterns (DP) and depressive symptoms in community-dwellers older adults.

Methods: NutBrain is an Italian ongoing cross-sectional study of adults aged ≧65 years living in Northern Italy. At baseline, socio-demographic characteristics along with dietary, medical, and neuropsychological data were recorded using validated questionnaires. Depressive symptoms were assessed through the Center for Epidemiologic Studies Depression (CES-D) scale. The *a*-priori Mediterranean Diet score (MDS) was calculated based on a 102-semi-quantitative food frequency questionnaire. Nutrients and energy intake was calculated using the Italian food composition database. *A*-posteriori nutrients DP were derived using principal component analysis based on 28 micro- and macronutrients. To estimate odds ratios (OR) with 95% Confidence Intervals (CI) of depressive symptoms (CES-D≧16), multivariate logistic regression models were used, adjusting for sex, age, education, living status, energy intake, physical activity, smoking status, and polypharmacy.

Results: Among the 425 participants recruited (mean age 74.0 years ± 6.5 SD, 59.9% females, 48.7% high education), 18.8% reported depressive symptoms. Compared with participants without depression, those with depressive symptomatology were mainly females (83.3%), lived alone (36.3%), had low education (26.9%), and had low adherence to MDS. Five major DP were identified: Plant-, Meat and dairy-, Plant-derived fats, Starch-, and Fish products. In the multivariate-adjusted model, the highest vs the lowest tertile of MDS score was associated with a reduced probability of having depressive symptoms (OR 0.23, 95%CI 0.10-0.50). Plant- (OR 0.37, 95% CI 0.17-0.82), and Fish products (OR 0.47, 95%CI 0.24-0.93) were associated with reduced odds of depression. Other DP were not appreciably associated with the outcome.

Conclusion: These findings suggest that older adults following healthy dietary habits characterized by high consumption of fruits, vegetables, legumes, whole grains, and fish have fewer depressive symptoms. The current study indicates that dietary interventions have the potential to be included as a primary prevention strategy for depression even in the old population.

Relationship between anthropometric variables and the shape of Senegalese children aged 6-59 months suffering from moderate acute malnutrition

Adji Mbene Niaye[1], Laura Medialedea[2], Adama Diouf[1], Olouwafêmi Mistourath Mama[1], Mane Hélène Faye[1], Nicole Iohou-Dossou[1]

1. Laboratoire de Recherche en Nutrition et Alimentation Humaine, Universite Cheikh Anta Diop de Dakar (Senegal), 2. Technical Engineering, Action Against Hunger (Spain)

Background and objectives: Community-level screening is essential for identifying children aged 6-59 months suffering from acute malnutrition as well as saving lives, but several issues can cause misdiagnosis and lead to reduced coverage. Since 2015, Action Against Hunger has developed an alternative real time and image-based screening tool for severe acute malnutrition (SAM), named SAM Photo Diagnosis App®. The first results from studies carried out with this technology have described the morphological variability of SAM children and the accuracy of shape variables to identify SAM or moderate acute malnutrition (MAM). However, the relationships between morphogeometric and anthropometric characteristics of MAM children have not been explored in depth. This study aimed to analyse the relationship between the morphogeometric component of the left arm of MAM children and their anthropometric variables.

Methods: A cross-sectional study was carried out on 91 MAM children aged 6-59 months living in Senegal. Weight, height and mid-upper arm circumference (MUAC) were measured and anthropometric indicators: weight-for-height (WHZ), height-for-age (HAZ), weight-for-age (WAZ) and MUAC-for-age (MUAC-AZ) were estimated from the WHO reference standards. Pictures of the left arm were collected using SAM Photo Diagnosis App®. Twenty (20) anatomical landmarks were identified on the images and digitized into 2D-coordinates to obtain morphometric variables. Multivariate regression analyses of shape on anthropometric variables were performed with a confidence of 95%.

Results: The study shows a positive association between shape variables and weight (r=0.71; P<0.001), height (r=0.8; P<0.001), and MUAC (r=0.28; P<0.007), being the height the variable that explains the greatest variability in the shape (36.63%). A positive relationship between shape and WHZ (r=0.43; P<0.001), HAZ (r=0.23; P=0.02) and MUACAZ (r=0.35; P<0.001) was also evidenced. The highest amount of left arm shape variability was explained by WHZ (9.62%).

Conclusion: These results reveal a positive and significant relationship between anthropometric variables and shape. Height and WHZ are the variables that most influence morphogeometric variability in the left arm of children with MAM. This result will be considered in the process of developing and improving the SAM Photo Diagnosis App® tool.

PAB(T3)-59

Closing the capacity gap in quality nutritional counselling as part of improving antenatal and postnatal care services in Tanzania

Joyceline Emmanuel Kaganda[1], Alex Rotich Rutto[1], Victoria Christian Marijani[1], Carolyn D'Alessio O'Donnell[2], Ben. K. Stephens[2]

1. Save the Children International (Tanzania), 2. Save the Children International (USA)

Background and objectives: Despite recent improvements in select nutritional indicators for children under five in Tanzania, only 59% of children under six months are exclusively breastfed, while 58% of children (6-59m) are anemic. Stunting remains problematic in key regions, with 56% of children under five stunted in Rukwa (TDHS, 2015-16). Antenatal (ANC) and postnatal care (PNC) services are entry points to counsel pregnant and lactating women on nutritional practices, yet health care workers' knowledge and practice varies greatly in terms of quality nutritional counseling. Through Lishe Endelevu, the USAID-funded program, strengthened the availability of quality nutritional counseling within ANC and PNC services in selected health care facilities through a training and mentorship approach.

Methods: A rapid assessment of 987 facilities showed that only 380 (18%) of 2,111 reproductive and child health (RCH) staff had training on nutritional counseling, while 158 (7.5%) had received onsite clinical mentorship. Lishe Endelevu implemented a package of training and three-month onsite mentorship for RCH providers in 600 health facilities in four regions of Tanzania.

Results: Lishe Endelevu trained 690 clinical mentors in quality RCH services, including nutritional counseling as part of ANC and PNC. Following the training, clinical mentors provided on-the-job training and mentorship to 1,367 RCH providers. Supportive supervision data show that 97% (115/118) of mentored RCH providers communicated health and nutrition counseling messages correctly to clients, as per IYCF standards, while 98% (116/118) delivered nutrition messages correctly per the counseling job aid. RCH providers noted that job aides had clear messaging, were easy to use, and improved time efficiency during nutritional counseling. During this time, Lishe Endelevu conducted client exit interviews with RCH clients to measure their experience. Overall, 69% (222/324) said the provider discussed the importance of nutrition and nutritional requirements during pregnancy, and 72% (218/303) reported the provider discussed the importance of exclusive breastfeeding for children under six months.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: Lishe Endelevu helped to close the capacity gap in quality nutritional counseling for RCH providers using an on-the-job training and mentorship approach. The model offered a fast, collaborative, and practical approach to transferring knowledge between healthcare workers.

Leveraging service delivery experiences from program partners: Key to integrating UNIMMAP MMS into existing ANC platforms in India

Ashutosh Mishra[1], Neha Sareen[2], Aishwarya Panicker[1], Pankaj Verma[2], Shruti Menon[2], Kristen M. Hurley[1], Clayton Ajello[1], Monica Fox[1], Quinn Harvey[1]

1. Vitamin Angels (USA), 2. Vitamin Angels (India)

Background and objectives: regnant women in low-resource settings are at an increased risk of food insecurity and poor diets that lead to multiple micronutrient deficiencies including iron, iodine, vitamin A, B12, C, D, and zinc. In India, around 52.2% of pregnant women are anemic- a discernible sign of other deficiencies. UNIMMAP's multiple micronutrient supplement (MMS) got included in the WHO Model List of Essential Medicines in 2021 and comprises of 15 essential vitamins and minerals to address the increased micronutrient requirements during pregnancy. This study explores the role of non-government organizations (NGOs) in improving access to MMS and how their service delivery can be leveraged toward integrating MMS into the existing antenatal care platforms.

Methods: Since 2012, Vitamin Angels (VA) India has distributed MMS to over 500,000 pregnant women through 1000 program partners. In 2021, VA conducted a qualitative assessment as part of a landscape analysis, to synthesize MMS implementation experience of 18 program partners across India. Respondents included heads of charitable trusts and hospitals, NGOs, and medical institutions.

Results: Program partners adopted the following strategies to optimize MMS implementation

Established strong government partnerships: Building strong partnerships with local government health authorities allowed program partners to connect with hard-to-reach communities.

Strengthened existing service delivery platforms: Leveraging MMS delivery through existing nutrition services provided opportunities for systems strengthening.

Created community buy-in by mobilizing health professionals: Facilitating MMS awareness among doctors, nurses, and health volunteers resulted in greater community receptivity to MMS uptake.

Diversified and expanded the reach of service delivery channels: Delivering services through a range of platforms like mobile health vans, community health camps, and ANC health facilities improved the reach.

Monitoring MMS uptake and adherence: Deploying monitoring strategies like physical records (including out-patient charts, community camp health records, and ANC registers) to track MMS uptake and adherence.

Conclusion: This work highlights the importance of leveraging both government and non-government service delivery platforms to ensure increased coverage and equitable reach of nutrition interventions such as UNIMMAP MMS. Further implementation research is required to understand how NGO service delivery platforms can be optimized to improve MMS access and acceptability.

Prevalence of morbidity symptoms among women in the iLiNS-DYAD trials in Ghana and Malawi: a secondary outcome analysis

Seth Adu-Afarwuah[1], Charles D. Arnold[2], Anna Lartey[1], Harriet Okronipa[1,3], Kenneth Maleta[4], Per Ashorn[5,6], Ulla Ashorn[5], Kathryn G. Dewey[2]

1. University of Ghana (Ghana), 2. University of California, Davis (USA), 3. Oklahoma State University (USA), 4. University of Malawi (Malawi), 5. Tampere University (Finland), 6. Tampere University Hospital (Finland)

Background and objective: Maternal small-quantity lipid-based nutrient supplements (SQ-LNSs) are beneficial for birth outcomes, but less is known about their impact on maternal morbidity. We aimed to examine the period prevalence and percentage of days with morbidity symptoms among women in 2 randomized controlled trials of SQ-LNS.

Methods: From enrolment (≦ 20 wk gestation) to 6 mo postpartum, Ghanaian (*n* = 1320) and Malawian (*n* = 1391) women were assigned to consume daily: 60 mg iron and 400 µg folic acid until childbirth and placebo thereafter (IFA group); or 18 vitamins and minerals including 20 mg/d iron (MMN); or 20 g/d SQ-LNSs containing the same micronutrients as the MMN plus 4 additional minerals. Within country, we compared the period prevalence and percentage of days with fever, gastrointestinal, reproductive, and respiratory symptoms during the second and third trimesters of pregnancy and 0-3 and 3-6 mo postpartum using repeated measures logistic regression and repeated measures ANOVA.

Results: In Ghana, groups did not differ in the morbidity outcomes except for mean (SD) percentage of days with nausea,

which was greater among the LNS (4.0 (11.9)) and MMN (3.9 (10.6)) women than IFA (3.6 (8.3)) women in the third trimester (P=0.04), and among the LNS (0.7 (3.9)) than MMN (0.6 (3.5)) and IFA (0.6 (3.1)) women at 0-3 mo postpartum (P=0.03). In Malawi, only the period prevalence of severe diarrhea at 3-6 mo postpartum differed by group, with higher prevalence among the LNS (5.6%) and IFA (5.4%) women than MMN (4.5%) women (P=0.041).

Conclusión: The period prevalence and percentage of days with fever, reproductive, and respiratory symptoms do not differ between women who receive SQ-LNS, MMN or IFA. The differences in prevalence of nausea (Ghana) and severe diarrhea (Malawi) are small and possibly due to chance. *Clinicaltrials.gov identifiers:* NCT00970866; NCT01239693.

Acceptance of orange-fleshed sweet potato blend as complementary food for infants and young children in Sierra Leone

Abdulai Kandeh[1], Jobson Mamie[1], Philip John Kanu[2], Alhaji Sankoh[2], Aminata Shamit Koroma[3], Mariama Margai[3], Kadie Bangura[3], Mary H. Hodges[1], Hamid S. Turay[1]

1. Helen Keller International (Sierra Leone), 2. Milton Margai Technical University (Sierra Leone), 3. Directorate of Food and Nutrition, Ministry of Health and Sanitation (Sierra Leone)

Background: Consumption of micronutrient rich foods remains sub-optimal among children in Sierra Leone. A National Nutrition Survey conducted in 2021 showed 26% of children U5 are stunted, only 23% of children 6-23 months of age receive MDD and 85% cannot afford a diet that supports long-term health. OFSP is a rich source of pro-vitamin A. Helen Keller International, in collaboration with the Ministry of Health and Sanitation formulated nine blends with OFSP flour for children. The blends also contained locally-sourced sorghum, sesame, pigeon-pea or soya.

Objective: To use consumers' preferences to guide selection of the most acceptable blend for a locally-produced, nutrient-rich, ready-to-use commercial food product that could compete price-wise with imported products marketed nation-wide.

Methods: To reflect a diversity of potential consumers, caregivers of children were purposively sampled in three districts and across three age categories: 6-23 months, 2-5 years, and 6-12 years old. An organoleptic test was conducted with 30 participants from each age category totaling 90 participants per district (total 270). The samples were labelled F1-6 (without soya) randomly tasted by 120 children from all three groups in the ratio (1:2:1 or 1:1:2) and others SF1-3 (containing soya) randomly tasted by 30 children from the 6-23 months category alone. The researchers explained the purpose of the study and how to rank the different flours using criteria of acceptability to both mother and child: ease of preparation, color, taste, smell, texture and appearance. Each sample was ranked based on 1=Strongly dislike; 2=Dislike; 3=Okay/fine; 4=Like; 5 Really like, and means calculated for each blend.

Results: The results identified two blends with texture being the main differentiating factor, rough texture ranked poorly versus smoother texture. This feedback guided a slight modification that also took the nutritional value and consumer price into consideration. This lead to a new product branded 'PetetePap' that, including a vitamin-mineral premix, was certified by the National Standards Bureau as suitable for consumption by young children.

Conclusion: A locally-produced OFSP flour was deemed acceptable by caregivers of children above 6 months of age. Next steps will be testing willingness to pay and feasibility of marketing by women traders**.**

PAB(T3)-63
Consumption of differing frequencies, varieties, and amounts of fruit & vegetables among children 6-23 months of age and their association with dietary and health outcomes: a systematic narrative syntheis

Christina Oh[1], Leila Harrison[1], Zulfiqar Bhutta[1]

1. Hospital for Sick Children (Canada)

Background and objectives: Suboptimal breastfeeding and complementary feeding practices, when combined with infectious diseases, are the leading causes of malnutrition during the first two years of life, and continue to be highly prevalent, especially in LMICs. The objective of this review was therefore to assess the impact of complementary feeding practices, in terms of differing frequencies, varieties, and amounts of fruit and/or vegetable (FV) consumption, on dietary and health outcomes in children aged 6-23 months.

Methods: We evaluated primary studies of experimental and observational design that reported FV consumption (reported as frequency, variety and/or amount consumed) in healthy children aged 6-23 months. Qualitative studies and reviews were excluded. Electronic databases (MEDLINE, Embase, CINAHL, LILACS, AIM, CENTRAL, eLENA) and grey literature were searched using appropriate keywords, MeSH, and free text terms. Screening, data extraction and risk of bias assessments (ROB-2 tool for RCTs; NIH tool for observational studies) were completed in duplicate. GRADE assessments were conducted to evaluate the certainty of the evidence.

Results: We included 17 studies that analyzed data from 37,550 children aged 6-24 months at time of dietary data measurement. Eight studies were conducted in HICs and nine

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

studies from LMICs. We found very low certainty evidence for less frequent consumption of FV with higher likelihood of stunting and underweight. Conversely, more frequent consumption of FV was associated with higher likelihood of being overweight, improved linear growth, reduced likelihood of anemia, and higher scores for child development based on very low certainty evidence. Very low certainty evidence pointed to an association between greater amounts of fruit consumed with increases in waist circumference. Lastly, more varied and more frequent consumption of FV during the complementary feeding period was associated with improved subsequent consumption and taste preferences of FV items later in life.

Conclusion: This review suggests that more frequent and varied consumption of FV during infancy is associated with improved FV consumption later in life. However, higher quality research is needed to confirm this finding, and overall, this review has highlighted a major gap in the evidence, underscoring the need for more research to be conducted on this topic.

PAB(T3)-64
Nutritional care for children with feeding difficulties and disabilities: A scoping review

Catherine Kirk[2], Alyssa Klein[1], Malia Uyehara[1], Madina Olomi[1], Andrew Cunningham[1]

1. JSI Research & Training Institute, Inc. (USA), 2. Save the Children (USA)

Background and objectives: One billion people worldwide have a disability, and 80 percent of them live in LMICs. The prevalence of feeding problems ranges from 25 to 45 percent in non-disabled children and 33 to 80 percent in children with disabilities. USAID Advancing Nutrition conducted a scoping review of nutrition programs focused on supporting nutritional care of children with disability and non-disability related feeding difficulties.

Methods: The scoping review included a desk review of peer-reviewed and gray literature, as well as existing tools. In all, 102 documents identified through keyword searches and snowballing met the inclusion criteria. We also conducted 42 key informant interviews with experts in nutrition and disability. Findings were organized using structured matrices following the Nurturing Care Framework's Universal Progressive Model based on challenges and opportunities in these areas: (1) the prevalence of feeding difficulties, (2) identification of children with feeding difficulties or disabilities, and (3) support to manage feeding difficulties.

Results: The review found insufficient policies, programs, and evidence to support children with feeding difficulties and their families. While some resources exist to identify and support these children, they are not standardized or universally used, staff are not trained to use them, and there is not enough funding to implement them. The combination of challenges in identifying disabilities and feeding difficulties, a lack of understanding of the link between disabilities and feeding, and weak or nonexistent referral or specialized services, puts these children at risk of malnutrition. Additionally, their families face challenges providing the care they need, including coping with high care demands, accessing support, obtaining appropriate foods, and managing stigma. The review also found innovative examples that may be replicated elsewhere.

Conclusions: Four areas of recommendations emerged to support children with feeding difficulties and disabilities. 1. Strengthen systems to improve identification and service provision, and expand the availability of feeding services. 2. Provide direct support to families to address determinants that affect nutrition outcomes. 3. Conduct advocacy to raise awareness of the needs and opportunities. 4. Build the evidence base on effective interventions to identify and support these children and their families.

PAB(T3)-65
An evaluation study on promoting holistic nurturing care into nutrition delivery systems to improve early childhood outcomes in Mozambique

Catherine Kirk[1], Katija Momade[2]

1. Save the Children, USA (USA), 2. Save the Children, Mozambique (Mozambique)

Background and Objective: The Nurturing Care Country Profile data for Mozambique show that less than half (41 percent) of infants under 6 months of age are exclusively breastfeed, only 11 percent of children have a minimum acceptable diet, 33 percent are engaged in activities that promote early learning, and only 3 percent have playthings at home (UNICEF 2019). Thus, in Mozambique, caregivers need support to provide nurturing care for young children, particularly around adequate nutrition, responsive care, and early learning. USAID Advancing Nutrition is addressing this gap by supporting the local consortium, Transform Nutrition (TN) to improve early childhood development (ECD) by integrating responsive care and early learning in community-based sanitation and hygiene (SH) and nutrition services delivered through peer groups and home visits.

Methods: The study will employ a mixed-methods design to estimate program impact on children's ECD outcomes and will use qualitative and quantitative data to understand the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

implementation fidelity and quality. A random sample of around 900 caregiver-child dyads (children 0 to 2 years) from 12 districts in Nampula Province will participate in caregiver surveys, interviews, focus groups, child anthropometric assessments, and child assessments. The Ages and Stages Questionnaire (ASQ 3), and the Global Scale for Early Development (GSED) Short Form, Long Form, and Psychosocial Form will be administered at baseline (2022) and end line (2023). This study will also provide data to validate the GSED measure.

Results: Study findings will indicate if the integration of responsive care and early learning, particularly through caregiver counseling, has a greater effect on ECD outcomes compared to the nutrition/SH intervention alone. Results will also provide evidence on the feasibility, acceptability, and experience of integration. Finally, this study will provide evidence on validation of the GSED measure.

Conclusions: Findings from this study have the potential to be used by USAID Mozambique and other stakeholders who are considering integrated approaches to improve children's development outcomes and contribute to the global evidence base on measuring child outcomes for children 0–2 years.

Keyword: responsive care, early learning, early childhood development, counseling, global child development measures

PAB(T3)-66
Diversity of vegetables and fruit in children's diet in Finland and association with parental educational level

Korpunen Katri[1], Skaffari Essi[1], Vepsäläinen Henna[1], Nissinen Kaija[1,2], Lehto Reetta[1,3], Erkkola Maijaliisa[1], Roos Eva[3,4], Liisa Korkalo[1]

1. University of Helsinki (Finland), 2. Seinäjoki University of Applied Sciences (Finland), 3. Folkhälsan Research Center (Finland), 4. Uppsala University (Sweden)

Background and objectives: A high diversity of different vegetables and fruit in the diet is suggested to be associated with health benefits. Our aim was to describe the vegetable and fruit diversity in the diet of 3- to 6-year-old children in Finland and to analyse whether it is associated with parental educational level.

Methods: We used data from the cross-sectional DAGIS Survey carried out in eight municipalities in Finland in 2015-2016 (n=864). Parents and early childhood education and care (day care) personnel kept a 3-day food record for each child. For this analysis, we included 3- to 6-year-old participants with 3 complete days in the data (n=766). We disaggregated composite dishes into ingredients, coded all vegetables and fruit (including fresh, cooked, frozen, canned) into categories, and calculated the consumption in grams. We also constructed a 3-day vegetable and fruit diversity score using a variable where 1 indicated a minimum of 10 gram consumption of a category in a day and 0 indicated less or no consumption on that day. We grouped fruit juices and fruit soups as a single category 'fruit juices' regardless of the number of species the product was made of. The final score was the sum of unique categories consumed during 3 days. Finally, we used a hierarchical linear model to analyse whether parental education level (3 categories) was associated with the child's score.

Results: The top ten categories, in descending order of the amount consumed in grams, were fruit juices, apple, banana, cucumber, carrot, tomato, all types of mandarins, pear, strawberry, and grapes. The median (25^{th}; 75^{th} percentile) diversity score was 10 (8; 13). The highest parental educational level was associated with a higher variety score in the child's diet compared to the lowest parental education. The association remained significant after adjusting for child's age and sex.

Conclusions: Parental educational level was positively associated with the fruit and vegetable diversity of children's diets. Serving a large variety of different vegetables and fruit at the day care meals could be an opportunity to increase the vegetable and fruit diversity in children's diets regardless of their socioeconomic background.

PAB(T3)-67
Impact of the second wave of COVID-19 pandemic on the nutritional habits of Romanian youth

Lucia Maria Lotrean[1], Octavian Baiu[1], Anda Valentina Trandafir[1], Milena Man[1]

1. Iuliu Hatieganu University of Medicine and Pharmacy (Romania)

Background and objectives This study aims to document the impact of the second wave of Covid 19 pandemic on the nutritional habits of Romanian youth.

Methods The study was performed during the second wave of COVID-19 pandemic in Romania (October 2020-February 2021) when due to epidemiological situation schools and faculties offered mainly online educational activities. Data collection was performed by means of online questionnaires among 457 medical students from one medical faculty from Cluj-Napoca, Romania and 481 school children aged 10-15 years from 7 schools situated in urban areas from 2 counties of the country. One section of the questionnaire investigated how the food consumption in the last two weeks differed from the same period, but one year before, when the pandemic was not in place.

Results The results show that for both groups the most stable consumption was declared for meat, dairy products and bread (more than 60% declared that the consumption was similar with the period before pandemic). Among medical students the highest decrease was noticed for fast food products

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

(for more than half of the participants) and bought cooked food (for more than 40%) followed by decrease in consumption of processed meat products (such as salami, sausages) and sweets for around one third of the participants. Among school pupils the strongest decrease was with regard to consumption of chips and snacks as well as soft drinks (for around 40% of them) followed by the decrease in consumption of bought cooked food (around one third) as well as processed meat products and sweets (the percentage was a bit lower than 30%). Eating home cooked food increased for more than half of students and one out of thee pupils. The consumption of fresh fruits and vegetables increased for more than one third of both students and pupils. Several differences were noticed based on gender, nutritional knowledge and education.

Conclusions The study contributes to the body of literature regarding the impact of COVID-19 on different population groups and formulate recommendations for future research and practice during the recovery period.

Testing the responsive care and early learning addendum to improve early childhood outcomes in Ghana and the Kyrgyz Republic

Lesley Oot[1], Cholpon Abdimitalipova[1], Kelsey Torres[1], Joyce Apoasaan Jambeidu[1], Catherine Kirk

1. JSI Research & Training Institute, Inc (USA), 2. Save the Children (USA)

Background and Objective: Research shows that children who receive a combination of nutritional and nurturing care interventions have improved nutrition and early childhood development outcomes. Therefore, USAID Advancing Nutrition is pilot testing the integration of a new responsive care and early learning [RCEL] Addendum package (two components of nurturing care) with the widely used nutrition package—UNICEF Community-Based Infant and Young Child Feeding (C-IYCF) Counseling Package—in Northern Ghana and the Kyrgyz Republic to assess the feasibility, acceptability, and effectiveness of the RCEL Addendum to promote optimal early childhood outcomes.

Methods: USAID Advancing Nutrition is using a mixed method design to conduct implementation research. Baseline data will be collected in March–April 2022 and monitoring data will be collected throughout implementation between April and October 2022. The study includes multiple data collection components, including a pre-post survey design, focus group discussions, individual interviews, and pre-post training evaluations to answer six research questions in Ghana and five research questions in the Kyrgyz Republic related to the feasibility, acceptability, and effectiveness of the package.

Results: While results of the studies are pending, they are expected to illustrate the feasibility of adapting a generic reference material to different country contexts, highlighting key points where adaptation was necessary. Results will also provide evidence on the efficacy of the training program, following the cascade of the training to the community level, to enable frontline workers to deliver the Addendum context. Results will also provide insights into the feasibility of delivering the package, examining barriers and enablers to its effective implementation, such as the value of on-the-job coaching through supportive supervision. Last, endline results will provide evidence on the efficacy of the package to support behavioral changes related to RCEL practices among the study population (caregivers of children under two).

Conclusions: Overall, the study will provide evidence on the feasibility, acceptability, and efficacy of implementing the Addendum in two unique contexts, though existing government systems, and will offer insights into how such an integrated package may impact early childhood development outcomes.

Keyword: responsive care, early childhood development, feeding difficulties, counseling, implementation research

PAB(T3)-69
Proliferation of marketing of breastmilk substitutes and complementary foods for infant and young children through various online platforms in the Philippines

Rose Ann Ibardeloza Marquez[1], Cherry Cristobal Maramag[1], Mary Christine Ramos Castro[1], Brenda Brewer[2], Alexander Evans[2]

1. Nutrition Center of the Philippines (Philippines), 2. Westat (USA)

Background and Objective: The Philippine Milk Code was enacted in 1986, with its Implementing Rules and Regulation (IRR) revised in 2006, in response to the International Code of Marketing of Breastmilk Substitutes (The Code) and relevant World Health Assembly Resolutions to impose strict regulations on advertising, promotion, and marketing of breastmilk substitutes (BMS) and commercially available complementary food (CACF) products. The Philippine Milk Code is substantially aligned with The Code including prohibiting the advertising or other form of promotion to the general public of the products within the scope of The Code. However, the revised IRR does not cover online marketing. We aimed to determine the extent of

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

proliferation of marketing of breastmilk substitutes and complementary foods through various online platforms.

Materials and Methods: This study was conducted from February 5 to March 25, 2020. Presence of marketing and health and nutrition messages on BMS and CACF products were assessed by monitoring online retail platforms available in the Philippines such as Shopee, Lazada, Galleon, Carousell, and Baby Mama. Promotion types and health and nutrition claims on the product packages were recorded.

Results: A total of 33 product promotions were found in online retail platforms during the 8 weeks of monitoring. 30% were related to BMS products and 70% were attributed to CACF. Product promotions were either price discounts, or incentives to purchase products, or both. On the other hand, review of the product's package revealed the presence of health and nutrition claims in some of the BMS and CACF products. Examples of messages recorded were that products enhance child intelligence; build the immune system; are a source of nutrients such as iron, bifidus, Vitamins B1 and C, and fiber; are healthy; and that the formulations are new or improved.

Conclusion: There was a proliferation of various types of promotions on BMS and CACF products in online retail platforms. The lack of provisions in the Philippine Milk Code regulating the marketing of BMS and CACF products in online channels can undermine optimal infant and young child feeding practices. The review and revision of the IRR to include regulation of the selling of BMS and CACF products through online retail platforms should be fast tracked.

Evaluation of dietary habits on the prevention for physical frailty in the community-dwelling older Japanese adults

Saki Nakamura[1,2], Xin Liu[2], Tianshu Chu[2], Tao Chen[4], Kenji Narazaki[3], Hiro Kishimoto[3]

1. Ginowan City Hall (Japan), 2. Kyushu University (Japan), 3. Fukuoka Institute of Technology (Japan), 4. Tongji University (China)

Background and objectives: It is essential to curb or postpone the need for long-term care for older adults to extend healthy life expectancy and reduce health inequalities. If lifestyle-related habits such as proper diet and physical activity improve at the stage before the need for nursing care, such as Frailty, the impact on the prevention of the need for nursing care will be significant. This study aimed to investigate the relationship between dietary habits and frailty syndrome at baseline in the frailty prevention program for the elderly in the community.

Methods: The subjects were 182 participants of the "Itoshima Frailty Prevention Study (IFS)" who lived in Itoshima City, Fukuoka Prefecture, and were 65 years old or older (excluding those requiring support and nursing care). The number of subjects analyzed was 172 in December 2018, excluding 10 deficient frailty evaluations in the pre-intervention assessment. Evaluation items are lifestyle questionnaire (e,g. subjective health, dietary satisfaction, enjoying meals, variety of meals, frequent twice-daily consumption of meals consisting of grain, fish and meat, and vegetable dishes, eating behavior, presence/absence of co-eating). Physical frailty was measured based on five criteria proposed by Fried scale: shrinking, fatigue, low physical activity, late walking speed, and low muscle strength were classified into three groups as robust, physical pre-frailty (pre-frail), and physical frailty (frail).

Results: Among 172 participants, 50.5% of men, mean age and BMI were 72.4 years old and 23.4 kg/m^2. The percentages of frail, pre-frail, and robust were 7.0% (n=12) and 59.9% (n=103), 33.1% (n=57), respectively. Regarding meals, 85.3% of participants were satisfied with their daily meals, and 73.5% enjoyed mealtime. Furthermore, 80.0% of the participants consumed a meal that included a staple meal, main dish, and side dishes at least twice a day and at least four days a week.

Conclusion: Most participants enjoyed their mealtime and were satisfied . The percentage of older adults who eat a meal each day that includes a staple, main dish, and side dishes at least twice a day is similar to or higher than the percentage reported in the National Health and Nutrition Examination Survey.

Correlations of maternal and cord blood 25-hydroxyvitamin D vary by maternal vitamin D binding protein level

Siew Siew Lee[1,2], Su Peng Loh[2,3], King Hwa Ling[4], Raman Subramaniam[5], Maiza Tusimin[6], Kartini Farah Rahim[7]

1. School of Biosciences, Faculty of Science and Engineering, University of Nottingham Malaysia (Malaysia), 2. Department of Nutrition, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia (Malaysia), 3. Research Centre of Excellence for Nutrition and Non-Communicable Diseases, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia (Malaysia), 4. Department of Biomedical Sciences, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia (Malaysia), 5. Fetal Medicine and Gynaecology Centre (FMGC) (Malaysia), 6. Prince Court Medical Centre (Malaysia), 7. Avisena Specialist Hospital (Malaysia)

Background and objectives: *In utero,* the fetus depends on the maternal supply of vitamin D through transplacental transfer of 25-hydroxyvitamin D (25OHD). This has been confirmed by a consistently high correlation between maternal and cord 25OHD concentrations. Vitamin D binding protein (VDBP), the major

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

carrier protein of 25OHD, could be an important determinant of placental transfer of 25OHD. Maternal VDBP concentrations increase two to three folds during pregnancy but the influence of VDBP on the transplacental transfer of 25OHD has remained unexplored. Therefore, the present study aims to explore the associations and potential interactions of maternal VDBP concentrations and genotypes on the correlation of maternal and cord 25OHD.

Methods: A total of 217 mother–neonate dyads were recruited between 2015 and 2017. Plasma 25OHD concentration was measured in maternal and umbilical cord blood using ultra-high-performance liquid chromatography (UHPLC). VDBP concentrations were measured using a commercial enzyme-linked immunoassay (ELISA) kit. Maternal and cord VDBP single nucleotide polymorphisms (SNPs) (rs4588 and rs7041) were genotyped by restriction fragment length polymorphism (RFLP).

Results: A strong correlation was observed between maternal 25OHD and cord 25OHD (Spearman's rho=0.6, p<0.0001). In multivariate logistic regression, low maternal VDBP level was associated with two times higher risk of umbilical cord blood vitamin D deficiency (defined as 25OHD <30 nmol/L). No association was observed between maternal and cord VDBP genotype and cord 25OHD. This suggests that VDBP concentration but not the VDBP affinity affects the maternal-fetal transfer of 25OHD. Further analysis shows that the correlation of maternal and cord 25OHD was stronger when the VDBP level was high.

Conclusions: This study suggests the role of maternal VDBP in the transplacental transport of 25OHD. However, further studies are warranted to confirm the role of VDBP in the transplacental transport of 25OHD.

Iron status of infants and their mothers prior to starting complementary feeding

Cathryn Anne Conlon[1], Lesley Savage[1], Jeanette Rapson[1], Pamela Ruth von Hurst[1]

1. Massey University (New Zealand)

Background and objectives: Iron deficiency (ID) in infancy may cause irreversible cognitive deficits, in addition maternal postpartum anaemia can adversely affect the mother-infant bond and development; hence ID should be avoided during these vulnerable periods. The objectives of this research were to investigate the iron status of infants and mothers, and their relationship. To determine the differences in infant iron status according to mode of milk feeding, before commencing complementary feeding.

Methods: This study reports the baseline iron status of 133 mother-infant pairs. Healthy, term infants, 3-6 months of age (before complementary feeding), and their mothers were recruited. Haemoglobin and serum ferritin concentrations were measured to determine iron status. Demographic and feeding data was collected via questionnaires. Pearson's and Spearman's rho correlations were used to determine the relationship between maternal and infant iron status. One-way ANOVA and Kruskal-Wallis tests determined the differences in infant iron status according to mode of milk feeding.

Results: Most infants (93.2%; SF ≧10 μg/L, Hb ≧110 g/L) and mothers (80.5%; SF ≧15 μg/L, Hb ≧120 g/L) had sufficient iron stores. No infants or their mothers had iron deficiency anaemia (infant: SF <10 μg/L, Hb <110 g/L; maternal: SF <15 μg/L, Hb <120 g/L). No infants had ID (SF <10 μg/L, Hb ≧110 g/L) but 6.8% had anaemia without ID (SF ≧10 μg/L, Hb <110 g/L). One mother had ID (0.8%; SF <15 μg/L, Hb ≧120 g/L), 9.8% had mild ID (SF <30 μg/L, Hb ≧120 g/L), 7.5% had serum ferritin ≧150 μg/L indicating iron overload and 1.5% had anaemia without ID (SF ≧15 μg/L, Hb <120 g/L). There was a weak positive relationship between maternal and infant serum ferritin (r=0.19, P(two-tailed)=0.03), but no relationship between maternal and infant haemoglobin (P=0.91). There were no significant differences in serum ferritin (P=0.92) or haemoglobin (P=0.50) concentrations between milk feeding modes (breast milk vs. infant formula vs. mixed feeding).

Conclusions: Most infants and their mothers were iron-replete before starting complementary feeding and their iron stores were weakly related at 3-6 months postpartum. In addition, infant iron status did not differ by the type of milk infants received.

Lunch quantity (portion size) and Body Mass Index of preschool children in Japan

Naoko Yamada[1]

1. Fukuyama University (Japan)

Background and Objectives: Obesity is a global health problem for children, and one of the causes is overeating. It is important to acquire healthy eating habits from an early age not only to prevent obesity but also to maintain good health for a lifetime. Therefore, dietary education is necessary in kindergartens. However, children bring their lunch in a lunchbox from home and many public kindergartens in Japan do not have dietitians. Therefore, it is beneficial for non-specialist kindergarten teachers to use an index for assessing the amount of food children should consume. This study aimed to clarify the type and amount of food eaten for lunch by preschool children, and establish the relationship between the amount consumed and BMI.

Methods: This was a cross-sectional study conducted at a single center. In total, 63 children (30 and 33 in the younger [age 4–5 years] and older [age 5–6 years] classes, respectively) who

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

attended a public kindergarten in Tokyo participated in this study. Lunches in lunchboxes were weighed and photographed before and after eating. Parents of the participants indicated the household economic situation via a questionnaire. Additionally, the height, weight, and birthdate of the children were collected. These measurements and photo surveys were conducted for four days in November 2016. Based on the lunchbox weight before and after eating, we calculated the consumed weight of each meal and confirmed the contents of the lunch box from the photographs.

Results: Most lunches included rice as the major cereal. Many also included meat, fish, eggs, and vegetables. The amount of food consumed varied considerably between individuals in the younger class, and the relationship between the amount consumed by the children and their BMI was significant only in the older class and in children with normal BMI.

Conclusions: The amount of lunch consumed may be a measure of energy intake in the older class (5–6-year-old children) with normal body types. This could be attributed to most meals of preschoolers who follow a traditional Japanese dietary pattern.

PAB(T3)-74
The influence of availability of nutrients and bone mineral density in women training with different level

Ulle Parm[1], Anna-Liisa Tamm[1], Simone Kallas[1], Triin Aasmäe[1], Aivar Orav[1], Kaido Liiv[1], Taimi Taimalu[1], Maire Aruots[1]

1. Tartu Health Care College (Estonia)

Background and objectives: We need nutrients and adequate physical activity to develop bones and maintain bone mineral density (BMD), but there is little data on the availability of nutrients and their effects on body composition and BMD in women who train heavily on daily basis. The aim of the study was to elucidate the availability of micro- and macronutrients in women training heavily (>300min in week) in comparing not physically active women, and their BMD.

Methods: Participants completed demographic and personal behavior questionnaire (incl. IPAQ). Whole body and areal BMD were tested with dual energy X-ray absorptiometry; calcium, magnesium, vitamin D and B12 were measured from the fasting blood samples. Energy and nutrient intakes were assessed using Nutridata System. For statistical analysis continuous data and proportions were compared by t-test and Chi-square, respectively. The influences were calculated by linear regression analyses.

Results: Altogether 68 participants (mean age 36.4±7.3) were enrolled in study (equally 34 physically active and controls). Although, there were no differences in body-mass and body mass index (BMI) in two study groups, controls had higher level fat-mass (p=0.001) and fat% (p<0.001), but lower level fat-free-mass (p=0.039). Physically active women acquire from food more kcal (p=0.027), carbohydrates (p=0.048), proteins (p=0.006), but no differences in bone associated micronutrients were detected. In physically active group the vitamin B12 level in blood was higher (p=0.015) and it was influenced by the value they acquire from food (coef:6.54; p=0.032). Physical activity had no influence to the BMD. The main positive influence on BMD was fat-free-mass (total: coef 8.98e-06, p<0.001; lumbar area: coef 1.243e-05, p<0.001; femoral neck: coef 8.374e-06, p=0.004), that stayed important in multivariate analysis. In univariate analyses positive BMD and values of height, body-mass, fat-mass and fat% were detected. As food supplement consumed calcium had negative influence, and vitamin from food positive influence to BMD.

Conclusions: Physical activity in adulthood does not influence BMD, but rises fat-free-mass. Short women with small body-mass are more likely to have insufficient BMD. Micro-nutrients that affect BMD, such as calcium, should be obtained with food and not with food supplement.

Keyword: nutrition, physical activity, bone mineral density, women

PAB(T3)-75
Locomotive syndrome risk test and lifestyle-related habits among university students

Hisae Shinohara[1], Noriko Tanaka[2], Ikue Hamaguchi[3], Kurumi Tsuruta[1], Etsuo Chosa[1]

1. University of Miyazaki (Japan), 2. Kobe Women's University (Japan), 3. Konan Women's University (Japan)

Background and objectives: Locomotive syndrome (LS) is one of the most important health issues for older adults in Japan. Preventive measures should be initiated during childhood as 10% of children (age:7-15 years) already show signs of musculoskeletal disorders or dysfunction that may lead to LS. Many common health problems observed in Japanese young adults—such as decline in physical strength and weight issues (either underweight or obese)—are caused by the lack of exercise. The LS risk test was developed to quantify the decrease in mobility among adults. This study aimed to elucidate the association between the LS risk test and lifestyle-related habits of university students.

Methods: In 2019 and 2021, we surveyed 281 healthy students (99 men, 182 women) who consented to participate and underwent baseline assessments. We used the two-step test (TST), stand-up test (SUT), and grip strength as screening tools for LS. The K6 screening scale was used to assess mental health. A cut-off score of >=5 on the K6 scale was used to identify persons with mental stress. Data on lifestyle factors and dietary habits were obtained through a self-administered questionnaire, including a brief self-administered diet history questionnaire (BDHQ).

Results: The mean BMI of the participants was 22.9±4.2 (men) and 20.9±2.5 (women). The Advanced Glycation End-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

products (AGEs) values were 1.4±0.2 (men) and 1.5±0.2 (women). These results were below the age-specific standard for approximately 18% of men and 26% of women in the TST and for 22% of men and approximately 18% of women in the SUT. Those with below-the-standard SUT scores were less likely to exercise daily and lacked confidence in their physical strength. Approximately 18% of men and 26% of women had a K6 score of >=5. Approximately 60% of students took irregular meals, and approximately 30% reported <6 h of sleep per night. The intake of various vitamins and minerals was less than the standard value for all participants.

Conclusion: To prevent LS in the future, we recommend that university students receive counseling regarding eating habits and lifestyle practices, such as regular exercise.

Using child growth monitoring and promotion data for decision-making in Ghana and Nepal

Lutuf Abdul-Rahman[6], Enam Aidam[9], Kelsey Torres[2], Nashna Maharjan[3], Jyoti Shrestha[3], Faith Agbozo[4], Abdulai Abubakari[5], Akriti Singh[1], Lisa Sherburne[8], Altrena Mukuria-Ashe[7]

1. USAID Advancing Nutrition/Helen Keller International (USA), 2. USAID Advancing Nutrition/JSI Research & Training Institute, Inc. (USA), 3. Mother and Infant Research Activities (Nepal), 4. University of Health and Allied Sciences (Ghana), 5. University of Development Studies (Ghana), 6. USAID Ghana (Ghana), 7. USAID Advancing Nutrition/Save the Children (USA), 8. USAID Advancing Nutrition/The Manoff Group (USA), 9. Independent Consultant (Ghana)

Background and objectives: Health system actors can use anthropometric data collected for growth monitoring and promotion [GMP] to support individual child growth and development, as well as for program improvement. While previous studies have documented the use of GMP data for individual purposes, few studies have examined how health workers and other government officials use the data to strengthen service delivery. The objective of this study was to examine how government staff track and use GMP data for decision-making.

Methods: As part of a case study on GMP in Ghana and Nepal, we conducted semi-structured interviews with national and sub-national government officials (Ghana: 12; Nepal: 12), health workers/volunteers (Ghana: 16; Nepal: 24), and development partners (Ghana: 5; Nepal: 5) to understand GMP data collection, monitoring, and how it is used for program improvement. We coded and analyzed interview notes for themes related to data collection and use.

Results: In both countries, health workers described a systematic way to collect, document, and enter anthropometric measurements (mainly weight) taken at GMP service delivery points on paper registers and an electronic platform. Sub-national officials in both countries reported a system to review GMP program data, but noted that they did not review it as frequently as required. During monitoring visits, sub-national officials reported prioritizing data accuracy, such as through routine data quality audits in Nepal, over data use. While there were notable examples of data use for program improvement, such as health workers advocating for infant and young child feeding training in Ghana, several health workers and government officials in both countries were unaware of how to use data for decision-making other than for reporting purposes. Respondents did not describe existing guidance on how to use program data.

Conclusions: Without written guidance on how to use anthropometric data collected for GMP, health workers and their managers focused more on reporting and checking data accuracy than on using the data to strengthen service delivery. Global organizations and the governments of Ghana and Nepal should develop guidance for health workers and national/sub-national government officials on how to use GMP data for program improvement and accountability.

Low carbohydrate diet and new cardiometabolic risk markers among Taiwanese children and adolescents

Yi-Chen Huang[1], Hsin-Yun Wu[1], Yi-Chieh Chen[1,2]

1. China Medical University (Taiwan), 2. Chang Bing Show Chwan Memorial Hospital (Taiwan)

Background and objectives: Low carbohydrate intake helps reduce body weight and may be associated with lower cancer risk and mortality among adults. However, the association between low carbohydrate intake and new cardiometabolic risk predictors is unclear among children and adolescents, who are in the physiological development stage.

Methods: We recruited 1739 children and adolescents (age, 7-18 years) from the Nutrition and Health Survey in Taiwan from 2013 to 2016. Carbohydrate consumption was calculated from 24-h dietary recall through face-to-face interviews. We used a low carbohydrate diet (LCD) score to indicate the percentage of energy obtained from carbohydrates; higher scores indicate lower carbohydrate intake. LCD was classified into 3 groups by tertile (T) distribution. Physical examination was conducted to obtain anthropometric measurements, and biochemical markers were quantified through laboratory analysis. Cardiometabolic risk factors were evaluated using the blood lipid profile and triglyceride/glucose index (TyG index), TyG and waist circumference (TyG-WC), TyG and body mass index (TyG-BMI), and visceral adiposity index (VAI).

Results: T2 and T3 participants in the LCD group had lower TyG index (median: 8.05, 8.08 vs. 8.12), and VAI (median: 1.7,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

1.67 vs. 1.78) than T1 participants. After adjustment for confounding factors, the odds ratio (OR) of T2 and T3 participants in the LCD group was 0.69 (95% CI, 0.53-0.90) and 0.75 (95% CI, 0.57-0.99) for the TyG index compared with T1 participants. TyG-WC was also inversely but not significantly associated with LCD intake in the T2 and T3 groups. Furthermore, T3 participants had a 26% (95% CI, 0.56-0.99) lower risk of high VAI than T1 participants (p for trend < 0.05).

Conclusions: Our findings demonstrated that a relatively low carbohydrate diet was linked with lower risks of cardiometabolic factors and abdominal obesity among Taiwanese children and adolescents.

PAB(T3)-78
Oral function in adolescent female students: relationship between dietary habits and oral condition

Eriko Osugi[1], Maki Nakahigashi[1], Chizuko Hotta[1]

1. Suzuka University of Medical Science (Japan)

Background and objective: In recent years, it has been suggested that oral function is declining in adolescents. The study was conducted to understand the oral function status of adolescent female students. In addition, the dietary habits of their adolescent and schoolchild periods, as well as their current oral status, were also investigated and examined.

Methods: The study was conducted on 26 female students beginning in April 2019. The numbers of utterances of “Pa,” “Ta,” and “Ka” were measured using an oral function measuring device. The measured values were divided into two groups, the low and standard value group, referring to the measured values of healthy subjects. The survey asked about their dietary habits in their adolescent and schoolchild periods ("How many days a week do you eat breakfast?" and "Do you eat three meals a day every day?” etc.) and their current oral condition ("Are you prone to mouth ulcers?" and "Do your teeth bleed when you brush them?" etc.). It used the Mann-Whitney U test and the $\chi 2$ test for between-group comparisons.

Results: The oral function of female students, measured by the numbers of utterances of “Pa,” “Ta,” and “Ka,” differed significantly between the low and standard groups. The percentage of students in the low value group for “Pa” was high at 70%. With regard to oral function and the current dietary habits and oral condition, there was an association between the low and standard value groups for “Pa” in terms of "Do you currently have regular meal times for all three meals?," “Do you have at least 28 teeth?,” and “Do you often chew gum with xylitol?,” and for “Ta” in terms of "How many meals a week do you currently have with your family at home?"

Conclusions: The oral function of female students was suggested to be lower in terms of the number of utterances of “Pa.” Among the low and standard value groups of oral function in the numbers of utterances of “Pa” and “Ta,” an association was found between dietary habits and oral condition in the adolescent period. Therefore, dietary habits and oral condition during adolescence may be important for maintaining oral function during adolescence.

Gut microbiota altered by maternal carbohydrate restriction improve obesity and associated metabolic syndrome in offspring

Kohei Yamaguchi[1], Fuyuka Murase[1], Wataru Machida[1], Chisato Hara[1], Yukari Egashira[1], Shizuka Hirai[1]

1. Chiba University (Japan)

Background and objectives: Maternal nutritional restriction during pregnancy is known to adversely affect glucose and lipid metabolism in offspring. We have previously found that carbohydrate restriction during late pregnancy in mice did not exacerbate high-fat diet (HFD) -induced obesity and dyslipidemia and further improved glucose metabolism in offspring. Recently, gut microbiota has been reported to be involved in host energy metabolism. Furthermore, it is demonstrated that maternal nutritional restriction causes gut dysbiosys. On the other hand, we found that maternal carbohydrate restriction significantly increased the abundance of *Prevotella*, which is reported to be involved in the improvement of glucose metabolism, in the intestine of offspring. In this study, we investigated whether transplantation of the gut microbiota of offspring altered by maternal carbohydrate restriction leads to improved glucose metabolism in recipient mice.

Methods: Eight-week-old male and female C57BL/6J mice were mated. In late pregnancy, female mice were divided into the following three groups with different nutritional restrictions: control (C), total energy restriction (R) (40% calorie restriction), or carbohydrate restriction (CHR) (40% calorie restriction by reducing only carbohydrate) group. After giving birth, each group of dams was allowed free access to a control diet and raised their own pups. After weaning at 3 weeks of age, feces were collected from pups, suspended in sterile water, and the supernatant after centrifugation was used as fecal microbiota transplantation (FMT) samples. Seven-week-old male germ-free C57BL/6N mice were administered FMT samples from either group and fed with 60%kcal HFD for 18 weeks. Mice were dissected one week after an oral glucose tolerance test.

Results: After 18 weeks of HFD intake, body weights gain, liver and some white adipose tissue weights were significantly reduced in the recipient mice administered FMT samples from the CHR group compared to C group. Food intake was significantly increased in recipient mice in R group compared to C group.

Conclusions: The results of this study showed that gut microbiota altered by maternal carbohydrate restriction could

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

improve obesity and associated metabolic syndrome in offspring.

Child and paternal factors associate with a health-promoting dietary pattern in Finnish primary school-aged children

Ella Koivuniemi[1], Lotta Pajunen[1], Tero Vahlberg[1], Outi Nuutinen[2], Kirsi Laitinen[1]

1. University of Turku (Finland), 2. University of Eastern Finland (Finland)

Background and objectives: Increasing evidence suggests that specific dietary patterns may promote health. The aim of this study was to identify dietary patterns in 7–13-year-old Finnish primary school-aged children and to study associations between child and parental factors and adherence to the dietary patterns.

Methods: Families were recruited in Southwest (Turku city area) and Eastern Finland (Kuopio city area) using a random sample of the age group drawn from the Finnish Population Information System. Children filled in a five-day food diary with the help of their parents and a portion picture booklet. Dietary patterns were identified using principal component analysis. Child and parental factors were assessed with a questionnaire. Child's weight and height were measured and overweight/obesity status was defined using national growth charts.

Results: A total of 266 children (48% girls) with a mean age of 9.7±1.7 years were included in the study. Of the children, 79% had normal weight and 21% had overweight or obesity. Two dietary patterns were identified: 'healthier dietary pattern' with higher loadings of e.g. vegetables, fruits and berries, whole grain and fish and 'unhealthier dietary pattern' with higher loadings of e.g. butter and other fats, meat and high-fat dairy products. Of the children, 46% adhered to the healthier dietary pattern. Living in Kuopio area (adjusted OR 3.2 [95%CI 1.7−5.9], p<0.001) and child's male sex (adjusted OR 2.5 [95%CI 1.4−4.6], p=0.001) were associated with the adherence to the healthier dietary pattern. Furthermore, children with fathers <45 years of age (adjusted OR 2.8 [95%CI 1.5−5.2], p<0.001) and those whose fathers had university education (adjusted OR 1.8 [95%CI 1.0−3.3], p=0.047) were more likely to adhere to the healthier dietary pattern. Child's age, overweight/obesity status and maternal factors were not related to the adherence to the dietary patterns.

Conclusions: Two dietary patterns were identified among Finnish primary school-aged children. Geographical area, i.e. living in Kuopio area located in Eastern Finland, child's male sex as well as fathers younger age and university education were associated with the adherence to the healthier dietary pattern. The results may assist in understanding factors contributing to child's health-promoting eating and health in long-term.

Keyword: diet pattern, dietary intake, sociodemographic factors, primary school, children

PAB(T3)-81
Effect of prenatal multiple micronutrient supplementation during the first 1000 days of life: A review

Erica Ooi Ming Yi[1], Snigdha Misra[1], Seok Shin Tan[1], Rokiah Don[2]

1. International Medical University (Malaysia), 2. World Alliance for Breastfeeding Action (WABA) (Malaysia)

Background and objectives: First 1000 days of life is the period from conception to one's second birthday. This critical time frame offers an opportunity to develop lifelong health and intelligence in a child. Suboptimal micronutrient intakes during pregnancy increase the risk of poor pregnancy outcomes and may cause stunting in the first 2 years of life. Achieving optimal micronutrient intakes remain a major concern among pregnant women in low-middle income population, as they encountered multiple obstacles such as poverty, food insecurity, food accessibility as well as poor sanitation and hygiene. This review discusses the effect of prenatal multiple micronutrient supplement (MMS) versus iron-folic acid supplement (standard of care) on birth outcomes, maternal haemoglobin status during pregnancy and growth of infant up to 24 months of age.

Method: This review includes only full-text randomised controlled trials that evaluated the effect of prenatal MMS versus standard of care on the outcomes of interest, including birthweight, low birth weight, small-for-gestational age, stillbirth, preterm birth, maternal haemoglobin level, weight-for-age, length/height-for-age, weight-for-length/height, and head circumference-for-age. Eligible studies published in English were identified through electronic search of PubMed, EBSCOhost, Ovid, and Google Scholar databases.

Result: The use of MMS among pregnant mothers from the context of environment fragility and food insecurity is perceived to be strongly associated with better birth outcomes. These beneficial outcomes from MMS may have potential benefit on child's growth, however, the evidence on child's growth is limited.

Conclusion: Supplying multiple micronutrient supplement during pregnancy may provide long-term benefits on child's health and can be practical for policymakers to consider the use of MMS in pregnant women as part of existing antennal programmes. Further studies on the effect of prenatal MMS on growth of infant up to 24 months of age are recommended.

Effect of a 2-year multidomain lifestyle intervention on change in grip strength from baseline to 2 and 7 years of follow-up − The FINGER Study

Katri Saaksjarvi[1], Jenni Lehtisalo[2,1], Satu Havulinna[1], Riitta Antikainen[3,4], Tiina Laatikainen[1,2,5], Timo Strandberg[6,7], Hilkka Soininen[2,8], Jaakko Tuomilehto[1,6,9,10], Miia Kivipelto[1,2,11,12,13], Tiia Ngandu[1,11]

1. Finnish Institute for Health and Welfare (Finland), 2. University of Eastern Finland (Finland), 3. University of Oulu (Finland), 4. Oulu University Hospital (Finland), 5. Joint municipal authority for North Karelia Social and Health Services (Finland), 6. University of Helsinki (Finland), 7. Helsinki University Hospital (Finland), 8. Kuopio University Hospital (Finland), 9. King Abdulaziz University (Saudi Arabia), 10. South Ostrobothnia Central Hospital (Finland), 11. Karolinska Institute (Sweden), 12. Karolinska University Hospital (Sweden), 13. Imperial College London (UK) grip strength, intervention, diet, exercise, agein

Background and objectives: Previous studies indicate an association between low muscle strength and several adverse health outcomes among older people. We aimed at assessing the effect of a 2-year multidomain lifestyle intervention to prevent muscle strength decline 2 and 7 years later.

Methods: Participants were drawn from the FINGER study, a randomized controlled trial designed for studying preventing cognitive decline in at-risk people aged 60–77 years and enrolled in 2009-2011. Participants were randomized (1:1) to a 2-year multidomain intervention (diet, exercise, cognitive training, vascular risk monitoring, n=631), or a control group (general health advice, n=629). Grip strength (kg) was measured using a hand-held dynamometer. Mixed-model repeated-measures analyses were used to assess between-group differences (group×time interaction) in the modeled changes from baseline to 2 and 7 years based on data from all participants with at least one post-baseline measurement.

Results: Information on grip strength measurement was available for 1 037 and 567 individuals at 2 and 7 years, respectively. There were no differences in participation rates of follow-up visits between intervention and control groups. Estimated mean change in grip strength at 2 years was -1.0 kg in the intervention group and -1.5 kg in the control group, and at 7 years -3.2 kg and -3.5 kg, respectively. The between group difference in change was significant at 2 years (p for group×time interaction =0.04), but not at 7 years (p=0.50).

Conclusions: Grip strength declined less in the intervention group than in the control group at 2 years, but the difference between groups was nonsignificant at 7 years. These findings suggest that a multidomain lifestyle intervention may help in alleviating the age-related decline in muscle strength, but more research is needed to assess the long-term effects of such intervention. However, even small effects on preventing the age-related decline in muscle strength might be important for maintaining functional capacity and performing activities of daily living during ageing.

Effects of two-day prenatal methionine deficiency on pancreatic development in newborn rats

Dwina Juliana Warman[1], Takami Watanabe[1], Nobuaki Shiraki[2], Shoen Kume[2], Huijuan Jia[1], Hisanori Kato[1]

1. The University of Tokyo (Japan), 2. Tokyo Institute of Technology (Japan)

Background and objectives: Our previous *in vitro* study showed that two-day methionine or threonine depletion reduced the number of endocrine progenitor cells and pancreatic β cells, respectively. To confirm this, we conducted an *in vivo* study using rats. Considering methionine as the main methyl donor for methylation that is important during embryogenesis, first we focused on the effect of two-day prenatal methionine deficiency (MD) on pancreatic development in newborn rats.

Methods: Male and female Wistar rats (8-week-old) were mated, and the female rat was fed with control or 86% methionine-deficient diet on day 12.5–14.5 of pregnancy, during which the endocrine progenitor cells develop in rodents. After birth, the pups were sacrificed immediately, then pancreatic development and function were investigated.

Results: Ingenuity Pathway Analysis (IPA) listed genes involved in glucose and lipid metabolism as a fluctuated gene cluster category due to prenatal MD. Interestingly, we found that prenatal MD affected newborn's pancreas function differently by gender. In male offspring, significantly lower plasma insulin levels were observed. Remarkably, although there was no significant change in the mRNA expression level of genes directly involved in insulin secretion (*Ins1*, *Ins2*, *Glut2*), there were significant changes in gene expressions related to glucose and lipid metabolism (*Fbp1*, *Rbp4*, *Gpi*, *Gapdh*, *Pparα*, *Aco2*). Moreover, a significant increase in *Ngn3* and *Nkx2.2* mRNA level expressions suggested that pancreatic β-cell differentiation was promoted to compensate the decrease in insulin secretion. This is also supported by an enhanced *Kcns* methylation, which is required for insulin secretion and is involved in the development of pancreatic β-cell. On the other hand, in female offspring, while no significant change was observed in the plasma insulin level, a tendency to decrease the mRNA expression level of *Ttr* was confirmed, suggesting that MD affected pancreatic α-cell differentiation.

Conclusions: MD during the development of endocrine progenitor cells significantly affected the embryo's pancreatic development, consequently altering the next-generation pancreatic function, which is differentiated by gender. This study presents a novel and notable nutritional perspective that even a short-term malnutrition during pregnancy is worth our attention for a better quality of the offspring's life.

Breastfeeding and diet of infants in the Maternal and Child Health Study of Iceland (Ice-MCH)

Inga Thorsdottir[1], Brynjolfur Gauti Jonsson[2], Birna Thorisdottir[1,3]

1. Unit for Nutrition Research, Health Science Institute, University of Iceland (Iceland), 2. Statistical Consulting Center, Health Science Institute, University of Iceland (Iceland), 3. Faculty of Sociology, Anthropology and Folkloristics, School of Social Sciences AND Health Science Institute, University of Iceland (Iceland)

Background and objectives. Combination of national health registers has given us the opportunity to construct a data set on maternal and child health variables in Iceland, Maternal and Child Health Study (Ice-MCH). The focus of the Ice-MCH is to explore the Primary Health Care and the Prescription Medicines Registers. The aim of the present abstract is to describe breastfeeding and the diet of Icelandic infants as listed in the health care system register for infants and young children.

Methods. Descriptive statistics were used on data from two reports from the medical record system Saga: "Continuation of breastfeeding" (period 15.1.2009-16.6.2015, total number of children in breastfeeding calculations n = 21,068) and "Complementary foods by age" (period 20.9. 2009-16.6.2015, total number of children in food calculations n = 36,185).

Results. At one week of age, 97% of infants received breastmilk and 82% were exclusively breastfed. At four, five and six months of age, 79%, 76% and 70% of children received breast milk and 48%, 35% and 18% of children were exclusively fed breastmilk with supplements, such as vitamin D. The proportion of children receiving vitamin D increased with age, from 82% at two months to 96% at 10 months. At the age of 10 months, fish liver oil replaced vitamin D drops as the most common source of vitamin D. When 2-months old 25% of the infants received infant formula and 33% when 3-8-months old. When 8-months old 25% got follow-on formula and 50% when 12-months old. At 10, 12 and 18 months of age, 11%, 20% and 40% of children received cow's milk. Porridge was the most common first complementary food (16% of four-month-olds, 47% of five-month-olds, 76% of six-month-olds) along with fruits / vegetables (5% of four-month-olds, 26% of five-month-olds, 65% of six-month-old). 59% and 25% of eight-months old got meat and fish, but only few six-months old did.

Conclusions. The results are in good agreement with other data on breastfeeding and diet of Icelandic infants. The Ice-MCH-Study will explore breastfeeding and diet associations to growth and drug use.

PAB(T3)-85
Availability of global adolescent's dietary intake data: a scoping review

Kathrin M. Demmler[1], Ty Beal[2], Mona Ghadirian[3], Lynnette M. Neufeld[4]

1. Global Alliance for Improved Nutrition (UK), 2. Global Alliance for Improved Nutrition (USA), 3. McGill University (Canada), 4. Global Alliance for Improved Nutrition (Switzerland)

Background and objectives: Dietary intake during adolescence is of crucial importance to nutrition, growth, and future health outcomes. However, the availability of (high quality) data on adolescent's dietary intake are scarce with great global differences. We sought to provide an overview of available most recent adolescent's dietary intake data and their quality and identify countries and regions with evidence gaps.

Methods: We conducted a scoping review (in February 2020, updated in December 2021) including articles published in the academic and grey literature from 2010 onwards. Studies from all countries and languages including any sub-set of adolescent boys and girls between 10-24 years of age and including any information related to types of food consumed, diet composition, dietary diversity, or meal patterns were considered. We excluded studies with insufficient methodological information or unclear description of population, samples sizes below 25, school-based data sets set in less than six schools, and studies with unhealthy study population.

Results: A total of 32,102 titles were located from the literature search and 753 articles are retained and currently analysed. About one third of the articles stem from the grey-literature search. While some dietary data were found for 154 (62%) of all 249 countries, preliminary findings suggest that nationally representative, detailed dietary data were only available for a small share of mainly high-income countries, predominantly in the Americas, Europe, or Asia. Most of all studies displayed data that could not be further disaggregated by sex or location (urban vs. rural).

Conclusions: The preliminary findings of the review highlight that nationally representative adolescent's dietary intake data are still scarce, especially given the fact that a substantial share of data are only available as grey literature. For most of the countries, where data are available, granularity of the data does not permit a meaningfully characterization of dietary patterns among subgroups. Furthermore, representative data are particularly scarce in some world regions, most notably Africa. While further analysis will provide more detailed insights the preliminary findings emphasize the need for more representative, detailed, and granular data to understand global and regional data gaps and ultimately address adolescent's diet quality.

PAB(T3)-86
Association of child hemoglobin across the first 2y of life with child cognition at 6y

Lan Mai Tran[1], Melissa F Young[1], Phuong Nguyen[2,3], Long Quynh Khuong[2], Usha Ramakrishnan[1], Reynaldo Martorell[1]

1. Emory University (USA), 2. Thai Nguyen University of Pharmacy and Medicine (Viet Nam), 3. International Food Policy Research Institute (USA)

Background/Objectives: Anemia in early childhood is associated with poor intellectual functioning but less is known about the significance of changes in hemoglobin (Hb) during the first two years of life for child health and development. We examined the associations between child Hb trajectories and cognitive functioning at age 6y (Wechsler Intelligence Scale for Children).

Methods: We used data from a micronutrient supplementation randomized controlled trial (PRECONCEPT) conducted in Vietnam. We analyzed data for 648 mother-infant pairs with child Hb values at 3 mo, 6 mo, 12 mo and 24 mo and cognition at 6y. Multivariable linear regression models were used to assess the association between Hb trajectories and five measures of cognitive functioning, adjusting for maternal (age, education, depression, intervention group), child (sex) and household (socioeconomic status, home environment) characteristics.

Results: Four distinct child Hb trajectories were identified. Track 1 (2%): mean child Hb concentrations were 6.6 g/dL at 3 mo but between 10-11 g/dl thereafter. Track 2 (49%): mean child Hb concentrations were 10.1 g/dl at 3 months and remained between 10-11 g/dl thereafter. Track 3 (7%): mean child Hb concentrations were 9.9 g/dl at 3 months , 8.2 g/dl at 1y and 10.5 g/dL at 2y. Track 4 (42%): children had mean Hb concentrations >10.5 g/dl throughout the first 2y of life. Compared to children in track 2, those in track 3 had lower perceptual reasoning index (-3.96; 95% CI:-8.12-0.21), whereas track 1 children had higher processing speed index (6.24; 95% CI:1.02-11.45). Child Hb trajectories were not associated with full-scale intelligence quotient at 6 years.

Conclusions: Child hemoglobin trajectories across the first two years of life had weak associations with child cognition at age 6 years. Declines in child Hb were associated with lower cognitive scores while children whose Hb increased during first two years of life had higher cognitive scores. Further research is needed understand to examine the utility of monitoring hemoglobin values in young children.

PAB(T3)-87
Assocition between dietary patterns and cognitive change: A systematic review

Rebecca Townsend[1], Prof. Jayne v Woodside[2], Dr. Federica Prinelli[3], Dr. Claire T McEvoy[4]

1. Queen's University Belfast (UK), 2. Queen's University Belfast (UK), 3. Institute of Biomedical Technologies, National Research Council (Italy), 4. Queen's University Belfast (UK)

Background and objectives: Currently the role of diet in relation to brain ageing is unclear. Analyses of dietary patterns (DP) may improve our understanding of this potential relationship. This review aimed to investigate potential relationships between DPs and measures of cognitive change. Data presented are part of a broader systematic review exploring the role of DPs in brain ageing.

Methods: Protocol was registered with PROSPERO(CRD42020181423). EMBASE and MEDLINE databases were used to search for studies up to March 2020. Eligible studies were published in English, were prospective, and examined DPs in relation to cognitive change in adults, measured via neuropsychological tests conducted at >1 time point. The Newcastle-Ottawa Scale (NOS) was used to assess risk of bias. Meta-analysis was not performed due to heterogeneity between studies, particularly in measures of diet and cognition.

Results: From 9216 articles screened, 41 studies met inclusion criteria. Sample sizes ranged from 70 to 27860 and follow-up periods ranged from 1 to 24.8 years. Two thirds (N = 28) of studies were conducted in middle-aged to older adults (51-74 years), six in very old adults (≧75 years), two in young adults (36-50 years) and five were mixed age. Populations spanned globally, however nearly half (N = 20) were from North America. DPs derived a-priori were analysed most frequently (N = 28), with the Mediterranean DP (MeDi) studied the most often (N = 22). Eight studies used a-posteriori methodology to derive DPs and five studies used both a-priori and a-posteriori. Overall, from 41 studies, 15 (37%) found a beneficial association of DP on cognitive change, 16 (39%) found no association, eight (19%) found mixed associations (often due to different DPs studied) and two (5%) found a negative association. Five studies were rated as low quality on the NOS, 28 as medium and 8 as high.

Conclusions: The review found the MeDi was the DP explored most frequently. Although findings were not consistent, they suggested the MeDi may preserve cognition during ageing. However, evidence for the influence of other DPs was unclear. Future research should investigate DPs other than the MeDi, especially within non-Mediterranean populations, to help determine their impact on brain ageing.

PAB(T3)-88
Ultra-processed food and semen quality in men

Anna Danielewicz[1], Jakub Morze[1], Katarzyna Eufemia Przybylowicz[1]

1. University of Warmia and Mazury in Olsztyn (Poland)

Background and objectives: Moderate grade of food processing may be beneficial to the bioavailability of nutrients, but extreme processing and additives used to improve storage stability may be detrimental to health. The quality of male sperm, which is sensitive to external factors, may be negatively affected by a diet based on ultra-processed foods (UPF). Thus, the aim of the study was to determine the association between UPF intake and the semen quality parameters of men.

Methods: This cross-sectional study was carried out in 208 men aged 18-53 years from Northern-Eastern Poland. Semen samples were collected at the clinic. Semen microscopic measurements were determined with the use of computer-aided semen analysis (CASA). Dietary data were obtained using a validated frequency questionnaire. The extent of food processing was categorised according to the NOVA classification. The NOVA groups were calculated as an isoenergetic share of the food group. The association between NOVA groups and semen parameters were analysed with an adjusted linear regression model.

Results: In the analysis we include 168 men with median age of 26.0 years and BMI of 24.8 kg/m2 (IQR 22.9-26.8 kg/m2). Based on the NOVA classification, we can indicate that the diet of the subjects consisted of 46.1% non- and minimally processed food (NPF), 2.3% culinary ingredients (CI), 21.3% processed food (PF) and 29.8% UPF. The results of the analysis of the association of NOVA classification with semen quality parameters showed a negative relationship of CI with progressive and total motility (β=-3.0; 95%CI: -5.3,-0.63 and β=-4.0; 95%CI: -6.8, -1.3). PF were positively associated with sperm count (β=35.0; 95%CI: 2.9, 67) and morphology (β=0.93; 95%CI: 0.03, 1.8). No association of UPF with semen quality parameters was shown.

Conclusions: Our results suggest that higher consumption of culinary ingredients may negatively affect progressive and total sperm motility and processed food may be positively related to sperm count and morphology. Furthermore, our results did not present an association between ultra-processed food with semen quality parameters.

Project financially supported by Minister of Education and Science in the range of the program entitled "Regional Initiative of Excellence" for the years 2019-2022, Project No. 010/RID/2018/19.

PAB(T3)-89
Dyslipidemia, hyperglycemia, hypertension and obesity as biomarkers of metabolic syndrome among pregnant women in non-urbanized Ghana

Faith Agbozo[1], Johnpaul Amenu[1], Abdulai Abubakari[2], Albrecht Jahn[3]

1. University of Health and Allied Sciences (Ghana), 2. University for Development Studies (Ghana), 3. Heidelberg University Hospital (Germany)

Background and objectives: Metabolic syndrome (MetS) is a multifactorial comorbid disease heightened in pregnancy by the hormone-regulated state that stimulates inflammation, metabolic disturbance and chronic stress. Among pregnant populations residing in non-urbanized settings, the epidemiologic linkages between the component syndromic disorders are not established. Our aim was to determine the co-occurrence, associated maternal socio-medical factors and the outstanding correlates of MetS.

Methods: We prospectively followed a cohort of 454 women attending peri-urban and rural healthcare facilities in Ghana from trimester one to six weeks postpartum. After obtaining socio-demographic and anthropometric data in the first trimester, participants were scheduled for fasting plasma lipid panel and glucose testing in the second trimester while pregnancy weight gain, blood pressure and proteinuria were assessed throughout gestation. Concurrent presence of three or more biomarkers containing dyslipidemia, hyperglycemia, hypertension or adiposity was diagnosed as MetS. Analyzing in Stata, we used unordered multinomial regression to identify interactions between socio-medical factors and metabolic biomarkers, adjusting for covariates and weighting for non-response.

Results: MetS was 2.20% . Dyslipidemia (53.35%) was the most prevalent MetS biomarker manifesting as elevated triglycerides (20.98%), total cholesterol (4.68%), low high density lipoprotein (38.31%) and low density lipoprotein (4.45%), followed by hyperglycemia (15.19%) resulting from elevated fasting glucose (11.03%) and 2-hour oral glucose tolerance test (8.77%) alongside pre-existing diabetes (7.05%). Of the 13.41% adiposity cases, 11.75% were obese and 7.01% had upper-arm circumference above 35cm. Chronic hypertension (3.74%) and pregnancy-induced hypertension (2.86%) were the least prevalent. Maternal age 20-24 years (RR:0.18, 95% CI:0.05-0.65) and peri-urban residency (RR:2.08, 95%CI:1.02-4.24) independently interacted with at least one abnormal MetS biomarker but not with MetS per se. Hypercholesterolemia (r=0.652), obesity (r=0.515) and pre-prandial glucose (r=0.507) were the moderately strong correlates of MetS.

Conclusions: In line with the epidemiological transition, we see higher risk of MetS among urbanized dwellers. Dyslipidemia resulting from hypertriglyceridemia and hypercholesterolemia were most common, affecting 20-40% of the population, but the latter was the strongest MetS correlate. Meanwhile, in Ghana, lipid profiling is requested only during cardiovascular emergencies. Awareness of its risk of triggering long-term health

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

events and advocacy on routine lipid testing and nutritional preventive strategies are crucial.

Knowledge of preconception care among in-school adolescents in two local government areas of Kano state

Grace Chinoya Chimara[1], Shirley Isibhakomen Ejoh[1]

1. University of Ibadan (Nigeria)

Background and objectives: Preconception care acknowledges that many adolescent girls and young women will be pushed into motherhood lacking the knowledge, skills or support needed for optimum health outcomes. While studies exist on knowledge of preconception care among women of reproductive age and health practitioners in Nigeria, very few focus on adolescents and not much has been published about the unique case of the northern region. The aim of this study was to determine the level of knowledge of preconception care among in-school adolescents in selected local government areas in Kano state.

Methods: This study was a descriptive cross-sectional study which utilized quantitative methods of data collection. The study population comprised of in-school adolescents of selected secondary schools within the local government areas with sample size of 410. A pre-tested semi-structured self-administered questionnaire was used to collect the data on reproductive health risk factors, exposure to reproductive health information and pregnancy prevention and contraception. Data was analysed using descriptive statistics and inferential statistics at $p<0.05$ with the aid of Statistical Package for Social Sciences version 22.0.

Results: Respondents' ages ranged between 15 years to 18 years and 33.9% (134) were 18 years with a mean age of 16.83±1.05. The findings from this study showed that 8.9%. 77.5% and 13.7% of the respondents had poor, average and good knowledge respectively. The mean score for the level of knowledge was 8.7±2.4. From the study, a statistically significant association was found between respondents' gender, having had a family member that experienced complications during pregnancy and having had a close friend or relative since they were 12 years of age, get pregnant, with knowledge of preconception care as $p<0.05$.

Conclusions: Majority of the respondents had average knowledge of preconception care. Based on these findings, there is need to employ a holistic approach to further improve knowledge. Preconception care, adolescent and sexuality education should be incorporated into the school curriculum putting into consideration the cultural disposition of the northern region. This will aid cultural acceptance and an effective intervention regarding preconception care among this target population.

Strengthening nutrition interventions during antenatal care improved maternal dietary diversity and consumption of iron-folic acid supplements in Ethiopia

Sunny S Kim[2], Celeste Sununtnasuk[2], Rock R Zagré[3], Hanna Yemane Berhane[1], Tamirat Walissa[4], Abdulaziz Oumer[4], Yonas Asrat[4], Tina Sanghvi[5], Purnima Menon[6]

1. Addis Continental Institute of Public Health (Ethiopia), 2. International Food Policy Research Institute (USA), 3. International Food Policy Research Institute (Senegal), 4. FHI Solutions (Ethiopia), 5. FHI Solutions (USA), 6. International Food Policy Research Institute (India)

Background and objectives: The importance of integrating maternal nutrition interventions in antenatal care (ANC) to improve maternal and child health is widely recognized. In Ethiopia, the coverage and quality of maternal nutrition interventions remains low, despite their adoption into national guidelines. We tested the impact of a package of counseling interventions delivered through government health facilities and community platforms and implemented by Alive & Thrive (A&T) on maternal dietary diversity, iron-folic acid (IFA) consumption, and early breastfeeding practices.

Methods: We used a cluster-randomized trial design, comparing 15 health center catchment areas in A&T intervention areas to 15 in control areas in the SNNP and Somali regions. We surveyed 540 pregnant women and 1,889 recently delivered women in July-September 2021, following a year of program implementation. We used linear regression models, adjusted for geographical clustering, to test for differences in maternal dietary diversity, IFA consumption, and early breastfeeding practices between groups. In adjusted models, we controlled for gestational or maternal age, cesarean section, child age and sex, household food security and wealth, and region.

Results: Pregnant women in A&T areas consumed 0.6 more food groups and had 1.9 higher odds of achieving minimum diet diversity than women in control areas. Women in A&T areas consumed a significantly larger number of IFA tablets during pregnancy (35 tablets) than control areas at endline, with improvements in consumption of 90+ and 180+ IFA tablets. There were no significant impacts on both early initiation of breastfeeding and exclusive breastfeeding in the last 24 hours, or number of ANC visits during pregnancy. There was significantly higher exposure to maternal nutrition and breastfeeding counseling during ANC in A&T areas at endline; however, exposure was also >50% in control areas.

Conclusions: Despite interruptions to implementation due to the COVID-19 pandemic, strengthening the delivery of maternal nutrition interventions delivered through government ANC services were effective in improving maternal nutrition

practices. Impacts and differences between groups may have been attenuated, as there appeared to be substantial spillover in control areas.

Trends and determinants of the double burden of malnutrition among adolescent girls in Nairobi slums in Kenya: Findings from a cohort study 2017-2019

Milka Njeri Wanjohi[1], Gershim Asiki[1], Elizabeth Kimani Murage[1], Calistus Wilunda[1], Nelson Langat[1], Kerstin Klipstein Grobusch[2]

1. African Population and Health Research Center (Kenya), 2. Utrecht University (Netherlands)

Background and objectives: Rapid and unplanned urbanization in low and middle-income countries (LMICs) has led to nutrition transition and burgeoning of urban slums characterised by abject poverty and high rates of food insecurity, which are linked to the double burden of malnutrition (DBM). We examined the trends and determinants of DBM, among adolescent girls living in the urban slums of Nairobi in Kenya.

Methods: A prospective cohort of 494 adolescent girls was followed for three years (2017-2019). Anthropometric, socio-demographic and mental health (adverse experiences and depressive symptoms) data were collected once in each year. Indicators of over nutrition (overweight and obesity) and undernutrition (stunting and thinness) were computed from BMI for age and BMI for height Z-scores. Change from normal nutrition at recruitment to either overweight/ obesity or stunting/ wasting during follow-up was defined as 'transition to overnutrition' or undernutrition respectively. Multiple mixed effects logistic regression, with random effects at the individual level was used to establish the determinants of the transition to over or under nutrition.

Results: At baseline, prevalence of overweight/obesity was 12% stunting 9% and thinness 9%. During the follow-up period, overweight / obesity and stunting increased by 5% and 2% respectively, while thinness reduced by 4%. Adolescents whose mothers were employed had lower odds of transitioning to overweight/obesity compared to those whose mothers were not employed (OR 0.197, CI, 0.04 to 0.92), while those who perceived their neighbourhood as safe had lower odds of transitioning to stunting, compared to those who perceived their neighbourhood as unsafe (OR 0.35, 95% CI 0.12 to 0.97).

Conclusions: The findings depict a growing burden of overweight/ obesity, alongside stunting in urban slums. Multisectorol and nutrition sensitive interventions to prevent transition to both undernutrition and overweight should consider targeting women empowerment through education and employment opportunities and improving the safety of neighbourhoods, as a strategy to curb double burden of malnutrition in adolescents, especially in low income communities.

PAB(T3)-93
Association between defecation status and energy intake during breakfast, lunch, and dinner among university students—a cross-sectional study

Tomomi Yasuda[1]

1. Ryukoku University (Japan)

Purpose: Constipation is a relatively common physical symptom, especially among young women. Studies of university students have shown that skipping breakfast and irregular meal times were associated with constipation. However, few studies have examined the association between the amounts consumed during breakfast, lunch, and dinner and constipation. Therefore, we aimed to estimate the association between defecation status and energy and nutrient intake during breakfast, lunch, and dinner among university students.

Methods: This study was conducted annually from May 2018 to June 2021 among university students using a 19-item questionnaire, including defecation status, physical activity, lifestyle, and fluid intake, and an 82-item semiquantitative food frequency questionnaire. The 461 university students (74 males and 387 females) were divided into two groups according to defecation frequency: a regular stool group (R): 285 students (63 males and 222 females), who defecated at least 5 times per week, and a tend-to-be-constipated group (T): 176 students (11 males and 165 females) who defecated 4 times per week or less. Considering the distribution, the t-test and Welch's test were used for comparison between groups. IBM SPSS Statistics 24 for Windows was used for analysis ($p<0.05$).

Results: In the females, the energy intake during breakfast, lunch, and dinner was significantly lower in the T group than in the R group. In the males, there was no significant difference between the energy intake at each meal; however, there was a weak negative correlation between the breakfast energy intake and frequency of defecation. Among the females, the T group had significantly lower carbohydrate, protein, and fat intake than the R group, whereas no significant difference was observed in the males.

Conclusion: These results suggest that there is an association between the defecation status and the energy intake during breakfast, lunch, and dinner among female university students, which may be influenced by a deficiency of the three major nutrients that provide energy. Among the male university students, breakfast intake may be associated with the defecation status.

Keyword: Defecation

PAB(T3)-94

Determinants of low minimum dietary diversity among Syrian refugee children aged 6 to 23 months living in Greater Beirut, Lebanon including the perspectives of mothers and health staff

Theresa Jeremias[1], Joana Abou-Rizk[1], Lara Nasreddine[2], Lamis Jomaa[2], Nahla Hwalla[2], Jan Frank[1], Veronika Scherbaum[1]

1. University of Hohenheim (Germany), 2. American University of Beirut (Lebanon)

Background and objectives: Worldwide, nearly 3 out of 4 children aged 6 to 23 months are not achieving a minimum diversity in their diet putting them at risk of malnutrition. Syrian refugees living in a challenging food environment face socio-economic barriers to an adequate nutrition of their offspring. The objectives of the study were (1) to specify the determinants of two minimum dietary diversity (MDD) indicators and (2) to elucidate the knowledge, attitudes and perceptions (KAP) of mothers and health staff towards young child nutrition.

Methods: A cross-sectional survey using a mixed-methods approach was conducted at primary health care centers in Greater Beirut, Lebanon from July-October 2018. Quantitative 24 hours dietary recall data and hemoglobin levels were collected from 215 Syrian children aged 6 to 23 months and their mothers. Multivariate logistic regression analyses using minimum dietary diversity indicators (MDD7: 4 out of 7 food groups, MDD8: 5 out of 8 food groups including breastmilk) as outcome variables and thematic analyses of qualitative data were performed.

Results: The Syrian families had on average 2.5 (± 1.5) children and 6.3 (± 2.9) family members. The prevalence of children achieving a minimum dietary diversity was low while anemia was high (MDD7: 42.2%, MDD8: 33.0%, anemia: 42.1%). MDD7 and MDD8 were positively associated with the age of the child, the number of times the child ate foods and the mother consumed snacks. The odds of a child achieving a MDD7 was 8.4 (95%CI: 2.9-24.6) and a MDD8 was 4.8 (95%CI: 1.9-11.7) times higher when the mother achieved a minimum dietary diversity (MDD-W) as when she did not. Both MDD indicators were not associated with anemia, anthropometric and socio-economic variables. The KAP of Syrian refugee mothers on nutrition varied greatly, whereas the Lebanese health staff attached great importance to dietary diversity and adequate complementary feeding: "*First, we direct them to nutrition, to food, the most important thing is nutritious food*." *(Nurse)*

Conclusions: The child's dietary diversity is linked to maternal dietary diversity. Improving the KAP of Syrian mothers on good nutrition through health staff might be a pathway to improve the young children's diet.

The effect of infant feeding on infant development: A longitudinal study, on healthy term babies at a tertiary care hospital in Colombo, Sri Lanka

Marianne Nishani Lucas[1], Sashiprabha Udani Ranasinghe[1], Pulani Lanerolle[1], Upul Senarath[1], Andrew Peter Hills[2], Vithanage Pujitha Wickramasinghe[1]

1. University of Colombo (Sri Lanka), 2. University of Tasmania (Australia)

Background: Sri Lanka was awarded green status for breastfeeding in 2020. Breastfeeding results in better cognitive development. This is the first Sri Lankan study to describe the association between infant feeding and development.

Objective: To determine if infants fed according to Infant and Young Child Feeding (IYCF) guidelines, have higher Bayley III Development scores compared to those who are not.

Methodology: Descriptive longitudinal study, 2015-2019, at Professorial Unit, De Soysa Hospital for Women. Healthy, term babies born to mothers, >18years of age, who agreed to attend monthly follow-up were enrolled. Single trained assessor used Bayley III at 3,6,9,12,18 and 24 months of age. All IYCF indicators were taken as per definition given in IYCF 2021 guidelines. Data was collected monthly and two-monthly during the first and second year via 24-hour dietary recall and interviewer administered questionnaire. An IYCF score was calculated by awarding a point for adhering to each IYCF indicator. Independent sample t-test and simple linear regression was used for statistical analysis (SPSSv27). Ethics approval was obtained from Faculty of Medicine, University of Colombo.

Results: A total of 723 Bayley III assessments were carried out. At 24 months of age, infants with minimal meal frequency had higher cognitive scores [scaled(10 vs8, p= 0.003), composite scores(99 vs 90, p=0.003)], children who did not consume salt had higher social emotional score [scaled(18 vs 17, p<0.001) composite(140 vs 134, p<0.001)], infants who were not bottle fed had higher receptive language scores [raw (27 vs 23, p=0.004), scaled (10 vs 8, p=0.01) and growth score (592 vs 563, p=0.008)], language scores [scaled(19 vs13, p=0.006), composite (97 vs 88, p=0.018)] and motor scores(17 vs 13, p=0.019). Babies who were exclusively breastfed for 6 months had higher scaled scores for language (p<0.001) as well as motor (p<0.001) domains. Each unit increase in IYCF score increased cognitive, language and motor scaled scores by 0.5, 2.285 and 2.064 respectively. Each month of exclusive breastfeeding increased language, motor and general adaptive scaled scores by 2.12, 1.93 and 8.5 respectively.

Conclusion: Adherence to IYCF guidelines results in higher Bayley III scores for cognitive, language, motor and social emotional development.

Growth faltering during first 18 months of life in a cohort of children in an urban area of Sri Lanka and the associated feeding practices

Pujitha Wickramasinghe[2], Dulani Samaranayake[2], Kausala Sithamparapillai[1]

1. The Lady Ridgeway Hospital for Children, Colombo (Sri Lanka), 2. University of Colombo (Sri Lanka)

Background and objectives: Faltering in physical growth in exclusively breastfed infants is commonly seen during 4 - 6 months of age in Sri Lanka. This study was designed to assess pattern and timing of growth faltering and its association with the feeding practices in children up-to 18 months of age.

Methods: A cross sectional descriptive study was conducted in 254 children aged 12 and 18 months attending an immunization clinic. Weight and length were measured using standard methods and data on previous growth were extracted from the Child Health Development Record. Feeding practices were assessed using interviewer-administered questionnaire. A drop of >0.25 in weight-for-age Standard Deviation Score (SDS) from birth SDS was defined as weight faltering.

Results: Study population included 53.1% (n=135) of 12-month-olds and 44.5% (n=113) were females. Weight-for-age SDS <-2SD was seen in 19.3% (n=49) and length-for-age SDS <-2SD in 10.2% (n=26) at 12 and 18 months of age. Weight-for-length SDS <-2SD was seen in 17.7% (n=45), and 22.2% of them were <-3SD. Weight faltering occurred at some point in 64.2% (n=163) during first 18 months of life, and 78.5% of whom, had the onset ≦4 months of age. Majority (76.6%, n=98) with weight for age faltering by 4 months remained weight faltered at 12 months (p=0.497), while 29.7% (n=38) had a weight-for-length <-2SD (p<0.001). Prevalence of weight faltering was 50.4%, 46.1%, 48.4% and 48% at 4, 6, 9 and 12 months respectively. Exclusive breastfeeding was given at least until 4 months in 88% (n=223) and up to 6 months in 60% (n=153) while 92.9% (n=236) were breastfed at 12 months, with 38.2% (n=97) were breastfed on demand after six months. Complementary feeding was started before 6 months in 40.6% (n=52) with early weight faltering, but only 20.3% received it with proper consistency. Breastfeeding throughout the night was significantly associated with current weight-for-length being <-1SD (OR=1.89, CI, 1.04 - 3.45; p=0.037).

Conclusions: Early growth faltering was found in this population with high exclusive breastfeeding rates and persisting growth faltering was associated with poor feeding practices. Therefore, timely individualized interventions need to be taken to improve long term growth.

Breakfast habits of newly enrolled women's university students and related factors in a Japanese registered dietitian training school

Ken'ichi Egawa[1], Hiroyuki Tanaka[1], Yoshie Kanazawa[1], Mitsuhiko Hara[1], Haruko Sakai[1], Emiko Saito[1], Naoko Shirota[1], Maki Kubo[2], Mihoko Nishimura[1]

1. Tokyo Kasei Gakuin University (Japan), 2. Chuo-Honcho Area Comprehensive Health Support Section (Japan)

Background and objectives: T University students lack knowledge about lifestyle-related diseases and do not acquire appropriate health behaviors. This study aimed to analyze the relationship of consciousness of eating breakfast and related factors among university freshwomen.

Methods: For 141 freshwomen, physical fitness measurement (height, weight, standing trunk flexion, grip strength, sit-ups, side-step test and 20-m shuttle run test) and questionnaire survey (eating breakfast, exercise and sleep habit) were conducted.

Results: Full dataset was obtained from 116 students. The results showed that the percentages with consciousness of eating breakfast were 79.3%. The percentages with good sleep more than 6 days a week were 48.3%. On the other hand, the percentages of those who engaged exercise or sports activity were 6.9%. By comparing with and without eating breakfast habit, it was clear that the group with eating breakfast habit had high total score in physical fitness than the group without eating breakfast habit. By logistic regression analysis, the factors related consciousness of eating breakfast were total score in physical fitness (odds ratio; OR = 0.922, 95% confidence intervals; CI: 0.856, 0.992) and side-step test score (OR = 0.752, 95%CI: 0.566, 1.000).

Conclusions: From the results, physical fitness practices should be also considered for improving breakfast habit. This showed that university freshwomen in the Japanese registered dietitian training school did not do exercise practice although they had consciousness of eating breakfast.

Protein restriction during the fetal period upregulates IL1B and IL13 while suppressing MUC2 expression in the jejunum of mice after weaning

Haruka Adachi[1], Mifuyu Kudo[1], Shiori Ishiyama[1], Kazuki Mochizuki[1]

1. University of Yamanashi (Japan)

Background and objectives: Several recent studies have suggested that malnutrition during developmental periods affects organ function, including that of the small intestine, after birth. However, it is unclear whether carbohydrate or protein restriction during pregnancy affects the expression of mucins and cytokines within the small intestine.

Methods: We examined mRNA and protein expression of cytokines and a mucin *Muc2* by qRT-PCR and western blot, respectively, in the jejunoileum of 28- and 46-day-old mice born from mothers fed a low-carbohydrate (LC) or low-protein (LP) diet compared with those born from mothers fed a control (AIN-93G) diet during pregnancy.

Results: The mRNA and protein expression of *Il1b* and *Il13* in the jejunum in 28-day-old mice was higher in the LP group. *Il1b* mRNA expression in the jejunum in 46-day-old mice was higher in the LC and LP groups than in controls. However, the mRNA and protein expression of *Il18* in the jejunum in 28-day-old mice was no difference between the LC or LP groups and controls.The protein levels of MUC2 in 46-day-old mice were lower in the LP group than in the control group.

Conclusions: Fetal protein restriction in mice disrupts jejunal immune-and barrier function-related expression after weaning.

Keyword: IL1B, IL13, MUC2, fetal malnutrition, jejunum

PAB(T3)-99

Nutritional perceptions, practices, and priorities of women during and outside pregnancy in Kisosonkole zone in urban central Uganda

Georgina Seera[1]

1. Kyoto University (Japan)

Background and objectives: The nutritional practices of women in their life course and particularly during pregnancy are associated with maternal and child health outcomes. This study aimed to establish the prevalent perceptions, practices, and priorities of eating during and outside pregnancy, among women in the Kisosonkole zone, in urban central Uganda.

Methods: The study adopted a mixed-method design. It included 80 women; 20 pregnant women and 60 women who had given birth during the last five years, ages 25-35. The selection of the participants in the study was done by non-probabilistic sampling with a margin error/ confidence interval of 0.1, using the formula; error = 1/√N. Data was collected using semi-structured interviews and analyzed both descriptively and theoretically.

Results: The average number of children was 2-3 (SD=0.7). The average number of pregnancies that were not carried to full term was 1 (SD=1.1). 23% of the women reported experiencing problems during pregnancy, the commonest problem was weakness. Fruits and vegetables, and variety were commonly perceived as necessary. Alcohol and fatty foods were perceived as harmful. However, most women commonly ate foods from only one food group in a day and most women reported that they did not change their eating habits during pregnancy. When the women changed their eating habits during pregnancy, they predominantly increased their intake of high energy staples, but not their intake of high protein foods or micronutrient-rich fruits and vegetables. The most common concerns that inspired dietary modifications during pregnancy were strength, the health of the baby, the risk of having a big baby and needing a c-section delivery, and painless delivery.

Conclusions: Despite the knowledge that fruits and vegetables, and variety are beneficial for pregnancy, women did not modify their diets to achieve this, likely due to the high cost associated with it. Furthermore, the recurrent concerns of women during pregnancy were the health of mother and baby, and the ease of pregnancy and childbirth. Addressing the food accessibility issues of women and strengthening nutrition education on how to improve the health of mother and child, and minimize complications continues to be imperative.

Nutritional status and iodized salt use among school-aged children living in Phu Kut city, Xieng Khouang province, Lao PDR

Khouanheuane Sengkhamyong[1], Chansathit Taikeophithoun[2], Thongmai Phommyxay[3], Pimnapanut Sridonpai[4], Tippawan Pongcharoen[4], Sueppong Gowachirapant[4]

1. Ministry of Health (Laos), 2. University of Health Sciences (Laos), 3. Xieng Khouang Provincial Health Office (Laos), 4. Institute of Nutrition, Mahidol University (Thailand)

Background and objectives: Iodine deficiency (ID) in school-aged children (SAC) remains a public health problem worldwide. ID is the leading cause of growth retardation and delayed cognitive development. Presently, there is a scarcity of surveillance data of nutritional status and iodine deficiency among SAC in Lao PDR. Therefore, this study aimed to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

investigate the nutritional status and iodized salt use of SAC living in Phu Kut city, Xieng Khouang province.

Methods: General information including seafood consumption were interviewed using questionnaire. Weight and height of SAC were measured using a standard procedure. Nutritional status were classified based on the WHO growth reference data for 5-19 years. A sample of salt consumed in the child's household was obtained and iodine content was analyzed using iodometric titration technique.

Results: Three hundred and sixty seven SAC with mean aged of 7.8 ± 1.5 years participated in the study. More than half (54.8%) of children were males and about 41% were the first child of family. Only 25% of the populations consumed seafood in the past week. Mean weight and height were 23.2 ± 5.4 kilogram and 121.5 ± 9.6 centimeter, respectively. Mean z-score of height for age (HAZ), weight for age (WAZ) and BMI for age (BAZ) were -1.2 ± 1.1, -0.9 ± 1.0, and -0.3 ± 1.0, respectively. Using the WHO cutoffs, 23.2% and 16.3% of children were classified as stunting and underweight. On the other hand, 3.8% and 9.5% of children were classified as thinness and overweight/obesity. In addition, 85.9% of salt samples from the households contained less 20 ppm of iodine, indicating low iodine in salt.

Conclusions: School-aged children living in Phu Kut city, Xieng Khouang province are facing with several nutritional problems. Furthermore, the coverage of using adequately iodized salt is extremely low. Therefore, quality assurance of iodized salt production and ID surveillance program in SAC and other vulnerable populations are urgently needed.

PAB(T3)-101
Determinants of early initiation of breastfeeding among postpartum mothers in the Tamale metropolis, Ghana

Abdulai Abubakari[1], Ridwan Alhassan[2], Faith Agbozo[3]

1. University for Development Studies (Ghana), 2. University for Development Studies (Ghana), 3. University of Health and Allied Sciences (Ghana)

Background and objectives: Early initiation of breastfeeding which is breastfeeding within the first hour after birth is highly recommended to promote the establishment of breastfeeding, and consequently survival and proper growth of a child. However, the prevalence of early initiation of breastfeeding in Tamale Metropolis keeps declining. Therefore, the aim of this study was to identify the determinants of early initiation of breastfeeding in the Tamale metropolis.

Methods: A retrospective cross-sectional study design entailing a consecutive sampling technique was used to select 370 mothers with their infant pairs aged 0-6 months attending child welfare clinics at the Tamale Central and West Hospitals, Tamale Reproductive Child Health Unit and the Tamale Teaching hospital in Ghana. Pearson Chi-square and binary logistic regression analyses in Stata aided to find associations and to establish the adjusted odds ratio (AOR) of delayed breastfeeding initiation.

Results: Prevalence of early initiation of breastfeeding was 77.8%. Mothers who had primary and secondary education were 82% (AOR=0.126, 95% CI:0.04-0.38, p=<0.0001) and 62% (AOR=0.381, 95% CI:0.19-0.76, p=0.006) less likely to delay breastfeeding initiation when compared to those without formal education. Although regularity of antenatal care visits did not show any significant association, mothers not counseled on breastfeeding initiation during prenatal care (AOR=4.1, 95% CI:2.18-7.69, p<0.0001) nor had knowledge on the benefits of early initiation of breastfeeding (AOR=2.23, 95% CI:1.29-3.86, p=0.004) were more likely to delay breastfeeding initiation. However, women whose spouses had secondary (AOR=5.70, 95% CI:2.05-15.84, p=0.001) and tertiary education (AOR=4.32, 95% CI:1.53-12.21, p=0.006) were 4-6 times more likely to delay breastfeeding initiation. Health-related correlates that significantly delayed breastfeeding initiation included birthing in private facilities (AOR=6.6).

Conclusion: Both socio-demographic and health-related drivers such as maternal education, counselling on early initiation and knowledge on the benefits of early initiation were protective of early initiation while delivery facility and spouse education delayed initiation. In order to enhance timely breastfeeding initiation, education on the importance and benefits of early breastfeeding initiation needs strengthening during prenatal care, with spouses actively involved in the process. Private healthcare providers require supervision to implement and promote baby friendly birthing practices.

PAB(T3)-102
Changing health and nutrition behaviour to address stunting through peer support and community action: A Case Study of the First 1,000 Days Program in Vanuatu.

Adaeze Oramalu-Ogwuche, Jennifer Weiss, Leiwaku Noah, Carolyn O'Donnell, Anne Crawford, Adele Harmer

Background and objectives: Globally, chronic malnutrition, which is evident by stunting, has declined steadily since 2000 – but faster progress is needed to reach the 2030 Social Development Goals target. According to the 2021 Global Nutrition Report, stunting rates in Vanuatu increased from 25.7% to 28.9% between 2008 and 2013 and the prevalence of anemia among women of reproductive age increased from 24% in 2010 to 25% in 2016. Further research has shown that stunting

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

occurs in-utero hence interventions to address stunting are targeted at the first I,000 days window. Save the Children (SC) implemented the ***First 1,000 Days Program*** in Vanuatu across 22 communities in Shefa and Sanma Provinces between 2017-2021 with the aim of contributing to the reduction of stunting in children under 2 by increasing coverage of evidence-based health and nutrition practices among pregnant and lactating women (PLW) and caregivers.

Methods: SC used the ***Peer Support Group Approach*** to deliver preventive nutrition interventions directly to beneficiaries including promotion of maternal and child health and nutrition (MCHN) practices among PLW, elderly caregivers, men, community and religious leaders. In addition, a **Community Action Planning (CAP)** approach was used to establish Development Committees, develop community-led solutions, and strengthen community engagement in the adoption of appropriate MCHN behaviours.

Results: Endline evaluation among beneficiaries revealed reduced stunting rates from 20.8% to 13.8%, and minimum acceptable diet increased from 35.7% to 54.2%. The knowledge of key MNCH practices increased significantly among women (84.9%) and men (81.8%), increase consumptions of grains/roots, dairy, flesh foods and vitamin A-rich fruits & vegetables for children 6-23months and women of reproductive age. Also, over 40% of women reported making decisions for their own and their child's health and nutrition, while 77% of men agreed that decisions regarding the health and nutrition of mother and child should be jointly made.

Conclusions: In Vanuatu, the use of proven approaches like peer support groups and investing in community activities that are directly linked to support health and nutrition outcomes increased the adoption of MCHN behaviours and will inform scale-up to other Pacific Countries.

The Effect of Dietary Medium-Chain Triglycerides for High School Sports Club Students.

Yuchie Hoshina[1,2], Shiori Sugawara[3], Toshiyuki Kasai[1], Masazumi Nishikawa[1]

1. Miyagi University (Japan), 2. Sendai Seiyo Gakuin College (Japan), 3. Sendai Shirayuri Woman's College (Japan)

Background and Objectives: The present study, a survey was conducted with rapidly growing late adolescent high school athletes with the aim of understanding basic figures such as pre- and post- exercise physical measurements, body metabolism, and effective exercise performance fatty acids intake. The participants (n=24; male=11, female=13) in the study were first- and second-year high school students who belong to their school's basketball club.

Methods: Data collection in the study consisted of the participant's physical measurements and blood test, and their Rating of Perceived Exertion (RPE) before and after exercise. The exercise intensity was calculated using the Metabolic Equivalents (METs) of daily club activities. The participants completed a dietary intake survey using Brief-type self-administered Diet History Questionnaire for 15-years-olds (BDHQ15y). The participants also completed a physical measurements and blood test, and a Rate of Perceived Exertion (RPE) before and after exercise. We investigated the effect of a 2-week regiment of food containing medium-chain triglycerides (MCT) and long-chain triglycerides (LCT).

Results: Results of the study showed significantly higher values Creatine Kinase (CK) after the 2-week period. Participants also showed no significant difference between males and females before and after. No severe adverse effect was observed.

Conclusions: This study suggests that MCT intake up to 6g/day is safe for high school students. Further study will be needed to define of muscle fatigue reduction.

Estimation of the Sodium-to-Potassium Ratio by Meal Patterns in Japan

Kaori Ohmura[1], Tamie Inose[2], Ishii Yoshiko[2], Saki Yamanaka[2], Kazuhiro Uenishi[2], Hiromi Ishida[2]

1. Teikyo University (Japan), 2. Kagawa Nutrition Unversity (Japan)

Background and objectives: Prevention of hypertension is an important health issue in Japan, and sodium and potassium play an important role in the development of hypertension. Recently, there has been an increased interest in the sodium-to-potassium (Na:K) ratio as an indicator of salt and potassium intake. Our study focused on dietary Na:K and aimed to compare the Na:K ratio of meal patterns in Japan.

Methods: Female dietetics college students (n=237) were invited to participate in the study in April 2021. We collected anthropometric measurements, 24-hour urinary sodium and potassium excretion data, and one-day meal records. We excluded participants who did not provide consent, had missing data, provided an unrealistic food record, or if the dietary Na:K ratio was not consistent with urinary Na:K excretion (Bland–Altman analysis). The final sample for analysis was 144. Calculation of sodium and potassium content of the meals was performed using the Standard Tables of Food Composition in Japan 2020. Dishes were classified into 16 categories by type and combined for the meal. The Na:K ratio was examined by meal patterns.

Results: Comparison of the 10 most frequently occurring meal patterns revealed that the combination of "staple food,main dish,side dish,soup" had a higher salt content compared with "staple food,main dish,side dish" and "staple food,main dish" (median 3.3 g vs. 2.2 g and 1.6 g, respectively,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

all p < 0.05); however, there were no significant differences in the salt content between any other combinations. The Na:K ratio was significantly lower in "staple food,main dish,side dish" compared with "combined dishes," "combined dishes,beverage," and "staple food,side dish" (median 1.2 vs. 2.1, 2.3, and 2.7, respectively, all p<0.05).

Conclusion: The combination of "staple food,main dish,side dish" had a lower Na:K ratio than "combined dishes" despite no significant difference in sodium and salt. This result indicates that the combination of "staple food,main dish,side dish" is recommended for better health outcomes.

Keyword: staple food, main dish, side dish, sodium-to-potassium ratio

PAB(T3)-105
A core outcome set for pregnancy nutrition research (PRENCOS)

Sarah Louise Killeen[1], Shauna L. Callaghan[1], Sharleen L. O'Reilly[1], Fionnuala M. McAuliffe[1]

1. University College Dublin (Ireland)

Background and objectives: Core outcome sets (COS) are lists of the most critical outcomes to report in an area of research. Their use helps to standardise outcome reporting across studies, enabling systematic reviews and meta-analyses. Given the role of diet in a promoting a healthy pregnancy and the large heterogeneity in outcome reporting in this area, a COS for pregnancy nutrition is urgently needed. The aim of this study is to develop a COS for pregnancy nutrition research (PRENCOS).

Methods: Candidate outcomes were identified through a systematic review of intervention and observational studies and one-to-one semi-structured interviews with women with experience of pregnancy (n=26) that were transcribed and analysed using inductive thematic analysis. Outcomes were consolidated, organised into domains, and categorised using the Core Outcome Measures in Effectiveness Trials (COMET) taxonomy. Plain language definitions were developed and piloted during the interviews. A two-round, modified Delphi survey (May-August 2021) invited healthcare professionals (HCPs), researchers, and women to vote on how critical each outcome was to include in PRENCOS using a nine-point Likert scale. All outcomes that did not reach consensus were discussed at a consensus meeting.

Results: 53,091 papers were identified, and outcomes were extracted from 427. The qualitative data yielded 45 outcomes and an additional 24 came solely from the literature. After refinement, 30 outcomes were included in the Delphi survey. In round one, 82 participants ranked each outcome, nine additional outcomes were suggested, and one was included in round two. In the second round, participants (n=60) voted 12/31 outcomes as critical to include PRENCOS (pregnancy complications; anaemia, gestational weight change; maternal vitamin and mineral status; mental health; diet quality; nutritional intakes; need for treatments, interventions, medications, and supplements; pregnancy loss or perinatal death; birth defects or congenital anomalies, neonatal complications, new-born anthropometry and body composition). The remaining 20 were reviewed at the consensus meeting and two outcomes were included (maternal wellbeing and delivery complications). Anaemia was incorporated into maternal vitamin and mineral status, resulting in 13 outcomes in PRENCOS.

Conclusions: Use of PRENCOS will support standardisation in outcome reporting across dietary studies in pregnancy. This will ensure researchers measure what matters most from the perspective of key stakeholders and enable high-quality evidence generation on the impact of diet on these critical maternal and child outcomes.

Optimal IYCF practices and nutritional status among refugee and host community children- Implications for policy and programming

Muniirah Mbabazi Mbabazi[1], Joweria Nambooze[2], Lilian Nyanzi[1], Grace Rukanda[3], James Kakande[4]

1. Nutrisat Uganda (Uganda), 2. Kyambogo University (Uganda), 3. Lutheran World Federation, Uganda (Uganda), 4. Soland Associated consults Limited (Uganda)

Introduction: In humanitarian settings, the risks to feeding and caring practices for Infants Young Children and their mothers are high. These risks aggravate their vulnerability to diarrhoea and other diseases due to poor sanitation, reduced access to food and deterioration in living conditions.

Objective: This study assessed the nutritional status IYCF practices among children 6-59 months of age

Methods: A cross-sectional quantitative survey was undertaken among women of rreproductive age with children 6-59 months. 456 households were sampled in Palorinya refugee settlement, Uganda representing 70:30 ratio of refugee and host populations. A multi-stage cluster sampling design was adopted for this study. Comparisons between the different groups and bivariate analyses were also made to establish relationships between dependent and independent variables.

Results: Global Acute Malnutrition was prevalent at 8.1% among the sampled children in the host communities and 7.2% in the refugee settlement. Severe wasting was more prevalent in the host communities (2.3%) among children 6-17 months

(6.1%) compared to the refugee settlement (1.1%). Underweight was higher in host communities than in refugee communities (14.8 vs 13.3%). Over 90% of the children in both communities were reportedly breastfed. However, 18.7% in the settlement and 6.3% in the host communities received pre-lacteals in the first 3 days after birth. Bottle-feeding was highly prevalent in the settlement than in the host communities (34% Vs 25%). Only 33% of the children in the settlement and 38.2% in the host communities achieved minimum dietary diversity. A further 48.9% of the breastfed children in the refugee settlement and 58.6% in host communities achieved minimum meal frequency compared to only 13.3% of the non-breastfed children in the settlement and none in the host community. Only 16% of the breastfed children in the settlement and 25.7% in the host communities achieved minimum adequate diet (MAD). 13.3% of the non-breastfed children in the settlement and none in the host communities achieved MAD.

Conclusion: IYCF practices are sub optimal in both refugee and host communities. More attention may be required for programmes to focus interventions in the host communities to improve integration, health and nutrition outcomes of the populations.

PAB(T3)-107
Exploring the role of genetically determined BMI in infancy, childhood and early adulthood on colorectal cancer development in later life

David J Hughes[1] , Nikos Papadimitriou[2], Caroline J Bull[3], Neil Murphy[2], Mazda Jenab[2]

1. University College Dublin (Ireland), 2. International Agency for Research on Cancer (France), 3. University of Bristol (UK)

Background and objectives: Compelling evidence implicates obesity as a major factor in colorectal cancer (CRC) development. We hypothesize that varying obesogenic inherited predisposition in early- and later-life stages may differentially impact the onset of adulthood CRC. We are currently examining genetically determined BMI across the life-course in association with CRC risk, within a pilot project funded by the International Hundred K+ Cohorts Consortium (IHCC); https://ihccglobal.org/announcing-recipients-of-ihcc-pilot-project-awards/.

Methods: Using published GWAS-associated SNPs with obesity, we have constructed specific genomic risk scores (GRS) for obesity in infancy, childhood, and adulthood. We will assess their association with CRC risk and whether the associations differ by age, sex, and select modifiable exposures, utilizing large, international cohort studies contributing to the IHCC, from Europe, North America, China, Japan, and Korea (UK Biobank, EPIC, GECCO, and ACCC). In a related Mendelian Randomization (MR) analysis (led by collaborators Dr Nikolaos Papadimitriou and Dr Neil Murphy), we constructed genetic instruments (derived from a GWAS of 453,169 UK Biobank participants) for 'recalled' early life body size at age 10 (305 SNPs) and measured adult BMI (557 SNPs). These were then associated with CRC risk via a meta-analysis of three genetic consortia (CORECT, CCFR, & GECCO) of 125,478 participants (58,131 cases and 67,347 controls).

Results: By the conference date, we will present our GRS analysis results. In the multivariable MR analysis, genetically-predicted adult body size was estimated to increase risks of colorectal, colon, and proximal colon cancer (but not distal or rectal cancer). After accounting for adult body size, genetically-predicted early life body size had no significant association with colorectal (OR: 0.97, 95% CI: 0.77-1.22) colon (OR: 0.97, 95% CI: 0.76-1.25) or distal colon cancer (OR: 1.27, 95% CI: 0.90-1.77), although the latter finding had a similar magnitude but more imprecise estimate to the significant result in the univariable analysis (OR: 1.25, 95% CI: 1.04-1.51) (Papadimitriou et al 2022, *manuscript in review*).

Conclusions: Our results thus far suggest that childhood adiposity putatively influences CRC risk due to a long-term effect of remaining overweight throughout life. Further research is required to further examine the role of early life body size in distal colon cancer risk.

Keyword: obesity, colorectal cancer, life-course, genomic risk scores, Mendelian randomization

Conflict of Interest Disclosure: All authors have no conflicts to disclose.

Further Collaborators We wish to acknowledge all our colleagues and participants involved in the UK Biobank, EPIC, ACCC, GECCO, CORECT, and CCFR cohort studies.

The relationship between Body Mass Index and menstrual disorders among University of Ghana undergraduate athletes and nonathletes.

Nana Ama Serwaa Osei[1], Abena Achiaa Boakye[2], Fredrick Vuvor[3]

1. University of Ghana Noguchi Memorial Institute for Medical Research (Ghana), 2. University of Ghana (Ghana), 3. University of Ghana (Ghana)

Background and objectives: Menstruation is a natural periodic uterine bleeding due to the reduced production of estrogen and progesterone during healthy young women's lives. There are several types of menstrual disorders which include dysmenorrhea, premenstrual symptoms, oligomenorrhea, polymenorrhoea, abnormal bleeding, amenorrhea, and menorrhagia. These disorders are affected by factors such as Body Mass Index (BMI), dietary intake, and stress. This study

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

aims to identify the relationship between BMI and menstrual disorders among University of Ghana athletes and nonathletes.

Methods: A cross-sectional survey of undergraduate females between the ages of 16-27 from the University of Ghana was conducted. A semi-structured questionnaire was used to collect background information of the participants, history of the menstrual cycle, and anthropometric measurement. The variables were described using means and standard deviations for continuous variables and frequencies and percentages for categorical variables. Athletes and non-athletes (16-27 years) anthropometric data were categorized as underweight, normal weight, and overweight. Pearson's correlation and binary logistic regression were used to predict the odds of association between menstrual disorders and BMI.

Results: The total number of students who participated in the study was 104. Out of this number, 37 (36%) were athletes, and 67 (64%) were non-athletes. Most of the participants were between the ages of 16-27 with mean ages of 20.76 ±1.44years for athletes and 20.52±1.70years for non-athletes. There was a statistical significance between oligomenorrhea and age and also, oligomenorrhea and BMI. The majority of the participant had normal BMI with a percentage of 59.1% for nonathletes and 59.5% for athletes. The presence of pain during menstruation has the highest distribution of 73% and 79% respectively in both athletes and non-athletes (P = 0.41). Pain during menstruation was prevalent in both athletes and non-athletes but was not statistically significant.

Conclusions: This study revealed that there is a higher prevalence of dysmenorrhea in athletes than in nonathletes. The association between dysmenorrhea, irregular menstrual cycle, primary and secondary amenorrhea, and BMI in both athletes and non-athletes was found to be statistically insignificant. A statistically significant association was found between BMI and Oligomenorrhea and also BMI and age.

Regional variations in the growth status and prefecture-specific indicators among Japanese infants and young children

Chisa Shinsugi[1], Hidemi Takimoto[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Background and objectives: In Japan, universal health coverage and regular health checkups for infants and young children may contribute to their favorable health status. However, the current status of child malnutrition have not been examined across the 47 prefectures in Japan. This study aimed to assess regional variations in the growth status and prefecture-specific indicators among Japanese children under 5 years old.

Methods: Data on the 2010 National Growth Survey on Preschool Children were used for this analysis (n=6,584). Growth status (Weight-for-age z-score (WAZ), length/height-for-age z-score (HAZ), body mass index (BMI)-for-age z-score (BAZ), weight-for-height z-score (WHZ)) were evaluated with reference to the WHO growth standards. Maternal working status, birthweight by gestational age (BWGA), pre-pregnancy BMI, gestational weight gain (GWG), maternal smoking status during pregnancy, smoking status of father or family member during pregnancy, birth order was considered as exposure. We calculated the prefecture-specific means for each indicator and examined the associations between growth status and indicators.

Results: The prevalence of underweight (WAZ<-2), stunting (HAZ<-2), wasting (WHZ<-2), and overweight including obesity (WHZ>2) was 3.4%, 7.1%, 2.3%, 1.5%, respectively. Most of the prefectures' mean WAZ were close to -0.5, ranging from -0.67 in Nagano to 0.03 in Akita. HAZ was ranging from -0.91 in Tokushima to -0.15 in Akita. BAZ was ranging from -0.34 in Nagano to 0.17 in Akita. WHZ was ranging from -0.35 in Nagano to 0.18 in Akita. Multiple regression analyses found that prefecture-specific HAZ means were positively associated with BWGA and GWG, and negatively related with maternal working status and birth order.

Conclusions: This study shows that the regional disparities in malnutrition among children under 5 years in Japan are relatively small. Given the high prevalence of stunting, further studies are needed to determine other social factors which may affect child growth, such as poverty.

Dietary risk factors for esophageal cancer in a Zambian population

Violet Kayamba[1], Paul Kelly[1,2]

1. University of Zambia (Zambia), 2. Barts and the London School of Medicine and Dentistry (UK)

Background and objectives: Esophageal cancer (EC) is one of the leading causes of cancer related deaths in East Africa, and risk factors influencing its development are being investigated in several countries within the region. The aim of this study was to identify contributory dietary factors associated with EC in Zambia.

Methods: We conducted a hospital-based case-control study in Lusaka, Zambia. Cases were patients with EC while the controls were healthy individuals. Dietary data were collected using interviewer-administered food frequency questionnaires (FFQs). We included commonly consumed foods in Zambia, adapted from an FFQ that was used in a previously published gastric cancer study. In the questionnaire, we enquired how often each food type was consumed and considered it regular if it was consumed at least one a week. Data were analysed in Stata version 15.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Results: We included 361 individuals (123 cases and 229 controls). Among cases, the male to female ratio was 1.6:1 and the median age was 56 years (IQR 46-65years). Unadjusted odds ratios showed an association between regular consumption of salted fish (OR 2.0, 95% CI 1.1-3.5; *P*=0.02) and EC. There was a negative association with regular fruit intake (OR 0.5, 95% CI 0.3-0.8; *P*=0.001) or cassava (OR 0.5, 95% CI 0.3-0.9; *P*=0.01) and EC. Adjusted odds ratios using stepwise logistic regression showed the three food types when consumed regularly were independently associated with EC: salted fish (OR 2.7, 95% CI 1.4-5.3; *P*=0.003), fruit (OR 0.3, 95% CI 0.1-0.9; *P*=0.03) and cassava (OR 0.4, 95% CI 0.2-0.8; *P*=0.007). There were no significant associations with regular intake of beans, maize meal, chicken, pork, beef, eggs, rice, vegetables or smoked fish.

Conclusions: Regular consumption of fruit or cassava is protective against EC, while salted fish increases the odds of developing the disease. Cancer prevention messages should encourage regular consumption of fruits and use of non-salt based food preservation techniques.

Exploration into School-Children's Food Preferences Aged between 7 and 12 Years: What Do We Know?

Wai Yew Yang[1], Shu Hwa Ong[1], Yi De Lee[1], Pei Ling Yen[1], Kah Yen Lim[1], Nenad Naumoskvi[2], Rati Jani[2]

1. International Medical University (Malaysia), 2. University of Canberra (Australia)

Background and objectives: Feeding practices exert a definite influence over children's experiences. The study aims to explore parental feeding practices and investigate the prediction domain of food preference from parent-child perspectives.

Methods: Two individual studies were conducted on Malay families with children aged 7 to 12 years. In Study 1, mothers (n=17) participated in semi-structured focus group interviews on their knowledge of foods and feeding practices. In Study 2, parent-child pairs (n=14) answered a 36-item, 5-point Likert scale Food Preference Questionnaire followed by virtual structured qualitative interviews. The interviews were digitally recorded, transcribed verbatim, backtranslated, and analysed according to the framework analysis technique.

Results: In Study 1, mothers perceived vegetables, chicken, fish, and plain water as healthy foods and drinks while discretionary options were snacks, fast foods, and carbonated drinks. The mothers defined healthy foods as foods handled safely with health benefits. They used 'healthy' cooking methods to prepare preferred foods and overtly controlled the child's access to discretionary food. In Study 2, the food groups reported by parent-child pair's report were consistent for the most preferred foods [snacks, median (IQR), parent: 4.5 (1.0) vs child: 4.5 (0.0), p>0.05] and least preferred food [legumes, parent: 2.0 (1.0) vs child: 2.0 (1.0), p>0.05]. Parents cited taste as the most significant determinant of food preference.

Conclusions: These studies were the first to qualitatively explore parents' perceptions of foods affecting their feeding practices among the Malaysian community to highlight the cultural contribution. Key insights into children's food intake and factors influencing their food preferences were identified.

Keyword: food, parenting, school-aged children, family, Malaysia

Food Quality Factors to increase Appetite towards Personalising Nutrition in the Elderly

Soojin Park[1]

1. Semyung University (Korea)

Background and objectives: Anorexia or poor appetite can be a major cause of malnutrition and frailty in the elderly. To understand the quality factors of food selection perceived by the elderly and important factors contributing to an increase in appetite and food intake.

Methods: A comparative questionnare survey was conducted between the elderly aged 65 and over (74±5.4 y, n=151) and the adults (55±8.5 y, n=102).

Results: Among elderly subjects, 47.6% had a risk in chewing and swallowing, evaluated by chewing and swallowing risk questionnaire but their self-awareness was low. When the elderly have difficulty chewing or swallowing food, it appers to modify into smaller pieces (72.7%) or adjust the concentration to thinner (18.2%) or to thicker (7.3%). The elderly subjects considered the importance of food quality factors in the order of digestibility, nutrition, chewing comfort followed by taste, health functionanlity, ease of swallowing and raw material quality. As an important factor for promoting appetite, except for taste, the elderly appeared in the order of food texture > nutrition = temperature > atmosphere, and shape, but for adults, there was a difference in the order of flavor > temperature, shape, texture, and nutrition. Additionaly, when a sample with the same sweetness intensity was presented, the elderly perceived the sweetness intensity of the sample improved with nutritional information or prettier shape and preferred it more. It was found that the elderly place importance on 'nutrition and health' when choosing food. Providing information on nutritional enhancement of food can increase the preference for food, and the visual appeal of food has been shown to have a significant effect on the preferences of the elderly.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: In conclusion, it could be important to provide nutritional information and visual appeal to food quality factors in order to increase appetite and food preference in the elderly.

Keyword: appetite, elderly, food quality, nutritional information, visual appeal of food

Effects of childhood school lunch intake on skipping breakfast as adults

Asuka S Sawai[1], Hitoshi Fujii[2], Nobuyasu Kaneko[3], Yoshinobu Tomita[4], Masato Ohno[5], Moe Takenaka[3], Rumiko Nishio[3], Kimio Shibata[6], Mayu Fujisawa[3], Riho Takaki[1]

1. Kanagawa Instutute of Techinology (Japan), 2. Mejiro University (Japan), 3. Yokohama City University (Japan), 4. ITOCHU Techno-Solutions Corporation (Japan), 5. Yonago College (Japan), 6. Gifu University (Japan)

Background and objectives: Many reports have shown the evils of not eating (impairment of mind and body, decreased work efficiency and learning ability). In Japan, the rate of skipping breakfast is high and is highest in those in their 20s (about 30%), so measures are required. In Japan, the rate of taking lunch at elementary schools is 99% but varies in junior high schools depending on the municipality. Lunch at school is considered to play a role in education by meals. This study aimed to investigate school lunch and the relationship between current and past eating habits, especially among university students in Kanagawa Prefecture, where junior high school lunches are infrequent provided.

Methods: We conducted a web-based questionnaire of the relationship between current eating habits (breakfast intake, etc.) and past lunch intake in junior high schools. The survey was conducted among students in Yokohama City University and Kanagawa Institute of Technology and with members of the Yokohama City University Alumni Association. Data was performed a survival analysis. Analyzed values were indicated by a risk rate of 5%.

Results: The overall rate of skipping breakfast among the 753 respondents was 32% (27.4% for men; 34.4% for women). The group of Skipping breakfast was higher ate the snacked after dinner than in eat breakfast group. The results of survival time analysis using breakfast skipping as the event showed that the number of skipping breakfast began suddenly increase in adolescents, and new breakfast skippers did not increase rapidly when 20s. The breakfast skipping habit began earliest in adolescents, who were the earliest group to purchase lunch in a store, followed by the lunchbox group and school lunch group, and breakfast skipping habit began at a significantly lower age in this group versus the other two groups.

Conclusions: This study showed that skipping breakfast began in adolescence, and those who continued to skip breakfast during this period developed a habit of skipping breakfast after the age of 20. Education by homeroom teachers and school dieticians was considered the reason for the low number of people skipping breakfast when they became university students.

Bridging the vitamin A and deworming coverage gap among underserved populations in India through government and civil society organization partnerships

Shilpa Bhatte[1], Jamie Frederick[2], Samantha Serrano[3], Clayton Ajello[4], Zaynah Chowdhury[5], Temjentsungla Jamir[6], Longri Kichu[7], Temsu Longchar[8], Ruchika Chugh Sachdeva[9], Neha Sareen[10]

1. Independent Consultant (India), 2. Vitamin Angels (USA), 3. Vitamin Angels (USA), 4. Vitamin Angels (USA), 5. Vitamin Angels (USA), 6. Department of Health and Family Welfare, Nagaland (India), 7. Department of Health and Family Welfare, Nagaland (India), 8. Department of Health and Family Welfare, Nagaland (India), 9. Vitamin Angels and Bill & Melinda Gates Foundation (India), 10. Vitamin Angels (India)

Background and objectives: In 2006, Vitamin Angels (VA), India partnered with several locally-based civil society organizations (CSOs) in Nagaland state, India to deliver Vitamin A Supplementation (VAS) in capsule form and deworming tablets to increase coverage. During this time, vitamin A coverage increased from 6.7% to 27% (2006 to 2016). In 2016, VA expanded its partnership to provide VAS and deworming (VAS+D) to more CSOs in coordination with the Nagaland State Government (who delivers VAS in syrup form), with the goal of further improving coverage. This study was conducted with the objective to: 1) evaluate VAS+D coverage in Nagaland through government and CSOs partnerships, 2) examine socio-demographic barriers and facilitators to VAS+D coverage, 3) examine associations between socio-demographic characteristics and source of VAS coverage, and 4) to model impact of VAS on health outcomes due to increased coverage through government and CSOs partnerships.

Methods: a cross-sectional survey was conducted in Nagaland to determine coverage of VAS among children aged 6-59 months and deworming among children 12-59 months. Total of 1,272 caregivers of children aged 6-59 months were interviewed.

Results: Most children (77.2%) received VAS in the past six months, of which 28.1% received VAS in capsule form (provided through CSOs) and 70.2% received it in syrup form (provided through government). Total coverage of deworming among eligible children was 74.2%, with 43.5% who received both VAS+D. Barriers to receiving VAS included lower pre-school enrollment (47.4% not enrolled vs 80.9% enrolled, $p<0.001$) and lower maternal education (72.5% less than high school vs 81.9% high school or above, $p<0.001$). Barriers to receiving VAS+D included lack of knowledge of benefits of VAS+D ($p<0.001$). Children of caregivers in lower wealth quintiles were 2.2 times more likely to receive VAS through CSO platform (OR = 2.2, 95%

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

CI: 1.6,3.1) than children of caregivers in higher wealth quintiles. Based on Lives Saved Tool modeling, increasing VAS coverage by 22% through the CSO platform resulted in an estimated 114 stunting cases averted, 25,017 diarrhea cases averted, and 9 lives saved.

Conclusions: Government and CSO partnerships can reduce gaps in VAS+D coverage, especially in areas that are underserved.

The influence of FTO and ADRB2 gene polymorphisms on pregestational BMI and gestational weight gain in women with diabetes mellitus: Results of a randomized nutrigenetic trial

Karina dos Santos[1], Eliane Lopes Rosado[1], Ana Carolina Proença da Fonseca[2], Gabriella Pinto Belfort[1], Letícia Barbosa Gabriel da Silva[1], Marcelo Ribeiro-Alves[2], Verônica Marques Zembrzuski[2], J Alfredo Martínez[3], Cláudia Saunders[1]

1. Federal University of Rio de Janeiro (Brazil), 2. Oswaldo Cruz Foundation (Brazil), 3. IMDEA Food Institute (Spain)

Background and objectives: Obesity and diabetes mellitus (DM) are multifactorial diseases that increase the risk of adverse outcomes of pregnancy. We investigated the influence of FTO (rs9939609 / rs17817449) and ADRB2 (rs1042713 / rs1042714) gene polymorphisms on pregestational BMI and gestational weight gain (GWG) in pregnant women with DM.

Methods: The study was conducted in a public hospital at Rio de Janeiro/Brazil (2016-2020). Seventy pregnant women with pregestational DM were randomly assigned at the beginning of prenatal care to one of the nutritional intervention groups: traditional diet (a healthy Brazilian dietary pattern) or DASH diet (Dietary Approach to Stop Hypertension), until the childbirth. Pregestational BMI was calculated as pre-pregnancy weight/height². Excessive GWG was the total weight gain above the upper limit of the Institute of Medicine recommendations. Genotyping was performed using real-time PCR. Medians were compared using non-parametric tests. Time-to-event analysis was performed to investigate the risk for progression to excessive GWG.

Results: Participants had 32 (IQR 25.7 – 36.0) years old, 51.4% had type 1 DM. Pregestational BMI was 27.8 kg/m² (IQR 24.4 – 32.3). All women with GG genotype for rs1042714 had type 1 DM and lower pregestational BMI than the CG or CC carriers (23.3 kg/m² [20.1 – 26.4] vs. 28.0 kg/m² [24.6 – 32.4]; p= 0.02). The other polymorphisms evaluated had similar distribution between the types of DM and were not associated with pregestational BMI. There was no difference in GWG between diet groups, 52.9% of women had excessive GWG. Regardless the dietary pattern or DM type, AT carriers of rs9939609 (FTO) and AA carriers of rs1042713 (ADRB2) had higher risk of earlier exceeding GWG compared to TT (aHR 2.4; CI 95% 1.0–5.8; p = 0.04) and GG (aHR 3.9; CI 95% 1.1–13.7; p = 0.03) genotypes, respectively, as the AG carriers for FTO haplotype rs9939609:rs17817449 compared to TT carriers (aHR 1.8; CI 95% 1.0–3.1; p = 0.02).

Conclusions: FTO and ADRB2 gene polymorphisms influenced maternal body weight. It may be considered hereafter to investigate personalized nutrition with potential to protect maternal and child health in pregnancies affected by DM.

PAB(T3)-116

Nutrimetry to reduce linear growth retardation by 40% in children younger than 1000 days by 2025; in the health center of the municipality of tenabo, in estate of campeche, mexico.

Jorge enrique selem[1], Monica Hattori[2], Maria Carolina Selem[3], Fernando Jose Sandoval[4]

1. centro de salud de tenabo campeche (Mexico), 2. programa secretaria de educacion del gobierno del estado de yucatan (Mexico), 3. Universidad vizcaya de las americas (Mexico), 4. Escuela de Medicina de la Universidad Autonoma de Campeche (Mexico)

Background and objectives: In 2022 the WHA 65.5 resolution supported the application of a comprehensive nutrition plan with the goal of reducing growth retardation by 40% by 2025. Nutrimetry (described extensively in other publications) allows for prevalence comparisons by year and nutrition at-risk groups, assisting in achieving the established goals.

Methods: Data from 328 children was collected from 2010-2017 at the Tenabo health centre, Campeche, Mexico. For the analysis, data crossed were length for age Z score and BMI for age Z-score with nutrimetry, comparing prevalence by year and nutrition at-risk group Z-scores using Kruskal Wallis analysis, resulting in the following prevalences. For the 2010 at-risk group1 0%, 4 11.76%, 7 2.94% and 13 2.94% P=17.64%. 2011 at-risk group1 3.45%, 4 10.34%, 7 3.45% and 13 3.45% P=20.69%. 2012 at-risk group1 3.85%, 4 7.69%, 7 7.69% and 13 0%. 2013 at-risk group1 2.17%, 4 8.7%, 7 4.35% and 13 2.17% P=17.39%. 2014 at-risk group1 0%, 4 13.04%, 7 2.17% and 13 0% P=15.21%. 2015 at-risk group1 0%, 4 10%, 7 0% and 13 0% P=10%. 2016 at-risk group1 5%, 4 17.5%, 7 5% and 13 0% P=27.5%. 2017 at-risk group1 4.88%, 4 9.76%, 7 0% and 13 0% P=14.64%.

Results: At-risk group1 2010-2013 P= 2.36%, 2014-2017 P=2.47%. at-risk group4 2010-2013 P=9.62%, 2014-2017

P=12.57%. at-risk group7 2010-2013 P=4.60%, 2014-2017 P=1.79%. at-risk group13 2010-2013 P=2.14%, 2014-2017 P=0%. We compared the averages of both 4-year spans and found differences of -1.9%, although we found a clear decrease, multiple efforts are needed to achieve the 2025 goals.

Conclusions: At-risk group1 showed persistency in prevalence without significant changes, at-risk group4 with a significant increase, at-risk groups7 and 13 showed a significant decrease in the prevalence of overweight and obesity with short stature, which demonstrates the utility of nutrimetry for understanding the changes that occur in the population of children younger than 1000 days. The authors declare no conflict of interest.

Keyword: Nutrimetry, Nutritional risk groups (at risk group), Z score, cross variable, prevalence (P)

PAB(T3)-117
Study on the Effects of Participatory Obesity Prevention Program for Elementary School Children

Joohee Woo[1], Jieun Jo[1], Hyunji Lee[1], Changbum Kang[1]

1. Korea Health Promotion Institute (Korea)

Background and objectives: Obesity in children and adolescents is gaining attention due to the high likelihood that obese children and adolescents will progress to adult obesity. If a child is obese in elementary school, he or she will remain obese throughout adolescence, and the deviation from normal weight will widen. As a result, more proactive prevention and intervention programs for childhood obesity are required.

Methods: This program, which is based on the theory of behavior change, provides experiential nutrition education and play-based physical activity programs to children who attend after-school classrooms and local children's centers in order to develop healthy eating habits and increase physical activity. To assess the program's effectiveness, changes in obesity, nutrition, and physical activity-related knowledge and behavior were quantified and analyzed using SPSS.

Results: Between March and July 2020, a total of 7,597 elementary school students in the first and second grades participated in the program, and 3,280 of them were analyzed for pre- and post-comparative analysis. To begin, the nutritional knowledge score increased by 12.96 points, as did the eating behavior score (P<0.001).The change in physical activity score increased by 0.51 points, while the proportion of children in the maintenance stage, the highest stage in the stages of change in physical activity, increased by 11.6%p (P<0.001).Second, in terms of changes in childhood obesity rates, the ratio of overweight to obese children decreased by 0.2%p, the number of underweight children decreased, and the number of children with normal weight increased. (p<0.05)

Conclusions: Although the change was not significant due to the fact that circumstances such as irregular program operation and restrictions on face-to-face education were reflected as a result of COVID-19 disease control measures, it demonstrated the effect of decreasing the obesity rate in overweight/obese children. It is believed that by allowing children to manage their own healthy eating habits through experiential nutrition/physical activity education, it will be possible to promote the foundation for lifelong health maintenance.

Keyword: Childhood obesity, obesity prevention, elementary school care, nutrition, physical activity

PAB(T3)-118
Maternal Vitamin D Deficiency during the COVID-19 Pandemic in Japan

Satomi Minato-Inokawa[1,2], Yasuna Tabuchi[2], Yuna Naraoka[2], Koutatsu Maruyama[1], Momo Hosokawa[2]

1. Ehime University (Japan), 2. General Incorporated Association Luvtelli (Japan)

Background and objectives: Maternal vitamin D deficiency (VDD) may cause low vitamin D status of infants. However, the characteristics of maternal VDD under the COVID-19 pandemic are unknown. Thus, we aimed to investigate the features of maternal VDD evaluated by questionnaire survey during the COVID-19 pandemic in Japan.

Methods: From December 2021 to April 2022, an online questionnaire survey was conducted for Japanese pregnant women aged 20 years or over. Participants were recruited from all over the country using poster and leaflets at government's maternal and child department or social media. The questionnaire included dietary habits and lifestyles before (by March 2020) and during the COVID-19 pandemic, healthy eating literacy (HEL), and the VDD questionnaire (VDDQ-J). Of the 556 consented pregnant women, 421 were included in the analysis. VDDQ-J score of 31 or higher and not taking vitamin D supplements were defined as VDD. Unpaired t-test, chi-square test, and logistic regression analysis with backward stepwise selection method were performed.

Results: The mean age was 32 years old and primipara was 58.4%. Percentages of women in first, second, and third trimester were 13.3%, 45.8%, and 40.9%, respectively. Thirty-eight percent of subjects took supplements containing vitamin D and 49.9% was VDD. The VDD group was younger (p=0.001), of lower HEL (p=0.001), and tended to have lower food expenditure before the COVID-19 pandemic (p=0.07) than the non-VDD group. Pre-pregnancy body mass index, educational background, employment status, household income, frequency of working remotely, and morning sickness were not significantly different between both groups. Age (odds ratio (OR) : 0.94, 95% confidence interval (CI): 0.89-0.98), HEL (OR: 0.67, 95%CI: 0.51-0.89), and food expenditure before the COVID-19 pandemic (OR: 0.75, 95%CI: 0.59-0.94) were associated with VDD.

Conclusions: Prevalence of VDD was 49.9% and younger age, lower HEL, and lower food expenditure were the characteristics of VDD in Japanese pregnant women under the COVID-19 pandemic. Our findings suggest that more observational or intervention studies are needed to clarify the risk factors for VDD

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

among pregnant women whose dietary habits and lifestyle has changed during the pandemic.

Keyword: Pregnant women, Vitamin D deficiency, Healthy eating literacy

PAB(T3)-119

The effect of nutritional improvement of children and maternal women participating in the Nutri-Plus program

Jieun Jo[1], Hyunji Lee[1], Joohee Woo[1], Changbum Kang[1]

1. Korea Health Promotion Institute (Korea)

Background and objectives: This study investigated whether the NutriPlus program improved children and maternal women nutritional status, nutrition knowledge and attitudes in low-income families. The NutriPlus program is developed to improve maternal and child nutritional status in South Korea. Each participant receives specifically designed home-delivered supplementary food packages and nutrition education for 6 to 12 months. Especially, In response to the demand for nutrition education during the COVID-19 pandemic, we were introducing online E-learning system to the NutriPlus participants.

Methods: This study included maternal women(N=7,170) and 1-to 5-year-old children(N=9,924) participating in the program in 2021. Anthropometric, biochemical, and dietary information was collected on pregnant woman and children. Participant nutritional status was determined by anemia prevalence and intake level of 8 main nutrients. Nutrition knowledge and attitude information was collected from the children's guardian before and after the program. All analyses were conducted with SPSS.

Results: The number of children with weight-for-height and height-for-weight percentile less than 10 significantly decreased ($p<0.001$). Anemia prevalence decreased from 44.3% to 11.6% ($p<0.001$) and MAR(mean adequacy ratio) was also significantly increased from 0.74 to 0.86 ($p<0.001$).

Conclusion: The NutriPlus program is a maternal and child nutrition support system that has been promoted throughout Korea for the past 17 years, and has been consistently proving the effect of improving the nutritional status of children and maternal women of low-income families. The total fertility rate in Korea is continuously decreasing, and nutrition management support for children and maternal women, which are at-risk groups in terms of nutrition, is becoming more important. The nutritional improvement results of the NutriPlus program suggested that it is necessary to expand the Nutriplus program coverage for pregnant women and infants.

Keyword: maternal and child nutritional status, nutrition education programs, nutrition supplementation programs

The association between nutritional status and cognitive development of school-age children in southern Ethiopia – A Cross sectional study

Befikadu Tariku Gutema[1,2], Muluken Bekele[2], Sifray Batire[2], Bruno Levecke[1], Amina Abubakar[3], Stefaan de Henauw[1], Souheila Abbeddou[1]

1. Ghent University (Belgium), 2. Arba Minch University (Ethiopia), 3. Kenya Medical Research Institute (Kenya)

Background and objectives: Brain's development starts in the womb, continues rapidly during pregnancy and early childhood, while higher cognitive functions continue to mature during school-age. Nutrition and infections impair, at different degrees, the cognitive development and can lead to long-term detrimental effects on schooling and productivity. In the context of intermittent iron and vitamin A supplementation study, the association between nutritional status and cognitive development of schoolchildren at Arba Minch health and demographic surveillance site (HDSS), southern Ethiopia at baseline was assessed.

Methods: Schoolchildren aged 7-10 years (n=986) were enrolled in the study from nine schools. At baseline, height, weight, and hemoglobin concentration (Hb) were collected at the schools. Children were tested and treated for confirmed malaria based on the rapid diagnostic test (RDT) and for soil-transmitted helminths (STH) using the kato-katz test. Cognitive development was assessed using digit span forward and backward, Raven's Colored Progressive Matrices (RCPM) and Visual search cancellation task. Multivariate logistic models were used to assess the association.

Results: The prevalence of STH infection was 43.7% (the infection of ascaris, Trichuris and hookworm was 19.5%, 19.9% and 14.5%, respectively). One in five children was infected by *Schistosoma mansoni*. Only seven children were RDT positive, 23.7% had adjusted Hb < 11.5 g/dL, and 26.9% and 8.6% had height-for-age z-score (HAZ) and body mass index-for-age z-score (BMI-AZ) < -2.0 SD, respectively. Stunted children were respectively almost twice and one and half time as likely as non-stunted children to be in the low 25th percentile of digit span forward (AOR 1.67: 95%CI, 1.17, 2.37) and of performance index (AOR 1.54: 95% CI, 1.05, 2.25). Thinness and anemia were not associated with cognitive outcomes.

Conclusions: Stunting was associated with short term memory and concentration of schoolchildren.

Keyword: Cognitive development, Nutritional status, anemia, stunting, thinness

Conflict of Interest Disclosure: No conflict of interest

PAB(T3)-121
Seasonal and menstrual rhythms of dietary intake - CYCLES in Iceland

Perla Ósk Eyþórsdóttir[2], Bryndís Eva Birgisdóttir[3], Ingibjörg Gunnarsdóttir[4], Geir Gunnlaugsson[5], Virginia J. Vitzthum[1]

1. Indiana University (USA), 2. University of Iceland (Iceland), 3. University of Iceland (Iceland), 4. University of Iceland (Iceland), 5. University of Iceland (Iceland)

Background and objectives: Hormonal fluctuations may occur with the rhythms of changing seasons and changing phases of the menstrual cycle. This study aims to investigate whether consumption of food from several food groups and intake of macro- and micronutrients differ between two seasons (winter and summer) and within phases of the menstrual cycle (menstrual-, late follicular- and late luteal phase).

Methods: CYCLES is an observational multidisciplinary research project that took place in Iceland in 2016-2017. Data was collected for the same participants over two cross sectional events, including dietary intake. In total 23 healthy female participants, mean (SD) age of 32.1 (5.1) years, completed six 24-hour dietary recalls. Three dietary recalls were collected in summer and three in winter, each spanning across a single complete menstrual cycle. Intake was compared, between seasons and menstrual cycle phases, from selected food groups, as well as intake of energy, macro- and micronutrients. Analyses were corrected for multiple comparisons.

Results: Only a small fraction of the sample achieved the recommended intake of vitamin D, folate, iron and iodine. Mean total energy (SD) was 2026 (532) kcal during the summer and 1932 (436) kcal during the winter. Individual variation was large in dietary intake between seasons: some had higher intake during the winter compared to the summer, while inverse for others with no clear trend. After correction for multiple comparison, no statistically significant difference was observed for dietary intake between seasons. However, the results indicated differences in fiber and iron intake. After correction for multiple comparison, no statistically significant difference was observed in dietary intake within menstrual phases, while indicative for fat, with mean intake (SD) for the same phases at 74g (27g), 84g (26g) and 94g (38g).

Conclusions: After correcting for multiple comparisons, no statistically significant difference in dietary intake was found between seasons nor phases of the menstrual cycle, possibly due to small sample size. However, large individual variations give way to interesting further analysis within the CYCLES Iceland project, where the dietary data will be analyzed along with other lifestyle factors, inflammatory factors and hormonal status.

PAB(T3)-122
Exploring Dietary Habits and Lifestyle for the Prevention of Menstrual Pain

Yuna Naraoka[1,3], Satomi Minato Inokawa[2,3], Momo Hosokawa[3]

1. Juntendo University (Japan), 2. Ehime University (Japan), 3. General Incorporated Association Luvtelli (Japan)

Background and Objective: In the recent years, the percentage of working women in Japan has been increasing annually, reaching 44.4% in 2019. Among women-specific health problems, dysmenorrhea and premenstrual syndrome (PMS) often reduce the quality of life of women at the reproductive age, leading to economic losses. The purpose of this study was to compare the food and drink intake and lifestyle habits of the groups with mild and severe menstrual pain, and to identify dietary habits to prevent menstrual pain.

Methods: Healthy women aged 18–39 years were included in the study. Dietary surveys using the brief-type self-administered diet history questionnaire (BDHQ), body composition measurements, and questionnaire surveys on menstrual status and lifestyle habits were conducted. The subjects were divided into two groups: a heavy group consisting of those who answered that the cramps were "painful to the point of falling asleep" and they "cannot spend time without painkillers," and a light group consisting of those who answered that they encounter "no obstacle in daily life" and "almost no obstacle". We compared the amount of nutrient intake against the lifestyle habits and used the SPSS software (IBM, ver. 26) for analysis. Mann–Whitney U-test and χ-square test were used, and the significance level was set at $p<0.05$.

Results: Comparing the intake of nutrients per 1000 kcal in the two groups, the heavy group consumed significantly more saturated fatty acids, especially lauric acid, myristic acid, stearic acid, and arachidic acid, and unsaturated fatty acids, namely the n-6 unsaturated fatty acids, heptadecenoic acid, eicosadienoic acid, alpha-linolenic acid, and linoleic acid ($p<0.05$). Among foods, ham, ice cream, and mayonnaise intake were significantly higher in the heavy group, suggesting that these foods, which are high in animal fatty acids, may be responsible for causing menstrual cramps. The heavy group was also significantly more likely to have pain-related symptoms during PMS, such as lower abdominal pain ($p<0.05$).

Conclusion: Excessive intake of saturated and n-6 fatty acids may lead to pain induction not only in menstrual pain but also in PMS symptoms.

Keyword: Menstrual Pain, Lifestyle, saturated fatty acids, n-6 unsaturated fatty acids, Premenstrual Syndrome

Status and socio-demographic correlates of processed food consumption among Bangladeshi adolescents: Findings from a nationwide survey

Malay Kanti Mridha[1], Abu Ahmed Shamim[1], Md. Mokbul Hossain[1], Md. Showkat Ali Khan[1], Mehedi Hasan[1], Abu Abdullah Mohammad Hanif[1], Fahmida Akter[1], Mohammad Aman Ullah[2], SM Mustafizur Rahman[2]

1. BRAC University (Bangladesh), 2. National Nutrition Services (NNS) (Bangladesh)

Background and objectives: Consumption of processed food, including, savory crispy or fried snacks (SCFS), sugary snacks (SS), and sugar-sweetened beverages (SSB) is associated with obesity and the onset of non-communicable diseases. Using data from a nationwide survey, we assessed SCFS, SS, and SSB consumption among Bangladeshi adolescent boys and girls, and reported the sociodemographic factors associated with the consumption.

Methods: We interviewed 4,907 boys and 4,865 girls for 24-hour and 7-day recall on intake of SCFS, SS, and SSB from 82 randomly selected clusters (57 rural, 15 non-slum urban, and 10 slums) in Bangladesh. The weighted prevalence of consumption of SCFS, SS, and SSB was estimated by gender. Multivariable linear regression models were run to estimate adjusted mean differences in the frequency of weekly consumption of SCFS, SS, and SSB.

Results: The prevalence of daily consumption of SCFS, SS, and SSB was 11.6%, 28.9%, and 25.6% among adolescent boys and 4.9%, 24.8%, and 20.7% among adolescent girls. The mean frequency of weekly consumption of SCFS, SS, and SSB was higher among boys (SCFS: 2.50±2.73 times in boys and 1.58±2.11 in girls, $p<0.001$; SS: 4.64±4.45 times in boys, 4.08±3.98 times in girls, $p<0.001$; SSB: 3.99±6.05 in boys and 2.90±5.08 in girls, $p<0.001$). Adolescent boys and girls of older age (15-19 years), belonging to the richest households, living in a female-headed household, and living in non-slum urban areas had a higher frequency of consumption of SCFS. The weekly mean frequency of SCFS, SS, and SSB consumption was higher among girls with mothers having ≧10 years of schooling. The weekly mean frequency of SS and SSB consumption was higher among boys with fathers having ≧10 years of schooling.

Conclusions: The frequency of consumption of SCFS, SS, and SSB was higher in adolescent boys A number of socio-demographic factors are associated with the consumption of SCFS, SS, and SSB among both boys and girls. Policy and programs to discourage the consumption of these processed foods are urgently needed. Future researchers should use quantitative dietary intake methods to determine the contribution of such foods and drinks to the overall intake of salt, sugar, and fats.

Dutch women at risk of micronutrient inadequacy during pregnancy

Marjolein H. de Jong[1], Alida Melse-Boonstra[2], Johanna M. Geleijnse[2], Janneke Verkaik-Kloosterman[1]

1. National Institute for Public Health and the Environment (RIVM) (Netherlands), 2. Wageningen University (Netherlands)

Background and objectives: Adequate micronutrient intake before and during pregnancy is important for both mother and child. A diet providing adequate micronutrient intakes prior to pregnancy will require less dietary changes during pregnancy and results in a good start in life for the offspring. In this study the micronutrient intakes of women of childbearing age was evaluated to examine if they are prepared for the (higher) demands during pregnancy.

Methods: Food consumption data of women (20-45 yrs.) from the Dutch National Food Consumption Survey 2012-2016 (n=484) and the Dutch Food Composition Database (NEVO version 2016) were used to calculate habitual intakes of micronutrients from foods using the Statistical Program to Assess habitual Dietary Exposure (SPADE). The prevalence of inadequacy was assessed by comparing habitual intakes to the dietary reference values (DRVs) set by the Health Council of the Netherlands for non-pregnant and pregnant women. For micronutrients with an average requirement Beaton's full probability approach was applied to quantify the prevalence with inadequate intakes. If the adequate intake (AI) was available a qualitative evaluation was made.

Results: Compared to DRVs for non-pregnant women, prevalence with inadequate intakes was high (>10%) for vitamins B2 (58%), calcium (52%; 20-24 y olds, 30%; 25+ y olds), vitamin A (38%), folate (36%) and vitamin B6 (19%). With equal or increasing DRVs during pregnancy, for more micronutrients the prevalence with inadequate intakes was high (>10%): vitamin B2 (76%), calcium (52%; 20-24 y olds, 30%; 25+ y olds), vitamin A (47%), B6 (35%), zinc (17%) and vitamin B12 (14%). Median potassium, selenium (only for the AI for non-pregnant women), folate (only for the AI for pregnant women) and vitamin D intakes were below the AI for non-pregnant and pregnant women and therefore no statement on the risk of inadequacy could be made.

Conclusions: Dutch women seem at risk of inadequate micronutrient intakes before, but also during pregnancy. Additional research on nutritional status or clinical signs of health effects is recommended. In addition, food consumption research among pregnant women is recommended to see if a changing dietary pattern in this period may increase the micronutrient intake.

Keyword: micronutrient, inadequacy, pregnancy, preconception, habitual intake

PAB(T3)-125
Closing the gap between maternal and child diet diversity in Nigeria: insights from the 2018 Nigeria Demographic and Health Survey

Rebecca Heidkamp[1], Hana Tasic[2], Nadia Akseer[1,2]

1. Johns Hopkins Bloomberg School of Public Health (USA), 2. Modern Scientist Global (Canada)

Background and objectives: Improving the quality of diets for women and children during the "first 1000 days" is a policy priority in Nigeria but progress is slow. In 2018 only 22% of Nigerian children 6-23 months old met the criteria for Minimum Dietary Diversity Child (MDD-C); a slight increase from 16% in 2013. Maternal diet quality is a known determinant of child diet quality. However, nationally-representative data on women's food group intake were not available until the 2018 Nigeria Demographic and Health survey (DHS). We use these data to describe the relationship between child and maternal diet diversity in Nigeria and highlight implications for design of infant and young child feeding (IYCF) programs.

Methods: We identified 8975 pairs of children 6-23 months and mothers 15-49 years with available data on food groups consumed in the previous 24 hours. For each pair we calculated rates of consumption concordance (i.e. both did or did not consume) and discordance (i.e. one consumed, other did not) across seven food groups. Next, we calculated MDD-C (at least 5 of 8 groups) using the seven food groups plus breastmilk. Finally, we modeled MDD-C assuming each child also consumed any discordant groups consumed by the mother. All analyses were stratified by child age (6-11m, 12-23m) and zone.

Results: Mother-child concordance was high for grains, tubers and roots (90%) and eggs (88%), moderate for legumes and nuts (64%), dairy (73%), flesh foods (74%), vitamin A rich fruits and vegetables (61%), and lowest for other fruits and vegetables (43%). Discordant consumption was more likely by mothers for all groups except dairy. Nationally, MDD-C was 22% per survey compared to 64% modeled. Difference between survey and modeled estimates varied by 38-47% pts across the 7 zones.

Conclusions: Findings suggest that there are food groups available in households that are not being fed to young children in Nigeria. Focusing IYCF counseling messages on these divergent food groups might dramatically increase MDD-C. With the recent addition of MMD-W to the DHS-8 global questionnaire, many countries will be able to do similar analyses to inform IYCF program design and monitoring.

PAB(T3)-126
Drama as a tool for improving breastfeeding self-efficacy of pregnant women in selected rural communities of Oyo State, Nigeria

Yetunde Omotola Ogundairo[1], Oladejo Thomas Adepoju[1], Adesola Oluwafunmilola Olumide[1]

1. University of Ibadan (Nigeria)

Background: Breastfeeding self-efficacy remains a key modifiable factor which enhances exclusive breastfeeding and positive health outcomes for infants and their mothers. Numerous interventions targeting the prenatal and postnatal periods have been developed to increase the breastfeeding self-efficacy of mothers. There is paucity of studies utilizing drama-based interventions for improving breatsfeeding self-efficacy of women.

Objectives: The study assessed the effect of a drama-based intervention on breastfeeding self-efficacy of pregnant women in rural communities in Lagelu and Egbeda Local Government Areas (LGAs),Oyo State, Nigeria.

Methodology: A quasi-experimental study was conducted. Selected communities in Lagelu and Egbeda LGAs were randomized into experimental and control groups. Using multistage sampling, pregnant women in second trimester were subsquently selected to participate in the study. A total of 200 pregnant women, 100 in the experimental and 100 in the control groups were selected and followed up to one, three and six months postpartum. The six-session intervention comprised a four episode drama that covered factors promoting breastfeeding and two sessions on hygiene practices. Sessions were presented to pregnant women in their communities prior to delivery. Control group received usual antenatal care. Information on socio-demographic characteristics, breastfeeding self-efficacy and pregnancy related issues were obtained using an electronic questionnaire prior to delivery and postpartum. Breastfeeding self-efficacy was assessed using breatsfeeding self-efficacy short form tool and yielded minimum and maximum obtainable scores of 0 and 70 respectively. Scores >52 were categorized as high breastfeeding self-efficacy. Data were analysed using descriptive and inferential statistics.

Results: The mean ages of women in the experimental and control were 27.29 ±6.03 and 28.27±6.68 respectively and 7.0% and 5.0% of experimental and control women had at most tertiary level of education. Pre-intervention, 89.0% experimental and 71% control women had high breastfeeding self-efficacy scores. The mean breastfeeding self-efficacy scores for the experimental women were 57.69±6.45, and, 57.41±6.08, pre-delivery, one, three and six months postpartum, 59.29±.294 and 58.76±.277 respectively (P value=0.00). Corresponding figures for control women were 58.91±.404 and 58.99±.408 (P value=0.00)

Conclusion: The drama-based intervention resulted in an improvement in breastfeeding self-efficacy of mothers in the experimental groups

Gender differences in diet quality and dietary diversity among geriatric population in Bangladesh: Findings from a nationally representative survey

Fahmida Akter[1], Md Mokbul Hossain[1], Abu Ahmed Shamim[1], Md Showkat Ali Khan[1], Mehedi Hasan[1], Abu Abdullah Mohammad Hanif[1], Mohammad Aman Ullah[2], S M Mustafizur Rahman[2], Malay Kanti Mridha[1]

1. BRAC James P Grant School of Public Health, BRAC University (Bangladesh), 2. National Nutrition Services (NNS), Institute of Public Health Nutrition (IPHN) (Bangladesh)

Background and objectives: With the rising trend of life expectancy in Bangladesh, the proportion of people aged 60 and above is predicted to reach 21.3% by 2030. Healthy dietary practices are critical for healthy ageing in both males and females. However, as Bangladesh lacks national-level data on diet quality and dietary practices in this age group, we aimed to assess the gender-specific status and determinants of diet quality and dietary diversity (DD) among elderly males and females in Bangladesh.

Methods: A total of 4,817 people aged 60 years and above (males:2,482 and females:2,335) were enrolled, interviewed, and anthropometrically assessed from 82 clusters randomly selected from all eight administrative divisions of Bangladesh during 2018-2019. For dietary data collection, we employed a list-based (24-items) recall method and aggregated these items into 10 food groups following FAO guidelines. Diet quality and DD were determined by the consumption of foods from nutrient-rich food groups, the prevalence of inadequate DD (IDD, defined as consumption of 5 food groups out of 10) and the DD score using a 24-hour recall period. We used multivariable logistic regressions to identify factors associated with IDD in males and females separately.

Results: Overall, 58.6% of the elderly population had IDD, with females having a substantially higher prevalence than males (61.2% vs. 56.3%, p=0.028). Men and women had mean (±SD) DD scores of 4.3±1.6 and 4.1±1.7, respectively. Among the food groups, females consumed significantly less fish and eggs than males (fish: 51.0% vs. 57.8%, p=0.002; egg: 17.1% vs. 22.1%, p=0.004). Poor education, residing in rural areas, living in homes with fewer individuals, and living in food-insecure households were associated with IDD in both sexes. Furthermore, among males, higher age and not being currently married were associated with IDD; and among females, lower age, and living in households with poorer and middle wealth status were associated with IDD.

Conclusions: There exists a gender-based disparity in terms of diet quality and several socio-demographic factors that influence DD among the elderly people of both sexes in

A systematic umbrella review on the effects of size at birth on health, growth, developmental and behavioural outcomes in children and adolescents

Zeina Jamaluddine[1,2], Eman Sharara[3], Vanessa Helou[4], Nadine El Rashidi[3], Gloria Safadi[3], Nehmat El-Helou[3], Hala Ghattas[3], Miho Sato[2], Hannah Blencowe[1], Oona MR Campbell[1]

1. Faculty of Epidemiology and Population Health, London School of Hygiene & Tropical Medicine, London (UK), 2. School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki (Japan), 3. Faculty of Health Sciences, American University of Beirut, Beirut (Lebanon), 4. Faculty of Medicine, American University of Beirut, Beirut (Lebanon)

Background: Size at birth, an indicator of intrauterine growth, has been extensively studied in relation to subsequent health, growth, developmental, and behavioural outcomes. A search in PubMed turns up nearly half a million articles - an unwieldy and unmanageable field to navigate. Evidence from the extensive literature on this topic has not been synthesized to understand where there is conclusive knowledge and where more research might be needed. This umbrella review aims to examine the evidence from systematic reviews and meta-analyses on the effects of size at birth on subsequent outcomes in children and adolescents and to identify gaps in this literature.

Methods: We searched five databases from inception to 15 July 2021 to extract evidence from systematic reviews and meta-analyses (PROSPERO CRD42021268843). We synthesized evidence from all the associations identified between 12 size-related risk factors (birthweight and/or gestation) and 69 outcomes grouped in seven themes: (a) mortality and hospitalization (b) neonatal and early childhood acute ill-health (c) lung-related ill-health (d) chronic ill-health (e) growth and nutrition (f) developmental and (g) behavioural and mental health.

Results: 16,641 articles were screened, 318 systematic reviews identified and 1,005 associations between size at birth and outcomes were mapped. Thirteen outcomes had reviews without meta-analysis. Small size at birth was associated with most half of the sub-themes examined 32/56 while large size at birth was associated with fewer outcomes 8/19. Ten reviews, and 69 meta-analyses within these, compared risks by size for gestational age stratified by preterm and term babies. Analyses including the co-occurrence of premature and small-for-gestational-age compared to term appropriate-for-gestational, were ideal and enabled us to understand and distinguish mechanism related to prematurity and intrauterine growth

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

restriction. For mortality and cognition, prematurity was relatively more important that small-for-gestational-age, while for undernutrition being small-for-gestational was more important.

Conclusion: Our study compiles evidence from 1,005 associations, and our results show where there is good, weak, or absent evidence on the roles of prematurity and intrauterine growth restriction in the fetal origins of disease. We identified gaps in risk factors assessed large size at birth, size at birth adjusted for gestational-age and stratification by maturity and growth.

Factors related to inter-professional work for food allergy management of childcare workers and food service workers in nursery schools

Sakiko Nishizawa[1], Kaori Watanabe[1], Shoko Ario[1], Hatsumi Onouchi[1], Kayo Tamura[2], Hyun-jung Park[1], Kyoko Ando[1]

1. Aichi Bunkyo Women's College (Japan), 2. Aichi Gakusen University (Japan)

Background and objectives: "The Guidelines for Food Allergy (FA) Management in Nursery Schools" provides a shared understanding and organizational management of FA for all nursery school workers, regardless of their occupation. The purpose of this study was to clarify the factors related to inter-professional work (IPW) for FA management, and to establish a system to prevent FA incidents in nursery schools.

Methods: This study used the data from an anonymous self-administered questionnaire survey in 2017 to the workers at 1415 nursery schools in Japan. It included 4245 childcare workers and 1415 food service workers. The Mann-Whitney U test, Kruskal-Wallis test, and logistic regression analysis were used to examine the individual and organizational factors related to about IPW for FA management by each workers.

Results: Both childcare workers(n=2427,57.1%) and food service workers(n=640,45.2%), the score of IPW for FA management has significant differences in term of individual factors such as the years of job experience in nursery schools, organizational factors such as utilization of FA management guidelines in nursery schools, IPW according to FA guidelines and opportunity to share information with other professions ($p<.05$, respectively). In addition, childcare workers have significant differences in term of age, accident experiences related to FA and position of nursery school ($p<.001$, respectively). Both of IPW high-scored childcare workers(n=2336,55.0%)and food service workers(n=609,43.0%) were related to the years of job experience in nursery schools, utilization of FA management guidelines in nursery schools and IPW according to guidelines (odds ratio [95% confidence interval] : 5.84 [1.74-19.6] and 4.07 [1.24-13.34],2.65 [1.62-4.32] and 2.69 [1.19-6.07],3.73 [2.30-6.06] and 2.34 [1.05-5.20], respectively). And, accident experiences related to FA and an organizational factor of opportunity to share information with other professions were particularly related to the high-scored childcare workers (2.22 [1.39-3.56], 4.90 [2.22-10.8], respectively).

Conclusions: The years of job experience in nursery schools, utilization of FA management guidelines and opportunity to share information with other professions were related to the IPW for FA management in nursery schools. Hence, the necessity of awareness of FA management guidelines to childcare workers, while food service workers and promoting the organizational utilization was suggested.

Keyword: Food Allergy, nursery school, inter-professional work, childcare worker, food service worker

PAB(T3)-130
Placental VDR-SOD3 axis mediates the benefits of maternal exercise on offspring health

Joji Kusuyama[1]

1. Tohoku University (Japan)

Background and objectives: The occurrence of obesity in mothers of reproductive age serve as prominent risk factor for the transmission of obesity and type 2 diabetes to subsequent generations, thus propagating a vicious cycle of metabolic dysfunction. Our previous studies have demonstrated that maternal exercise improves the metabolic phenotypes of offspring in adulthood, including improved glucose tolerance and liver function. Moreover, superoxide dismutase 3 (SOD3) is an exercise-induced, placenta-derived protein that transmit the benefits of maternal exercise to offspring liver via epigenetic changes. Here, we determined coordinated mechanism that responsible for placental SOD3 production by maternal exercise and nutrition.

Methods: To identify the critical regulators for SOD3 expression in placenta of trained dams, we performed RNA-seq of placenta from sedentary or trained dams and analyzed the potential binding sites of putative transcription factors in the Sod3 upstream region. We then established placenta-specific knockout mice using trophoblast-specific protein a (Tpbpa)/adenosine deaminase (Ada) Cre/loxP system to examine its effects on placenta and in vivo glucose tolerance in offspring. Female mice were housed in cages with (Trained) or without (Sedentary) running wheels for 2 wks prior to breeding and during gestation. Offspring were sedentary and normal diet-fed.

Results: RNA-seq revealed that 26 transcription factors were upregulated in the placenta from trained dams. Sod3 reporter assay identified that vitamin D receptor (VDR) signaling is necessary to induce Sod3 expression in trophoblasts, main component cells in placenta. High vitamin D (10,000 unit)

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

feeding improved the effects of maternal exercise on hepatic gene expression and glucose metabolism in offspring, however these effects was diminished by placenta-specific Sod3 knockout. Conversely, detrimental effects of maternal low vitamin D (100 unit) diet on offspring metabolism were recovered by the injection of recombinant SOD3 protein using exo utero developmental system. Placenta-specific VDR knockout showed decreases of placental SOD3 production, epigenetic disturbance of hepatic genes, and impaired glucose tolerance in adult offspring.

Conclusions: Placental VDR-SOD3 axis is necessary for the beneficial effects of maternal exercise on offspring glucose metabolism. Cooperative intervention of exercise intervention and vitamin D supplementation may maximize the benefits of exercise to pregnant women and their offspring.

Keyword: placenta, pregancy, obesity, type 2 diabetes, vitamin D

Differences In Knowledge, Eating Habits, And Lifestyle In Indonesian Students Based On The Ethnic Group During Covid-19 Pandemic

Vitria Melani[1], Laras Sitoayu[1], Lintang Purwara Dewanti[1], Sarah Mardiyah[2]

1. Universitas Esa Unggul (Indonesia), 2. Universitas MH. Thamrin (Indonesia)

Background and objectives: During the covid-19 pandemic, a person's behavior related to health tends to get better. One of the community groups experiencing these changes is students. Culture, especially ethnic differences, is one factor that influences behavior changes. This study aims to analyze Indonesian students' differences in knowledge, eating habits, and lifestyle based on the ethnic group during the covid-19 pandemic.

Methods: The design of this study was cross-sectional, with an independent t-test analysis conducted on 941 students from seven ethnicities in Indonesia.

Results: The results showed that as many as 54.1% of students have poor nutritional knowledge. In addition, most respondents experienced changes in their eating habits (89.1%) and lifestyle (64.1%) during the pandemic. Independent t-test analysis shows differences in student knowledge between different ethnic groups (pv=0.008). Meanwhile, there are no differences in changes in eating habits, breakfast, and stress levels in students based on different ethnic groups.

Conclusions: In this study, different tribes did not show different eating behavior. It might be caused by raising awareness about eating healthy food in all ethnic groups.

Keyword: Eating Habit, Ethnic, Lifestyle, Indonesia, Student

Dietary pattern of iron intake, iron status and haemoglobin level among school age adolescents in a small island of Indonesia

Healthy Hidayanty M.Kes[1], Devintha Virani Sp.GK[2], Sabaria Manti Battung[3], Dian Sidiq Arsyad[4]

1. Hasanuddin University (Indonesia), 2. Hasanuddin University (Indonesia), 3. Hasanuddin University (Indonesia), 4. Hasanuddin University (Indonesia)

Background and objectives: Iron deficiency anaemia among adolescents does not only occur in rural and urban areas, but also occurs in small islands that are rarely identified. This study aims to assess dietary pattern of iron intake, iron status and haemoglobin level among school age adolescents in a small island of Indonesia.

Methods: The study used a cross sectional design. It involved 231 adolescent school age of 10-18 years were randomly selected in a small island in Indonesia. Multiple-pass 24 hour-recall, iron food frequency questionnaire consisting 37 food items, and semistructures questionnaire were administered. Variables consisted of sociodemographics, dietary factors and haemoglobin level. Chi-square (X^2) test, exploratory factor analysis, and partial correlation (r) tests were used for data analysis.

Results: Mean age of respondents was 14.8 years. Six iron dietary pattern explaining 45.6% of the total variance were identified: iron dietary pattern 1 (22.6%), iron dietary pattern 2 (5.6%), iron dietary pattern 4 (4.6%), and iron dietary pattern 5 (4.2%) composed of iron-rich, iron enhancing, and iron-inhibiting foods; iron dietary pattern 3 (4.9%), and iron dietary pattern 6 (3.7%) comprised of iron-rich and iron-inhibiting foods. Sex ($X^2=5.2$, $p<0.05$), age group ($X^2=10.0$, $p<0.05$), and having hives or allergic ($X^2=4.7$, $p<0.05$) significantly affected dietary iron intake. Sex ($\beta=0.32$, $p<0.05$), breakfast skipping ($\beta=2.83$, $p<0.05$), and low of mother education ($\beta=0.39$, $p<0.05$) were associated with anaemia among adolescents. Analysis of partial correlation showed statistically significant relationship between iron dietary pattern 1 and dietary iron ($r= -0.241$, $p<0.05$), iron dietary pattern 1 and dietary fiber ($r= -0.142$, $p<0.05$), iron dietary pattern 4 and haemoglobin ($r= 0.217$, $p<0.05$), iron dietary pattern 5 and dietary iron ($r= 0.217$, $p<0.05$), iron dietary pattern 5 and dietary fiber ($r= 0.138$, $p<0.05$), iron dietary pattern 6 and dietary iron ($r= 0.131$, $p<0.05$), dietary iron and haemoglobin ($r= 0.198$, $p<0.05$)

Conclusions: Sex, age group, and having hives or allergic were significantly associated with dietary iron intake. Sex, breakfast skipping and low of mother education were positively associated with anaemia.

Assessing women's knowledge on benefits of iron and folic acid and its consumption during pregnancy in northern Nigeria

Ayodele Gbemileke[1], Amina Ohunene Atta[1], Titilola Abolade[1], Femi Adegoke[3], Ekundayo Arogundade[3], Jacqueline Kung'u[2], Colin Beckworth[2]

1. Nutrition International, Nigeria (Nigeria), 2. Nutrition International, Canada (Canada), 3. Oxford Policy Management (Nigeria)

Background and Objectives: Anemia during pregnancy remains a public health concern in Nigeria with a national prevalence of 61%[1]. The prevalence is higher in the northern states of Sokoto, Kebbi, Jigawa, Katsina, and Yobe (60%-74%). WHO (2016) recommends daily iron-folic acid (IFA) supplementation beginning as early as possible in pregnancy with a dose of 60mg of elemental iron and 0.4mg of folic acid where the prevalence of anaemia is severe (i.e. >40 percent)? Nutrition International partnered with the government in these five mentioned states since 2019 to improve access to maternal nutrition services with focus on IFA supplementation. A phone survey was conducted in May 2021, to assess women's knowledge on benefits of IFA and its consumption during pregnancy in these states.

Methods: A multi-sampling method was employed for the selection of clusters and respondents who participated in the survey. Thirty clusters were selected across the states according to population proportional to size. A sample of nearly 40 women who gave birth in the past 0-5 months were randomly selected from each cluster, and questionnaires were administered through a telephone interview adopted due to the impact and restrictions caused by the COVID-19 pandemic. A total of 1,091 women completed questionnaires across the 5 states.

Results: About 56% of the women interviewed reported hearing messages on IFA, 50% could describe one benefit or reason for consuming IFA, while 54% reported exposure to behavioral change interventions on the importance of daily IFA during pregnancy. Although about 88% of women reported consuming IFA at least once during pregnancy, 42% consumed at least 90 days and only 17% consumed IFA at least 150 days.

Conclusion: The findings indicate the need to continue to improve the reach of IFA interventions, with related messages, and the need to identify reasons for low consumption of IFA during pregnancy.

Food security better in rural than urban areas, and associated with less under two diarrhea and undernutrition and having family members without TB in Western Province, Papua New Guinea

Georgia Sue Guldan[1], Margaret Morisause[1], Clement Chipokolo[2]

1. University of Papua New Guinea (Papua New Guinea), 2. World Vision Papua New Guinea (Papua New Guinea)

Background and objectives: Papua New Guinea (PNG) has high burdens of Tuberculosis (TB), and for infants and young children, high rates of undernutrition. To understand more about food security and whether it is associated with TB or children's children's growth in TB-affected communities, we looked at food security, two-week prevalence of diarrhea and presence of TB in families in the largest province, remote and sparsely populated, in the country, where we surveyed cross sectionally 750 caregivers of infants and young children under two years in PNG's Western Province's districts.

Methods: A pretested interviewer-administered questionnaire and standard anthropometric methods were used to collect data in TB-affected communities. Data were entered into MWater software and transferred to SPSS version 22 for analysis.

Results: The sample included 403 (53.7%) males, and four age groups: 245 (32.7%) aged 0-5.99m, 97(12.9%) aged 6-8.99m, 94 (12.5%) aged 9-11.99m and 314 (41.9%) aged 12-23.99m. Diarrhea prevalence in the last two weeks was overall 20.7%, differing by age group, with the youngest group having 9% and the oldest three groups 26-29% ($p<0.001$). A Food Insecurity Experience Scale (FIES) used the first 7 questions' responses to calculate a 7-point scale which showed that food insecurity was substantial, with 61.9% of the surveyed households obtaining scores of 5 or higher, and surprisingly higher in urban than rural areas. Caregivers who reported an infant or young child who had diarrhea in the last two weeks had a significantly higher FIES (4.9 ± 2.1 vs 4.5 ± 2.2; $p=0.037$) than those without such a child. Caregivers who reported a family member currently diagnosed with TB or on TB treatment had a significantly higher FIES (5.1 ± 1.9 vs 4.5 ± 2.2; $p=0.002$) than caregivers without such a family member. Being worried about not having enough food was associated with a lower WHZ score, and running out of food was associated with a more wasting.

Conclusions: Even though this study cannot confirm causality, results suggest that food insecurity might be a factor contributing to raising the risk for undernutrition, diarrhea and TB in the province in the surveyed TB-affected communities.

The outcome of food insecurity on adolescents health in Albania

Shtiza Diamant[1], Shkurti Enkelejda[1]

1. University of Medicine (Albania)

Background: The influence of food insecurity on health and welfare of a population has remained the subject of considerable investigations. Nevertheless, restricted exploration has examined its outcome on adolescents' health and welfare in Albania.

Methods: We used statistics from the Jima Longitudinal Family Survey of Youth to observe the social, behavioral and economic factors of their health and welfare. 1,536 individuals were involved in the study. They distributed data associated with food insecurity practices and health status. Logistic regression and trend model was used to inspect the correlation among food insecurity and their health status.

Results: The outcomes showed that the mean (±SD) age of adolescents was 18.3(±1.2). 54.4% of them were female. The size of self-rated health status was moderately unbalanced reaching from 15.2%, 36.8% . Correspondingly, 17.5%, 44.8% and 19.3% of youngsters were food unconfident through every successive round of the study. Experience with food diffidence is intensely related to health status ($\beta = 0.23$, $P < 0.05$) and reduced self-rated health was extra marked for some time ($\beta = 1.17$, $P < 0.001$) and decay after a turning topic ($\beta = -0.27$, $P < 0.001$).

Conclusions: These results suggest that any social, nourishment and public health interventions intended to progress adolescent health should reflect fundamental social factors of health like food insecurity.

Nutrition service delivery practices in early newborn care in Burkina Faso

Joseph Lamport[1], Maurice Zafimanjaka[1]

1. FHI Solutions (Burkina Faso)

Background and objectives: Getting timely appropriate services, including nutrition interventions, as part of early essential newborn care (EECN) to those who need them has been shown to reduce neonatal morbidity and mortality. FHI Solutions/Alive & Thrive supported the Ministry of Health in Burkina Faso to conduct a quality improvement nutrition intervention integrated in EENC in 2021. We assessed standard nutrition service delivery practices into EENC in a region in Burkina Faso.

Methods: A cross-sectional study was conducted from March 9-20, 2021, in the "Centre-Nord" region of Burkina Faso. Twenty-nine health care professionals were selected using purposive sampling technique from 18 health centers with direct observation of their nutrition service delivery practices during antenatal care, in delivery room, and in post-partum wards. Data were collected by observation of the counseling on breastfeeding and the care provided to the newborn. Each observation question item was scored as 0 or 1, and the sum represented the score of service delivery. The results were presented using descriptive statistics.

Results: The mean score for nutrition service delivery practices was 9.5 (plus or minus 2.8 SD) and ranged from 2 to 15. The proportion of women who received good nutrition service practices (score greater than or equal to 12) following a vaginal delivery was 25.7%. Of the 35 recently delivered women, 24 (68.6%) had their babies dried immediately after birth, three (8.6%) received skin-to-skin contact, and 14 (40%) received delayed cord clamping. Eight (22.9% of women) were instructed to breastfeed their child immediately after delivery and five (14.3%) were instructed to delay (greater than 24 hours) the newborn's first bath. Thirteen (37.1%) received vitamin K1. The mean score for counseling on breastfeeding was 1.6 (plus or minus 2.8 SD) and ranged from 0 to 13. Of the 53 pregnant women, 7 (13.2%) were counseled on the advantage of colostrum and nine (17.0%) were explained the definition of exclusive breastfeeding.

Conclusions: The overall nutrition service delivery practices toward early newborn care was not satisfactory. Results demonstrate a need to identify health facility and health staff factors for these poor practices and to bring appropriate support to improve these practices.

PAB(T3)-137
Dietary diversity and associated factors of pregnant women from the Free State Province of South Africa: The NuEMI study

Corinna May Walsh[1], Angelique Carson-Porter[1], Mariette Nel[1]

1. University of the Free State (South Africa)

Background and objectives: Dietary diversity is closely linked with nutrient adequacy. During pregnancy nutrient needs are increased, and poor dietary diversity can lead to nutrient deficiencies, which may lead to poor outcomes for both the mother and baby. The study determined the dietary diversity and associated factors among pregnant women participating in the Nutritional Status of Expectant Mothers and their newborn

Infants (NuEMI) study attending an antenatal clinic in a regional hospital in South Africa.

Methods: A cross-sectional study was conducted. Dietary diversity score (DDS), socio-demographics and household food security were determined. Dietary diversity (DD) was assessed using the Women's Dietary Diversity Score; food security using the Household Food Insecurity Access Scale and socio-demographic status using a self-developed questionnaire.

Results: Starchy staples were consumed by most participants (99.4%), followed by meat and fish (80%). Very few participants had eaten organ meat during the previous day (6%). Median DDS was 4 and 52.6 % of participants fell in the medium diversity score category. About one third (32.5%) of participants were categorized as moderately food insecure and 29.9% were severely food insecure. Monthly income ($p<0.0001$), education level ($p<0.0001$), employment status ($p<0.0001$) and owning of a fridge ($p=0.0021$) were significantly associated with dietary diversity. More participants with an income between R0- R3000 (56.1%), those with only secondary education (83.3%) and unemployed participants (74.2%) had a low DDS. Almost all participants that owned a fridge had a high DDS (94.2 %). A significantly higher percentage of participants that had a low DD (40.6%) were food insecure ($p=0.0002$).

Conclusion: A lower monthly income, lower education level, unemployment and food insecurity were associated with lower dietary diversity, while ownership of a fridge was associated with better DD. Interventions should be aimed at encouraging a culture-sensitive, healthy lifestyle with a focus on consuming a diverse diet. Interventions should focus on addressing barriers to healthy lifestyles during pregnancy such as poverty and food insecurity.

PAB(T3)-138
Nutritional intervention to prevent progression from pre-frailty to frailty in the elderly with Agaro-Oligosaccharides intake: A Pilot Study.

Ryoji Hirota[1], Ikuya Shirai[2], Koji Karasawa[2], Yumiko Fujioka[1]

1. Matsumoto University (Japan), 2. Ina Food Industry Co., Ltd (Japan)

Background and objectives: Frailty can be defined as "*a state of reduced resilience to stress due to age-related loss of reserve capacity*," and it is generally regarded as a preliminary step to a state of need for nursing care. Frailty has also been defined as possessing three or more of the following attributes: weight loss, muscle weakness, fatigue, walking speed decrease, and physical inactivity. Pre-frailty is defined as having one or two of these attributes. Agaro-Oligosaccharides (AOSs) is a food product produced by breaking down agar and developed by Ina Food Industry Co., Ltd. AOSs are expected to be effective in ameliorating pre-frailty due to their biological activities, including anti-inflammation and inhibition of muscle atrophy. The purpose of this pilot study is to test whether AOSs intake is effective in preventing the progression from pre-frailty to frailty in the elderly.

Methods: Thirteen male elderly subjects, who agreed to the study were divided into randomized two groups and measured. The primary endpoint was 10-meter Walking Speed test, and secondary endpoints were 30-second Chair-Stand test, Time Up and Go test (TUG), and so on. After assessment of frailty at baseline, pre-frailty subjects were selected. AOSs group (n=3) received 6 AOSs tablets per day and Placebo group (n=5) received 6 placebo tablets per day for 12 consecutive weeks in a double-blind controlled study. The above measurements will be performed 4, 8, and 12 weeks after ingestion, and proof of effect is planned to be demonstrated by a no correspondence T-test of difference from baseline.

Results: After 8 weeks, the difference from baseline in 10-meter Walking Speed was +0.48 ± 0.08 m/sec in the AOSs group versus +0.08 ± 0.21 m/sec in the placebo group ($p = 0.012$). After 4 weeks, the difference from baseline in TUG was -2.18±0.41 sec in the AOSs group versus -0.55±0.94 sec in the placebo group ($p = 0.016$), and after 8 weeks that was -2.55±0.53 sec in the AOSs group versus -0.95±0.93 sec in the placebo group ($p=0.021$).

Conclusions: AOSs intake expected to be effective for prevent progression from pre-frailty to frailty by increase in walking speed.

One-carbon metabolism-related nutrients during youth and young adulthood and breast density

Eunyoung Han[1], Joanne F. Dorgan[2], Linda Van Horn[5], Erin LeBlanc[4], Linda Snetselaar[3], Seungyoun Jung[1]

1. Ewha womans university (Korea), 2. University of Maryland School of Medicine (USA), 3. University of Iowa College of Public Health (USA), 4. Kaiser Permanente Center for Health Research (USA), 5. Northwestern University Feinberg School of Medicine (USA)

Background and objectives: One-carbon metabolism is a complex network of biochemical reactions involving multiple B vitamins that helps maintain DNA integrity and epigenetic signatures. Intake of one-carbon metabolism-related nutrients may enhance genomic stability of the breast, particularly during rapid growth and development that occurs before full differentiation following the first full-term pregnancy, which could lower breast cancer risk. We examined long-term associations between youth and young adult intakes of one-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

carbon metabolism-related nutrients and breast density, a strong risk factor for breast cancer.

Methods: During 18 years of follow-up in the Dietary Intervention Study in Children (DISC) and the DISC06 Follow-up Study, diets of 176 women were assessed by three 24-hour recalls on five occasions between ages 8-18 and at ages 25-29. Multivariable-adjusted linear mixed-effects regression was used to examine associations between intakes of one-carbon metabolism-related nutrients and MRI-measured percent dense breast volume (% DBV) and absolute dense breast volume (ADBV) at ages 25-29.

Results: Folate intake during youth was significantly inversely associated with % DBV and ADBV. Mean % DBV decreased from 20% to 17% from the lowest to highest quartile of folate intake (P_{trend}=0.008), while ADBV decreased from 80.0 cm^3 to 68.0 cm^3 (P_{trend}=0.03). Inverse associations of folate with breast density phenotypes were significant among postmenarche but not premenarche girls. Among postmenarche girls, % DBV decreased monotonically from 22.0% to 16% across increasing quartiles of folate (P_{trend}=0.02), while ADBV decreased monotonically from 92.6 cm^3 to 67.1 cm^3 (P_{trend}=0.008). In contrast among premenarche but not postmenarche girls, ADBV increased monotonically from 67.2 cm^3 to 92.3 cm^3 across increasing quartiles of vitamin B2 intake (P_{trend}<0.001). Young adult folate and vitamin B6 intakes were significantly inversely associated with % DBV; with increasing quartiles of intake, mean % DBV decreased from 23.6% to 17.2% for folate and from 20.8% to 15.1% for vitamin B6 (both $P_{trend} \leqq 0.02$). Young adult vitamin B6 intake also was significantly inversely associated with ADBV; mean ADBV decreased from 74.0 cm^3 to. 63.0 cm^3 with increasing quartiles of intake (P_{trend}=0.01).

Conclusions: One-carbon metabolism-related nutrient intakes during youth and young adulthood were associated with % DBV and ADBV, suggesting possible long-term influences on breast cancer risk.

A high protein low glycemic index diet limits gestational weight gain in pregnant women with overweight or obesity

Nina Rica Wium Geiker[1,2], Faidon Magkos[1], Helle Zingenberg[2], Jens Svare[2], Elizaveta Chabanova[2], Henrik S Thomsen[2], Christian Ritz[1], Arne Astrup[1]

1. University of Copenhagen (Denmark), 2. Herlev Gentofte Hospital (Denmark)

Background and objectives: More than 30% of pregnant women are overweight or obese before pregnancy and more than half of these exceed the recommendations for gestational weight gain (GWG). Both pre-pregnancy overweight and excessive GWG increase the risk of complications and offspring obesity. We aimed to investigate the effect of a high protein low glycemic index (HPLGI) diet on GWG among pregnant women with obesity.

Methods: In this randomized controlled trial, 279 women with pre-pregnancy overweight or obesity (BMI 28-45 kg/m^2), aged 18-45 years and in their late first trimester with singleton pregnancies were included. The women were allocated to one of two ad libitum diets: an HPLGI diet (25-28% of energy from protein and glycemic index below or equal to 55) or a moderate protein moderate glycemic index diet (MPMGI: 15-18% of energy from protein and glycemic index of approximately 60) from gestational week 15 and throughout pregnancy. The women received dietary guidance from a clinical dietician nine times to facilitate adherence. GWG was calculated as the last measured weight before birth minus the self-reported pre-pregnancy weight and magnetic resonance imaging was performed at gestational weeks 15 and 28 and just after birth.

Results: A total of 105 and 104 women out of 141 and 138 randomized to the HPLGI and MPMGI diets completed the intervention (75%). In the available case analyses, GWG was 6.8 ± 1.3 kg among women assigned the HPLGI diet and this was significantly lower by -1.7 kg (95%CI -2.8, -0.5; P=0.004) than the GWG of 8.5 ± 1.3 kg among women assigned the MPMGI diet. There were no differences between diet groups in changes in liver, muscle, subcutaneous or visceral fat contents. There were no reported maternal, fetal or neonatal deaths and the incidence of miscarriages (1-2%) was equal in the two groups.

Conclusions: A moderate increase in dietary protein in conjunction with a reduction in the glycemic index during the last two trimesters of pregnancy reduced GWG among women with overweight or obesity.

Effects of Lutein complex supplementation on improving dry eyes syndrome in healthy young subjects

Ling-Wen Hsu[1], Yu-Shan Lee[1], Evelyn Jou Chen Huang[2,1], Tung-Ching Lin[3], Yi-Wen Chien[1,2]

1. Taipei Medical University (Taiwan), 2. Taipei Medical University Hospital (Taiwan), 3. Daiken Biomedical Co. (Taiwan)

Background and objectives: Dry eye syndrome (DES) is the highly prevalent ophthalmological problem, and the age of patients has a trend of becoming younger. Long-term use of steroids for dry eye treatment could cause early cataract and increased intraocular pressure. Clinical studies have reported that lutein supplementation could reduce oxidative stress

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

damage caused by blue light exposure and prevent age-related macular degeneration; however, lutein alone did not improve dry eye symptoms. Therefore, we would like to study whether the combination of lutein with other supplements could improve dry eye.

Methods: This study was aimed to explore whether lutein combined with other antioxidants and phytochemicals could improve dry eye syndrome and visual function. In this experiment, twenty-six young healthy subjects were recruited and took lutein complex supplementation daily (20mg free lutein, 4mg free zeaxanthin, 40mg maqui berry extract, astaxanthin, 80mg BS7® bilberry extract, flaxseed oil, and vitamin E) for eight weeks. Corrected visual acuity, contrast sensitivity, intraocular pressure, dry eye test, tear break-up time, macular pigment optical density (MPOD), and serum lutein level were assessed on the baseline, week 4, and week 8 of the experiment. The eye comfort level was assessed by questionnaires.

Results: The results showed that after the intervention of lutein complex supplementation, the serum lutein level, MPOD, dry eye test, tear break-up time, and eye comfort level were significantly increased (p<0.05); moreover, intraocular pressure was significantly decreased (p<0.05), but did not affect visual acuity, contrast sensitivity, and central macular thickness.

Conclusion: Lutein complex supplementation has beneficial effects on improving dry eye syndrome, the serum lutein level, and macular pigment optical density.

PAB(T3)-142
Nutritional intake and determinants of nutritional quality during pregnancy and postpartum - a longitudinal study

Mathilda Forsby[1], Erik Hulander[1], Anna Amberntsson[1], Petra Brembeck[1], Anna Winkvist[1], Linnea Bärebring[1], Hanna Augustin[1]

1. University of Gothenburg (Sweden)

Background and objectives: It is well known that adequate energy and micronutrient intake during pregnancy and lactation are important for health of both women and their children. However, longitudinal studies investigating nutritional intake and quality in pregnancy and postpartum among Swedish women are lacking. Our objectives were to 1) describe nutritional intake and quality from third trimester to 18 months postpartum, and 2) study the determinants of change in nutritional quality.

Methods: Women were studied longitudinally (n=72) at gestational week 35-37, two weeks, four, twelve and 18 months postpartum. At each study visit maternal characteristics and four-day food diaries were collected. The estimated intake of macro- and micronutrients were compared to reference values from the Nordic Nutrition Recommendation 2012. Nutritional quality was assessed by the energy adjusted Nutrient Rich Food Index 11.3, including eleven nutrients to encourage and three nutrients to limit. Linear mixed models were used to analyze change in nutritional quality and its potential determinants.

Results: The average estimated intake for most nutrients, except vitamin D, exceeded the average requirement both in pregnancy and postpartum. However, less than 40% of the women adhered to recommended intakes of saturated fat, fiber, vitamin D, folate, and iron at all study visits. The carbohydrate energy percentage [E%] and fiber intake were higher in third trimester compared to postpartum. In contrast, the E% of protein and monounsaturated fat increased from third trimester to postpartum. Estimated intakes of vitamin A, vitamin C, and potassium were higher in third trimester compared to postpartum. Overall, nutrition quality did not differ significantly from third trimester to postpartum. Shorter duration of lactation was related to decreased nutritional quality over time, whereas higher age and BMI were related to increases.

Conclusions: Macro- and micronutrient intake differed from third trimester compared to postpartum. Determinants of change in nutritional quality were lactation, age, and BMI. Low adherence to recommended intake of certain nutrients during pregnancy and postpartum highlight the necessity of qualified dietary counselling during this period in life.

PAB(T3)-143
Maternal plant–based diets and neonatal DNA methylation: Findings from the Avon Longitudinal Study of Parents and Children (ALSPAC)

Peiyuan Huang[1], Carolina Borges[1], Kate Northstone[1], Gemma Sharp[1,2]

1. University of Bristol (UK), 2. University of Exeter (UK)

Background and objectives: Adherence to vegetarian/plant–based diets (PBDs) during pregnancy has been related to fetal outcomes such as lower birth weight. DNA methylation (DNAm) is a possible biological mechanism underlying this relation. We performed an epigenome–wide association study (EWAS) to examine cord blood DNAm in relation to maternal PBDs during pregnancy.

Methods: A total of 693 British mother–child pairs with both pregnancy food frequency questionnaire and cord blood DNAm data were included. PBD adherence was assessed using 3 indices (all ranging from 18 to 90): an overall plant–based diet index (PDI), a higher score representing greater plant food intake; a healthful (hPDI) and unhealthful PDI (uPDI) further distinguished between intakes of healthy and unhealthy plant foods. DNAm was measured by Illumina 450K arrays. Linear regression adjusted for maternal age, education, parity, child sex, blood cell

types, and batch (Model 1). Model 2 further adjusted for maternal lifestyle factors. We excluded polymorphic sites and performed functional analyses and lookups for the findings.

Results: At p−value <1×10^{-5}, there were 3 (cg13180232, cg24265806, cg04896381), 1 (cg11760198), and 2 (cg22254580, cg24810917) differentially methylated cytosine−phosphate−guanine (CpG) sites identified in Model 1 in relation to PDI, hPDI, and uPDI, respectively; only cg13180232 passed the threshold for false discovery rate (FDR) correction (FDR−corrected p=0.049). Associations were slightly strengthened in Model 2 for most CpG sites. Neither model identified any overlap between top CpGs for the 3 indices. According to the EWAS Catalog, adult rheumatoid arthritis and maternal glucose levels have previously been associated with cg04896381 (in *TBKBP1*) in whole and cord blood, respectively, and clear cell renal carcinoma with cg24810917 (in *ODZ4*) in adults. cg22254580 (in *GOLGA3*) was associated with gene expression of *ANKLE2*, *CHFR*, *ZNF605*, and *ZNF84* in a publicly available *cis*−expression quantitative trait methylation database from child blood. Based on our EWAS results, we identified 1 differentially methylated region associated with PDI on chromosome 3:128968351−128968543 (in *CFAP92*, effect estimate=-2.55×10^{-3}, standard error=4.14×10^{-4}, p=7.09×10^{-10}). No firm evidence of enrichment was found for gene ontology, pathways, or tissue−specific DNaseI hypersensitivity regions.

Keyword: Plant-based diet, Pregnancy, Birth, Epigenetics, Intrauterine programming

Conclusions: Adherence to different PBDs during pregnancy was associated with differential cord blood DNAm patterns.

PAB(T3)-144
Effects of a meat-based complementary diet on infant growth, sleep activity, and neurodevelopment.

Kinzie Matz[1], Richard Boles[1], Kathryn Davis[1], Lillian Berman[1], Nancy Krebs[1], Minghua Tang[1]

1. Department of Pediatrics, Section of Nutrition, University of Colorado Anschutz Medical Campus (USA)

Background and objectives: The impact of complementary feeding on infant growth, sleep activities, and neurodevelopment is not clearly understood. This study aimed to evaluate the effects of a meat-based complementary diet on these health indicators.

Methods: 37 healthy 5-month-old full term, exclusively breastfed infants were recruited from the Denver metro area (Colorado, USA); participants were randomized to an intervention or control arm. Infants in the intervention group consumed pureed meat daily until 12 months of age at 1-2 jars per day (prescribed), while infants in the control group followed standard-of-care. At 6, 9, and 12 months of age, sleep activity was obtained using the Micro-minimotionlogger actigraph from Ambulatory Monitoring Inc. (Ardsley, New York). Infant anthropometry was also measured. At 12 months, neurodevelopment was evaluated using the Bayley-III developmental assessment. Results presented are preliminary data.

Results: Infant weight-for-age z-score [WAZ] and weight-for-length z-score [WLZ] at 6 months averaged -0.61 ± 0.14 and -0.17 ± 0.15, respectively, for combined groups. At 12 months, WAZ averaged -0.48 ± 0.13; WLZ averaged -0.13 ± 0.11 for combined groups; these changes are not statistically significant. The 24-hour average sleep fragmentation index [SFI] decreased significantly from 1.71 ± 0.18 at 6-months to 0.98 ± 0.45 at 12 months (effect of time p=0.006), without differences between group. The 24-hour average sleep duration changed significantly in the intervention group only, from 1281 ± 21.53 minutes at 6 months to 1340 ± 12.88 minutes at 12 months (p=0.04). Pearson's correlation at 12 months revealed positive associations between sleep duration and growth in the control group (WAZ p=0.03) and intervention group (WLZ p=0.03 and WAZ p=0.04). Infants in the intervention group performed better than the control in Social-Emotional development and Adaptive Behavior (Communication, Social, Self-Care) evaluations by the Bayley-III assessment.

Conclusions: In these preliminary analyses, complementary diets with varying meat intakes potentially influenced infant growth trajectories, sleep activities and neurodevelopment scores. These data suggest the important role complementary feeding plays in infant development, warranting further investigations with large sample sizes of the underlying mechanisms of the diet-growth-sleep/neurodevelopment interplay to make definitive conclusions.

PAB(T3)-145
The association between asymmetric dimethylarginine and sarcopenia in community-dwelling older women

Miyuki Yokoro[1], Naoto Otaki[1], Megumu Yano[1], Tomomi Imamura[1], Norikazu Tanino[1], Keisuke Fukuo[1]

1. Mukogawa Women's University (Japan)

Background and objectives: Asymmetric dimethylarginine (ADMA) is a modified amino acid and an endogenous inhibitor of endothelium nitric oxide synthesis. Increased ADMA causes endothelial dysfunction. Several studies have shown a relationship between endothelial dysfunction and a decline in muscle mass and grip strength in older adults. However, the association between ADMA and sarcopenia in older adults has not been studied. We evaluated the correlations between plasma ADMA levels and sarcopenia in community-dwelling older women.

Methods: Participants in this study included community-dwelling elderly women living alone who attended annual health examinations at voluntary lunch events. Plasma ADMA levels were measured in our laboratory using a competitive enzyme-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

linked immunosorbent assay. Sarcopenia was assessed according to the guidelines of the Asian Working Group for Sarcopenia 2019 Consensus.

Results: Plasma ADMA levels in participants with sarcopenia were significantly higher than in those without. A receiver Operating Characteristics curve estimated the cutoff value of plasma ADMA for sarcopenia at 0.57 mM. In those with higher plasma ADMA, the ratio of sarcopenia was significantly greater than in those with lower ADMA group (48.0% vs. 16.8%, *p*= 0.002). Logistic regression analysis found a crude odds ratio of higher plasma ADMA levels of 4.57 (95% CI, 1.82–11.47; *p*= 0.001). The association between sarcopenia and plasma ADMA levels remained significant after adjustment for relevant variables. Reductions in the skeletal muscle mass index over 2 years were significantly greater in those with higher plasma ADMA.

Conclusion: Increased plasma ADMA levels were significantly associated with sarcopenia in community-dwelling older women.

Keyword: sarcopenia, asymmetric dimethylarginine, grip strength, skeletal muscle mass, community-dwelling older women

Different gut microbiota in US. formula-fed infantsconsuming meat vs. dairy-based complementary foods

Minghua Tag[1], Daniel N. Frank[1], Cheng Ma[2], Akbar Waljee[2], Charles E. Robertsn[1], Jennifer M. Kofonow[1], Lillian M. Berman[1], Eileen M. Haus[2], Ji Zhu[2], Nancy F. Krebs[1]

1. University of Colorado Anschutz Medical Campus (USA), 2. University of Michigan (USA)

Background & objectives: Limited research has addressed the effects of solid foods (complementary foods) on infant gut microbiota development, especially in relationship with infant growth trajectories. This project aimed to evaluate the impact of meat- vs. dairy-based complementary foods on gut microbiota and how it relates to growth.

Methods: Full-term, formula-fed infants were recruited from the metro Denver area (Colorado, US) and randomized to a meat- or dairy-based complementary diet from 5 to 12 months of age. Infant's length and weight were measured every month, and stool samples were collected at 5, 10, and 12 months. 16S rRNA gene sequencing was conducted and short-chain fatty acids were analyzed in the stool samples.

Results: 64 infants completed the dietary intervention (n=32 per group), 61 stool samples were collected at baseline (5 months), 54 at 10 months and 56 at 12 months. Overall, Weight-for-age Z scores increased over time in both groups and length-for-age Z scores (LAZ) increased in the meat group only, which led to a significant group-by-time interaction (P=0.02) of weight-for-length Z score. Microbiota composition (Beta-diversity) differed between groups at 12 months (weighted PERMANOVA P=0.015) and had a group-by-time interaction of P=0.090. Microbial community richness (Chao1) increased in the meat group only. Several taxa changed over time at the genus level, including *Bifidobacterium, Escherichia-Shigella, Blautia* and *Ruminococcus*. A significant fold change of butyric acid from 5 to 12 months was found in the meat group (+1.75, P=0.011) but not in the dairy group. However, the quantitative analysis did not reveal a significant effect of time or group. Regression analysis showed that Chao1 had a negative association with WLZ and WAZ. Several genera also had significant associations with all growth Z scores.

Conclusion: Complementary feeding not only impacts infant growth but also affects gut microbiota maturation. Complementary food choices can affect both the gut microbiota diversity and structures. In addition, these complementary-food-induced changes in gut microbiota are associated with infant growth.

Keyword: microbiota, infant, complementary feeding, growth

Conflict of Interest Disclosure: No conflict of interest.

Investigation of reasons for skipping breakfast among female university students in nutritionist training courses -Is it true that there is no time?-

Akie Abe[1], Akemi Misawa[1]

1. Tokyo Kasei gakuin University (Japan)

Background and objectives: Many studies have cited lack of time as a reason for skipping breakfast. In this study, we examined female university students in the nutritionist training course to see if they actually did not have time to eat breakfast.

Methods: 64 female university students enrolled in the dietitian training course were asked to take a questionnaire on breakfast, record their daily activities for one week, and conduct a survey on their breakfast intake status and lifestyle activities. The subjects were divided into three groups: the group that did not skip breakfast (group I), the group of 1 ~ 3 days a week of skipping breakfast (group II), and the group of 4 ~ 7 days a week of skipping breakfast (group III). Approved for the Tokyo Kasei Gakuin University Ethics Review.

Results: 64 peoples responded to the survey, with 51 valid responses. As a result of the daily life survey, the waking time on weekdays was 7:00±1:05 in group I, 7:25±0:44 in group II, and 7:12±0:45 in group III. The time from waking up to going out on weekdays was 82.1±14.4 minutes in group I, 88.8±22.3 minutes in group II, and 84.4±18.2 minutes in group III, with no significant difference among the three groups. The time required to prepare breakfast was 7.1±1.2 minutes in Group I, 5.5±6.0 minutes in Group II, and 6.6±8.5 minutes in Group III, with no significant difference observed. When people in Groups II and III who skipped breakfast were asked why they skipped breakfast,

50% said they wanted more sleep, 31% said they didn't have time to eat breakfast, and 9% said they didn't have time to prepare breakfast.

Conclusions: This suggests that people who skipped breakfast have physical time, but they do not have time psychologically, and that eating breakfast is a low priority among daily activities after waking up.

Keyword: skipping breakfast, time

PAB(T3)-148
Nutritional status in poor rural elderly in six elderly centres in rural Tamil Nadu, India

Biswajit Paul[1], Rita Isaac[1], Pavithra R[1], Rakesh Kumar S[1], Murugan R[1]

1. Christian Medical College Vellore (India)

Background: Nutrition plays a vital role throughout life course and is especially important at extremes of life for preventing morbidity and premature mortality due to disease. Elderly population have to deal with various physical, psychological, social and financial conditions influencing their nutrition and quality of life. RUHSA hospital takes care of health and socio-economic development of 138,000 population of the K V Kuppam block (an administrative unit of government). In response to the community's needs of taking care of elderly population left behind to fend for themselves due to their children moving out for jobs or being too insecure financially to take care of their parents, the poorest of the poor elderly were chosen by RUHSA to provide least a nutritious meal per day, yearly medical check-up and a facility (elderly centre) for group exercises, social participation and exchanging life experiences. Nutritional assessment was done for all elderly chosen under this scheme.

Methods: Data on Socio-demographic characteristics, weight and height was collected and 24-hour dietary recall method was used to collect data on food variety and quantitative intake. These were used to assess the nutritional status in terms of BMI and nutritional deficiencies.

Results: In the six elderly centres under RUHSA, nutritional assessment was done for 49 elderly individuals of which 39 (79.6%) were females. The mean age of elderly population was 67.2 $\pm$ 7.3 years, 40 (81.6%) were Hindus and rest Christians. Except one, all belonged to backward castes. 40 (81.6%) lived in their own houses and rest in relatives' house or unused public shelters. 32 (65.3%) were illiterate and all were currently unemployed. Old age pension by government was only source of income for 37 (75.5%) of elderly and rest had no means of subsistence. Nutritional status assessment revealed that 22 (44.9%) of elderly were underweight and all of the were practically under nourished with total calorie deficiency, protein and fat deficiency. Micro-nutrient deficiency was seen among all with specific deficiency of vit. B2, Vitamin C, iron and zinc.

Conclusion: Poor nutritional status and micronutrient deficiency was common among the poor elderly population of rural Tamil Nadu, India.

Keyword: nutritional status, elderly, micronutrient deficiency

Associations of coffee and tea consumption with dysmenorrhea among reproductive-age women in Beijing, China: a cross-sectional study

Jian Zhao[1]

1. Peking Union Medical college (China)

Background and objectives: Dysmenorrhea is the most common health-related problem in reproductive-age women. It can reduce the quality of life and hinders social activities, especially when it as accompanied by symptoms such as headache, fatigue, nausea and vomiting, diarrhea, chills and muscle cramps. Despite the association between drinks and dysmenorrhea, especially coffee and tea consumption, the results of association are still inconsistent. Therefore, the aim of the current study was to investigate the associations of coffee and tea consumption with dysmenorrhea among women in the reproductive age.

Methods: A cross-sectional study was conducted on 1247 women who participated in the health screening at 6 community health service centers in Beijing from September to November, 2021. A validated food frequency questionnaire (FFQ) was used to measure the consumption of drinks. Dysmenorrhea severity was assessed with the use of the Numeric Pain Rating Scale (NPRS). Multinomial logistic regression was performed to assess the association of drinks and dysmenorrhea. Other information, such as demographic factors, was also collected and assessed in relation to dysmenorrhea.

Results: Dysmenorrhea affected 92.9% of the interviewed women. Among them, 69.0%, 21.7% and 2.2% had mild, moderate and severe dysmenorrhea, respectively. Regular consumption of coffee (More than 1 cup/bottle per day, 1 cup/bottle ≈ 300 mL) was associated with a higher prevalence of dysmenorrhea (for mild dysmenorrhea: aOR =1.97 (95% CI 1.03 to 3.79); for moderate-to-severe dysmenorrhea: aOR =3.27 (95% CI 1.59 to 6.73)). Regular intake of green tea and bubble tea appeared to positively associated with the prevalence of moderate-to-severe dysmenorrhea (green tea: aOR =3.02 (95% CI 1.31 to 6.96); bubble tea: aOR =2.91 (95% CI 1.31 to 6.43)). Occasional coffee consumption was also associated with moderate-to-severe dysmenorrhea (aOR =2.19 (95% CI 1.20 to 3.99)), whereas occasional intake of green rea and bubble tea had no association with dysmenorrhea. No association of red tea and flower tea consumption was observed with dysmenorrhea.

Conclusions: Drinking coffee and tea were associated with a higher prevalence of dysmenorrhea.

Keyword: coffee, green tea, bubble tea, dysmenorrhea

Survey on dietary characteristics of Nikkei residents living in Paraguay and Brazil (Nikkeijin), and Japanese living in Japan

Rutsuko Kajita[1], Tomomi Tsukaguchi[1], Satomi Ishii[1]

1. Rakuno Gakuen University (Japan)

Background and objectives: Japanese migration to Paraguay in 1955 and to Brazil began in 1908. The main objective of this study is to determine the relationship between protein intake and diet in people of Japanese ancestry living in Paraguay and Brazil and Japanese living in Japan.

Methods: Subjects were 25 Nikkeijin living in Itapua prefecture of Paraguay 30 Nikkeijin living in Sao Paulo, Brazil and 87 Japanese living in Japan(50 young and 37 middle-aged). Dietary intake was assessed using comprehensive (Japanese residents) and brief-type (for Paraguayan and Brazilian residents) dietary history questionnaires(a self-administered diet history questionnaire: DHQ,and Brief-type self-administered diet history questionnaire:BDHQ).

Results: The mean age of Nikkeijin living in Paraguay was 52 years, that of Nikkeijin living in Brazil was 51 years, that of middle-aged Japanese living in Japan was 48 years, and that of young Japanese was 18 years. There were no significant differences in amount of protain intake and carbohydrate intake among Nikkeijin living in Paraguay and Brazil and middle-aged Japanese. However, young people living in Japan had significantly higher fat intake.

Conclusions: There were no differences in dietary characteristics between Nikkeijin living in Paraguay and Brazil and middle-aged Japanese living in Japan, but the diets of young people were associated with significantly higher fat intake and unhealthy diets.

Keyword: Nikkeijin, Japanese, nutrition, protein intake, Nikkei residents

Clinical, Physical, and Nutritional Effects of Weight Loss Program for Obese and Infertile patients

Nao Kawabata[1], Yoichi Ishida[2], Chieko Nagamine[1], Yuki Shitanda[4], Shizu Sakuma[4], Satsuki Mogi[1], Hiroyuki Fujiwara[2], Shun Ishibash[1,3]

1. Department of Clinical Nutrition, Jichi Medical University Hospital (Japan), 2. Department of Obstetrics and Gynecology, Jichi Medical University (Japan), 3. Division of Endocrinology and Metabolism, Department of Internal Medicine, Jichi Medical University (Japan), 4. Department of Nursing, Jichi Medical University Hospital (Japan)

Background and objectives: In recent years, obesity and insulin resistance have been reported to reduce fertility. Therefore, it is important for obese females who wish to have children to lose weight toward the healthy weight. We examined the effects of a team-based weight loss program on clinical and nutritional changes in obese females seeking infertility treatment.

Methods: Forty-seven obese females with a BMI of 30 kg/m^2 or more wishing to be treated for infertility and to participate in the weight loss program were enrolled in this study. We analyzed changes in body compositions during the program and compared blood pressure, laboratory data, intake of nutrients and food before and after the weight loss interventions. We compared these parameters between subjects with and without successful pregnancies within one year after the program.

Results: During the program period, body weight, body fat mass, skeletal muscle mass, BMI, and body-fat percentage significantly decreased, while the ratio of skeletal muscle mass vs body fat amount significantly increased. Blood pressure, HOMA-IR, AST, and ALT decreased significantly after the program compared to the baseline. Furthermore, the intake of energy, fat, n-6 polyunsaturated fatty acids, carbohydrates, salt, meats, confectioneries, beverages, fat and oils decreased significantly. In contrast, the intakes of light vegetables, mushrooms, algae, and fish and shellfish increased significantly. There were no differences in body weight loss and BMI between those with and without a successful pregnancy.

Conclusions: Our team-based weight loss program improved the nutrients, body weight, body compositions, thereby leading to the improvement of blood pressure, liver function and insulin resistance.

Keyword: Body composition, Obese, Nutritional guidance, Multidisciplinary approach

Nutrition-related risk of severe hypoglycemia outpatient settings among older adults with and without diabetes

Yoshinobu Kimura[1,2], Naoya Kimura[1], Manabu Akazawa[2]

1. Soka Municipal Hospital (Japan), 2. Meiji Pharmaceutical University (Japan)

Background and objectives: The Geriatric Nutritional Risk Index (GNRI) helps to assess the risk of complications (aspiration pneumonia, pressure ulcers, etc.) and mortality associated with malnutrition. However, it is not clear whether the GNRI are associated with hypoglycemia in outpatient settings. In this study, we investigated the association between severe hypoglycemia and nutrition-related risk among outpatients.

Methods: This study investigated the nutritional status of outpatient settings with severe hypoglycemia who presented at the emergency department of the Soka Municipal Hospital, a secondary care institution in Japan, using electronic medical records. Outpatients aged ≧65 years presenting with severe hypoglycemia between September 1, 2018, and June 15, 2021 were eligible for this study. Patients with missing data on height, weight, or serum albumin levels, precluding GNRI calculations

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

were excluded. The patient characteristics and the association between nutritional status and severe hypoglycemia were descriptively summarized.

Results: Seventy-five outpatients presented with hypoglycemia that required 50% glucose injection. Among them, 58 patients experienced impaired consciousness. Overall, 17 patients had data on serum albumin levels, height, and weight values that were required for the GNRI calculation. Four (23.5%) were type 1 diabetes patients, 5 (29.4%) were type 2 diabetes patients, and 8 (47.1%) were without diabetes. Severe hypoglycemia occurred even in patients who were not receiving treatment to lower blood glucose levels. Thirteen of 17 (76.5%) had nutrition-related risks. Among 8 patients without diabetes, 1 patient had insulin autoimmune syndrome, which may cause spontaneous hypoglycemia; consequently, this patient was excluded from further analysis. Among patients without and with diabetes, the median GNRI was 68 (67.0-81.5) and 95 (92.0-100.0), respectively.

Conclusions: We conducted a detailed investigation of older adult outpatients who developed severe hypoglycemia, and found that they had problems with their nutritional status as assessed by GNRI, regardless of whether they had diabetes or not. To prevent the occurrence of hypoglycemia in the future, we would like to identify high-risk patients, including their nutritional status, and examine whether interventions to improve their nutritional status can reduce the risk of occurrence of hypoglycemia.

Keyword: Nutrition, Hypoglycemia, Geriatric Nutritional Risk Index, GNRI

PAB(T4)-3
About the current state of diet remedy and Eating habits satisfaction of adult type 1 diabetic patients

Hiroyuki Horio[1], Ikuho Suzuki[1], Kanna Nakai[1], Manami Mitsushima[1], Nazuna Konishi[1], Sayaka Yamakoshi[1]

1. Tokai Gakuen University (Japan)

Back ground and objectives: Type 1 diabetes can lead a life similar to that of a healthy person if proper dietary intake and insulin supplementation are performed accordingly, but it has various problems because the treatment lasts for a lifetime. Therefore, we conducted a questionnaire survey of patients and investigated their current dietary status.

Methods: A questionnaire survey was conducted on 16 adult type 1 diabetic patients belonging to the patient association in Chugoku region of Japan.

Results: According to the results of the questionnaire, none of the patients answered that they "use the food exchange table frequently", and 38% of the patients answered that they "use it occasionally". 38% of patients said they "use the carbohydrate counting method" and 38% said they "use it occasionally". When asked if their daily diet was stressful, 25% said they "think very much" and 25% said they "think a little". When asked that they couldn't enjoy their meals because they were concerned about blood sugar control, 25% said they "think very much" and 25% said they "think a little". When asked if they were satisfied with their diet and treatment, 25% said they "think very much" and 38% said they "think a little". When asked where to get information about meals after the onset, it was "patient association, advice from doctors and nurses, study sessions, online information, etc."

Conclutions: The patients who responded to this questionnaire were 30 to 70 years old, 13% had a medical history of 3 to 5 years, 38% had a medical history of 5 to 10 years, and 50% had a medical history of 10 years or more. There were many patients who developed the disease when dietary guidance was relatively strict. In this survey, many patients were stressed by the diet itself, but even in the previous survey, none of them received dietary guidance at each visit, and information from patient associations seems to be important. Now that the weight of diet in the treatment of type 1 diabetes is increasing, we feel the importance of the opportunity to provide appropriate nutrition (diet) information to patients.

Keyword: adult type 1 diabetic patients, Eating habits satisfaction

Conflict of Interest Disclosure: There are no conflicts of interest to disclose.

PAB(T4)-4
Development and implementation of a structured nutrition education course for caregivers of children with type 1 diabetes in Uganda.

Nicholas Bari Ndahura[1], Judith Munga[2], Judith Kimiywe[2], Ezekiel Mupere[3]

1. Kyambogo University (Uganda), 2. Kenyatta University (Kenya), 3. Makerere University (Uganda)

Background and objectives: Structured nutrition education courses for pediatric type 1 diabetic patients and their caregivers are lacking in Africa and this has been cited as one of the contributing factors to suboptimal management of type 1 diabetes (T1D) in the region. Furthermore, it is important that culturally appropriate structured nutrition education courses informed by the local context be developed and made readily available to caregivers as parental care positively influences glycemic and dietary outcomes of children with T1D. The objectives of the study were to develop a structured nutrition education course for caregivers of children (3-14 years) with T1D in Uganda and determine its effect on the level of T1D nutrition knowledge of the caregivers.

Methods: The study was a cluster randomised controlled trial in which 100 caregiver-child dyads were assigned to a control group and intervention group. The participants in the control group continued to receive routine medical care, while those in the intervention group received routine medical care and attended a structured group nutrition education course. The intervention lasted 12 weeks, it consisted of 8 face-to-face

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

sessions lasting 45 minutes each. The content of the training course was informed by gaps identified from a document review and needs assessment. A two-member team of a diabetes specialist nurse and a specialist diabetes dietician conducted the sessions.

Results: There was a significant difference in caregivers' nutrition knowledge scores following their participation in the structured nutrition education course ($p < 0.001$). The median nutrition knowledge score increased from 32% to 45 % post-intervention. There was no statistically significant difference in the children's glycated haemoglobin (HbAlc) levels following their caregiver's participation in the structured nutrition education course ($p = 0.748$).

Conclusions: A structured nutrition education course for caregivers of paediatric T1D patients can improve their nutrition knowledge. However, the lack of detection of a significant change in the children's HbA1c could be that glycated haemoglobin is influenced by various factors beyond nutrition knowledge which could be the case in this study since nutrition knowledge among caregivers improved.

Keyword: Diabetes, Nutrition, Education, Caregiver, Uganda

PAB(T4)-5
Effects of simultaneous carbohydrate and alcoholic beverage intake on blood triglyceride levels after fat loading at dinner

Junko Suzuki[1], Mami Matsushita[1]

1. Tenshi College (Japan)

Background and objectives: The Blood triglyceride (TG) level increases after consumption of a high-fat diet and alcoholic beverages. It is important to confirm whether there is an increase in chylomicron (CM) remnants, which are highly atherogenic, to consider the relationship between alcoholic beverages and health. This study aimed to determine the effects of simultaneous alcoholic beverage and carbohydrate intake on the blood TG level during a fat tolerance test.

Methods: The subjects were 16 healthy male volunteers in their 20s to 40s. The high-fat diet was adjusted to 50 g fat per body surface area using gyusara (stewed beef) and fat loading cream. The alcoholic beverage used was 1400 ml beer (61.6 g ethanol) and the carbohydrate used was 150 g white rice (50 g carbohydrate). Four meals were loaded: A (gyusara), B (gyusara + beer), C (gyusara + white rice + beer), and D (beer). Blood samples were drawn during fasting and at 30, 60, 120, 180, 360, and 720 minutes after meals. Measurements of TG, apoB-48, RLP-C, sd-LDL, glucose, and insulin levels were taken.

Results: After 720 minutes, TG, apoB-48, and RLP-C levels were significantly ($p < 0.05$) higher for B and C than for A. The level of sd-LDL was significantly higher for B than for A ($p = 0.002$), but there was no significant difference between sd-LDL levels for C and A. Insulin levels at 180 minutes were significantly lower for B than for C ($p = 0.014$).

Conclusions: Hypertriglyceridemia was observed after 720 minutes of simultaneous ingestion of a high-fat meal and alcohol. The high apoB-48 level suggested that the TGs may be CM remnants. Simultaneous ingestion of carbohydrates may result in lower sdLDL levels, which was predicted to be an effect of increased insulin secretion due to carbohydrates and lipoprotein lipase activation by insulin. When consuming alcoholic beverages, the risk of atherosclerosis could be altered by the combination of the amount of fat and carbohydrates that are simultaneously consumed.

Keyword: Postprandial hyperlipidemia, apoB-48, alcoholic beverage intake, high-fat diet, dyslipidemia

PAB(T4)-6
Excessive folic acid supplementation in pregnant mice induces glucose and lipid metabolic disorders in their offspring in infancy and/or adulthood.

Yuri Kintaka[1,2], Sadako Nakamura[2], Nobuhiro Wada[3,2], Asuka Okuda[2], Kenichi Tanabe[4], Kazuki Mochizuki[5], Tsuneyuki Oku[2]

1. Sapporo University of Health Sciences (Japan), 2. Jumonji University (Japan), 3. National Institute of Health and Nutrition (Japan), 4. Nakamura Gakuen University (Japan), 5. University of Yamanashi (Japan)

Background and objectives: Previous studies have shown that excessive maternal intake of folic acid (FA) predisposes to impaired glucose tolerance in the offspring. Then, we will examine ways to improve the situation. Therefore, we aimed to determine whether excessive FA intake during pregnancy affects the glucose and lipid metabolic disorder of mouse offspring in infancy and adulthood.

Methods: Pregnant C57BL/6J mice were fed AIN93G diet containing either 2 mg [control group (CN)] or 40 mg [high FA group (HFA)] FA/kg diet throughout their pregnancies. Experiment 1: On postnatal days (PD) 22 and 50, fasting blood glucose was measured in the offspring of both groups (n=10), and an oral glucose tolerance test (OGTT) was performed on PD 50. On PD 53, tissues were collected, and the tissue masses, area of insulin expression in the pancreas, liver triglyceride content, and gene expression were determined. Experiment 2: After weaning, each group (n=8) was fed a high-fat and high-sucrose diet (HFHS) to induce lifestyle-related lesions. Half of the groups were fed a diet in which a part of sucrose was replaced with fructooligosaccharides (FOS), and the changes in each group were observed.

Results: In female infant, the blood glucose concentrations were higher in HFA than CN offspring in infancy at 60 and 120 min of the OGTT. The serum insulin concentrations and the area of insulin expression in the pancreas were lower in HFA than CN offspring. The liver triglyceride content was higher in HFA offspring than CN offspring ($P < 0.05$). The liver mRNA expression

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of fat synthesis genes, *Pparγ2* (male and female) and *Cidec* (male), were higher in HFA than CN offspring ($P < 0.05$). In female adulthood mice adipose tissues accumulation due to consumption of HFHS after weaning was suppressed by FOS intake.

Conclusions: Excessive maternal supplementation of FA in mice leads to lower insulin synthesis and an impairment in hepatic glucose and lipid metabolism in the offspring, and the lesions are induced by HFHS in infancy and adulthood. Furthermore, the lesions may be suppressed by FOS intake. We further clarify the health effects of folic acid supplementation.

PAB(T4)-7
Effectiveness of transtheoretical model-based intervention on weight management in obese hospitalized patients

Chung-Mei Ouyang[1], Hsiao-Chun Lin[1], Yu-Ting Cheng[1], Tsung-Jung Lien[1]

1. National Taiwan University Hospital Hsin-Chu Branch (Taiwan)

Background and objectives: Obesity and overweight are global problems related to many chronic diseases. Given that these chronic diseases are important causes of hospitalization, it is reasonable to suspect that overweight and obese individuals would be at a greater risk for hospitalization than normal weight individuals. Several strategies have been used to treat obesity, and these typically emphasize dietary behaviors and physical activity. Here we evaluate the effect of intervention performed according to the stages of change of the transtheoretical model (TTM) for weight management during hospitalization and 3 months after discharged.

Methods: We screened all patients aged from 18 to 65 years, BMI ≧ 27 at a district hospital from July to September, 2019. After receiving their informed consent, we surveyed subjects' stage of change and offered basic information on weight control, nutrition education (individual and group intervention) and stretching class (video) according to their different stages. We collected subjects' anthropometric data as well as their knowledge, beliefs, self-efficacy and health-related dietary behaviors of weight management before and 3 months after discharged from hospital.

Results: A total of 153 patients attended the project and 120 subjects completed at the end. All participants (n=120) had an average body weight of 82.4±12.4 kg in the beginning and 79.9±12.1 kg at the end of the program (p<0.001). There were 67% of the subjects were at the stage of pre-contemplation (36%) and contemplation (31%) in the beginning, and only 26% of the subjects were at the stage of pre-contemplation (13%) and contemplation (13%) after intervention (p<0.001). There was no significant differences in knowledge of weight control; however, it was significantly increased in their self-efficacy and health-related dietary behaviors (p<0.05).

Conclusions: The TTM-based weight control intervention, combined with usual care, was an effective strategy in obese hospitalized patients. These results should encourage the use of interdisciplinary practices; nevertheless, research to identify additional strategies is needed to address barriers to weight maintenance.

PAB(T4)-8
Associations of review patterns of diet foods and drinks with self-reported weight changes among Japanese men and women.

Arisa Matsuzaki[1], Kotatsu Maruyama[1]

1. Ehime University (Japan)

Objective: Various diet products have been sold for weight control and beauty. Those products users tend to review the products and exchange opinions with the other users as "word-of-mouth communication (WOMC)" on the internet. Previous studies have shown that these WOMC identified several patterns, but few studies examined the association between those patterns and weight changes. Therefore, the purpose of this study was to examine WOMC patterns of diet foods and drinks and weight changes.

Methods: We received the WOMC data registered in the website "Diet Café" managed by T.M.Community Co., Ltd. between 2008 and 2019 (National Institute of Informatics Dataset Joint Use Research and Development Center: doi/10.32130/idr.11.1). A total of 15,822 WOMC with age, sex, height, weight before and after use diet foods or drinks, and period of use were analyzed. The WOMC pattern was identified by cluster analysis. The differences of weight change among those review patterns was tested by analysis of covariance after adjustment for age, sex, weight before use and food form (food / drink).

Results: We identified the following three review patterns. “product effect” pattern characterized as frequently using "effect”, “weight loss” and “constipation", and e.g. “I feel the constipation-relieving effect” and “My weight was reduced after consumption of this food / drink”, “weight change” pattern characterized as frequently using “weight”, “weight loss” and “change”, and e.g. “I feel that weight reduction was smooth after replacement of normal meal with this food / drink in the morning”, and “product detail” pattern characterized as frequently using "replacement”, “taste” and “deliciousness", and e.g. ”this food / drink is rich in taste and delicious”. The multivariable-adjusted mean of weight changes for “product detail” pattern was significantly lower than those for the other

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

two patterns. The respective multivariable-adjusted weight changes was -0.98 kg for the product effect pattern, -1.37 kg for the weight change pattern, and -1.56 kg for the product detail pattern ($p < 0.05$).

Conclusion: We found that the diet foods and drinks users who reviewed "product detail" pattern as WOMC on the internet had higher weight reduction.

Chronic exercise combined with restricted diet treatment improved pancreatic dysfunction of pancreatitis and diabetes with obesity in WBN/Kob rats.

Kumiko Minato[1], Yoko Shiroya[2], Yuka Kurosaka[2,3], Hideki Yamauchi[2]

1. Wayo Women's University (Japan), 2. The jikei University School of Medicine (Japan), 3. Juntendo University (Japan)

Background and objectives: Leptin receptor-deficient WBN/Kob-Fatty (WKF) rat was developed for a model of chronic pancreatitis and diabetes with obesity. We recently indicated that pancreatic dysfunction in the chronic pancreatitis with obesity could be improved by adequate exercise habit with restricted diet. Furthermore, we obtained that these treatments improved early lesions of pancreatic B-cells and acinar cells in this pancreatitis model rats. The purpose of this study was to investigate whether the autophagy system is involved in the amelioration of pancreatic dysfunction by chronic exercise combined with restricted diet in WKF rats.

Methods: [Animals] Male WKF rats (age, 6 weeks) were divided into fatty-obese (FOB; n=10), fatty-diet restriction (FDR; n=8), and fatty-exercise (FEX; n=9) groups. WBN/Kob (WK; not obesity) rats were used as lean control (C; n=6). [Food] The C and FOB rats had free access to food, the FDR and FEX rats had food intake restricted to 69% and 70% of the FOB level, respectively. [Exercise Training] The FEX rats were exercised voluntarily on the wheel ergometer with a load of 30% on their body weight every day. Mean running distance was 1711±458m/day. [Measurements] Following 6 weeks of experimental period, the pancreas were excised and weighed. Protein content and amylase activity in pancreatic tissue and serum parameters were measured. Autophagy-related protein (LC3) and ubiquitinated protein (UP) protein expression in the pancreas were evaluated with western blotting method.

Results: The FOB rats (12wks) had symptoms of obesity, diabetes, and pancreatitis with increased ER stress (XBP1) and inflammation (IL6) markers in the pancreas, while the FDR and FEX rats had ameliorated these symptoms and the markers. Furthermore, LC3 and UP were indicated same fluctuation as ER stress and inflammation markers.

Conclusion: These results suggested that male 12wks WKF rats had symptoms of pancreatitis and diabetes, but lean WK rats did not. Chronic exercise combined with restricted diet ameliorated these pancreatic dysfunctions induced by obesity with ectopic fat accumulation in WKF rats which may be involved homeostatic regular autophagy system.

Effects of obesity-induced leptin resistance on the level of type I collagen in the skin

Takumi Yamane[1], Ken Iwatsuki[1], Yuichi Oishi[1]

1. Tokyo University of Agriculture (Japan)

Background and objectives: Obesity increases the risk for metabolic disorders and can lead to leptin resistance. Leptin has been reported to influence the function of various cells, including dermal fibroblasts. However, some aspects of the relation between obesity-induced leptin resistance and skin function are unclear. This study aimed to reveal the effect of obesity-induced leptin resistance on type I collagen, which imparts tensile strength and stability to the skin.

Methods: To examine the effect of obesity-induced leptin resistance on the level of type I collagen, we used leptin-deficient *ob/ob* mice, leptin receptor-deficient *db/db* mice and their respective wild-type (WT) littermates as the control (8 weeks old). Skin tissue samples were fixed in 10% formalin neutral buffer solution and embedded in paraffin to use for the histopathological analysis. Serial sections were cut and stained with hematoxylin and eosin, and Masson's trichrome stains. We also investigated the levels of type I tropocollagen, which polymerizes to microfibrillar collagen to initiate aggregation. The levels of type I tropocollagen from the dermal skin were measured by using enzyme-linked immunosorbent assay.

Results: Both *ob/ob* mice and *db/db* mice were heavier than their respective control groups, thereby confirming the obesogenic effect of impaired leptin-signaling. Histological observation of the dorsal skin revealed a marked decrease in the dermal layer in both *ob/ob* mice and *db/db* mice. The skin tissues of both *ob/ob* mice and *db/db* mice showed lower amounts of collagen deposition compared with that in WT mice. The level of type I tropocollagen was significantly reduced in the skin of both *ob/ob* mice and *db/db* mice compared with WT mice.

Conclusions: These findings suggest that obesity-induced leptin resistance reduces the level of type I collagen in the skin, and these effects are deleterious for skin function.

The association between diabetic status and BMI change during the COVID-19 pandemic: the Toon Health Study

Daiki Kanno[1], Koutatsu Maruyama[1], Kiyohide Tomooka[2], Takeshi Tanigawa[2], Isao Saito[3]

1. Ehime University (Japan), 2. Juntendo (Japan), 3. Oita (Japan)

Background and objectives: The COVID-19 pandemic had a significant impact on individual's health and health-related behaviors. However, few studies have examined the association of diabetic status with changes in body weight during the pandemic in Japanese population. Therefore, this study aimed to examine the association between diabetic status and Body Mass Index (BMI)change during the COVID-19 pandemic among Japanese population.

Methods: This cohort study enrolled 1349 Japanese men and women aged 30-84 years who participated in the Toon Health Study. Height and weight were measured and BMI was calculated at the baseline survey (2014-2018). In 2021 (May-September), questionnaire survey was conducted and BMI was calculated from self-reported weight and height at baseline. The participants were classified into normal, borderline, and diabetes mellitus (DM) groups based on fasting and 2-hour postprandial blood glucose levels after 75 g oral glucose tolerance test, and diabetes treatment. Analysis of covariance and Tukey-Kramer test were used to compare the BMI change during the COVID-19 pandemic based on diabetic status after adjustment for sex, age and BMI at baseline.

Result: The BMI changes in the DM group was significantly greater than in both the normal and borderline groups. The multivariable-adjusted mean of BMI change was -0.07 kg/m^2 in the normal group, 0.06 kg/m^2 in the borderline group and -0.47 kg/m^2 in DM group ($p<0.01$). Analysis stratified by overweight status at baseline showed that the change in BMI in the DM group was significantly greater than in the other 2 groups of non-overweight individuals. The multivariable-adjusted mean of BMI change was -0.14 kg/m^2 in the normal group, -0.09 kg/m^2 in the borderline group and -0.72 kg/m^2 in DM group ($p<0.01$). On the other hand, we found no significant associations in overweight individuals. However, an interaction on the association diabetic status and BMI change did not reach significance.

Conclusions: This study showed that diabetic individuals had higher BMI loss compared to normal and borderline diabetes mellitus individuals.

Keyword: diabetic, weight change, COVID-19 pandemic

A Meta-Analysis of the Effect of High-Amylose Rice Consumption on Postprandial Glycemic Response.

Tingting Xu[1], Jia Li[1], Salsabila Khairunnisa[1], Satomi Inokawa[1], Koutatsu Maruyama[1]

1. Ehime University (Japan)

Background and Objectives: There is a growing body of evidence on the positive effects of high-amylose rice on postprandial blood glucose levels, but it has been controversial. Therefore, in this study, we conducted a meta-analysis of the effects of high-amylose rice on postprandial blood glucose levels.

Methods: We conducted a literature search of articles published between January 1980 and October 2021 by PubMed, Google Scholar, and the Ichushi-Web (in Japanese). The search terms were high-amylose rice, blood glucose, HbA1c, glycemic index and intervention study. We further searched the references of included literatures/studies to find other relevant publications. A random effects model was used to analyze the effects of high-amylose rice on postprandial blood glucose levels.

Results: Six articles were identified for this study. Three articles showed that postprandial blood glucose levels assessed as area under the curve (AUC) or increase in AUC (IAUC) after high-amylose rice consumption was lower than those of control rice, but the other three articles did not show the significant effect. We found a significantly lower mean of AUC for high-amylose rice than that for control rice; the pooled mean difference between high-amylose rice and control rice was -844.66 min･mg/dL (95% confidence interval (95%CI) : -1367.68 to -321.64, $p = 0.002$). We also found a significantly lower mean of AUC for high-amylose rice than for control rice; the pooled mean difference was -2599.92 min･mg/dL (95%CI : -3793.03 to -1406.82, $p < 0.00001$).

Conclusions: Our findings suggested that consumption of high-amylose rice may be beneficial for postprandial glycemic control.

A correlation between dietary oxidative stress and secretion of hormones involved in obesity in rats

Shizuka Hase-Tamaru[1], Misato Shimogawa[1], Eri Tsukamoto[1], Ayami Ito[1]

1. Fukuoka Institute of Technology (Japan)

Background and objectives: Hyperproduced reactive oxygen species (ROS) cause the oxidative stress, which could be risk factor of lifestyle-diseases developing. Recently, there are many reports related to suppression of oxidative stress, i.e., antioxidant activity of food components in vitro. However, it has not been demonstrated that whether the antioxidant effect is actually exerted after feeding of antioxidants resulting the lifestyle-diseases prevention in vivo. In this study, we investigated whether the dietary oxidative stress with feeding of diet containing fat and cholesterol leading to obesity affects oxidative stress and/or antioxidant parameters in rats. Then, we demonstrated the correlation between these parameters and hormonal secretion involved in obesity in rats, because hormonal therapy such as insulin and leptin for lifestyle-related diseases including obesity has been focused more recently.

Methods: Male Sprague-Dawley rats (5 weeks old) were purchased. After acclimation, rats were fed Control diet (commercial CE-2 powder) or FC diet containing 15% of fat and 0.5% of cholesterol prepared according to AIN-93G composition *ad libitum* for 4 weeks. Serum oxidative stress degree (d-ROMs value) and antioxidant potential (BAP value) were analyzed using with redox-analyzing instrument (REDOXLIBRA). Serum superoxide dismutase (SOD) activity, serum insulin, leptin, and adiponectin levels, serum lipid parameters, and hepatic lipid levels were measured with commercial kits.

Results: Adipose tissue weights significantly increased with feeding of FC diet. FC diet developed liver enlargement and hepatic lipid (triglyceride and cholesterol) accumulation. Hence, FC diet leading to obesity could put a load of dietary oxidative stress on rats. Dietary oxidative stress could be reflected in parameter as lowered antioxidant potential (BAP value and SOD activity), but not as heightened oxidative stress degree (d-ROMs value). Adipose tissue weights and serum insulin and leptin levels, which were increased with FC diet, indicated negative correlation with BAP value and SOD activity. On the other hand, adiponectin levels lowered with FD diet indicated positive correlation with BAP value and SOD activity.

Conclusions: These results suggested that antioxidant parameters may be able to be index of obesity and lifestyle-related diseases prevention.

Development of Development of “Seto Inland Sea” Dietary Ppattern and Iits Aassociation with Bbody Mmass Iindex among Japanese Individuals

Ryunosuke Doi[1], Koutatsu Maruyama[1], Tetsu Kinoshita[2]

1. Ehime University (Japan) (Japan), 2. Ehime University (Japan),Institute of Community Life Sciences Co., Ltd. (Japan)

Objective: With reference to the Mediterranean diet which is one of the well-known healthy dietary pattern, we developed “Seto Inland Sea” Dietary pattern (SISD pattern) which is characterized as foods produced and culturally rooted in the area around Seto Inland Sea in Japan. Furthermore, we examined that the association between SISD pattern and body mass index (BMI).

Method: We selected the foods which had a higher production output in the area around Seto Inland Sea (Ehime, Kagawa, Hiroshima, Okayama, Yamaguchi, and Oita prefectures) based on official statistics published by the Japanese government and foods culturally rooted in the area around Seto Inland Sea. We selected 37 foods and classified them into 7 groups; fruits, vegetables, potatoes, fish, seaweeds, olive oil, and barley. To analyze the association between SISD pattern and BMI, we used body weight, height, and 7-day dietary records data from 35 borderline diabetic (pre-diabetic?)men and women from 2011 to 2012. Individuals with intake above the sex-specific median intake of each food groups were scored 1, and the sum of all food group scores was calculated as SISD pattern score. We further added the scores of non-selected vegetables and nuts intakes because higher intake of those foods could work for obesity prevention (modified SISD pattern score). We finally compared BMI between lower than median (low) and above median (high) SISD pattern score groups using analysis of covariance adjusted for sex, age, and energy intake.

Result: High score group tended to have lower BMI than low score group, the multivariable-adjusted mean of BMI was 23.07 for high score group and 24.64 for low score group (p=0.16).

High modified score group tended to have lower BMI than low score group, the multivariable-adjusted mean of BMI was 22.86 for high modified score group and 24.71 for low modified score group (p=0.10).

Conclusion: Although we observed insignificant association between SISD pattern score and BMI, modification by other foods in relation to prevention for obesity including vegetables and nuts might fortify SISD pattern against increased body weight.

Although we observed an insignificant association between SISD pattern score and BMI, modification by other foods (e.g vegetables and nuts) might strengthen the effect of SISD pattern towards obesity prevention.

Effect of very low-carbohydrate diet with different protein ratio on diet-induced non-alcoholic fatty liver disease

I-Ting Wu[1], Hsuan-Chih Huang[1], Hsin-Yi Yang[1]

1. Fu-Jen Catholic University (Taiwan)

Background and objectives: Non-alcoholic fatty liver disease (NAFLD) is commonly found in obese population. Although studies have shown that low-carbohydrate diet can help lose weight rapidly, the effects of low-carbohydrate diet in NAFLD remains controversial and the ratio of dietary protein may also affect the effectiveness. Therefore, we aim to investigate the effects and underlying mechanisms of very low-carbohydrate diet with different protein ratio in NAFLD rats.

Methods: Rats were fed with high-fat-high-sucrose diet for 16 weeks to induce NAFLD. After the induction period, rats were divided into three groups receiving isocaloric normal diet (NC group), very low-carbohydrate diet (NKD group, protein: carbohydrate: lipid = 6:1:93) or very low-carbohydrate diet with high protein ratio (NLC group, protein: carbohydrate: lipid = 20:1:79) for 8 weeks.

Results: Although both NKD and NLC group reduced more body weight than NC group and no difference between the two groups was found at the end of the study, NLC group had lower circulatory ketone body levels. NKD group had not only higher blood and hepatic lipids, but also higher pro-inflammatory cytokines including tumor necrosis factor (TNF)-α and interleukin (IL)-1β than other two groups. Moreover, no difference in endotoxin, toll-like receptor 4 (TLR4) and myeloid differentiation primary response 88 (MyD88) was found among groups, but NKD group had higher expression in TRIF (TIR-domain-containing adapter-inducing interferon-β) than other two groups. In addition, NKD and NLC group had lower α-diversity and different gut microbiota composition when compared to NC group.

Conclusions: Our results suggested that very low-carbohydrate diet reduced body weight and led to change in gut microbiota in NAFLD rats, but high dietary protein ratio improved liver inflammation and steatosis induced by very low-carbohydrate diet.

Keyword: NAFLD, low-carbohydrate diet, protein, steatosis, inflammation

Brief Intervention for Treatment Adherence: a pilot study of an intervention strategy that improves nutritional adherence during weight loss treatment

Karina Gonzalez-Becerra[1], Joel Gonzalez-Cantero[1], Angelica Martin-Moreno[1], Elisa Barron-Cabrera[1], Alondra Mora-Jimenez[1], Erika Martinez-Lopez[1]

1. Universidad de Guadalajara (Mexico)

Background and objective: Obesity is a chronic disease with a high prevalence worldwide. In this regard, integral treatments are necessary to achieve better results in obesity management. Nowadays, behavior change interventions can be successful in achieving weight loss treatments; in this sense we propose the use of the Brief Intervention for Treatment Adherence (BITA) strategy for enhancing nutritional adherence to weight loss treatment in participants with obesity.

Methods: A clinical trial with a total of twenty-three subjects with obesity were included, the subjects were assigned in two study groups, group with BITA and group without BITA. They received an energy-restricted diet (20% reduction in the total energy expenditure) and the macronutrient distribution was 50% carbohydrates, 30% lipids, and 20% proteins. The nutritional intervention period was for 16 weeks.

Results: The use of BITA strategy in the intervention group significantly improved adherence to nutritional counseling *vs* participants who did not receive BITA ($p<0.05$). The patients who received BITA had greater adherence (adherence rate between 71.8 to 80%). The group with BITA showed significant improvements in weight loss (-4.9±4.0 kg weight lost), body mass index (-1.7±1.3 kg/m^2), body fat mass (-3.1±4.0 kg), and abdominal fat (-1.1±2.8%) ($p<0.05$), in comparison with the group without BITA.

Conclusions: The BITA strategy demonstrated to be useful for improving adherence to a nutritional intervention, achieving a greater weight loss.

High or low Glycaemic Index (GI) meals at dinner negatively affects glucose homeostasis compared with breakfast in people with diabetes type 2 with poor chrono-nutrition status

Neelam Rathod[1], Suneeta Chandorkar[1]

1. The Maharaja Sayajirao University of Baroda (India)

Background and Objectives: Food is an external cue to entrain the circadian rhythm. Diurnal variation in glucose metabolism via circadian control is well established but how the GI of meals interacts with the timing of meals and influences glucose metabolism is understudied and crucial. The study examines the relationship between chrono-nutrition status and glucose homeostasis of people with diabetes type 2 (PWDs).

Methods: A sample size of 227(age: 35-60 years, years of diabetes :< 5, no comorbidities) was calculated considering the prevalence of diabetes in the district. Chrono-nutrition questionnaire assessed eating window, breakfast skipping, evening latency, evening eating, night eating, and largest meal of PWDs. Body composition and dietary intake were assessed using BIA and 72 hours food records. Glycaemic control was assessed using the gold standard methods- HbA1c, FBS, and PP2BS. Lipid profile was assessed. Chi-square, spearman correlation, AUC, linear regression, and multinomial logistic regression were used for statistical analysis.

Results: Fifty-two percent of PWDs reported having a poor chrono-nutrition status. A total of 4086 meals from 681 days of dietary records from 227 PWDs were studied. PWDs who followed circadian fasting rather than intermittent fasting had better glycaemic control and lower adiposity ($p<0.05$). PWDs with poor chrono-nutrition status ate twice as many carbohydrates and half as many proteins for dinner as PWDs with good chrono-nutrition status, resulting in late breakfast consumption ($p<0.05$) and a higher atherogenic index of plasma and HbA1c ($p<0.05$). Evening latency of 2-6 hours was strongly associated with controlled FBS (OR: 10, $p=0.01$). PWDs who consumed high GI meals before 10 am had better glycaemic status than PWDs who consumed high or low GI post 7 pm ($p<0.05$).

Conclusion: High or low GI meals consumed at dinner result in significantly worse glucose homeostasis than high or low GI meals consumed at breakfast by PWDs with a late eating pattern. Intermittent fasting, in which breakfast is skipped, can aid in weight loss, but circadian fasting not only aids in weight loss but also in blood glucose control.

Dietary Patterns, Cardiometabolic Indicators and Their Association with Components of Metabolic Syndrome; A Cross-Sectional Study in Polish Adults with metabolic disorders

Jadwiga Hamulka[(1)], Agnieszka Bialkowska[(1)], Monika Anna Zielinska-Pukos[(1)], Magdalena Gornicka[(1)], Joanna Frackiewicz[(1)], Anna Ciecierska[(1)], Marta Jeruszka-Bielak[(1)], Malgorzata Drywien[(1)]

1. Warsaw University of Life Sciences (WULS-SGGW) (Poland)

Background and objectives: Metabolic syndrome (MetS), characterized as a cluster of metabolic abnormalities, including central obesity, dysglycemia, elevated triglyceride (TG) levels, low high-density lipoprotein cholesterol (HDL-C) levels, and hypertension, is a major medical problem also in Poland. We investigated the associations between dietary patterns (DPs), anthropometrics parameters, cardiometabolic indicators and the number of MetS-components.

Methods: This case-control study involved 300 adults (53.1±12.9 years) from Central Poland with metabolic disorders. Data were collected with validated questionnaires (KomPAN, IPAQ). Anthropometric, blood pressure and serum concentrations of lipids and glucose were measured. MetS was defined based on the criteria of the International Diabetes Federation. Considering the number of MetS components (MetS-components) presence, the study group was divided into three groups: 0-2 MetS-components, 3 MetS-components, 4-5 MetS-components. The anthropometric obesity indexes including body mass index (BMI), waist circumference (WC), waist-height ratio (WHtR) and the cardiometabolic indicators such as visceral adiposity index (VAI), lipid accumulation product (LAP), a triglycerides-glucose index (TyG), and cardiometabolic index (CMI) were calculated. DPs were identified using *k-means* based on the 17 food groups frequency consumption. Statistical analysis was conducted in STATISTICA ver. 13.3 and included Shapiro-Wilk, Kruskal-Wallis ANOVA and $Chi^{(2)}$ test.

Results: Among the study population, 59% were women, and 52% had insufficient physical activity according to IPAQ. Only 23% of participants had normal body weight (mostly women 29% vs. 15% of men), while 25% had overweight and 48% – obesity. Significantly more men than women had more (4-5) MetS-components (68% vs. 23%). Although, the DPs were not significantly related to MetS-components groups, significant relationships were found for the lower frequency consumption of processed meats and cheese in subjects with 0-2, and 3 vs. 4-5 MetS-components. Subjects classified as having more MetS-components had significantly higher age, anthropometrics parameters (BMI, WHtR) and cardiometabolic indicators CMI, LAP and VAI.

Conclusions: In MetS management, special attention should be paid to lowering the consumption of highly processed food, especially processed meats and cheese. There is also a need to monitor the cardiometabolic and anthropometric indicators in the context of MetS risk.

Evaluation of sesamin on improvement of symptoms in STZ-induced diabetes rats

Shu-Ming Huang[(1)], Yung-Yen Cheng[(1)], Hung-Chang Hun[(1)], PO-Wei Tsai, Cheng-Hung Chuang

1. Nantou Hospital, Ministry of Health and Welfare (Taiwan)

Background and objectives: Diabetes is a chronic metabolic disease. The complications such as heart disease, stroke, blindness, and kidney failure. The chemical component in sesame is lignan Lignans, mainly Sesamin, the pharmacological activities, including lowering cholesterol,anti-oxidation, anti-inflammatory, decrease blood pressure and blood sugar, immune mediation activities. In this experiment, sesamin will be used to inject Streptozotocin (STZ) + nicotinamide into rats to induce type 2 diabetes, and then sesamin will be administered to observe the changes in blood glucose of the rats.

Methods: A total of 30 male Wistar rats, six weeks old. After the rats were acclimatized for one week, divided into 5 groups. groups 2-5 were injected intraperitoneally with nicotinamide 200 mg/kg/body weigh on the 1, 15, 29 and 43 days, and then intraperitoneally injected 15 minutes later STZ 55 mg/kg/body weight. On the 8th day, groups 3 and 4 were given 20 and 60 mg/kg/body weight of sesamin by tube every day, and the 5th group was given by tube every day metformin 250 mg/kg/body weight. During the experiment, blood was collected to monitor blood glucose values. The experiment lasted for 50 days. On the 50th day, sacrificed after the end of the experiment, the blood and organs were.

Results: The blood glucose level was measured on the 8th day after STZ administration. The results showed that the blood glucose level of the STZ treatment group was significantly higher than that of the control group to 190 mg/dL ($P<0.05$). The results of blood glucose detection on 15 and 22 days were obvious, and the STZ treatment group was also significantly different from the control group. However, the blood glucose level of the STZ treatment group on the 15th day was significantly lower than that on the 8th day by 13.3% ($P<0.05$). Compared with the control group, the glycosylated hemoglobin (HbA1c) of the STZ treatment group was significantly higher than 82% ($P<0.05$).

Conclusions: Sesamin is one of the effective ingredients of sesame seeds. In this study found that sesamin can reduce blood sugar in diabetic rats. It can also provide people with effective assistance in hyperglycemia symptoms when eating sesame seeds.

Consumption of carbohydrates, lipids and their relationship with the oxidant/antioxidant balance in patients with DMT2

Beatriz Elina Martinez-Carrillo[(1)], Flor de María Cruz-Estrada[(1)], Jocelyn García-Alvarado[(1)], Roxana Valdés-Ramos[(1)], Amapola de Sales-Millán[(1)]

1. UAEM (Mexico)

Introduction and objective: Type 2 diabetes *mellitus* (T2DM) continues to be a public health problem. The dietary intervention allows to achieve glycemic control, improve the metabolic state and therefore prevent complications. The objective of the study was to evaluate the consumption of Carbohydrates and lipids and their relationship with the modification of the oxidant/antioxidant balance in patients with DMT2.

Results: In both groups, the female sex prevailed (with DMT2 -78.7%-, without DMT2 -66%-), the mean age was 50 years for the group with T2DM and 43 years for the group without T2DM. The T2DM group consumed fewer calories (2,031 kcal/day), Carbohydrates (191 g/day), lipids (64 g/day), low concentrations of glutathione reductase (59.5 mMol), Thiobarbituric acid (TBARS: 5.6 mMol), and Total Antioxidant Capacity (TAC: 12.2 mMol), with an increase in blood glucose 152 mg/dL, Total Cholesterol (203 mg/dL), and Triglycerides (182 mg/dL). In contrast, the group without T2DM consumed more calories (2362 Kcal/day), Carbohydrates (194.2 g/day) and lipids (71 g/day), with an increase in the concentration of glutathione reductase (61.5 mMol), Thiobarbituric acid (TBARS: 5.8 mMol) and Total Antioxidant Capacity (TAC: 12.7 mMol), but a more favorable biochemical profile (Glycaemia 86 mg/dL, Total Cholesterol 186 mg/dL and Triglycerides 163 mg/dL).

Conclusions: The group with T2DM, consumed less carbohydrates and lipids, but showed lower antioxidant capacity with reduction in lipid peroxidation products, and show a damaging biochemical profile. The contrary effect shown in patients without T2DM, where is evident the diet effect and how modify and influence both biochemical and metabolic parameters.

Relevance of metformin administration to serum levels of zinc and homocysteine in patients with type 2 diabetes

Sadako Matsui[1], Chika Hiraishi[2], Ryo Sato[3], Takai Kojima [3], Kiyotaka Ando[3] , Kei Fujimoto [4], Hiroshi Yoshida[2,3]

1. Japan Women's University (Japan); 2. The Jikei University Graduate School of Medicine (Japan); 3. The Jikei University Kashiwa Hospital (Japan); 4. The Jikei University Daisan Hospital (Japan)

Background and objectives: We investigated relevance of metformin treatment to serum levels of zinc and total homocysteine (Hcy), an indicator of metabolic vitamin B12, in patients with type 2 diabetes (T2DM).

Methods: This cross-sectional study enrolled 138 T2DM patients (89 men and 49 women) including diabetic kidney disease (DKD). Serum concentrations of Hcy, and vitamin B12, folic acid, zinc concentration as Hcy metabolic nutrition factors, and urinary albumin excretion were measured using clinical residual samples. The laboratory data, patient characteristics, and status of medication were collected from the medical records. Next, to investigate the effects of metformin treatment, the study subjects were divided into two groups, by 1: 1 propensity score matching using age, gender, and BMI as predictors, with metformin oral administration [Met(+); n=46)] and without metformin oral administration [Met(-); n=46)], and the data were analyzed before and after the matching. Furthermore, the metformin dose (mg/day) was divided into 3 groups, and the differences were examined between the two groups using multiple comparisons after one-way analysis of variance.

Results: After matching, there was no difference in glycemic control and renal function, but urea nitrogen (UN), creatinine (Cre), and Log transformed urea albumin-to-creatinine ratio (Log UACR) in Met(-) were significantly lower than in Met (+). In addition, the serum zinc concentration (μg/dL) was significantly higher in the Met(+) (78.0 ± 12.6 vs. 86.9 ± 11.6, p <0.001), while Log Hcy was significantly lower in the Met(+) (p<0.001). Furthermore, in multiple logistic analysis with the absence or presence of metformin administration, as an explanatory variable, serum zinc concentration was associated with the metformin administration, independently of glycemic control and renal function. In addition, the Log Hcy concentration was significantly higher in Met(-) (<0.05), and the Log vitamin B12 concentration was significantly lower in the higher metformin dose group (p<0.01).

Conclusions: The present study suggests that the difference of serum zinc concentration by metformin administration were independent of renal function and metformin administration may favorably influence on serum zinc levels. In addition, these metformin treatment effects on serum Hcy or vitamin B12 concentrations were found in a dose-dependent manner.

Effects of *Moringa oleifera* leaves on the lipid profile and heamatological parameters of type 2 diabetic subjects; a parallel group randomized clinical trial of efficacy

Ifeoma Christiana Afiaenyi[1], Elizabeth Kanayo Ngwu[2], Rufina Nkeiruka Ayogu[3]

1. University of Nigeria, Nsukka. (Nigeria); 2. University of Nigeria, Nsukka (Nigeria); 3. University of Nigeria, Nsukka (Nigeria)

Background and objectives: Diabetes has crept into the rural areas of Nigeria causing devastating effects on its sufferers; most of them could not afford diabetic medications. Moringa has been used extensively in animal models to demonstrate its antidiabetic qualities; however, there is scarcity of data on the antilipidaemic and haematinic potentials of graded levels of moringa leaves in human diabetic subjects. This study determined the effect of moringa leaves on the lipid profile and haematological parameters of type 2 diabetic subjects in a rural Nigerian community.

Methods: This study adopted a parallel group randomized control design. Participants included 24 adult male (10) and female (14) diabetic subjects who made it through the inclusion criteria and consented to participate in the study. The participants were randomly assigned to four groups (n=6), one control group and 3 experimental groups. The control group (1) was fed diets without *Moringa oleifera* leaves while the experimental groups (2, 3 and 4) received 20 g, 40 g and 60 g of moringa leaves respectively daily for fourteen days in addition to the diets. The subjects' baseline data (lipid profile, haemoglobin, packed cell volume and white blood cell count) and post intervention data were collected before and after the intervention respectively. The data obtained were analyzed using means and standard deviation, paired-samples t-test was used to compare the means of values collected pre and post intervention within the groups. Analysis of covariance was used to compare the means of post intervention values among the groups. Significance was accepted at $p < 0.05$.

Results: Groups 1 and 3 had non-significant (p> 0.05) decreases in their mean LDL cholesterol levels. There was a significant decrease in group 4's mean haemoglobin levels from “before intervention (M = 12.83, SD = 034) to “after intervention” (M =11.07, SD = 0.74) t = 5.94, P = 0.002. There was a significant difference between the post intervention values of HDL cholesterol among the groups after controlling for the pre intervention values.

Conclusion: There were marginal changes in the parameters assessed which were not dose dependent.

Involvement of interleukin-21 receptor (IL-21R) in nutritionally induced nonalcoholic steatohepatitis in mice

Noriko Suzuki-kemuriyama[(1)], Hina Mandokoro[(1)], Syuki Yoshida[(1)] , Anna Suzuki[(1)], Hayato Watanabe[(1)] , Sae Nakane[(1,2)], Katsuhiro Miyajima[(1)] , Dai Nakae[(1,3)]

1. Tokyo University of Agriculture (Japan); 2. TechnoPro R&D Company (Japan); 3. Teikyo Heisei University (Japan)

Background and Objectives: IL-21R has been implicated in immune functions such as lymphocyte maturation and autoimmune diseases. In this study, we analyzed the involvement of IL-21R in the development of nonalcoholic steatohepatitis (NASH) in order to investigate the life-style-related pathophysiological significance of IL-21R in the liver.

Methods: Six-week-old male C57BL/6J mice, wild-type or IL-21R deficient, were fed with a control diet or a choline-deficient, L-amino acid-defined, high-fat, trans-fat free diet (CDAA HF-T(-)) (45% fat by a shortening without trans fat, methionine 0.1%), for 4 or 13 weeks. A human hepatic stellate cell line, LX-2 was stimulated with TGF-β (10 ng/mL) or IL-21 (10, 50 ng/mL) alone or combined. Hepatic stellate cell activation was evaluated by the fibrosis-related gene expression profile and morphological changes. In addition, the effects of a TGF-β type 1 receptor inhibitor, SB431542, were assessed.

Results: In the CDAA-HF-T(-) group, liver and spleen weights, and blood alanine aminotransferase (ALT) activity were increased, and in the liver lipid accumulation, inflammation and fibrosis were developed with overexpression of IL-21and IL-21R. In the IL-21R-deficient mice, ALT elevation, liver steatosis, and inflammation were induced, but inhibited the increase of spleen weight and the development of hepatic fibrosis. In association with fibrosis, collagen type 1, 4, TGF-β type 1, and 2 gene expressions were elevated in the wild-type mice, and the upregulation of collagen type 1, type 4, and TGF-β type 2 gene expressions were suppressed in the IL-21R-deficient mice. In LX-2, TGF-β stimulation exhibited a spindle-shaped cell elongation and a network-like arrangement, and increasedαSMA protein, IL-21R gene, and fibrosis-related gene expressions, all of which were suppressed by the SB431542 pretreatment. IL-21 stimulation resulted in a slight increase in αSMA protein expression and a transient increase of collagen type 4 gene expression. Furthermore, combined administration of TGF-β and IL-21 revealed an enhanced effect on LX-2 activation.

Conclusions: In the murine NASH induced by the CDAA-HF-T(-), it is suggested that IL-21R is specifically involved in the progression of hepatic fibrosis, but not hepatic steatosis and inflammation, by at least in part to promote activation of hepatic stellate cells.

Thyroid Hormone was Associated with Obesity in Adolescents aged 12 - 19 years in the United States: Data from National Health and Nutrition Examination Survey (NHANES) 2011 – 2012

Tafere G Belay[(1)] , Maya Jensen[(1)], Susan Hawk[(1)] , David Gee[(1)]

1. Central Washington University (USA)

Background and objectives: Obesity is a highly complex disease that is increasing in prevalence globally. In the United States, 21.2% of adolescents aged 12 to 19 are obese. Despite its increasing prevalence, there is still much to learn about the disease. An area of controversy in obesity research has been the effect of thyroid hormones on obesity. Therefore, this study sought to investigate the relationship of thyroid hormones with obesity in adolescents in the United States.

Methods: 355 adolescents were sampled for obesity and thyroid hormone markers in the 2011 to 2012 NHANES dataset. The 2011 to 2012 NHANES dataset had the most recent information available on thyroid hormones. Percentages, frequency distributions, means (SD) were used as appropriate in describing the socio-economic and demographic characteristics of subjects, thyroid hormone markers and obesity. Multiple linear regression analysis was used to examine the relationship between obesity and independent variables.

Results: BMI was significantly associated with triiodothyronine (TT_3), thyroid stimulating hormone (TSH), family monthly poverty level, and hours spent on computer past 30 days. Waist circumference was significantly associated with TT_3, TSH, and family monthly poverty level.

Conclusions: This study showed that thyroid hormone markers were significantly associated with both obesity indicators, however, further research is warranted on a larger sample size.

Dietary combination of sucrose and linoleic acid synergistically accumulates the intramuscular lipid and decreases the muscle strength in Zucker diabetic fatty rats

Masaki Takikawa[(1)] , Hirokazu Ohminami[(1)], Masashi Masuda[(1)], Yutaka Taketani[(1)]

1. Tokushima University (Japan)

Background and objectives: We have previously found that the dietary combination of sucrose and linoleic acid synergistically induces glucose and lipid metabolism abnormalities, endoplasmic reticulum stress, and inflammatory responses in the skeletal muscle of rats with obesity. We hypothesized that such interactions in skeletal muscle may also affect muscle function. In the present study, we examined the effects of the dietary combinations of carbohydrates and lipids on muscle mass and motor function.

Methods: Five-week-old, female Zucker diabetic fatty rats were fed experimental diets (PO, PL, SO, SL) combining palatinose (P) or sucrose (S) and oleic acid (O) or linoleic acid (L) as major carbohydrate and lipid sources, respectively, for 12 weeks. The motor functions were measured by handgrip and treadmill test.

Results: The SL group showed the synergistic decrease in grip strength compared with the other groups, but there were no differences in muscle weight or mRNA expression of MuRF-1 and Atrogin-1. Interestingly, intramuscular neutral lipids accumulation in the extensor digitorum longus (EDL) muscle, a fast-twitch muscle, was significantly increased in the SL group. Furthermore, a negative correlation was observed between the amount of intramuscular lipid in the EDL muscle and grip strength, suggesting that the SL diet promotes intramuscular lipid accumulation as well as the loss of muscle strength. We examined the expression of genes involved in intracellular uptake and accumulation of lipids and found that they were elevated not only in the SL group but also in the PL group. On the other hand, the expression of genes involved in lipolysis and fatty acid oxidation was not elevated in the SL group, but only in the PL group.

Conclusions: It can be considered that simultaneous ingestion of sucrose and linoleic acid would result in relatively higher lipid synthesis in the EDL muscle, which leads to intramuscular lipid accumulation and that could decrease muscle strength. It was suggested that the dietary combinations of carbohydrates and lipids may contribute to muscle function by differentially affecting lipid metabolism and intramuscular lipid accumulation in obesity.

Influence of extracellular matrix deficiency on effects of vitamin E during recovery from the diet-induced NASH

Tomoko Ishikawa[(1)], Moriaki Kusakabe[(2)], Yoko Fujiwara[(3)]

1. Seitoku University (Japan); 2. University of Tokyo (Japan); 3. Ochanomizu University (Japan)

Background and objectives: Non-alcoholic steatohepatitis (NASH), a lifestyle-related diseases, is predicted to become a major cause of hepatic carcinoma in the future. In particular, hepatic fibrosis is attracting attention as a disease with extremely high unmet medical needs. We have reported that tocotrienol (T3), a vitamin E homologue, reduce inflammation and fibrosis in the early stages of a diet-induced NASH model. The effects of Vit E may be dependent on the hepatic interstitial environment, so we focused on tenascin C (TNC), which is a stromal regulator in wound healing and tumor invasion. In this study, we examined the influence of Vit E administration on the stromal environment during the recovery period from NASH and the influence of deficiency of TNC on the action of Vit E.

Methods: Wild-type (WT) and TNC knock out (TNCKO) BALB/cA male mice were divided into 4 groups, respectively, and fed a choline-deficient, L-amino acid-defined, high-fat diet for 3 weeks. The three recovery groups were fed a high fat diet (HFD), HFD containing 0.08% α-tocopherol (Toc), or 0.08% tocotrienol mixture (T3) for another 2 weeks. Blood samples were collected for biochemical analysis and liver tissues were subjected to morphological and gene expression analysis.

Results: After the recovery period, liver weight, AST and ALT levels were significantly decreased. In histological analysis, crown-like structures were prominent in WT, but less in Toc and T3 groups of TNCKO. In gene expression analysis, *Tgfb*, a major effector of fibrosis, *Pdgfb*, involved in stromal cell proliferation, migration and promotion of fibrosis, and *Vim*, a mesenchymal cell marker, were significantly decreased in Toc and T3 group of WT. In addition, *Dll4*, promotes capillarization and fibrosis, was also significantly decreased. However, *Col1a1* and *Col4a1* expression was not downregulated. In TNCKO, *Col1a1* was significantly decreased, and *Col4a1* tended to decrease during the recovery period, but no specific change was observed in the Toc and T3 groups.

Conclusions: It was suggested that Vit E and TNC deficiency may downregulate excessive fibrosis during the recovery period from NASH, respectively. Further studies are needed on the interactions among these molecules.

GlucoTRIG: measuring the impact of high carbohydrate and high fat composite meals on postprandial insulin and triglyceride responses – a randomised controlled crossover trial protocol

Wen Xin Janice Lim Lim[(1)] , Paul Moughan[(1)] , Pamela von Hurst[(2)], Cathryn Conlon[(2)], Harjinder Singh[(1)], Rohith Thota[(3)], Manohar Garg[(4)]

1. Riddet Institute (New Zealand); 2. Massey University (New Zealand); 3. Macquarie University (Australia); 4. University of Newcastle (Australia)

Background and objectives: GlucoTRIG is a recently developed novel index to rank the healthiness of composite meals by incorporating postprandial insulin and triglycerides responses. This study aims to examine the impact of high carbohydrate and high fat meals on postprandial insulin and triglycerides responses in humans in order to quantify and evaluate the GlucoTRIG values.

Methods: The study is a randomised controlled crossover trial including healthy adult participants (males and females, n=15). The study involves consuming three isocaloric meals (one reference meal and two test meals, Meal 1 and Meal 2) on separate visits of at least one week apart. The three meals comprise of white bread, shredded roast chicken, salad and Thousand Island dressing in different proportions. The reference meal (2001 kJ (477 kcal)) consists of 51.2% carbohydrate, 28.1% fat, 18.2% protein. Meal 1 will be a high-carbohydrate, low-fat meal (2008 kJ (478 kcal)) consisting of 71.4% carbohydrate, 9.4% fat, 17.1% protein. Meal 2 will be a low-carbohydrate, high-fat meal (2002 kJ (477 kcal)) consisting of 34.2% carbohydrate, 44.6% fat, 19.5% protein. At each visit, participants will arrive at the clinic after an overnight fast of at least 12 h. Details of physical activity questionnaire and 24-h food record will be collected. After taking a baseline blood sample at 0 min, participants will be asked to consume the meal within 20 min. Another blood sample will be taken postprandially at 180 min. GlucoTRIG value will be measured as (plasma triglycerides$_{180min}$ x plasma insulin$_{180min}$)-(plasma triglycerides$_{0min}$ x plasma insulin$_{0min}$). Study outcomes will be statistically analysed using repeated-measures analysis of variance (ANOVA, SPSS v28, IBM) and Bonferroni post-hoc test for multiple comparisons if applicable, and data presented as mean ± SEM.

Results: The GlucoTRIG value of each meal will be compared for differences in insulinaemic and lipaemic responses.

Conclusions: The study outcomes will determine if GlucoTRIG is able to detect changes in postprandial insulin and triglycerides after high carbohydrate and high fat composite meals. This project will provide further evidence for GlucoTRIG to be a physiologically relevant index for ranking the healthiness of composite meals for reducing the risk of diet-related metabolic diseases.

Early prediction for newly-diagnosed prediabetes and type 2 diabetes using the genetic risk score and oxidative stress score

Ximei Huang[(1)], Da Hyun Cho[(1)], Youngmin Han[(2)], Minjoo Kim [(1)]

1. Hannam University (Korea); 2. Yonsei University (Korea)

Background and objectives: We aimed to use a genetic risk score (GRS) constructed with prediabetes and type 2 diabetes-related single nucleotide polymorphisms (SNPs) and an oxidative stress score (OSS) to construct an early-prediction model for prediabetes and type 2 diabetes (T2DM) incidence in a Korean population.

Methods: The study population included 549 prediabetes and T2DM patients (cases) and 1,036 normal subjects (controls). The GRS was constructed using six prediabetes and T2DM-related SNPs, and the OSS was composed of three recognized oxidative stress biomarkers.

Results: Among the nine SNPs, six SNPs showed significant associations with the incidence of prediabetes and T2DM. The GRS was profoundly associated with increased prediabetes and T2DM (OR = 1.946, 95% CI = 1.545–2.453) compared with individual SNPs after adjusting for age, sex, and BMI. Three oxidative stress biomarkers, namely, malondialdehyde, oxidized low-density lipoprotein, and 8-epi-prostaglandin $F_{2\alpha}$, were markedly higher in the prediabetes and T2DM group than in the normal group. The OSS was significantly associated with increased prediabetes and T2DM (OR = 2.270, 95% CI = 1.865–2.764). Through stepwise linear regression analysis, we found BMI to be the most relevant factor for increasing the risk of prediabetes and T2DM. Based on the results of a receiver operating characteristic (ROC) curve analysis, the area under the ROC curve (AUROC) improved when BMI was added to the model with the OSS and GRS (from 69.3% to 70.5%).

Conclusions: We found that in subjects with prediabetes and T2DM, the GRS and a high OSS might indicate a higher risk of prediabetes and T2DM. The prediction model composed of the OSS, GRS, and BMI showed a significant prediction ability for the incidence of prediabetes and T2DM.

Circulating Adipokines and Gamma-Glutamyl Transferase As Markers Associated With Metabolic Syndrome in Mexican Children Aged 6 to 12 Years

Elizabeth Solis[(1)], Ana Maria Mar-Buruato [(1)] , Blanca E. González-Martínez [(1)] , Fernando Javier Lavalle-González[(1)], Jesús Zacarías Villarreal-Pérez[(1)], Juan Pablo Nuñez-Sánchez [(1)]

1. UANL University (Mexico)

Background and objectives: Obesity and metabolic syndrome are prevalent diseases in children. Circulating leptin, adiponectin, tumor necrosis factor alpha (TNF-α), interleukin 6 (IL-6), and gamma-glutamyl transferase (GGT) are markers associated with cardiometabolic diseases in adults. However, there is a lack of scientific evidence in children. Identifying these markers, which are non-invasive and allow early detection of these diseases, becomes crucial. We examined the association between circulating adipokines and GGT with the metabolic syndrome in Mexican children.

Methods: The non-probabilistic sample was 140 children aged 6 to 12 from Nuevo León, México. Nutritional assessment was performed using BMI Z-score from the WHO; the criteria for metabolic syndrome for children were from the IDF. Blood samples were obtained by puncturing the antecubital vein with a 12-hour fast. Serum levels of leptin, adiponectin, TNF-α and IL-6 were measured with the Luminex® xMAP® RIA Kit, and the GGT by kinetic reaction with the Dxc Beckman Coulter equipment. A multivariate statistical analysis was carried out to identify the association with this syndrome, using Student's T-Test and Simple Linear Regression with the IBM SPSS® software.

Results: 60 children (43%) presented overweight/obesity; 33 obese children were diagnosed with metabolic syndrome (55%). Leptin showed a significant association with waist circumference (P=0.00), systolic blood pressure (P=0.00), serum glucose (P=0.02), serum triglycerides (P=0.00) and HDL cholesterol (P=0.00). Adiponectin showed a significant association with waist circumference (P=0.00), systolic blood pressure (P=0.00), serum triglycerides (P=0.00), and HDL cholesterol (P=0.00). GGT showed a significant association with waist circumference (P=0.00) and HDL cholesterol (P=0.006); IL-6 only showed a significant association with HDL cholesterol (P=0.03) and TNF-α did not show a significant association with any of the components of the metabolic syndrome.

Conclusions: The main components of the metabolic syndrome associated to leptin, adiponectin and GGT are waist circumference and HDL cholesterol. The levels of TNF-α and IL-6 did not show a significant association in children with metabolic syndrome. The study highlights the clinical importance of circulating adipokines and GGT as early markers associated with metabolic syndrome in children.

Keywords: Obese children, metabolic syndrome, adipokines, gamma-glutamyl transferase

Orally supplemented of N-acetylneuraminic acid regulates adipocyte function and prevents obesity

Tomoko Kaburagi [(1)], Yuko Otsuka[(1)], Satoru Oshiro[(1)]

1. Daito Bunka University (Japan)

Background and objectives: N-acetylneuramic acid (NANA), a type of sialic acid, is a component present at the end of glycan chains. Our previous study found that NANA regulates adipocyte function, and its levels have been found to reduce in adipocyte due to obesity. In the present study, we investigated the effects of exogenous NANA addition on adipocyte function, in vivo and vitro.

Methods: Male C57BL6 mice were fed a high-fat diet (HFD) containing 1% NANA for 12 weeks, followed by analysis; (1) the sialylated protein expression in adipose tissue (AT), (2) the mRNA expression of lipid metabolism related genes and antioxidant enzyme genes in AT, (3) the morphological change of AT and liver, and (4) the serum biochemical markers. To observe the direct effects of exogenous NANA addition to adipocytes, 3T3-L1 cells were cultured with 1-1000 µg / ml NANA added.

Results: NANA supplementation inhibited body weight gain and hypertrophy of epididymal ATs induced by HFD. In mRNA levels of epididymal AT, NANA attenuated the reduction of *AdipoQ* and *Sod1*, and an increase of *Fabp4* by HFD. The Increase in serum total cholesterol and free fatty acid levels, and hepatic lipid droplets induced by HFD were reduced upon NANA intake. Notably, NANA supplementation significantly increased lipid accumulation, and not affected to antioxidant enzyme gene expressions in 3T3-L1 adipocytes. NANA level was not affected by glycosyltransferase *St6gal1* gene expression and level of sialylated protein in epididymal AT and 3T3-L1 adipocytes.

Conclusions: NANA intake may prevent obesity and obesity-related disorders via suppression of adipocyte dysfunction induced by HFD. Furthermore, these phenomena may represent indirect effect of NANA supplementation on adipocytes.

Evaluation of plasma alkaline phosphatase isoenzyme as an initial diagnostic biomarker for high fructose diet-induced metabolic syndrome using rat model

Yusuke Suzuki [(1)], Daigo Yokoyama [(1)], Hiroyuki Sakakibara [(1)]

1. Miyazaki University (Japan)

Background and objectives: High-fructose corn syrup is a liquid sugar refined from corn, potato, and other starches and consists of 50% glucose and 50% fructose. Many studies have shown that excessive fructose intake induces an increase in liver and blood triglyceride concentrations in both humans and rats and is one of the important risk factors for metabolic syndrome. Therefore, to prevent the development of metabolic syndrome from excessive fructose intake, it is necessary to know the physiological and pathological alterations that occur when excess fructose is consumed on a daily basis. In this study, rats were fed a high-fructose diet (HFD) *ad libitum* for 4 weeks to induce metabolic syndrome and the plasma hepatotoxicity markers and isozyme activities were analyzed over time to evaluate possible biomarkers that could be used for early and convenient monitoring of the effects of fructose.

Methods: Male rats were fed *ad libitum* on a 63% HFD for 4 weeks. Blood samples were taken before and every week after the start of feeding, and plasma samples were collected. The plasma samples were analyzed for hepatotoxicity markers, glycolipid system markers, and alkaline phosphatase (ALP) isozymes. After the final blood collection, autopsies were performed, and the liver, duodenum, jejunum, and ileum were collected for histopathological examination. In addition, duodenum was also used to measurement of mRNA expression for small intestinal tight junction-related protein by reverse transcription-polymerase chain reaction.

Results: As the result of feeding an HFD to the rats for 4 weeks, the livers showed increased weights, increased periportal vacuolation and macrovesicular fatty change in the hepatocytes, while the plasma lipid parameters and hepatotoxicity markers were also increased. In addition, increases in plasma liver-type ALP isozyme activities and decreases in plasma small intestinal-type ALP isozyme activities were noted soon after the start of feeding, even though total plasma ALP activity was not affected.

Conclusions: Our results clearly indicate that plasma ALP isozyme analysis could be a useful biomarker to predict the physiological effects of ingested fructose both on the liver and also on the small intestine at an early stage of the development of metabolic syndrome.

Effect of Intermittent fasting on weight and glucose control in Type 2 Diabetes Mellitus patients

Raweewan Lappichetpaiboon[(1)], Jatupahat Punjamat[(1)], Suthasinee Soonthornchai [(1)], Kanokporn Wonganankit[(1)]

1. Fort Nawamintharachinee hospital (Thailand)

Background and objectives: Numerous studies suggest that excess body weight is associated with delay the onset of Type 2 Diabetes Mellitus (T2DM). Nowadays, trend of healthy lifestyle is the global trend but the study on the effect of intermittent fasting (IF) in chronic illness like type 2 diabetes are limitation. This study was designed to investigate the relation between the blood sugar levels and the weight control by using intermittent fasting in type 2 Diabetes Meletus (T2DM) patients.

Methods: The Method of this study was under the health policy of Chon Buri province. Participants were five patients, who had diagnosis of T2DM and taking Diabetes Mellitus (DM) medicine. Participants were excluded if they had complication of T2DM, kidney disease and history of severe hypoglycemia. The three phase (baseline, intervention and follow up) observational study was designed. Participants reported their meals by photography to the online chat group throughout study stage. The fasting duration were set for participant. The self-monitored blood glucose in morning, afternoon and evening was reported twice week. The online consultation group was created for communicate between participant and the health care professional team. Every month participants were come to hospital for blood checkup and get individually nutrition intervention with dietitian.

Results: The five participants on average were overweight (Mean body mass index (BMI) 28.55kg/m^2). Average of blood glucose was decrease 36.8 mmol/dL. Three participants can reduce DM medicine. Two of all participants decrease in weight. IF led to overall spontaneous decrease in carbohydrate and caloric intake when compared with baseline as measured by food photography. Two of five participants would continue with modified IF after this study.

Conclusions: The result from this pilot study indicated that IF may improve the body weight and fasting glucose levels in T2DM. These finding should be explored for the larger and longer study.

A delayed eating schedule elevates the daily glucose level but not glycemic variability – randomized crossover study –

Yoichi Hatamoto[1,2], Yukiya Tanoue[2], Eiichi Yoshimura [1]

1. National Institutes of Biomedical Innovation, Health and Nutrition National Institute of Health and Nutrition (Japan); 2. The Fukuoka University Institute for Physical Activity (Japan)

Background and objectives: Skipping breakfast (BS) and late-night eating (LNE) are independently related with increased risk of type 2 diabetes. However, previous studies reported that both factors often occur at the same time (i.e., BS and LNE: delayed eating schedule) and it is also associated with metabolic syndrome. Additionally, although the influence of BS or LNE on diurnal blood glucose profiles was examined, respectively, there are no study about examining the influence of a delayed eating schedule on its. The aim of this study was to clarify the influence of eight consecutive days of "delayed eating schedule" on diurnal blood glucose profiles using continuous glucose monitors (CGM).

Methods: Eight healthy young men [mean (SD); age: 20.9 (0.8) years; BMI: 21.3 (1.8)kg/m^2; HbA1c: 21.3 (0.3)] participated in the two different feeding schedules for 8 days in a randomized crossover study. The participants were asked to start eating within the time as below; (1) Common feeding schedule (intake limited to Breakfast: 7:30-8:30, Lunch: 12:00-13:00, Dinner: 19:00-20:00) and (2) Late feeding schedule (intake limited to Lunch: 12:00-13:00, Supper: 16:30-17:30, Late-night eating: 23:00-24:00). The participants were served three meals with comparable energy and macronutrient contents during eight days in both interventions. The participants were also asked to keep sleep-wake cycles and exercise levels. At each intervention from Day 8 to 9, the experiments to assess the glucose parameters (markers of glycemic variability and levels) using the CGM (iPro2, Medtronic, Northridge, CA, USA) were performed under the highly controlled conditions in the laboratory.

Results: Glucose values of 24-h average, fasting and sleeping period were significantly higher on the Late feeding schedule compared to the Common feeding schedule ($p<0.05$). However, postprandial peak values except for breakfast, incremental area under the curve and markers of glycemic variability (MAGE: mean amplitude of glycaemic excursions and SD) were not differentially altered by the eating schedules.

Conclusions: The present study showed that delayed eating schedule elevated the average glucose level but not glycemic fluctuation. Delayed eating schedule may be part of the reason for the increased risk of diabetes.

Keywords: Late-night eating, continuous glucose monitoring system, meal timing, glucose fluctuation, randomized crossover study

Micronutrient deficiencies after Roux-en-Y gastric bypass versus sleeve gastrectomy in patients with obesity: A systematic review

Yeongkeun Kwon [1], Jane Ha[1], Sungsoo Park [1]

1. Korea University (Korea)

Background and objectives: Postoperative micronutrient deficiencies are a significant concern in bariatric surgery. Although Roux-en-Y gastric bypass (RYGB) and sleeve gastrectomy (SG) are the most prevalent bariatric surgical procedures, high-level evidence is scarce regarding the assessment of postoperative nutritional risk in RYGB versus SG. We compared the risk of micronutrient deficiencies after RYGB versus SG.

Methods: A systematic literature search was conducted for relevant studies published before Oct 25, 2021. Randomized controlled trials comparing RYGB and SG with reported incidence of postoperative micronutrient deficiencies (iron, vitamin B_{12}, or folate). The DerSimonian and Laird random-effects method was used to estimate the relative risk (RR) of postoperative micronutrient deficiencies after RYGB compared to SG.

Results: Nine randomized controlled trials involving 1160 participants were analyzed. There were no significant differences in the risk of postoperative iron deficiency (RR, 1.21; 95% CI, 0.95–1.60; *P* =.059; high level of evidence), or folate deficiency (RR, 0.69; 95% CI, 0.42–1.31; *P* =.321; moderate level of evidence). Patients undergoing RYGB had a higher risk of postoperative vitamin B_{12} deficiency than those undergoing SG (RR, 1.91; 95% CI, 1.18–2.98; *P* =.011; high level of evidence).

Conclusions: RYGB and SG have comparable risks of postoperative iron deficiency and folate deficiency. A higher risk of vitamin B_{12} deficiency was observed in RYGB than in SG, which implies that patients undergoing RYGB require more stringent vitamin B_{12} supplementation and surveillance than those undergoing SG. Healthcare professionals need to consider our findings in the assessment of postoperative nutritional risk of RYGB and SG for the appropriate selection of bariatric surgical procedures.

Effect of Whey Protein Intake after Resistance Exercise on Skeletal Muscle Mass, Strength, and Quality of Life in Older Adults with Sarcopenia: A Randomized Controlled Trial

Hiroyasu Mori [(1)], Yasunobu Tokuda [(2,3)]

1. Tokushima University (Japan); 2. Hyogo Locomotion-senior-tera-koya, General incorporated association (Japan); 3. Hyogo University (Japan)

Background and objectives: Previous studies have not clarified the treatment of older adults with sarcopenia. This study aimed to evaluate the effectiveness of a 24-week nutritional program with whey protein intake after resistance exercise to treat older adults with sarcopenia and improve their quality of life (QOL).

Methods: Eighty-one older adults aged ≧65 years from Hyogo, Japan were included in this three–arm, stratified, randomized, open–label, parallel–group trial performed over 24-weeks. Sarcopenia was defined by the Asian Working Group for sarcopenia criteria: low hand-grip strength or slow gait speed, and low skeletal muscle mass index (SMI). The study was approved by the ethics committee of Tokushima University. The participants were allocated to one of three groups: whey protein supplementation after exercise (Ex +Whey; n=27) group, exercise (Ex; n=27) group, and whey protein supplementation (Whey; n=27) group. A 24-week program of resistance exercise was carried out twice a week. Whey protein supplementation was 11.0 g of protein and 2,300 mg of leucine. The total energy and protein intake amounts for participants in all groups were controlled to reach at least 30 kcal/kg ideal body weight/day and 1.2 g/kg ideal body weight/day, respectively, during the intervention period.

Results: After the 24-week intervention period, the Ex +Whey group had a lower prevalence of sarcopenia (pre–intervention: 100 %, post-intervention: 60.9%, $p<0.01$) and greater physical QOL scores ($p<0.05$). The prevalence of low SMI (pre–intervention: 100 %, post-intervention: 73.9%, $p<0.05$) and low grip strength (pre–intervention: 100 %, post-intervention: 69.6%, $p<0.05$) was lower in the Ex +Whey group. The Whey and Ex groups showed no decrease in the prevalence of low SMI and low grip strength and no improvement in the QOL scores. These results suggest that a combination of resistance exercise and whey protein intake in older adults with sarcopenia improves multiple outcome measures, including low SMI, low grip strength, and physical QOL.

Conclusions: We demonstrated that a 24-week intervention comprising whey protein intake and resistance exercise increased muscle mass, strength, and QOL in older adults with sarcopenia.

Keywords: Sarcopenia, Whey protein, Exercise, Quality of life, Randomized controlled trial

The Association of β-Carotene Intake with Mild Cognitive Impairment: the Toon Health Study

Jun Ishiki [(1)], Koutastu Maruyama [(1)], Kiyohide Tomooka [(2)], Takeshi Tanigawa [(2)], Isao Saito[(3)]

1. Ehime University (Japan); 2. Juntendo University (Japan); 3. Oita University (Japan)

Background: Previous researches reported that carotenoids have antioxidant effects, and oxidative stress is associated with dementia. However, there were few evidence of the association between carotenoid intake and cognitive function or dementia. Thus, we examined the association between β-carotene intake with mild cognitive impairment (MCI) for elderly Japanese men and women.

Methods: We conducted a cross-sectional study with 438 men and 723 women aged 60-84 years who participated in the Toon Health Study from 2014 to 2018. The intakes of food group and nutrient were estimated by food frequency questionnaire, and the energy intake was adjusted via residual method. We calculated the multivariable odds ratio (OR) and 95% confidential intervals (CIs) of MCI according to sex-specific quartiles of β-carotene intake after adjustment for age, sex, education level, current drinking and smoking, diabetes, hypertension, sleep duration, physical activity, and intakes of energy, vitamin E and vitamin C by logistic regression model. Furthermore, we conducted the analyses stratified by median-split vitamin C intake which has antioxidant effects.

Results: Higher β-carotene intake tended to be associated with lower odds of MCI in whole individuals. The multivariable-adjusted OR (95%CI) of MCI for the highest quartile compared to the lowest quartile was 0.72 (0.50-1.03, p for trend= 0.11). After stratification by vitamin C intake, higher β-carotene intake was associated with lower odds of MCI in individuals with low vitamin C intake; the multivariable-adjusted OR (95%CI) of MCI for the highest quartile compared to the lowest quartile was 0.11 (0.02-0.55, p for trend= 0.04).

Conclusion: In this study, we found that higher β-carotene intake was associated with lower risk of MCI in individuals with low vitamin C intake.

Keywords: MCI, carotenoid, vitamin C, antioxidant

Necessity and barriers of shared decision-making in nutritional dietary guidance for the elderly from the perspective of a registered dietitian

Yuki Tamaura [(1)], Keiko Fujiwara [(2)], Kazuhiro Nishimura [(2,3)]

1. University of Niigata Prefecture (Japan); 2. Ryokufuso Hospital (Japan); 3. Komazawa Women's University (Japan)

Background and objectives: Shared decision-making (SDM) is an increasingly important process for medical providers to increase successful dietary adherence in patients, especially in older adults with chronic diseases. This study aimed to examine when dietitians feel SDM is necessary in dietary counseling, and the barriers to implementation; and to facilitate beneficial SDM for dietary counseling, especially for older patients.

Methods: From July to August 2021, an anonymous self-administered questionnaire survey was conducted online for registered dietitians engaged in dietary counseling at hospitals near the Kanto region. From the answers asked about the point of difficulty in dietary counseling for older patients, 1) situations requiring SDM and 2) barriers for implementing SDM were extracted using qualitative descriptive methods.

Results: The mean number of years of experiences among 75 participants was 12.5 (standard deviation=9.8) years, and 77.3% and 50.7% participants were engaged in metabolic diseases and malnutrition dietary counseling, respectively, at least once a week. Two categories including “Balance between dietary therapy and age, prognosis, and QOL (N=8)” were extracted for “situations requiring SDM”. “Barriers for implementing SDM” were ordered into dietitian/ organizational related factors (5 categories) and patient related factors (8 categories). One of the two categories in dietitian related factors was named “Beliefs of capabilities”, which included two subcategories, “Methods of conveying (e.g., choosing words)” and “Attention and decision processes based on patient's preference and situations (e.g., changing long-standing eating habits to maintain patient satisfaction)”. Additionally, “Health literacy (N=28)” and another seven categories were extracted as patient related factors.

Conclusions: This study suggested the need for implementation of SDM in dietary management/ restriction in dietary counseling for older patients. An approach that considers both dietitian/ organizational related factors and patient related factors when decreasing barriers is desired.

Keywords: Shared decision making, registered dietitian, qualitative study

Texture and sensory evaluation of whey protein jellies for nutritional care in the elderly

Momoko Kasuya[1], Narumi Takeyama[1], Shiori Tokuda[1], Mai Nakane[1], Masami Maeno[2], Yuka Tachibana[1], Shiori Nakanishi[1], Kayoko Yamazak[1], Atsuko Kiyama[1], Naoko Komenami[1]

1. Kyoto Women's University (Japan); 2. Nukumorinosato (Japan)

Background and objectives: The elderly are at risk of undernutrition due to deterioration of swallowing function, loss of appetite with aging, and social factors. The aim of this study was to contribute to improving energy and nutrition intake in the elderly to prevent frailty and sarcopenia. We prepared protein jellies containing whey protein and examined whether they are suitable snacks for the elderly through sensory evaluation and texture measurement.

Methods: Protein jellies (orange, apple, grape, grapefruit, and pineapple flavor) were prepared as snacks and sensory evaluation was performed for appearance, taste, aroma, stickiness, smoothness, hardness, ease of swallowing, and overall evaluation in 13 female students. Two improvement plans were then made for the snacks, and the same sensory evaluation was performed in 14 female students. The textures of hardness, cohesiveness, and adhesiveness were measured using a creepmeter (RE2-3305S, Yamaden). The proportion willing to eat the jellies from the two improvement plans was investigated in 78 elderly residents of a long-term care facility.

Results: Grape-flavored protein jelly was rated worst in terms of preference. The orange-, apple-, grapefruit-, and pineapple-flavored jelly retained their aroma and acidity when protein was added, but the grape flavor had weak aroma and acidity. Two improvements plans were made to improve the taste of the grape-flavored protein jelly: (1) enhancing acidity and sweetness by adding lemon juice and sugar to grape juice and (2) sprinkling grape sauce on a lemon-flavored protein jelly. The hardness and adhesiveness of all five types of protein jellies were low, but the cohesiveness was high due to the addition of protein. Classifications of the protein jellies according to the Dysphagia Diet Pyramid ranged from Level 0 to Level 3. The proportion willing to eat the protein jellies was 95.7% for improvement plan 1 and 97.8% for improvement plan 2.

Conclusions: These results suggest that the fruit protein jellies are appropriate snacks for the elderly to take in protein from the perspectives of taste and texture.

Inhibitory effects of tocotrienols on obesity development and obesity-related cognitive impairment

Yugo Kato[1], Koji Fukui[1]

1. Shibaura Institute of Technology (Japan)

Background: Prevalence of overweight or obesity has been increasing in not only developed countries but also developing countries, and obesity accelerates sever diseases onset and aging. Some natural compounds are focused by researchers to prevent obesity. Obesity also recognized as a risk factor of cognitive dysfunction. However, the detailed mechanisms of obesity-related cognitive impairment have not been elucidated. The elevation of brain oxidative level has been known as a cause of obesity development and cognitive decline, and calorie restriction attenuates body weight gain and accumulation of oxidative damage. From these evidences, we focused on tocotrienols (T3s), which are a part of vitamin E family and have antioxidant function, for attenuation of obesity and obesity-induced cognitive dysfunction.

Methods: C57BL/6 male mice (4 or 36 weeks of age) were fed high-fat diet (HFD) or high-fat high-sucrose diet (HFSD) in the presence or absence of T3s (10 or 50mg/100g diet) for 8 or 20 weeks. After treatment duration, the cognitive functions were measured using the Morris water maze and Rota rod test before dissection. To clear anti-obesity effect of T3s, changes in body and white adipose tissue weights, food intake volume, liver lipid droplets, serum parameters and energy metabolism were measured. Additionally, to investigate the relationship between obesity and brain oxidation, the lipid peroxide and 3-NT levels were measured.

Results: Treatment with HFD or HFSD significantly induced body weight gain compared to the controls. Additionally, treatment with T3s significantly increased energy metabolism and attenuated the increase of body weight, white adipose tissue weight, lipid droplet and serum cholesterol concentrations. The cognition of HFD-treated mice was not changed. On the other hands, the cognitions were significantly decreased, and the brain oxidation levels were significantly increased in HFSD-treated mice, and T3s significantly inhibited them.

Conclusions: This study revealed that T3s exhibit anti-obesity effects in diet-induced obesity model mice, and obesity induces cognitive dysfunction via brain oxidation, and T3s are effective for the attenuation of obesity-related cognitive decline.

Association between predicted body fat mass and mild cognitive impairment among community-dwelling Japanese men and women: the Toon Health Study

Saori Miyazaki[1], Koutatsu Maruyama[1], Kiyohide Tomooka[2], Takeshi Tanigawa[2], Isao Saito[3]

1. Ehime University (Japan); 2. Juntendo University (Japan); 3. Oita University (Japan)

Background and objectives: Recent studies reports that obesity is associated with developing dementia and mild cognitive impairment (MCI). However, few studies have reported the association between body fat mass and MCI. Therefore, the aim of present study was to examine the association between predicted body fat mass and MCI among community-dwelling Japanese men and women.

Methods: This cross-sectional study included 1,116 men and women aged 60-84 years in the Toon Health Study from 2014 to 2018. MCI was assessed by the Japanese version of Montreal Cognitive Assessment. Body fat mass was predicted by measured skinfold thickness (the back of the upper arm, lower scapula, and abdomen). Multivariate adjusted odds ratios (OR) and 95% confidence interval (CI) of MCI for sex-specific quintiles of predicted body fat mass were calculated by logistic regression models adjusted for sex, age, current drinking, smoking status, physical activity, educational status, diabetes mellitus, hypertension, and height.

Results: In this subjects, 421 participants were defined as MCI. We found that higher predicted body fat mass was associated with higher odds of MCI. The multivariable adjusted OR (95%CI) of MCI for highest quintile was 1.54 (1.01-2.36, p for trend = 0.03) compared with lowest quintile.

Conclusions: This study showed that higher predicted body fat mass may increase presence of MCI in community-dwelling Japanese men and women.

Keywords: Body fat mass, mild cognitive impairment, skinfold thickness

The Association Between N-3 Fatty Acids Intake and Risk of Dementia: A Systematic Review and Meta-Analysis

Salsabila Khairunnisa[1], Satomi Inokawa[1], Koutatsu Maruyama[1]

1. Ehime University (Japan)

Background and Objectives: Dementia refers to a collection of pathologies affecting the nervous system leading to an irreversible cognitive decline and loss of independence. Costs associated with this condition was high and cure was also

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

unavailable which necessitated an effective prevention strategy, one of which was through a nutritional approach. Previous studies found that intake of n-3 fatty acids (FA) may protect cognition, but association with dementia remained inconclusive. Therefore, we aimed to clarify the association between n-3 FA intake and dementia risk in cohort studies via systematic review and meta-analysis.

Methods: The primary exposure and outcome of interest were dietary n-3 fatty acids intake and dementia and Alzheimer's disease (AD) risk respectively. Studies were searched in PubMed, Google Scholar, and previous reviews from conception to March 2021. Inclusion criteria includes cohort study design, exposure from dietary intake of n-3 FA, and provide risk estimates and 95% confidence interval (CI) of dementia and/or AD. Pooled risk ratio was generated using random-effects model.

Result: Our search identified 9 studies fitting the inclusion criteria. The 9 studies included in the review consisted of 4 studies with dementia and AD as primary outcomes, 2 studies with dementia as primary outcome, and 3 studies with AD as primary outcome. We conducted the analysis for dementia and AD separately. Seven studies were included in the analysis for AD. Total subjects included was 446,798 with 3,410 dementia cases, of which 2,868 were AD cases. Increasing intake of n-3 FA was shown to be associated negatively with risk of dementia (pooled RR=0.75 (95% CI:0.57, 0.98), p=0.04) and AD (pooled RR=0.69 (95%CI:0.53, 0.91), p=0.008). However, we also found a significant inter-study heterogeneity (Dementia= I^2=74%, p=0.002; AD=I^2=76%, p=0.0003).

Conclusion: Considering the significant heterogeneity present in the study, it is advisable to interpret the result with caution. The present study demonstrated that increasing intake of n-3 fatty acids was negatively associated with risk of dementia and AD.

Effects of a balanced diet on blood parameters affecting bone density

Anna-Liisa Tamm[1], Ulle Parm[1], Kaisa Lohu[1], Triin Aasmäe[1], Kaido Liiv[1], Aivar Orav[1], Maire Aruots[1], Taimi Taimalu[1]

1. Tartu Health Care College (Estonia)

Background and objectives: Bone mineral density (BMD) deficiency and osteoporosis are common among women around the world. Different diets can provide adequate calories, but still lack various micronutrients, which also affect BMD. The aim of the study was to find out the reflection of the availability of microelements influencing women's BMD in blood analysis following the Fitlap diet, which is widely used in Estonia.

Methods: The study included adult women (excluding menopause) who followed the Fitlap diet (FDF) for at least three years and the same-aged controls who did not monitor nor restricted their diet. Participants completed questionnaire, incl. dietary recalls, which were analyzed with the Nutridata System for Research (www.nutridata.ee). Calcium, magnesium, vitamins D and B12 were measured from the fasting blood samples. Continuous data and proportions were compared by t-test and Chi-square, respectively; the influences were calculated by linear regression analyses.

Results: A total of 34 adult (22–48y) female FDF and same-aged controls were enrolled to the study. Energy consumption was similar; but FDF consumed more protein (p<0.001), fiber (p<0.001), calcium (p<0.001), and magnesium (p=0.007) than controls. The micronutrient levels of Fitlap diets in the blood did not differ significantly except for vitamin B12 (FDF *vs* controls p=0.001). The average serum vitamin D and calcium levels were mostly in accordance to reference values (50–250 nmol/L and 2.0–2.8 mmol/L, respectively) in both study groups despite the fact that, according to the menu analysis, dietary calcium intake was below the recommended intake (1000 mg/day). One FDF had calcium and 8 participants (7 controls and 1 FDF) vitamin D serum level under the recommendations. Results of regression analysis showed, that FDF are influenced to consume more fibers (coef 6.49; p<0.001) and proteins (coef 20.12; p<0.001); and it influenced also fat-free mass (coef 3674.8; p=0.008) and vitamin B12 value (coef 184.98; p<0.001). The additionally consumed magnesium decreased the magnesium (coef -0.03; p=0.05) and the intake of calcium in diet decreased the calcium value in blood (coef -0.0002; p=0.02).

Conclusion: Regular adherence to a balanced diet can benefit micronutrient intake (calcium and magnesium).

Keywords: Diet, nutrients, bone mineral density, women

The association between resting energy expenditure (REE) and phase angle (PhA) in older patients hospitalized on internal medicine: A Cross-Sectional Study

Fumiya Kawase[1,2], Yoshiyuki Masaki[3,4], Hiroko Ozawa[5], Manami Imanaka[4], Aoi Sugiyama[4], Hironari Wada[6], Shinya Kobayashi[3], Takayoshi Tsukahara[2]

1. Department of Nutrition, Asuke Hospital Aichi Prefectural Welfare Federation of Agricultural Cooperatives (Japan); 2. Graduate School of Nutritional Science, Nagoya University of Arts and Sciences (Japan); 3. Department of Internal medicine, Asuke Hospital Aichi Prefectural Welfare Federation of Agricultural Cooperatives (Japan); 4. Department of Community-based Medical Education, Nagoya City University Graduate School of Medical Sciences (Japan); 5. Department of Nursing, Asuke Hospital Aichi Prefectural Welfare Federation of Agricultural Cooperatives (Japan); 6. Department of Rehabilitation Therapy, Asuke Hospital Aichi Prefectural Welfare Federation of Agricultural Cooperatives (Japan)

Background and objectives: The resting energy expenditure (REE) is the main part of total energy expenditure. In an older patient, better clinical outcomes may be achieved through individualized nutritional management with energy

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

requirements calculated by REE. REE has been shown to decrease with aging, but the effect cannot be explained by a decline in skeletal muscle mass alone. The phase angle (PhA) can be measured using bioelectrical impedance analysis (BIA). Because the PhA has been associated with sarcopenia, nutritional status, mortality, and age, it may be a determinant of REE. Therefore, in this study, we aimed to investigate the association between REE and PhA in older hospitalized patients.

Methods: In this single–center, cross–sectional study, patients aged 70 years or older admitted to an internal medicine unit were included. REE was measured using indirect calorimetry (IC) (AE−300S) after fasting for at least 12 hours. Body composition was measured using BIA (Inbody S10) for PhA and skeletal muscle mass index (SMI). Generalized linear models were used to calculate standardized β (95% confidence interval) for REE and PhA adjusted for age, sex, and SMI. In addition, patients were classified into two groups using validated PhA cutoff values to compare the difference in REE.

Results: Totally, 110 patients were included (mean age 88.1 ± 6.7 years; 39% male). The previously reported cutoff values were used, and 53.6% of patients were classified into the low PhA group. In the generalized linear model, REE and PhA were significantly associated (0.173 [0.016, 0.330] p<0.033). Furthermore, the mean (95%CI) REEs were 884.9 (842.0, 927.8) kcal/day and 1066.6 (1021.9, 1111.3) kcal/day in the low and high PhA groups, respectively, with significant differences remaining after adjustment for age, sex, and SMI (P<0.049).

Conclusion: In older hospitalized patients, REE was associated with PhA and independently associated with body composition. Therefore, in the calculation of energy requirements, it may be necessary to consider PhA. Further research is needed to investigate the possibility that body composition and PhA may mediate the effects of aging on REE.

The improving effects of nutrition supplement drink on nutritional status in elderly with middle and high risk of malnutrition

Che-Yu Lee[1], Yi-Hsiu Chen[1], Qian Xiao[1], Min-Yu Ting[2], Suh-Ching Yang[1]

1. Taipei Medical University (Taiwan); 2. Jia-yin nutrition consulting center (Taiwan)

Background: Enough energy and protein intake can improve sarcopenia and frailty in elderly. On the other hand, around 20% of nursing home residents had malnutrition and around 50% in the high risk of malnutrition in Taiwan. Therefore, the purpose of this study is to evaluate the improving effects of nutrition supplement drink on nutritional status in elderly.

Materials and methods: This study was a randomized, parallel, multi-center clinical trial. One hundred participants with middle and high risk of malnutrition were recruited from several nursing homes in this study. Participants aged more than 65 years old were divided into two groups; one is nutritional education intervention (NE) group (n=50) and the other one is nutritional supplement drink (NSD) group (n=50), and the experimental period was 12 weeks. The participants of NE group accepted the nutritional education by dietitian. NSD group was provided with two packs of nutritional supplement drink (Mei Balance, Meiji Holdings Company, Japan) per day as a snack between meals and before bed. Body composition, muscle strength test and nutritional status and blood biomarkers were evaluated at the baseline, 6th week and the end of study.

Results: After 12 weeks of intervention, the score of the mini nutritional assessment short form (MNA-SF) and study of osteoporotic fractures (SOF) were significantly improved in NSD group when compared to the baseline. NSD group had also significantly higher body mass index (BMI) and lower 6-m usual walking speed test when compared to the baseline. There were no differences but a trend of higher body fat ratio, skeletal muscle ratio and serum albumin between baseline and the end point in NSD group.

Conclusion: In conclusion, nutrition supplement drink could significantly increase BMI and MNA-SF as well as improve physical performance such as SOF and 6-m usual walking test in elderly with middle and high risk of malnutrition.

Practices and Outcomes of Nutritional Support Focused on Menu Improvement in a Dementia Group Home

Kenichiro Yasutake[1], Marina Kawano[1], Shintaro Ohta[1], Kyoka Fujii[1]

1. Nakamura Gakuen University (Japan)

Background and objectives: Dementia group homes in Japan (group homes) are not required to have a dietician or registered dietitian on staff, and the nutritional value of the meals served in many group homes is not calculated, so the quality of the menus needs to be improved. Therefore, this study aimed to examine whether nutritional support for group homes would improve the quality of menus.

Methods: The target facilities were five group homes (A, B, C: intervention facilities and D, E: non-intervention facilities). Nutritional support was provided to the intervention facilities beginning in April 2019 at a frequency of once per week for six months, including nutritional assessment of residents, advice based on the implemented menu, recipe suggestions, and joint cooking by residents and caregivers. The average daily number of foods used in the implemented menus during the month was defined as the quality of the menus. It was calculated at baseline (October 2018) before the intervention period and at endline

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

(October 2019) after the intervention period and compared with and without intervention. The average number of foods per day was calculated for 14 groups (seafood, meat, eggs, milk, soy products, green and yellow vegetables, light-colored vegetables, seaweed, mushrooms, potatoes, grains, fruits, oils and fats, and confectionery) based on previous studies.

Results: There were no significant differences in residents' age, BMI, sex, and level of independence in daily living between the intervention and non-intervention facilities. There was no significant difference in the average daily number of foods used at baselines at both facilities [intervention facilities: 25.5±4.1 vs. non-intervention facilities: 25.5±2.8, *P*=0.795], however at the end line, intervention facilities were significantly higher than non-intervention facilities [intervention facilities: 26.6±4.0 vs. non-intervention facilities: 24.9±3.0, *P*=0.007]. In addition, the average daily number of foods used at the intervention facility increased significantly during the period [baseline: 25.5±4.1 to endline: 26.6±4.0, *P*=0.026], while no significant change was observed at the non-intervention facility.

Conclusions: It was suggested that six months of nutritional support at group homes could improve the average daily number of foods in the menu and improve the quality of the menu.

Effect of phosphatidylserine on cognitive function in the elderly: A systematic review and meta-analysis

Jihye Jang[1], EunYoung Kang[1], Fengjiao Cui[1], Gwang-woong Go[1]

1. Hanyang University, Seoul, Korea (Korea)

Background and objectives: Phosphatidylserine (PS), a vital component of the cerebral cortex, is involved in cognitive function. This systematic review aims to evaluate the efficacy of PS on cognitive function in the elderly.

Methods: The literature was searched in PubMed, EMBASE, Cochrane, and Web of Science, using "Phosphatidylserine" as a keyword. The present study was conducted only in literature that is a clinical study regarding humans, elderly participants, an indication of PS content, and oral administration. We screened literature by identifying the title, abstract, and full text. Selected works of literature were assessed for bias risk and quality of evidence. Randomized controlled trials were analyzed for meta-analysis. All procedures are independently carried out by two researchers.

Results: Nine articles meeting the inclusion criteria included 5 randomized controlled trials and 4 pre-post studies. The total number of participants included was 961. The dosage of PS supplementation varied from 100-300 mg/day, and the intervention period ranged from 6 weeks to 6 months. As for the risk of bias, 4 articles were rated 'some concerns', while the rest were examined to 'low'. The meta-analysis showed that PS supplementation enhanced cognitive function on memory but did not affect performing daily living activities.

Conclusions: In conclusion, PS supplementation improves cognitive function, especially within the memory domain, without side effects.

Keywords: Phosphatidylserine, cognitive function, the elderly, systematic review, meta-analysis

Effectiveness of Community-Based Intervention to Improve Nutritional Status and Frailty among Older Adults

Yu Ru Lin[1], Ya Wen Fan[1], Kang Wei Lee[1], Hsiao chun Lin[1], Tsung Jung Lien[1,3], Jui Chi Hsu[2], Yi Chun Chein[2], Meng Kan Chen[3], Chung Mei Ouyang[1]

1. Department of Dietetics, National Taiwan University Hospital Hsin-Chu Branch, Taiwan (Taiwan); 2. Department of Physical Medicine and Rehabilitation, National Taiwan University Hospital Hsin-Chu Branch, Taiwan (Taiwan); 3. Department of Family Medicine, National Taiwan University Hospital Hsin-Chu Branch, Taiwan (Taiwan)

Background and Objectives: Malnutrition is a very frequent condition in the frailest groups of the population, especially in elderly subjects. Malnutrition, frailty and sarcopenia in the elderly were associated with mortality and morbidity. The aim of this study was to conduct 12-week nutrition and exercise intervention program for older adults in the community, and to analyze the proportion of malnutrition risks and the influencing factors of malnutrition in those subjects.

Methods: We recruited participants aged over 65 years old at the community center in Hsinchu city, Taiwan. After receiving their informed consent, they engaged in a 12-week nutrition-exercise intervention project. We also collected data from MNA-SF, FRAIL scale questionnaires. The physical strength was assessed by using 8-foot up-and-go test and grip strength. Dietary, physical and anthropometric assessment were also be performed and collected at 0, 12 and 24-week.

Results: Thirty-five subjects completed the project. The results of this study showed that there were 22% subjects with malnutrition risk in the beginning, 78% within normal nutrition, 17% for frailty, and 46% for pre-frail. After 12 weeks of nutrition-exercise intervention, and 12 weeks of maintenance, the risk of malnutrition was decreased to 9%. Normal, frailty and pre-frail were 92%, 6% and 34% respectively. Their nutritional status and the condition of frailty were improved, and those results did not decline after the intervention stopped. The average walking speed was increased by 0.8 s/m at 24-week compared to 0-week, and the average grip strength was no significant differences. The result was a significant increase at the 0 week and the 12 week (p<0.001). There was a significant increase at 0 week and 24 week (p<0.001). In the dietary assessment, energy and protein intakes were no significant differences.

Conclusion: Nutritional status, frailty, and walking speed were improved after nutrition education and exercise

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

interventions. On the whole, the community-based nutrition and exercise project could improve the nutritional status and frailty of the elderly.

Keywords: community , elderly, nutrition intervention, frailty

Making rice flour bread that contributes to the prevention and improvement of sarcopenia

Teruyo Nakatani[1], Manami Tanaka[1]

1. Mukogawa Women's University (Japan)

Background and objectives: Sarcopenia is characterized by an age-related decline of muscle mass and physical function (strength) that affects the quality of life. With advancing age, there is anabolic resistance and a decreasing trend of eating, leading to muscle loss. Therefore, appropriate protein intake is essential in preventing the development of sarcopenia. It is known that the amino acid leucine activates mTOR signaling more efficiently than other amino acids, affecting inhibition of autophagy (protein degradation) and leading to stimulation of protein synthesis. In addition, lysin is known to suppress protein degradation through autophagy inhibition. Also, the soy protein glycinin prevents skeletal muscle atrophy by inhibiting the ubiquitin-proteasome degradation system. Another important point in considering efficient protein synthesis is distribution across meals; however, there is a tendency for lower protein intake at breakfast. In this study, taking gluten intolerance into account, rice flour with added soy powder was utilized for efficient protein synthesis; and the effects of sub-ingredients on the quality of bread were investigated.

Methods: Breads were prepared using an automatic breadmaker. A creep meter was used to determine the rheological properties of the breadcrumbs.

Results: Compared with 100% rice flour bread, soy bread improved nutritional value and increased the amount of leucine and lysin by 2 times and 3.4 times, respectively. A slice of soy bread (70g) satisfied almost one-fifth of the daily nutritional requirement (60kg body weight). However, in terms of bread quality, the specific volume of the soy bread decreased to 70%, but recovered by 88% and 90% when adding pregelatinized rice flour and/or cornstarch instead, respectively. Also, the cornstarch improved the viscosity affected by the pregelatinized rice flour. Improvement of specific volume by pregelatinized rice flour substitution was at the fermentation level, suggesting that increased adhesiveness due to the addition of pregelatinized rice acts like gluten.

Conclusion: It can be suggested that introducing rice flour bread with added soy in one's diet is effective as part of an initiative to prevent and improve sarcopenia.

Development of nutritional strategies within inpatient hospital menu for enhanced nutritional care of non-critical COVID-19 patients during hospital quarantine in India

Parmeet Kaur[1], Mahesh R[2], Ghazala Rehman[3], Veena Pandey[4]

1. All India Institute of Medical Sciences (India); 2. All India Institute of Medical Sciences (India); 3. All India Institute of Medical Sciences (India); 4. All India Institute of Medical Sciences (India)

Background and Objectives: During hospital quarantine of non-critical COVID-19 patients, particular focus is given on their general management and little is known regarding the nutritional profile. The present study was therefore conducted to assess their dietary predilections during hospital quarantine.

Methods: A prospective observational study was conducted in non critical COVID -19 patients admitted in isolation wards of All India Institute of Medical Sciences (AIIMS), New Delhi from 1st November 2020 to mid of January 2021. A dietician administered a pre validated questionnaire telephonically to obtain data on demographic, anthropometric and dietary characteristics. The results were expressed as mean, standard deviation and median. Chi square tests were used to compare category variables. Statistical analysis was performed using SPSS 9 version 20.0.SPSS, Inc., Chicago IL).

Results: 132 patients volunteered to enroll in the study. The mean age of patients was 34.6 **± 13.5** years. Increase in intake of fruits, vegetables, fluids and proteins supplements was observed in majority of patients. Portion size of foods and number of food groups consumed in breakfast, lunch and dinner, did not differentiate by BMI categories (Pearson's x^2>0.05). The mean body mass Index (BMI) was 23.75 **± 4.15**. Being overweight and obese correlated with taste issues (Pearson's x^2< 0.05).

Conclusions: Owing to the new emergent COVID-19 situation, the findings of the present study may be utilized in developing the most favourable nutritional strategies within the inpatient hospital menu for providing enhanced nutritional care.

In search of an easy way to help people follow dietary recommendations: the utility of diet self-monitoring using the qualitative, dietary diary Self-monitorYourDiet®

Lidia Wadolowska[1]

1. University of Warmia and Mazury in Olsztyn, Faculty of Food Science, Department of Human Nutrition (Poland)

Background and objectives: Since many people have difficulty in following dietary recommendations, there were two aims of the study: (1) to develop a qualitative, dietary diary to facilitate people's compliance with dietary recommendations by helping them in food selection and adequate food frequency consumption; (2) to test the usefulness of this diary and the possibility of ranking respondents and classifying them as those who follow dietary recommendations or not.

Methods: The dietary diary was developed as a simple, graphic-text tool based on subjects' self-monitoring their own diets named Self-monitorYourDiet®. The diary contains 11 foods, including 6 foods recommended for consumption and 5 foods with limited consumption, along with the indicated consumption frequency per day/week/month. The respondents' adherence to dietary recommendations was expressed as an Adherence Score to dietary recommendations (AdhS) in points (range 0-12). More points were awarded for better compliance with dietary recommendations. The diary was tested among 40 university students aged 20-24-years-old.

Results: Most of the participants reported that they were not burdened with the use of this diary. The fewest respondents followed dietary recommendations for vegetables and fruit in total (2%), dairy foods (8%), vegetables (12%) and fast foods (12%). More than 60% of respondents followed the dietary recommendations for legumes/nuts/seeds (88%), whole grains (72%), fruit (65%) and sweetened beverages/energy drinks (62%). The mean value of the AdhS was 4.2 points (SD 1.7), the median was 4.0 points. 15% of the sample received ≧6 points of the AdhS while no one received ≧8 points. Assuming that improving the diet (e.g. following dietetic counselling) may result in a 15–40% increase in the AdhS (e.g. from 8 to 9–11 points), an increase in the AdhS should be easily monitored within the full score range.

Conclusion: The Self-monitorYourDiet® diary can be recommended as a simple tool, easy to use for respondents. The study showed the usefulness of this diary: (1) the respondents can be ranked within range of the adherence score and classified as those who follow dietary recommendations or not, (2) to monitor changes in dietary behaviours, especially those behaviours that have been improved as a result of an intervention.

Department of Cardiac Biochemistry, All India Institute of Medical Sciences, New Delhi (India); 7. Department of Endocrinology and Metabolism, All India Institute of Medical Sciences, New Dehi (India)

Background and objectives: A metabolic syndrome is a group of symptoms that include glucose intolerance/insulin resistance, abdominal obesity, atherogenic dyslipidemia (low levels of HDL cholesterol and high levels of triglycerides), high blood pressure, a proinflammatory and prothrombotic state, and elevated blood pressure. Non-alcoholic fatty liver disease (NAFLD) is recognized as the most common liver disease, affecting one-quarter of the world's population and frequently associated with metabolic illnesses such as type 2 diabetes, hypertension, obesity, and cardiovascular disease. NAFLD is characterized by an increase in liver fat content in the absence of a secondary cause of steatosis. The present study was planned as a case-control study to investigate the association of metabolic syndrome with NAFLD.

Methods: A community-based case-control study was conducted amongst 268 age and gender-matched males and females aged 30-60 years residing in DELHI-NCR. Participants with grade II and III fatty liver, based on USG grading were enrolled as cases while participants with normal liver were enrolled as controls. Anthropometric and biochemical assessments were done and metabolic syndrome was diagnosed based on NCEP-ATP-III (2005 revised) criteria.

Results: The metabolic syndrome was significantly more prevalent in cases (86%) as compared to controls (50%) (p=0.000). Out of 5 metabolic parameters, significantly higher derangements were seen in cases versus controls on waist circumference (cases=69%, controls=28%, p=0.000); fasting blood glucose (cases=97%, controls=88%, p=0.009), and serum triglycerides levels (cases=58%, controls=31%, p=0.000). The two groups were statistically different on prevalence of any 4 criteria (cases=40%, controls=16%, p=0.000) or all five criteria (cases=12%, controls=4%, p=0.012).

Conclusions: Hence, patients with NAFLD are more likely to develop metabolic syndrome, which raises their risk of

developing cardiometabolic disorders such as Obesity, Diabetes, Hyperlipidaemia, and Hypertension. Hence it is imperative that individual metabolic risk factors be timely diagnosed and treated in these patients.

Dietary antioxidant indices and their association with cardiac disease: Baseline analysis of Kharameh cohort

Parisa Keshani [1], Maryam Jalali [2], Masoumeh Ghoddusi [3], Ramin Rezaeianzadeh [4], Seyed Vahid Hosseini [1], Abbas Rezaianzadeh [1]

1. Colorectal Research Center, Shiraz University of Medical Sciences (Iran); 2. Non-communicable Disease Research Center, Shiraz University of Medical Sciences. (Iran); 3. Breast Disease Research Center, Shiraz University of Medical Sciences. (Iran); 4. Student Research Committee, Shiraz University of Medical Sciences (Iran)

Background and objectives: Oxidative stress contributes to the development of cardiovascular disease. Tools for evaluating the anti-inflammatory and antioxidative characteristics of an individual's diet as a whole may be valuable for assessing the combined effects of dietary antioxidants on health. This population-based study aimed to investigate the association between dietary antioxidants and cardiac disease.

Methods: In this population based cross-sectional study, 10439 individuals aged 40-70 years were recruited during 2014-2017 in Kherameh cohort study which is a part of the Prospective Epidemiological Research Studies in Iran (PERSIAN). The food frequency questionnaire (FFQ) with 130 food items was used to assess the dietary intakes. Vitamin A, E, C, selenium, zinc and Manganese intakes were used to compute dietary antioxidant index (DAI) and dietary antioxidant quality score (DAQs).

Results: The participants' mean age was 52.1 years. Among all, 4356 (41.7 percent) were overweight and 1892 (18.1 percent) were obese. According to the results, odds of cardiac diseases decreased by increasing DAI score. Odds of cardiac diseases increased by lower DAQS after adjusting for demographic variables including age, sex, BMI, Marital status and hypertension.

Conclusion: The role of antioxidants in reducing the odds of cardiovascular disease is very important. Our results highlighted that DAQS and DAI had protective effect on the odds of cardiovascular disease by 20 and 21 times. Therefore, it is suggested that antioxidants as zinc, manganese, selenium, and vitamins A, E and C should be taken through food to reduce the risk of the disease.

Symptoms and nutritional counseling needs of patients with psychiatry disorder

Saori Koshimoto [1,2], Nanae Kuboki [3], Chihiro Gunji [3], Mayo Fujiwara[3,2], Yuki Oyake[3], Issei Murata[3], Naoko Shirota[1], Takashi Takeuchi[2], Eisuke Matsushima[2], Katsuya Ohta[3,2]

1. Tokyo Kasei Gakuin University (Japan); 2. Tokyo Medical and Dental University (Japan); 3. Onda-daini Hospital (Japan)

Background and objectives: Psychiatric disorders tend to be chronic. There are concerns about the development of dyslipidemia and diabetes due to side effects of medication and decreased activity. In our previous study using the Hospital Anxiety and Depression Scale (HADS), we found that patients with high anxiety desired nutritional counseling. In the present study, we investigated the symptoms and nutritional counseling needs of patients with psychiatric disorders.

Methods: We examined body composition, blood tests, symptoms, anxiety and depression, and assessed nutritional counseling needs among hospitalized patients with psychiatric disorders. Written consent was obtained. Statistical analysis was performed using SPSS 28 and the χ^2 test. Ethical review number was ONR-0005 and clinical trial number was UMIN 000037178.

Results: The study was carried out prospectively from August in 2019 to April in 2020. The mean age of patients was 58.0 (± 13.4) years. We found that patients (n = 67) with a body mass index (BMI) of less than 18.5 kg/m^2 or more than 25 kg/m^2 tended to request more nutritional counseling than those with a normal BMI (p= 0.092). Among the symptoms, those with diarrhea (p= 0.013), abnormal sense of smell (p = 0.029), and pain (p = 0.007) requested nutritional counseling; however, there were no significant associations with anorexia, excess appetite, nausea, constipation, stomatitis, taste abnormalities, or fatigue.

Conclusions: Patients with psychiatric disorders were more concerned about BMI and may have higher nutritional counseling needs. In addition, patients with diarrhea, olfactory abnormalities, and pain requested nutritional counseling, suggesting that nutritional support in psychiatry needs to be examined by a multidisciplinary team. Patients with psychiatric disorders are at multiple risks for hypo- or overnutrition including decreased activity, side effects of medications, and psychosocial factors. Therefore, it is important to determine the needs of individual patients and to take a multidisciplinary approach.

PAB(T4)-54
The role of intestinal Cytochrome P450 in vitamin D metabolism

Minori Uga[1], Ichiro Kaneko[1,2], Sumire Sasaki[1], Megumi Koike[1], Kazuya Tanifuji[1], Kota Kawahara[1], Yuji Shiozaki[1], Peter W. Jurutka[3], Hiroko Segawa[1]

1. Tokushima University Graduate School of Biomedical Sciences (Japan); 2. University of Hyogo (Japan); 3. Arizona State University (USA)

Background and objectives: Physiological vitamin D status is important for bone health. Vitamin D hydroxylation in the liver/kidney results in conversion to its physiologically active form of "1,25-dihydroxyvitamin D" (1,25D). 1,25D controls gene expression through the nuclear vitamin D receptor (VDR) mainly expressed in intestinal epithelial. Activation of VDR by 1,25D binding results in heterodimerization with the retinoid X receptor (RXR) and association with vitamin D responsive elements (VDREs) in the promoter region of vitamin D target genes. Cytochrome P450 (CYP) 24A1 is a catabolic enzyme expressed in kidney that is important for 1,25D inactivation and maintaining 1,25D homeostasis. Interestingly, a recently identified mutation in CYP3A4 (gain of function) caused vitamin D-dependent rickets, type III. Unlike CYP24A1, CYP3A4 is mainly expressed in liver and is a known xenobiotic enzyme. CYP3A4 has been reported to convert 25-hydroxyvitamin D to 4beta,25-dihydroxyvitamin D, in vitro. The CYP3A family in humans (3A4, 3A5, and 3A7) possesses high amino acid homology. These CYP3As and CYP24A1 are also expressed in intestine, but their hydroxylation activities towards vitamin D substrates are unknown.

Methods: We constructed human CYP3A4, 3A5, 3A7 and 24A1 expression plasmids, and evaluated their CYP activities on vitamin D action using VDRE-transcriptional assays, mammalian two-hybrid assay (VDR-RXR), or real-time PCR in human colon cultured cells. Moreover, we examined the expression level of CYPs in the intestine, kidney or liver from mouse by real-time PCR or western blotting.

Results: Expression of CYP3A4, 3A5, 3A7, and 24A1 all significantly reduced 1,25D-VDRE activity in HCT116. Moreover, CYP3A4, 3A5, and 3A7 significantly reduced VDR-RXR interaction/heterodimerization. In C2BBe1 cells, CYP3A4 also inhibited 1,25D-mediated induction of Transient Receptor Potential Vanilloid (TRPV6), a membrane calcium channel which is involved in Ca^{2+} absorption in the intestine. Finally, in mice, Cyp3a mRNA or protein was more expressed than Cyp24a1 in the intestine.

Conclusions: Therefore, CYP3As attenuate 1,25D action in intestine, and CYP3A inducers like phenytoin or phenobarbital, carbamazepine (anti-epileptic medicines), pioglitazone (hypoglycemic medicine), etc. could compete with vitamin D treatment in osteoporosis patients. Further studies are needed to clarify the physiological role of intestinal CYP3A and/or CYP24A1 in metabolism of 1,25D, in vivo.

Differences in urinary phosphorus excretion after animal or plant protein intake in healthy young Japanese women : An additional study by unifying dietary content

Junko Ishida[1], Tomomi Asano[1], Sayuki Hashimoto[2], Ayako Minematsu[1], Akihiko Kato[3], Kunihiro Sonoda[1]

1. Kinjo Gakuin University (Japan); 2. Kobe Shoin Women's University (Japan); 3. Hamamatsu University Hospital (Japan)

Background and objectives: We have previously reported the effects of protein intake and sources (animal or plant protein) on phosphorus excretion as a preliminary evaluation to prevent hyperphosphatemia and a diet therapy for chronic kidney disease (CKD) dialysis patients. However, in the above study, dietary content and intake were at the discretion of each subject, resulting in varied intakes of food ingredients, energy, and nutrients. Therefore, we conducted an additional study by unifying the dietary content for each diet group in this study.

Methods: Healthy young Japanese women were divided into three groups: animal protein meal intake group (animal), plant protein meal intake group (plant), and protein restriction meal group (low-protein), and were subjected to a 2-day dietary intervention. Amount of nutrition and menu planning were referred to the Dietary Reference Intakes for Japanese (DRIs) and adjusted for energy, fat, and carbohydrate within the target range. Protein was adjusted to the target range (1.2-1.4 g/kg) in the animal and plant, and half value (0.6-0.7 g/kg) in the low-protein group. The nutrients of the intervention diet were analyzed using the duplicate method, and the intake of each subject was calculated individually based on the dietary records (leftover weight) and photographs. Urine was collected before and after dietary intervention, then analyzed.

Results: There were no significant differences in the urinary urea nitrogen (U-UN), which indicates protein excretion, and urinary phosphorus (U-Pi) among the three groups on pre-intervention. However, after the intervention, U-Pi was significantly lower in the plant group than in the animal group, despite no significant difference in the U-UN; its excretion was at similar levels to the low-protein group.

Conclusions: In this study, as a result of unifying the dietary content for each group, we showed that the plant group reduced urinary phosphorus excretion to levels similar to that of the protein-restricted diet. Nevertheless, the protein intake was comparable to that of the animal protein diet. It supported our previous research.

Keywords: Urinary phosphorus, plant protein, animal protein

At-risk of malnutrition is strongly associated when older patients discontinued home-medical cares: A 1-year follow-up study

Taeko Tsuji[1,2], Daiki Habu[2], Kazuyo Yamasaki[3], Kyoko Kondo[4], Satoko Ohfuji[4], Wakaba Fukushima[4], Nobuko Hongu[2], Chika Momoki[5], Yoko Yasui[2], Keisuke Fukuo[1]

1. Mukogawa Women's University (Japan)
2. Osaka Metropolitan University Graduate School of Human Life Science (Japan), 3. Nishinomiya Social Welfare Corporation (Japan)
4. Osaka Metropolitan University Graduate School of Medicine (Japan)
5. Setsunan University (Japan)

Background and objectives: Malnutrition and at-risk of malnutrition (i.e. potential risk of malnutrition) are both prevalent among older patients receiving home-medical cares. Discontinuation of home-medical cares often happens when an older patient was admitted to a hospital, a nursing home or reporting death. Thus, the aim of this study was to assess prospective associations between nutritional status and discontinuation of home-medical cares in older patients.

Methods: This prospective study was conducted in Nishinomiya city, Hyogo Prefecture, Japan. Three hundred and thirty-three community-dwelling older patients (aged 65 years or older who were receiving home-visit nursing care services) were included in this study. Their nutritional status was assessed using the Mini Nutritional Assessment®-Short Form (MNA®-SF) and patients were classified into three groups (Well-nourished, At-risk of malnutrition and Malnourished). Outcomes were confirmed at one-year follow-up. Hazard ratios (HRs) and 95% confidence intervals (CIs) for discontinuation of home-medical cares of nutritional status were calculated using a cox proportional hazard model. Covariates included age, sex, living status, economic status, activity of daily living, comorbidity, and dysphagia status.

Results: A total of 297 patients (63.0% women; median age: 84 years) were analyzed. At baseline, 48.5% of patients were at-risk of malnutrition and 18.9% were malnourished. During the observation period of one year, 82 (27.6%) patients were discontinued home-medical cares. In adjusted model, HR for discontinuation of home-medical cares in the At-risk of malnutrition was 2.44 (95% CI: 1.34-4.45; p=0.003) times the Well-nourished. Although the Malnourished was significantly associated with discontinuation of home-medical cares (HR 2.21, 95%CI: 1.11-4.38; p=0.023) in crude analysis, was not significantly associated in multivariate analysis (HR 1.69, 95% CI: 0.77-3.72; p=0.189; referent: the Well-nourished).

Conclusions: At-risk of malnutrition was associated with discontinuation of home-medical cares among older patients. Our study suggests the need to strengthen nutritional strategies, such as providing individualized dietary counselling for older patients. Then, they may be able to continue receiving medical cares at their home, instead of starting them at hospital or nursing home.

The Association between Rice Intake and Snoring: the Toon Health Study

Yui Furukawa[1], Koutatsu Maruyama[1], Kiyohide Tomooka[2], Takeshi Tanigawa[2], Isao Saito[3]

1. Ehime University (Japan); 2. Juntendo University (Japan); 3. Oita University (Japan)

Background and objectives: Snoring is one of the symptoms of sleep apnea and is associated with various health problems such as hypertension, diabetes and coronary heart diseases. Prevention for snoring is important, but few studies have examined the preventive factors, in particular dietary factors, for snoring. Thus, we aimed to examine the association between rice, which is the major staple food for of Japanese, and snoring.

Methods: This cross-sectional study included 2032 Japanese men and women aged 30 to 79 years who participated in the Toon Health Study. Snoring was assessed by a part of Berlin Questionnaire, and we defined snoring as the occurrence of snoring >1 times a week The amount of rice intake was assessed by food frequency questionnaire, and adjusted for energy intake using residual method. The participants were divided into sex-specific quartiles according to rice intake. The multivariable-adjusted odds ratio (OR) and 95% confidence intervals (95%CIs) of the presence of snoring for the quartiles of rice intake was calculated using logistic regression after adjustment for age, sex, physical activity, current smoking, current drinking, body mass index, energy intake and sleep duration. We also performed a stratified analysis by current drinking status which was strongly associated with snoring.

Results: We found an insignificant association between rice intake and snoring in men and women; the OR (95%CIs) for the highest quartile compared to the lowest was 0.80 (95%CI:0.52-1.23, p for trend=0.25) in men, and 0.86 (95%CI:0.60-1.25, p for trend=0.57) in women, respectively. After stratification by current drinking status, we found that the OR for the highest quartile was significantly lower than that for the lowest in women with current drinking; the OR (95%CIs) is 0.51 (0.28-0.95, p for trend=0.08). This association remained significant after further adjustment for ethanol intake. We found an insignificant association between rice intake and snoring in men and nondrinking women.

Conclusions: In conclusion, higher rice intake tended to be associated with lower presence of snoring among Japanese women with drinking habit.

Keywords: Snoring, rice intake, drinking

Curcumin suppresses cancer metastasis by inducing anoikis in cancer cells

Hiroshi Endo[1], Masaya Tanaka[1], Saki Kurokawa[1], Mihiro Yano[1]

1. The University of Shiga Prefecture (Japan)

Background and objective: Cancer metastasis is one of main cancer complications resulting in poor patient outcomes. The metastatic potential of cancer cells has a strong relationship with anti-anoikis ability obtained by undergoing epithelial-mesenchymal transition (EMT). Since the induction of anoikis in cancer cells may be an effective means of preventing the metastasis of tumors, we examined the inhibitory effect of curcumin on anchorage-independent growth, leading to anoikis in cancer cells. Curcumin, a naturally occurring polyphenol extract, has been extensively studied for its anticancer properties. In this study, we focused on a critical role of 14-3-3 protein family in anoikis suppression because our previous data has indicated that its down-regulation by curcumin *in vitro* induces the apoptosis in A549 cells. Furthermore, we found that curcumin prevents the metastasis of lung cancer cells using mouse lunge carcinoma cells and allograft model *in vivo*.

Methods: To induce anoikis under anchorage-independent conditions, mouse Lewis Lung Carcinoma (LLC) were plated in an ultra-low attachment 96-well plate and curcumin was added to the medium at indicated concentrations. Cell viability was quantitatively measured by using WST-8 assay. Events linked to metastasis were evaluated by immunoblotting using extract from LLC. Cell migrations was evaluated by using 24-well transwell plates with 8.0 μm pore polycarbonate membrane inserts. After incubation, migratory cells were fixed with PFA and stained with crystal violet. An animal experiments were performed to determine whether localized treatment of subcutaneously growing LLC in C57BL/6 mice with intraperitoneal injection of curcumin affects the formation of distant metastasis.

Results: Curcumin inhibited the proliferation of A549 and LLC cells cultured in non-adherent condition by suppressing 14-3-3 β and γ. We also found that curcumin significantly inhibits LLC migration by using boyden chamber assay. On the other hands, *in vivo* analysis showed a significant decrease in the number of metastases in the lung of the curcumin-treated groups as compared with them of control. These observations indicate that curcumin inhibits cancer metastasis by inducing anoikis in LLCs and decreasing their cell migration ability.

Conclusion: Our results suggest that curcumin reduces the survival rate of cancer cells cultured in non-adherent condition and inhibits their migration, which may be responsible for the ability of curcumin to suppress metastasis *in vivo*. These findings may contribute toward the development of new and less toxic chemotherapies that use natural compounds against cancer metastasis.

Hypertension and associated risk factors among community-dwelling rural adults in abia state, Nigeria

Beulah Favour Ortutu[1], Patricia Ogechi Ukegbu[2], Sochima Diara[3], Chinaza Precious Uche[4], Andrew Ugwunna Ukegbu[5]

1. Michael Okpara University of Agriculture Umudike, Abia State (Nigeria); 2. Michael Okpara University of Agriculture Umudike, Abia State (Nigeria); 3. Michael Okpara University of Agriculture Umudike, Abia State (Nigeria); 4. Michael Okpara University of Agriculture Umudike, Abia State (Nigeria); 5. Federal Medical Centre, Umuahia Abia State (Nigeria)

Background and objective: Hypertension is a growing public health problem in developing countries contributing to morbidity and mortality of billions of adults worldwide. The study aimed to assess the prevalence and factors associated with hypertension among adults in rural communities of Ikwuano, Abia State, Nigeria.

Methods: The study was a community-based descriptive cross-sectional survey conducted among 429 apparently healthy rural adults aged 20 to 59 years using cluster sampling technique. Socio-demographic information was obtained using a validated questionnaire. Blood pressure and anthropometric measurements were carried out following standard procedures. Hypertension was defined as systolic blood pressure (SBP) equal or greater than 140mmHg and/or diastolic BP (DBP) equal or greater than 90mmHg. Logistic regression analysis was used to assess risk factors associated with hypertension.

Results: The prevalence of hypertension was 51.0% (58.1% in males and 43.1% in females). Hypertension was significantly associated with age, gender, marital status and BMI. In the adjusted model, older age (>40 years) (OR=1.96; 95% CL1.03 to 3.72; p<0.04) and overweight/obesity (OR=2.55; 95% CL1.50 to 4.34; p<0.001) were associated with higher odds of having hypertension. Female gender was associated with lower odds of hypertension compared to males (OR=0.32; 95% CI 0.20 to 0.52; p<0.001).

Conclusion: The study showed a high prevalence of hypertension among rural community-dwelling adults, underscoring the need for routine screening of adults for early hypertension diagnosis.

Hesperetin attenuates cancer stemness properties by down-regulating the expression of heat shock factor 1 in non-small lung cancer cells

Masaya Tanaka[1], Konatsu Sakusa[1], Hiroshi Endo[1], Mihiro Yano[1]

1. The University of Shiga Prefecture (Japan)

Background and objectives: Cancer stem cells (CSCs) have explained many cancer complications, including cancer recurrence, metastasis to distant organs, and multiple drug resistance. Therefore, current methods for the treatment of cancer are being investigated, which can target CSCs. While resistance to chemotherapy treatments is commonly associated with CSCs population, natural products, such as food components, have been a rich source of biologically active compounds for the pharmaceutical industry. In this study, we examined the effects of hesperetin on CSCs. Hesperetin, a predominant flavonoid found in citrus fruits, has received considerable attention in potential anti-cancer activity. To address the mechanisms of hesperetin targeting CSCs, we focused on the function of heat shock factor 1 (HSF1), a transcriptional regulator of heat shock proteins, because accumulated data have shown its important role in regulating the expression of cancer stemness-related factors.

Methods: Fluorescence-activated cell sorting (FACS) was used to measure the CSCs surface marker CD133(+) subpopulation in the non-small cell lung cancer cells A549. The effect of hesperetin on the self-renewal ability of A549 cells was examined using sphere-formation assays. Real-time PCR, Western blot, and immunofluorescence assays were used to evaluate the expression of HSF1 and cancer stemness-related factors. RNA interference was used for mechanistic studies. Wound healing assays and transwell assays were used for migration and invasion, respectively.

Results: Hesperetin reduced the number of CD133(+) cells, whereas cisplatin did not affect the number of CD133(+) cells in A549. Hesperetin also decreased the number of sphere formations. On the other hand, we found that hesperetin inhibited the expression of HSF1 in A549. Furthermore, the decreased number of spheres caused by the depletion of HSF1 by RNA interference is evidence that the inhibitory function of hesperetin on sphere formation is mediated by its effect on HSF1. Wound healing and transwell assays demonstrated that hesperetin suppresses migration and invasion ability in A549. In the present study, we also found that hesperetin inhibits the expression of self-renewal-related genes and epithelial-mesenchymal transition (EMT) marker genes via suppression of HSF1 expression.

Conclusions: We found that hesperetin suppresses cancer stemness related to metastasis and recurrence by suppressing HSF1 expression. Hesperetin, therefore, may be a key product to discovering a novel treatment demanded by the difficulty of targeting CSCs.

Keywords: Hesperetin, cancer stem cell, HSF1

The effects of factors related to muscle flexibility, joint laxity, and dietary habits on sports injuries and trauma

Junna Mori[1], Asumi Yoshida[1]

1. Kyushu Sangyo University (Japan)

Background and objectives: Sports injuries and trauma vary depending on the type of sporting event, age, and sex. Athletes are likely to develop stress-induced fractures due to accumulated daily fatigue, poor dietary habits, and lack of nutrients. This study aimed to examine sports injuries and trauma associated with muscle flexibility, joint laxity, and dietary habits and investigate factors affecting sports injuries and trauma.

Methods: Twenty male athletes participated in this study. We measured the speed of sound (SOS) and broadband ultrasound attenuation (BUA) as an index of calcaneus bone mineral density. Nutrient intake was assessed using a food frequency questionnaire (FFQg). Food intake and eating habits related to bone health were investigated using the calcium self-checklist of the Japan Osteoporosis Society. We evaluated muscle flexibility and joint laxity scores as described in previous studies. Participants' history of fractures, sprains, and overuse syndromes was obtained.

Results: There was a significant positive correlation between muscle flexibility and joint laxity scores. However, there was no correlation between SOS, BUA, and nutrient intake assessed using FFQg and the frequency of fractures. In addition, there was no significant correlation between calcium intake assessed using FFQg and the calcium self-checklist score. We examined the differences in joint laxity and muscle flexibility scores according to experiences of fractures, sprains, or overuse syndromes, and we found a significant difference between fracture experience and the muscle flexibility score. The regression analysis results showed that the muscle flexibility score, but not the joint laxity score, was an important predictor of the presence or absence of fracture experience.

Conclusions: The effects of muscle flexibility on fractures were confirmed, but that of joint laxity on fractures were not established. The frequency of fractures did not correlate with SOS, BUA, and calcium intake assessed using FFQg. Further research is needed to assess whole body bone mineral density and perform a detailed dietary survey.

Keywords: Bone mineral density, food frequency questionnaire, bone fracture, sprain, overuse syndrome

Intestinal microbes-derived hydrogen molecules in pregnant rats or mice fed fructooligosaccharide-containing diet, permeates into fetus and affects the oxidative stress

Asuka Okuda[1], Yuri Kintaka[1,2], Chihiro Ushiroda[1], Yuko Yamazaki[1], Misaki Kurawaka[1], Kenichi Tanabe[1,3], Akio Watanabe[1], Akito Shimouchi[4], Tsuneyuki Oku[1], Sadako Nakamura[1]

1. Jumonji University (Japan); 2. Sapporo University of Health Sciences (Japan); 3. Nakamura Gakuen University (Japan); 4. Chubu University (Japan)

Background and objectives: The nutritional environment during fetal life is considered to affect the risk factors of life style-relates diseases, asthma or allergy during developmental or adulthood periods. Nondigestible saccharides are recognized as a food component, metabolized by host intestinal microbes, and produce molecular hydrogen and short chain fatty acids *etc*. Intestinal microbes-derived hydrogen molecules (IMDH) transfers to peripheral tissues by blood circulation and regulates oxidative stress. In this study, we investigated whether IMDH of pregnant rats or mice fed with fructooligosaccharide (FOS)-containing diets permeates into the fetus and affects oxidative stress.

Methods: Female Wistar rats (n=5, CLEA Japan, Inc., Tokyo) and C57BL/6J mice (n=6, Japan SLC, Inc., Tokyo) on the first day of gestation were divided into two groups: CONT group fed AIN-93G and 5% FOS group replace with FOS for a half of sucrose in AIN-93G. On the 18th day of gestation, after the animals were dissected, blood, organs, tissues, and fetuses were collected, and prepared to measure the free IMDH. IMDH was measured using Breath Gas Analyzer BGA1000D (Research Institute of Expiration, Nutrition and Metabolism, Nara, Japan). Parameter of oxidative stress were measured by real time RT-PCR.

Results: In pregnant rats, IMDH in blood, uterus, liver, and perirenal adipose tissue in FOS group were significantly higher than those in CONT group (p<0.05). IMDH was also detected in other organs except heart and muscle, but no statistically significant difference was observed. In pregnant mice, IMDH in FOS group was also significantly higher than in CONT group (p<0.05). In the fetuses of both rats and mice, IMDH in FOS group showed significantly higher values than that in CONT group (p<0.05). The parameters of oxidative stress were affected by the feeding of FOS.

Conclusions: This is the first finding that IMDH in pregnancy by the feeding of FOS transfer to the fetus via blood stream in rats and mice. We believe that IMDH by the intake of nondigestible saccharide in pregnancy could reveal the beneficial functions equivalent to the external IMDH for the mother and their fetuses.

Keywords: fructooligosaccharide, intestinal microbes-derived hydrogen molecules (IMDH), pregnant, fetus

Conflict of Interest Disclosure: The authors thank Meiji Co., Ltd. for providing fructooligosaccharide.

Learning from the community to predict Nutrition Status of Children aged 6-24 months in Gulu District, Northern Uganda. A Matched Case-Control Study

Muzafaru Ssenyondo[1], Richard Kajjura[1], Hanifa Bachou[1], Richard Bukenya[1], David Guwatudde[1]

1. Makerere University (Uganda)

Background and objectives: In the last two decades, most health indicators for Ugandan children have improved. However, the prevalence of undernutrition is still of public health concern. Most of the nutrition studies have focused on unfavorable factors that contribute to malnutrition rather than on the favorable factors that promote good nutrition status among children. This study aimed at identifying factors and practices of mothers/ caregivers associated with better nutritional outcomes for their children aged six to 24 months compared to mothers/ caretakers of children with poor nutritional outcomes living in the same neighborhood.

Methods: This was a case-control study conducted in Gulu district on 300 (i.e.,100 cases and 200 controls) purposively selected sample of children in the age group of 6- 24 months. Controls were children of normal nutrition status with WAZ, HAZ and WHZ ≧-2 Z-scores. Cases were undernourished children 6 to 24 months of age with at least one of the indices WAZ, HAZ or WHZ <−2 Z-scores. Quantitative data was collected using a semi-structured questionnaire. Logistic regression was used at bivariable and multivariable analysis to determine the predictors of good nutrition status using Odds ratios (ORs) as the measure of association. Both the crude (COR) and adjusted odds ratios (AOR) were reported. A p-value less than 0.05 was considered statistically significant at 95% confidence interval.

Results: The mean age of the cases and controls was 15 months (SD ㊧ 6) and 13 months (SD ㊧ 5), respectively. At multivariable analysis, breastfeeding in the first hour of child's life (AOR=3.31 95%CI. 1.52, 7.23), use of family planning (AOR=2.21 95% CI. 1.25, 3.90), less number of under-fives in the household (AOR=0.31 95%CI. 0.13, 0.73) and handwashing with soap (AOR=3.63 95%CI. 1.76, 7.49) were significantly independently associated with child's optimal anthropometric nutrition status.

Conclusion: Interventions that could improve children's nutrition status include; breastfeeding in the first hour of child's life, use of family planning methods, child spacing and handwashing with soap.

Influence of body shape perception on body mass index and nutritional status in female patients with pulmonary nontuberculous mycobacterial lung disease

Yumi Takayama[1,2], Yukina Yumen[2], Fumiaki Hanzawa[3], Takamasa Kitajima[1], Noritsugu Honda[1], Naoki Sakane[4], Motonari Fukui[1], Narumi Nagai[2]

1. Tazuke Kofukai Medical Research Institute, Kitano Hospital (Japan); 2. Graduate School of University of Hyogo (Japan); 3. University of Hyogo (Japan); 4. National Hospital Organization, Kyoto Medical Center (Japan)

Background and objectives: Pulmonary nontuberculous mycobacterial lung disease (NTM-LD) is a chronic respiratory infection that occurs more commonly in thinner women. The lower body mass index (BMI), the worse the prognosis though, some patients are resistant to enough food intake and weight gain. We therefore hypothesized that female NTM-LD patients may overestimate their body shape like ordinary women. To confirm the hypothesis, we examined the influence of body shape perception (BSP) on BMI and nutritional status in female patients with NTM-LD.

Methods: Eighty-one female outpatients were included. As control, we used web survey data obtained from 111 ordinary women. BSP were evaluated using Japanese version of Body Image Scale. Participants identified the silhouette that best represented their own body (perceived silhouette). The silhouette number corresponding to patient's BMI is defined as actual silhouette, and body image distortion was calculated as the difference between perceived and actual silhouette. Body composition, dietary intake, appetite, and biochemical markers were examined during the hospital visits. First, BSP and BMI were compared between all patients and controls. Next, the data obtained from the patients were compared between underestimated-matched and overestimated groups.

Results: Patients had a significantly lower BMI than control (19.8±2.5 vs 22.4±3.2 kg/m^2, p<0.001), but 31 (38.3%) patients overestimated their body shape. In inter-patient comparisons, the overestimated group had a significantly lower BMI and body fat percentage (p<0.001, respectively), significantly larger weight loss since age 20 or their maximum weight (p=0.003, 0.016, respectively), and a trend toward lower protein intake and lymphocyte count compared to the underestimated-matched group. There was a negative correlation between body image distortion and BMI (r=−0.457, p<0.001). Multiple regression analysis revealed that body image distortion (β=−0.463, p<0.001) was independently related to BMI (R=0.568, p<0.001).

Conclusions: Despite remarkable thinness, approximately 40% of the patients overestimated their body shape, and such overestimation may be associated with low BMI and weight loss. These results suggest that to prevent and improve thinness in NTM-LD patients, it is necessary to provide adequate nutritional intake as well as guidance to understand and correct patients' perception of their body shape.

Effects of dietary fatty acids on high-density lipoprotein proteomic profile and quality

Elena Grao-Cruces[1], Alejandro Santos-Mejias[1], Maria del Carmen Millan-Linares[1], Sergio Barrientos[1], Maria Esther Martin-Rubio[1], Beatriz Bermudez[1], Sergio Montserrat-de la Paz[1]

1. University of Seville (Spain)

Background and objectives: High-density lipoproteins (HDLs) are circulating particles that carry out cholesterol efflux and anti-inflammatory and antioxidant functions which are determined by HDL composition. However, HDLs have been described to turn into pro-inflammatory and non-functional particles in pathological conditions, and different studies suggest that lifestyle factors, such as diet, could also alter HDL functionality. The aim of this study was to report the influence of the intake of dietary fatty acids from different sources on HDL proteome and functionality.

Methods: Forty subjects were allocated in two groups: normal-weight and metabolic syndrome. Anthropometric data and blood were collected after 12 h of fasting. Additionally, five healthy volunteers were recruited for an interventional study with different dietary fatty acids. Four different times, the volunteers were cited and asked to take a fat-rich (poly-unsaturated, mono-unsaturated, or saturated fatty acids) or no-fat emulsion. At Baseline, 2.5 h and 5 h after they took the emulsion, blood was collected. Blood was centrifuged and serum and plasma were stored at -20 °C until analysis. Biochemistry measures were conducted by enzymatic method. HDLs were purified and HDL proteome was analysed by the Orbitrap Fusion high-resolution mass spectrophotometer fronted with a NanoESi ion source and HDL quality was assessed by enzymatic methods.

Results: Participants with metabolic syndrome had significantly higher BMI, waist circumference, percent body fat, and abdominal fat relative to normal-weight participants. Biochemical measures showed higher triglycerides, fasting glucose and total cholesterol levels in metabolic syndrome patients. The HDL proteomic profile and functionality were significantly different between the two groups. The proteomic profile of the four postprandial curves anticipates that HDL proteome and functionality content could be modulated by postprandial hyperlipidemia.

Conclusions: Metabolic syndrome remodels the HDL proteomic and quality profile. Whereas, postprandial hyperlipidemia-associated HDL proteomic profile could help to understand the functional role of HDLs influenced by diet. In addition, our study could help to establish nutritional interventions to adjust the HDL proteomic profile based on a designed lipid intake, in order to assess HDL functionality improvements.

The Association between Dietary Diversity and Ischemic Stroke Incidence and Mortality by a Global Comparative study

Keiko Miyamoto[1,8], Tomoko Imai[2,8], Ayako Sezak[3,4], Chisato Abe[5,8], Takumi Kato[6,8], Norie Sugihara[7], Hiroshi Shimokata[3,8]

1. Nagoya University of Arts and Sciences (Japan); 2. Doshisha Women's College of Liberal Arts (Japan); 3. Graduate School of Nutritional Science, Nagoya University of Arts and Sciences (Japan); 4. Ryukoku University (Japan); 5. Tsu City College (Japan); 6. Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital (Japan); 7. Ochanomizu University (Japan); 8. Institute of Health and Nutrition, Nagoya University of Arts and Sciences (Japan)

Background and objectives: According to the World Health Organization,15 million people worldwide suffer a stroke annually. Of these, 5 million die and another 5 million are left permanently disabled, placing a burden on family and community. Dietary and other lifestyle factors are the contributors to stroke, and there is a need to promote dietary habits that prevent stroke. In this study, we focused on dietary diversity and conducted a cross-sectional and longitudinal analysis using international data to determine whether a highly diverse diet inhibits ischemic stroke.

Methods: Data of ischemic stroke incidence and mortality by country were derived from the Global Burden of Disease (GBD) database. Average food supply (g/day/capita) and energy supply (kcal/day/capita) by country, excluding loss between production and household, were obtained from the Food and Agriculture Organization of the United Nations Statistics Division database (FAOSTAT). Each food was sorted across 14 food groups, and dietary diversity was obtained from food groups using the Quantitative Index for Dietary Diversity (QUANTIDD). As covariates, we used GDP per capita, aging rate, years of education, smoking rate, physical activity, obesity rate, energy supply, sodium intake, average systolic blood pressure, and average LDL cholesterol concentration obtained from the World Bank database and other sources. A cross-sectional association between QUANTIDD and incidence and mortality in 2009 was examined in 140 countries with populations of 1 million or more for which all data were available. A longitudinal association of QUANTIDD in 2009 with stroke incidence and mortality from 2009 to 2019, controlling for covariates at baseline using linear mixed models was also examined.

Results: In the cross-sectional model, QUANTIDD was significantly negatively associated with stroke incidence (β ± SE; -136.7 ± 57.8, p = 0.02) and mortality (-132.4 ± 49.8, p = 0.006). In the longitudinal model between QUANTIDD and year, the main effects of QUANTIDD on incidence and mortality were -140.7 ± 53.2 (p = 0.009), and -109.0 ± 37.7 (p = 0.005), respectively.

Conclusions: Dietary diversity was associated with decreased ischemic stroke incidence and mortality by cross-sectional and longitudinal analysis using international data.

The associations between coronary artery disease (CAD) and the intakes of foods recommended as The Japan Diet in patients undergoing coronary angiography

Yukihiko Momiyama[1], Yoshimi Kishimoto[2], Emi Saita[3], Reiko Ohmori[4], Kazuo Kondo[5]

1. NHO Tokyo Medical Center (Japan); 2. Setsunan University (Japan); 3. Nagoya University (Japan); 4. Utsunomiya University (Japan); 5. Ochanomizu University (Japan)

Background and objectives: Several cohort studies reported some associations between food intakes and CAD in a Japanese population. The Japan Diet (JD) was recommended to prevent atherosclerosis by Japan Atherosclerosis Society. However, studies investigating the associations between such food intakes and CAD or acute coronary syndrome (ACS) in patients undergoing coronary angiography are scarce.

Methods: We investigated the intakes of 5 foods (fish, soybeans, green/yellow vegetables, fruits, and seaweed) recommended as JD and the green tea and alcohol intakes in 802 patients undergoing coronary angiography. Foods intakes were divided into 3 categories (<3, 3–4 and >4 times/week) and were scored 0 to 2 points. JD score was defined as the sum of scores of 5 foods intakes. Green tea intake was divided into <1, 1-3 and >3 cups/day, and alcohol intake was divided into <1, 1-6 and >6 times/week.

Results: CAD was found in 511 patients, of whom 185 had ACS. Intakes of fish, vegetables and fruits were significantly lower in patients with CAD, especially with ACS, than in those without CAD. Soybeans and seaweed intakes tended to be lower in patients with CAD than without CAD. Green tea and alcohol intakes were significantly lower in patients with CAD, especially with ACS, than in those without CAD. JD score was lower in patients with CAD (4.0±2.2) than without CAD (4.6±2.0) and lowest in ACS (3.8±2.1)(p<0.001). JD score >5 was less frequent in patients with CAD (40%) than in those without CAD (56%)(p<0.001). In multivariate analysis, JD score and green tea and alcohol intakes were independent factors for CAD. Odd ratios for CAD were 0.50 (95%CI=0.36-0.71) for JD score >5, 0.61 (95%CI=0.41-0.90) for green tea >3 cups/day, and 0.53 (95%CI=0.36-0.78) for alcohol >6 times/week. Green tea intake was also an independent factor for ACS, but JD score and alcohol intake were not. Odd ratio for ACS was 0.63 (95%CI=0.40-0.98) for green tea >3 cups/day.

Conclusions: Foods recommended as The Japan Diet and green tea intakes were inversely associated with CAD, suggesting protective roles against the development of CAD in Japanese patients. Moreover, green tea intake was also associated with ACS.

Impact of sodium chloride on allergic symptoms and gastrointestinal barrier function in ovalbumin-induced food allergy in mice

Marina Sato[1], Suzuno Ota[1], Ayaka Koida[1], Siro Takei[1], Hana Kozai[1], Mamoru Tanaka[1]

1. Chubu University (Japan)

Background and objectives: To our knowledge, there have been no reports on the relationship between salt intake and food allergies. In this study, we investigated the effect of NaCl on allergy symptoms using a mouse model of food allergy.

Methods: Five-week-old female BALB/c mice were divided into four groups: Control (C) (n = 5); OVA (n = 8); OVA-NaCl 5% (NaCl 5%) (n = 7); and OVA-NaCl 10% (NaCl 10%) (n = 7) groups. The OVA, NaCl 5%, and NaCl 10% groups were sensitized on days 7 and 21 by intraperitoneal administration of aluminum adjuvant containing egg white albumin (OVA) to lightly anesthetized mice. The non-sensitized (C) group was sensitized with aluminum adjuvant without OVA. On the 36th day of the experiment, 20 mg of OVA was dissolved in PBS for the C and OVA groups, and in PBS containing 5% and 10% NaCl for the NaCl 5% and NaCl 10% groups, respectively, and orally administered to the mice. The following items were evaluated: (1) anaphylactic symptoms; (2) OVA-specific IgE in serum; (3) digestion and absorption of OVA; and (4) expression of tight junction-associated proteins in the jejunum. Results: Rectal temperatures were significantly decreased in all sensitization groups compared with group C (p> 0.05). Serum OVA-specific IgE was significantly higher in all groups compared with group C (p> 0.001). The portal blood OVA concentration in the NaCl 10% group was significantly higher than in the other groups (p> 0.05). In the histological observation of the small intestine, inflammation number of sites were significantly greater in the 5% and 10% NaCl groups compared with the C and OVA groups (p> 0.05).

Conclusion: A single administration of a high concentration of NaCl in a mouse model of food allergy increased allergen absorption because of inflammation of the small intestine and exacerbated allergic symptoms. The digestion of OVA and the barrier function of the gastrointestinal tract as an indicator of tight junction-related protein expression will be evaluated and the results will be reported in this presentation.

Food voucher program improves the recovery rate of children aged 6-59 months suffering from moderate acute malnutrition (MAM) in the Far North Region of Cameroon

Ismael Teta[1,2], Kang Yunhee[6], Brice Ulrich Saha Foudjo[4], Jennifer Nielsen[1], Julius Oben[3], George Nguefack-Tsague[3], Francoise Raissa Ntentie[5], Volkan Cakir[1], Rolf Klemm[1,6]

1. Helen Keller International (USA); 2. University of Ottawa (Canada); 3. University of Yaounde I (Cameroon); 4. University of Bamenda (Cameroon); 5. University of Maroua (Cameroon); 6. John Hopkins University (USA)

Background: Research on moderate acute malnutrition (MAM) is limited, despite its high prevalence. This study assessed recovery and associated factors among children treated through a food voucher program (FVP) enabling access to local foods in Cameroon's Far North. All children 6-59 months were screened by community health workers using middle-upper arm circumference (MUAC). Children identified with MAM were referred to health facilities for confirmed diagnosis and enrollment in the FVP.

Methods: This longitudinal cohort study ran from March to August 2020 in Kaele health district. Study subjects were randomly selected among enrolled children using stratified sampling with the probability proportional to the size of each health area. At enrollment and bi-weekly follow-up examinations, health agents provided caretakers a voucher to redeem for a pre-defined food basket (milk, eggs, fruits, vegetables, red millet flour, sugar and oil) from pre-selected local vendors. Children remained in treatment until a MUAC measure of greater than 125 mm or the end of the 12-week program. Time-to-recovery was evaluated with multivariate Cox proportional regression hazard models with associations quantified using adjusted hazard ratio (aHR). The trend for MUAC, including its determinants, was studied with multivariate linear mixed effect models.

Results: Among 474 children aged 6-53 months in the study, MUAC increased significantly over visits (P<0.001). Overall, 78.3% recovered, half (50.9%) after the first food voucher. Recovery among children aged 24-53 months was 31% faster than those aged 6-11 months (aHR=1.31, p=0.05). Boys were 33% more likely to recover than girls (aHR=1.33, p<0.001). A one unit increase in weight-for-height Z-score (WHZ) was associated with 89% faster recovery (aHR=1.89, p<0.001). In multivariate models, children aged 12-23 months and 24-53 months showed 1.03 mm (β=1.03, p=0.002) and 2.44 mm (β=2.44, p<0.001) greater increase in MUAC during treatment than those aged 6-11 months. A one unit increase in WHZ was associated with 3.42 mm increase in MUAC (p<0.001). Mean MUAC in boys was 1.82 mm greater than girls (p<0.001)

Conclusion: Recovery in the FVP was comparable to Sphere standards, suggesting promise as an effective treatment for MAM. Child's WHZ, gender and age were associated with MUAC and time to recovery.

The association of homocysteine and angiogenesis in patients with hepatocellular carcinoma before and after tumor resection

Yung-Fang Hsiao[1], Yi-Chia Huang[1], Shao-Bin Cheng[2], Chia-Yu Lai[2], Hsiao-Tien Liu[2]

1. Chung Shan Medical University (Taiwan); 2. Taichung Veterans General Hospital (Taiwan)

Background and objectives: Hyper-angiogenesis plays an important role in the development of hepatocellular carcinoma (HCC). High plasma homocysteine has been shown to be associated with angiogenesis. However, the impacts of homocysteine change before and after tumor resection on angiogenesis have not been fully investigated. The purpose of this study was to investigate the changes and associations of homocysteine and angiogenesis markers before and after tumor resection in patients with HCC.

Methods: This was a cross-sectional study. Forty-two HCC patients who were going to receive tumor resection were recruited from Taichung Veterans General Hospital, Taiwan. Demographic data, clinical characteristics, medication uses, medical histories and fasting blood samples were recorded or collected before tumor resection and one month after tumor resection. HCC tumor and adjacent normal liver tissue were collected during tumor resection surgery. Plasma and tissue levels of homocysteine, vascular endothelial growth factor (VEGF) and nitric oxide were measured.

Results: Patients had significantly increased plasma homocysteine and nitric oxide levels after tumor resection compared to levels before tumor resection, while there was no significant change in plasma VEGF levels before and after tumor resection. VEGF levels in HCC tissue were significantly higher than those levels in the adjacent normal tissue. Plasma homocysteine was positively correlated with VEGF concentration at post-resection. Levels of homocysteine significantly correlated with VEGF in HCC tissue.

Conclusions: The results imply that homocysteine might have an important role in angiogenesis of HCC development.

Keywords: Homocysteine, vascular endothelial growth factor, nitric oxide, hepatocellular carcinoma, tumor resection

International Ecological Studies on Chronic Obstructive Pulmonary Disease (COPD) related risk factors - Association with Undernutrition

Toshie Honda[1], Hiroshi Shimokata[1]

1. Graduate School of Nutritional Sciences, Nagoya University of Arts and Sciences (Japan)

Background and objectives: In patients with COPD, resting energy expenditure is increased due to increased respiratory muscle oxygen consumption. There is also increased energy consumption and decreased appetite due to systemic inflammation, and more than 40% of patients have weight loss and undernutrition. Conversely, lower BMI may be a risk factor for COPD. We examined whether countries with a lower BMI have a higher prevalence of COPD and mortality after controlling for socioeconomic factors and lifestyle habits including smoking.

Methods: Prevalence rates and mortality of COPD and mean BMI for countries worldwide in 1990, 2005, and 2018 were obtained from the Global Burden of Disease (GBD) database. As covariates, we used GDP per capita, aging rate, years of education, smoking rate, physical activity, average BMI, energy intake, and air pollution (PM2.5 concentration) for each year obtained from the World Bank database and other sources. We conducted a linear regression analysis of COPD prevalence and mortality with mean BMI controlling for covariates in 144 countries with populations of 1 million or more for which all data were available.

Results: In the model between COPD prevalence and BMI controlling for covariates, β ± standard error of BMI was -235.8 ± 46.7 ($p<0.001$) in 1990, -125.6 ± 41.9 ($p=0.003$) in 2005, -84.7 ± 41.1 ($p=0.02$) in 2019. In the model between COPD mortality and BMI, β ± standard error of BMI was -7.63 ± 2.27 ($p = 0.001$) in 1990, -3.75 ± 1.57 ($p=0.02$) in 2005, -1.54 ± 1.31 ($p = 0.24$) in 2019. Smoking was significantly associated with COPD prevalence and mortality in all years.

Conclusions: BMI was significantly associated with COPD prevalence and mortality except mortality in 2019. The results that COPD prevalence and mortality were higher in countries with lower BMI suggests that underweight and undernutrition may have been risk factors for COPD. However, the effect of BMI on COPD prevalence and mortality has become smaller over time, suggesting that the influence of risk factors other than undernutrition may have increased.

Isoflavones inhibit hydrogen peroxide-stimulated secretion of angiotensinogen in mesangial cells

Masumi Kamiyama[1], Tamami Iwamoto[1]

1. Jumonji University (Japan)

Background and objectives: We previously reported that urinary angiotensinogen levels are increased during the development and progression of diabetic nephropathy. However, the regulation of angiotensinogen secretion in the kidneys is not clear. In this study, we investigated whether reactive oxygen species enhance the secretion of angiotensinogen by mesangial cells, and whether the antioxidative effect of isoflavones affects angiotensinogen secretion.

Methods: Mesangial cells were cultured in mesangial cell medium containing 2% fetal bovine serum (FBS), 1% mesangial cell growth supplement, and 1% penicillin/streptomycin. Cells were cultured in serum-free medium for 12 hours and then stimulated with hydrogen peroxide. Isoflavones (daidzein and its metabolite, equol) were also stimulated before the stimulation of hydrogen peroxide. Angiotensinogen levels in the culture media were measured using ELISA. The antioxidative effect (free radical scavenging activity) of the isoflavones was assessed using the DPPH method. 0.3 mM of DPPH solution was prepared in methanol and 0.5 mL of the solution was added to 0.5 ml of the diluted extract. The mixture incubated for 45 minutes in the dark, at room temperature, followed by absorbance reading at 515 nm. A lower absorbance indicated higher DPPH scavenging.

Results: Stimulation with hydrogen peroxide enhanced angiotensinogen secretion by 2.32-fold (0.157 ng/mL and 0.364 ng/mL in the control versus hydrogen peroxide group). Daidzein and equol suppressed hydrogen peroxide-mediated increase in angiotensinogen secretion by 59.3% and 62.3%, respectively. Analysis of the antioxidative activity of daidzein and equol using the DPPH assay showed that they decreased DPPH by 55.0% and 61.2%, respectively.

Conclusions: Our findings indicate that reactive oxygen species triggered angiotensinogen secretion by mesangial cells, which was suppressed by the antioxidative activity of the isoflavones.

Keywords: Isoflavones, angiotensinogen, antioxidative activity, kidney

Niacin supplementation attenuates capillary regression and oxidative phosphorylation enzyme depletion on unloading induced-skeletal muscle atrophy in rats

Hao Lin[1], Hao Ji Xing[1], Han Pan[1], Takumi Hirabayashi[1], Noriaki Maeshige[1], Hiroyo Kondo[1], Hidemi Fujino[1]

1. Kobe University (Japan)

Background and objectives: Inactivity causes muscle atrophy and capillary regression in skeletal muscle. Niacin induces hypermetabolism and may prevent capillary regression.

Methods: Adult female Sprague-Dawley rats were divided randomly into control, hindlimb unloading (HU), niacin (NA) and hindlimb unloading plus niacin supplementation (HU+NA) groups. Hindlimb unloading was carried out for 2 weeks in the rats belonging to the HU and the HU+NA groups. The rats of the NA and HU +NA group were administered niacin (750 mg/kg) using a feeding needle twice a day for 2 weeks.

Results: Hindlimb unloading resulted in capillary regression, decreased succinate dehydrogenase activity of the muscle fiber and slow fiber composition in the soleus muscle.

Conclusions: Niacin prevented capillary regression and mitochondrial dysfunction caused by the unloading of the soleus muscle. Thus, Niacin supplementation could be an effective therapy for maintaining the capillary network and mitochondrial metabolism of the muscle fiber under unloading condition.

Keywords: niacin, muscle atrophy, capillary regression, metabolism

Association of fish oil supplementation with incident dementia among diabetic patients

Pan Zhuang[1], Yin Li[2], Xiaohui Liu[3], Jingjing Jiao[4]

1. Zhejiang University (China); 2. Zhejiang University (China); 3. Zhejiang University (China); 4. Zhejiang University (China)

Background and objectives: Dementia is becoming a serious health problem with aging of the population worldwide. Typically, diabetic patients have a higher risk of developing dementia than healthy individuals and thus efficient preventative strategies are needed. Although supplementation of n-3 polyunsaturated fatty acids (PUFAs) has been favorably linked with the risk of dementia in the general population, data on the effect of n-3 PUFAs among diabetic patients is lacking. We aimed to evaluate the prospective association between fish oil

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

supplementation and all-cause dementia risk among older diabetic patients.

Methods: 16,061 diabetic patients aged over 60 years from the UK Biobank were followed up during a mean duration of 7.7 years. The use of fish oil supplements, demographic and dietary information were collected by the touch screen questionnaire. Dementia was diagnosed using the International Classification of Diseases (ICD-9 and ICD-10). The hazard ratios (HRs) and 95% confidence intervals (95% CIs) were estimated using Cox proportional hazards models to evaluate the association between fish oil supplementation and dementia risk.

Results: 337 cases of dementia were confirmed after 123,486 person-years of follow-up. Fish oil use was inversely associated with risk of developing dementia among diabetic patients (P = 0.031), after adjustment for potential confounding factors. The HR (95% CI) of dementia for fish oil users was 0.76 (0.60-0.98) compared with non-users. Such inverse association was not modified by the APOE ε4 genotype. Higher consumption of oily fish and non-oily fish (more than 1 serving/week) had no significant association with dementia risk (P-trend=0.271; P-trend=0.065) compared with nonconsumers.

Conclusions: In older diabetic patients, fish oil supplementation was associated with a lower risk of developing dementia while oily fish and non-oily fish consumption had no protective association. Our findings provide new population-based evidence to support the use of fish oils for the primary prevention of dementia among diabetic patients.

Effect of dietary canna starch intake on a mouse model of food allergy

Rina Kosaka[1], Ayaka Koida[1], Shiro Takei[1], Hiroyuki Watanebe[2], Mamoru Tanaka[1]

1. Chubu University (Japan); 2. University of Kochi (Japan)

Background and objectives: Previously, we have shown that feeding canna rhizome starch to mice may increase the intestinal barrier function and improve the intestinal environment. Here, we investigated the effects of canna starch intake in a murine food allergy model.

Methods: Five-week-old female BALB/c mice were divided into four groups: the CA and SA groups were fed ad libitum with AIN-93G; and the CC and SC groups were fed AIN-93G with 10% replaced with canna starch. In the sensitized groups, SA and SC, $Al(OH)_3$ containing egg white albumin (OVA) was administered intraperitoneally to lightly anesthetized mice on days 7 and 21. The mice in the non-sensitized groups, CA and CC, were administered $Al(OH)_3$ without OVA. Feces were collected on days 25–28. On day 28, 20 mg of OVA was orally administered to the mice. The following items were evaluated: (1) anaphylactic symptoms using rectal temperature as an index; (2) ability to produce various antibodies; (3) intestinal environment; (4) intestinal barrier function; (5) OVA uptake; and (6) tight junction (TJ)-related protein expression in the jejunum.

Results: Rectal temperature was significantly lower in the SA group, compared with the non-sensitized group, but no decrease was observed in the SC group. OVA-specific IgE was significantly higher in the SA group, compared with the nonsensitized, group, but was not increased in the SC group. The pH of the cecal contents showed a decreasing trend in the SC group, compared with the SA group. Fecal weight and fecal mucin content were significantly increased in the CC and SC groups, compared with the CA and SA groups. OVA uptake into the liver was increased in the SA group, and was decreased in the SC group to the same level as in the non-sensitized group. The level of claudin-1,7, a TJ-related protein, was decreased in the SA group and increased in the SC group.

Conclusions: Canna starch supplementation in a murine food allergy model leads to suppression of anaphylactic symptoms through suppression of OVA-specific IgE production, improvement of the intestinal environment, and a reduction in allergen uptake by increasing the intestinal barrier function.

Keywords: Canna starch, type-1 allergy, intestinal environment, IgE production, mice

Nutrient intake timing and exercise timing is associated with blood pressure.

Momoko Imamura[1], Hiroyuki Sasaki[1], Takae Shinto[1], Yu Tahara[1], Saneyuki Makino[1], Mai Kuwahara[1], Ayako Tada[2], Nanako Abe[2], Mikiko Michie[2], Shigenobu Shibata[1]

1. Waseda University (Japan); 2. Asken Inc. (Japan)

Background and objectives: cardiovascular diseases (CVDs) are one of the leading causes of death worldwide, and one of the most significant risk factors for CVDs is high blood pressure (BP). BP is associated with the intake of various nutrients, such as sodium, potassium, and cholesterol. However, research focusing on intake timing of these nutrients and BP has not been conducted. Furthermore, while physical activity has been suggested to take part in BP reduction, their timing effects also remain unclear. Therefore, we conducted two studies with the aim of hypertension prevention; (1) when each nutrient should be taken and (2) when exercise should be done.

Methods: (1) We used dietary data and a questionnaire asking about sleep, physical activity, and BP, collected from the food-log app "Asken" (N=2402), to investigate the relationship between the dietary data of nutrient intake in the breakfast, lunch, and dinner and BP.(2) We used questionnaire asking about the participants' systolic and diastolic blood pressure and weekly physical activity situation (length, frequency, intensity, and timing) to conduct analysis on their relationship (N=2343).

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Results: (1) Daily total intake of various nutrients such as sodium, sodium-to-potassium ratio, potassium, total energy, lipid, carbohydrate, and saturated fat showed a significant association with BP depending on the meal timing. From multiple regression analysis, eliminating the confounding factors, lunch sodium-to-potassium ratio, dinner energy, lipid, cholesterol, saturated fat, and alcohol intake were positively associated with systolic BP, whereas breakfast protein and lunch fiber intake showed a negative association. (2) Total physical activity, walking time and frequency, vigorous evening exercise (18:00-21:00) showed strong negative association with both systolic and diastolic BP. When participants were divided into groups according to the BP categories, compared to normal BP groups, higher BP groups exercised less in the evening.

Conclusions: Our results suggest that nutrient intake and exercise timing are important factors in the prevention of high BP. Our study provides possibilities to prevent hypertension by changing the timing of nutrient intake, especially sodium, together with potassium and lipids and by exercising in the evening. However, further research on the general population needs to be conducted.

Keywords: Blood pressure, Dietary pattern, Exercise, Chrono-nutrition, Sodium

PAB(T4)-77
Development of a murine food allergy model with oral sensitization using a combination of antigens and NaCl

Suzuno Ota[1], Marina Sato[1], Ayaka Koida[1], Hana Kozai[1], Mamoru Tanaka[1]

1. Chubu University (Japan)

Background and objectives: Elevated concentrations of Na^+ in the intestinal tract are predicted to cause injury to mucosal epithelial cells in the small intestine, leading to a reduction or loss of the barrier function, which increases the absorption of undigested allergenic proteins. The purpose of this study was to investigate the effect of NaCl on the absorption of allergenic proteins and the induction of oral sensitization by the continuous intake of NaCl and allergens.

Methods: Five-week-old female BALB/c mice were divided into two groups (n = 8): water and NaCl groups. The mice were fed CRF-1 diet and tap water or 1.0% NaCl solution ad libitum for 36 days. On the 36th day of the experiment, 10 mg of chicken egg white albumin (OVA) was administered into the stomach of sensitized mice, and the OVA concentration in portal blood was measured by sandwich ELISA. Next, to evaluate the effect of NaCl on oral sensitization, mice were divided into five groups (n = 8): Control; OVA; OVA–NaCl (ON); wheat gliadin (GD); and wheat gliadin–NaCl (GN) groups. For the rearing period during the experiment, the Control group was fed an AIN-93G diet, the OVA and ON groups were fed an AIN-93G diet containing 0.1% OVA, or 0.1% OVA and 1.0% NaCl, respectively, and the GD and GN groups were fed an AIN-93G diet containing 0.1% GD, or 0.1% GD and 1.0% NaCl, respectively, for 8 weeks. Serum OVA-specific IgE, IgG1, IgG2a, and IL-4 were evaluated every week using ELISA.

Results: The OVA concentration in portal blood after ingestion of 1.0% NaCl solution for 36 days was significantly higher in the NaCl group compared with the water group ($p < 0.001$). The levels of OVA-specific IgE, IgG1, IgG2a, and IL-4 in the serum will be determined to evaluate the effect of NaCl on oral sensitization and the results will be reported in this presentation.

High LDL-Cho-specific circulating miRNAs are predicted to be involved in metabolomic alterations and the development of a wide range of related diseases - target gene prediction and GO analysis.

Keito Tatsumi[1], Mio Ohashi[1], Erina Shigematsu[2], Nanae Kondo[1], Masashi Omura[1], Kouji Hirota[3], Seiichi Oyadomari[4], Kazuki Tajima[2], Makoto Ujihara[2], Taiji Ito[1,2,3]

1. Kamakura Women's University (Japan); 2. National Hospital Organization Yokohama Medical Center (Japan); 3. Tokyo Metropolitan University (Japan); 4. Tokushima University (Japan)

Background and objectives: The 2019 National Health and Nutrition Survey reported that more than 30% of men in their 40s have a high LDL cholesterol (LDL-Cho) level (F formula). Micro (mi) RNAs are small RNAs that collectively suppress the expression of various genes. Among the miRNAs are blood-secreted miRNAs (circulating miRNAs) that are secreted from secreting cells and act on target cells through the blood. In this study, we performed comprehensive identification of high LDL-Cho-specific circulating miRNAs, target gene prediction and Gene Ontology (GO) analysis, and aimed to predict the effect on metabolism and causality with related diseases.

Methods: Serum miRNA expression in healthy subjects and subjects with high LDL-Cho (serum LDL-Cho > 140 mg/dL) who had IC in men in their 40s and 50s was comprehensively analyzed by microarray, target gene prediction was performed using Targetscan and miRDB, and GO analysis was performed in conjunction with the Human Metabolome Database and Disease Jensen Database by Shiny GO application.

Results: We identified 30 circulating miRNAs with variable expression levels specific to high LDL-Cho, of which 4 miRNAs with increased expression were predicted to be involved in the alterations of metabolites such as phosphatidic acid (PA) (16:0 /

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

16:0) (Enrichment FDR = 0.0128; the same hereinafter), phosphatidylinositol (PI) (16:0 / 18:0) (0.0128), LysoPA (18:2 (9*Z*, 12*Z*) / 0:0) (0.0207), cytidine monophosphate (0.0261), and pyruvic acid (0.0354). Surprisingly, these four miRNAs were also predicted to be involved in the development of diseases associated with high LDL-Cho, including carcinoma (Enrichment FDR = 1.51E-177; the same hereinafter), acquired metabolic disease (8.51E-06), cardiovascular system disease (0.000864) and Alzheimer's disease (0.0103).

Conclusions: The results of this study suggested that the identified high LDL-Cho-specific circulating miRNAs are associated with metabolic alterations and the development of related diseases. In the future, we would like to describe the blood expression levels of the above miRNAs for each risk group with different numbers of important risk factors such as aging (men > 45 years), hypertension, diabetes mellitus, smoking, family history of coronary artery disease and low HDL cholesterol (< 40 mg/dL) for high LDL-Cho, and apply them to diagnostic markers.

The Investigation on Nutrition Status and Clinical Outcome of Common Cancers (INSCOC) Group (China)

Background and objectives: We aimed to investigate the association of fat mass (FM) to lean body mass ratio (RFL), percentage of body fat (PBF), FM with all-cause mortality among middle-aged and elderly patients.

Methods: This prospective population-based cohort study comprised 3206 patients with stage 0 to IV cancer aged >40 years. Fat mass, and percentage of body fat were measured by bioelectrical impedance analysis (BIA). Cox proportional hazard models were used and adjusted hazard ratios (HRs) were estimated.

Results: We revealed an inverted U-shaped association between RFL and all-cause mortality among men aged >60 years after adjusted for confounding factors. Compared with those in the lowest tertile of RFL, elderly men in the medium and highest tertile had a 38% and 33% lower hazard of death from any cause, respectively. After additionally adjusted for C-reaction protein, HR of medium tertile still remained significant, while HR of highest tertile was none. No significant association was observed among female or male aged less than 60 years. Similar trends were also found between PBF and FM and cancer mortality.

Conclusions: Our data indicated that supporting the improvement of fat reserve in tumor patients is of importance for long-term disease outcomes, especially for elderly men with inflammatory reaction.

PAB(T4)-80
A Functional Food Formulation for Diabetic Nephropathy

Krishna Kalyan Kalahasti[1], Nagaraju M[1], Sreenivasa Reddy S[1], Bhanuprakash Reddy G[1]

1. National Institute of Nutrition-ICMR (India)

Background and objectives: Diabetes is now a growing epidemic and became a life-threatening disease with subsequent chronic complications that arise. The distinctive pathways (polyol pathway, non-enzymatic glycation, and oxidative stress) are responsible for the disrupted molecular changes which leads to diabetic complications including diabetic nephropathy (DN). The current drugs maintain primarily blood glucose and hence, there is a need for adjunct therapies to address diabetic complications such as DN. Amla, Cinnamon, Ginger, Fenugreek, Pepper, Turmeric are proven to have a beneficiary role when individually tested against diabetes and its complications in our previous studies affecting the above-pathways. In the present study, we formulated a mixture of these functional foods in a specific proportion to study their synergistic effect against DN.

Methodology: Amla (0.2%), Cinnamon (0.2%), Turmeric (0.05%), Pepper (0.1%) Fenugreek (0.5%), Ginger (0.3%) has been fed in rat chow diet to STZ-induced SD rats of 8-week age. The formulation has been given in preventive/therapeutic approach. Proteinuria, AGEs-accumulation in glomerular region, podocyte structural protein disruption and inflammation were studied by biochemical, immunoblotting, qPCR, and immuno-fluorescence methods.

Result: The above functional food (FF) formulation has significantly prevented albumin and creatinine excretion (ACR) compared with diabetes. The mRNA levels of podocin were improved by 50% and nephrin by 80%. Immunofluorescence revealed FF ameliorated accumulation of CML and MGO in the glomerular region and receptor for AGE (RAGE). Expression of inflammatory markers (Tnf-Alpha, p-NfKb) was decreased in FF treated group. Increased autophagy (Beclin, ATG5, P62) protein expression of diabetes rats was corrected with the functional food.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusion: We have developed a FF formulation that has beneficiary effect in improving DN and can be used as an adjuvant therapy in managing DN.

Deciphering the role of dietary fatty acids on HDL (high-density lipoprotein) lipidome

Maria Esther Martin[1], Elena M Grao-Cruces[1], Maria C Millan-Linares[1], Lourdes M Varela[1], Beatriz Bermudez[1], Sergio Montserrat-de la Paz[1], Antonio Rivas Domínguez[1]

1. University of Seville (Spain)

Background and objectives: The serum level of high-density lipoprotein cholesterol (HDL-C) is inversely correlated with atherosclerosis and cardiovascular disease (CVD) risk. However, randomized controlled trials did not show evidence reducing CVD when HDL-C was raised pharmacologically. It is therefore necessary to study in detail the molecular composition of these heterogeneous particles. Previous research has established that HDL lipidome plays an active role on HDLs structure and bioactivity. The latest cutting-edge lipidomic technology may then be helpful in HDL-targeted therapeutics. Our study aims to determine whether our dietary consumption of a variety of lipids may modulate the HDL lipidome in healthy or pathological conditions, anticipating changes in lipoproteins biochemistry or biofunctionality.

Methods: Two strategies have been assessed prior to determine lipidomic profile, functionality and HDL particle size in humans. Blood samples were collected from 20 healthy and 20 overweight volunteers. Another 5 healthy subjects agreed to consume four different diets, including no fat or saturated/mono-unsaturated/poly-unsaturated fatty acids, and blood was also recovered. Anthropometric data such as BMI, waist circumference, percent body fat or abdominal fat were recorded in all cases. HDLs were purified using a commercial kit and lipidome analysis was assessed by mass spectrometry. Nuclear magnetic resonance was used to determine HDL particle size.

Results: Anthropometric data reveal higher values in overweight when comparing with normal weight subjects, but no such a difference was reported for the interventional diet volunteers. Overweight subjects show a lower presence of lipids in HDL, in terms of the relative intensity detected and the number of different molecular species in every lipid family analysed by mass spectrometry. However, in the interventional assay, lipidome values among the participants were more similar. Particle size determination of HDLs provide comparable values of the most abundant molecules in both studies.

Conclusions: Lipidome profile appears to be a promising tool to evaluate the lipid populations' enrichment in both healthy and pathological conditions, as well as, for nutritional assays. Our results also anticipate that interventional strategies help to understand biochemical and functional changes in HDLs-C molecules, known to influence atherosclerosis or cardiovascular risk.

PAB(T4)-82
Associations of vegetable intake and primary industry workers with vitality: the Toon Health Study

Yuya Yabuki[1], Koutatsu Maruyama[2], Kiyohide Tomooka[3], Takeshi Tanigawa[4], Isao Saito[5]

1. Ehime University (Japan); 2. Ehime University (Japan); 3. Juntendo University (Japan); 4. Juntendo University (Japan); 5. Oita University (Japan)

Background and objectives: Previous studies showed that farmers, which is a major type of primary industry workers, had a higher vegetable intake than non-farmers. Therefore, we hypothesized that primary industry workers are healthier than other occupational workers due to higher intake of vegetable. The purpose of this study was to examine the associations of vegetable intake and primary industry workers with health-related quality of life (HRQOL) among Japanese population.

Methods: The subjects of this cross-sectional study were 632 men and 1205 women aged 30-84 years who participated in the Toon Health Study from 2014 to 2018. Vegetable intake was assessed by food frequency questionnaire, and HRQOL was assessed by Short Form-8 (SF-8). The subjects were classified into three groups: primary industry workers, unemployed and housewives (husbands), and other occupational workers. Analysis of covariance and multivariable regression analysis were used to analyze the associations of vegetable intake and primary industry workers with vitality.

Results: We found that age-adjusted mean of vitality, intakes of green and yellow vegetables, and other vegetables for primary industry workers was higher than other occupational workers in men and women, respectively ($p<0.01$). We also found that higher intakes of green and yellow vegetables and other vegetables were positively associated with vitality (green and yellow vegetables: $\beta=0.020$ in men and $\beta=0.017$ in women; other vegetables: $\beta=0.010$ in men and $\beta=0.011$ in women, $p<0.01$). Comparing the age-adjusted differences of vitality between primary industry workers and other occupational workers ($\beta=-1.90$ in men and $\beta=-2.55$ in women, $p<0.05$), we found that differences were attenuated after adjustment for green and yellow vegetables intake in men ($\beta=-1.51$, $p=0.07$). However, we didn't find such attenuation after adjustment for green and yellow vegetable intake in women and for other vegetables in respective sexes.

Conclusions: Vegetable intake may contribute to higher vitality among male primary industry workers. However, we need to further examine the contribution of green and yellow vegetables intake for the differences of vitality between primary

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

industry workers and the other occupational workers using other statistical approaches.

Keywords: Primary industry workers, vitality, vegetable intake

Low-birthweight rat due to embryonic undernutrition-changes in body composition after fasting-refeeding condition

Yuki Morita[1], Takahiro Nemoto[1]

1. Nippon Medical School (Japan)

Background and Objects: When exposed to undernutrition, the fetus acquires a thrifty phenotype and a small body size as a trade-off that changes its own metabolic and endocrine systems. The thrifty phenotypes are beneficial for survival under malnourished conditions, but the mismatch between the thrifty phenotypes and the eutrophic environment increases the risk of developing the non-communicable disease. However, low birthweight infants do not always exhibit obesity, and the details of the molecular mechanisms underlying the basis of the thrifty phenotype are not yet understood. Therefore, we generated embryonic malnutrition-induced low birthweight model rats and investigated changes in bodyweight and body composition under starvation. In addition, we tested the effects of nutritional interventions on changes in bodyweight and body composition.

Methods: Low birthweight (LBW) rats due to maternal low carbohydrate-calorie restricted diet-fed were produced according to a previous report (Sci Rep, 10, 1339, 2020). All experimental procedures were reviewed and approved by the Laboratory Animals Ethics Review Committee of Nippon Medical School (#2020-003). As a nutrition intervention, lactating rats were fed a methyl modulator (IJMS, 22, 9767, 2021) diet for the first week soon after birth. Male rats were measured body weight, body composition, and blood hormone levels after exposed to fasting and refeeding.

Results: The LBW significantly lost bodyweight than control rats when exposed to fasting. After refeeding, the bodyweight of controls recovered to the basal level, whereas LBW failed to recover their weight gain. LBW did not reduce body fat percentage after fasting. LBW decreased skeletal muscle weight (per bodyweight) than controls during 48h-fasting and failed to recover after refeeding. Intervention with MD during lactation increased weight recovery after 48h-refeeding. Blood corticosterone, a catabolic hormone, levels were significantly higher in LBW than in the control, and blood IGF-1, an anabolic hormone, levels were significantly lower in LBW than in the control.

Conclusions: It was shown that our fetal malnutrition-induced low birthweight model rats may have acquired a thrifty phenotype with "hard-to-burn body fat" and "easy-to-lose muscle". The intervention after birth with methyl modulators for the thrifty phenotype may normalize such a phenotype induced by embryonic malnutrition.

The oral administration of D-fructose and D-allulose recovers the villous morphology and function of the small intestine in a rat model of total parenteral nutrition

Takuji Suzuki[1], Hanna Kobayashi[2], Mai Kantake[1], Maika Sugiyama[1], Takumi Takahashi[2], Moeko Otomo[2], Yuki Sato[2], Sumire Kadoya[2]

1. Doshisha Women's College of Liberal Arts (Japan)
2. Yamagata University (Japan)

Background and objectives: Small intestinal epithelial cells maintain intestinal homeostasis by recognizing luminal nutrient stimulations. The reaction becomes especially sensitive when small intestinal functions decline markedly. Although it is believed that monosaccharide stimulation is effective in recovering the small intestinal functions, the type of monosaccharide that is most efficient for small intestine function recovery is still unknown. Therefore, we focused on D-fructose and D-allulose, which is C-3 epimer of D-fructose, and analyzed whether these monosaccharides can help recover the weakened small intestinal function.

Methods: We conducted total parenteral nutrition (TPN) surgery on 8-week-old male Wistar rats. The TPN group was administered TPN liquid, equating a total calorie count of 250 kcal/kg body weight/day, through a catheter inserted into the jugular vein for 7 days. In another group, rats were treated with the TPN for 7 days and were subdivided into three groups. Each group was orally administered 3 g/kg/day D-glucose (Gluc group), D-fructose (Fruc group), and D-allulose (Allu group) for 2 days, respectively. The Sham animals (used as controls for the TPN-treated animals) were given a standard diet and water *ad libitum* until the completion of the study following surgery. Nine days after the start of experiments, jejunoileal samples were removed from all animals in the Sham, TPN, Gluc, Fruc, and Allu groups and used for morphological analysis, gene and protein expression analysis, and the measurement of disaccharidase activity.

Results: In the Fruc group, the expression of representative molecules associated with digestion and absorption of nutrients and villous morphology mainly recovered compared with the TPN group ($p < 0.05$). In the Allu group, the expression of intestinal barrier-related molecules primarily increased. Additionally, the expression of lipids absorption related molecules such as fatty acid binding proteins significantly increased compared with the TPN group ($p < 0.05$). Significant recovery was not observed in the Gluc group.

Conclusions: There is a possibility that D-fructose and D-allulose are useful for recovering the small intestinal functions,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

such as digestion and absorption of nutrients and the intestinal barrier.

Combined hypertension and hypoerythropoietinemia in zinc deficient rats

Aki Konomi[1], Katsuhiko Yokoi[2]

1. Yasuda Women's University (Japan); 2. Seitoku University (Japan)

Background and objectives: It is quite common that patients with chronic kidney disease (CKD) have hypertension and hypoerythropoietinemia. Some patients with CKD have iron- and erythropoietin-refractory anemia as well. We previously reported that zinc-deficient rats had decreased plasma erythropoietin concentration, i.e., hypoerythropoietinemia. Some scientists reported that zinc (Zn) deficiency induces hypertension, although the mechanism is not established. We aimed to investigate the physiological roles of zinc in erythropoietin production in kidney and blood pressure control.

Methods: Thirty 3-week-old male Sprague-Dawley rats were assigned into 3 dietary groups (n=10 each) and fed on experimental diets for 4 weeks: control group (AIN-93G; Control), zinc-deficient group (4.5 mg Zn/kg; ZD) and pair-fed group (AIN-93G; PF). At day 24-25, systolic, diastolic, and mean blood pressures were measured by the tail-cuff method. At day 27-28, body water distribution was measured. Quantitative real time RT-PCR using TaqMan proves was performed for mRNAs of EPO in kidney. Statistical analysis was performed by PLSD.

Results: Renal cortex EPO concentration was lower in ZD than PF. No significant difference was observed in renal medulla EPO concentration. Erythropoietin mRNA levels in both renal cortex and medulla were significantly different between ZD and PF. Blood pressures of ZD were highest and those of PF were lowest among all treatment groups. Blood pressures of ZD were significantly higher than PF. Plasma angiotensin converting enzyme activity and relative heart weight of ZD were significantly higher than PF and AC. Plasma angiotensin II concentration and intracellular water/extracellular water ratio of ZD were marginally lower than PF.

Conclusions: These results suggest that zinc deficiency causes both hypertension and hypoerythropoietinemia via decreased renal erythropoietin expression and thus production, and that zinc deficiency hypertension is not evoked by an increase of renin-angiotensin system and hemoconcentration.

Keywords: Zinc deficiency, anemia, hypertension, erythropoietin, renin-angiotensin system

Elucidating the novel regulatory mechanisms of beige fat cells by single-cell analyses and their implication in lifestyle diseases

Yasuo Oguri[1,2], Tsutomu Sasaki[1]

1. Laboratory of Nutrition Chemistry, Division of Food Science and Biotechnology, Graduate School of Agriculture, Kyoto University (Japan); 2. Beth Israel Deaconess Medical Center, Division of Endocrinology, Diabetes & Metabolism, Harvard Medical School (USA)

Background and objectives: Beige fat cells are an inducible form of thermogenic fat cells that exist within the white adipose tissue in a scattered manner. They are induced in response to certain external cues, such as cold exposure and nutritional factors. Increased beige fat biogenesis is reported to have a positive impact on metabolic health. Thermogenic fat in adult humans displays a molecular signature resembling murine beige fat cells. Therefore, beige fat cells could be a potential novel therapeutic target for the treatment of lifestyle diseases, such as obesity and type 2 diabetes. However, the developmental origin of beige fat cells and pathways regulating this process remain unclear due to adipose tissue heterogeneity.

Methods: We isolated the stromal vascular fraction from mouse adipose tissue and employed single-cell RNA sequencing. Adipocyte progenitor cells (APCs) were isolated using fluorescence activated cell sorting (FACS). Cluster of differentiation 81 (CD81)-deficient mice were generated using the CRISPR interference (CRISPRi) system.

Results: Single-cell RNA sequencing identified a unique subset of APCs marked by cell surface proteins, including platelet-derived growth factor receptor α (PDGFRα), stem cell antigen 1 (Sca1), and CD81. Thereafter, we isolated CD81 $^{+}$and CD81^{-} cells using FACS and confirmed that CD81^{+} cells possess cell-intrinsic plasticity to give rise to beige fat cells. Transcriptome analysis revealed that this beige APC population has high proliferative capacity relative to CD81^{-} cells. We then established experimental methods to analyze APC proliferation *in vitro* and *in vivo*. We identified some regulatory factors including cold exposure promote APC proliferation. To test whether CD81 is required for beige fat biogenesis, CD81-deficient mice (CRISPRi-*Cd81* mice) were generated. Compared with control mice, the CD81-deficient mice exhibited impaired APC proliferation and *de novo* beige fat biogenesis following cold exposure. Moreover, the loss of CD81 led to diet-induced obesity, glucose intolerance, and insulin resistance.

Conclusions: These data suggest that CD81 marks beige APCs and controls APC proliferation along with beige fat biogenesis and whole-body energy metabolism. Our findings indicating that nutritional factors promote beige APC proliferation could be a novel approach to promote beige fat biogenesis and prevent lifestyle diseases.

Keywords: Single-cell RNA sequencing, beige adipocyte progenitor cells, cell proliferation, energy metabolism, lifestyle diseases

Plant-protein Rich, Low-calorie Diet to Improve Metabolic Health in Prediabetic Chinese Adults – A Randomized Controlled Trial

Sumanto Haldar[1], Alvin Surya Tjahyo[1], Shalini Ponnalagu[1], Farhana Osman[1], Priya Govindharajulu[1], Hui Wong Kat Long[2], Shia Lyn Tay[1], Susanna Poh Suan Lim[1], Christiani Jeyakumar Henry[1]

1. Agency for Science Technology and Research, Singapore (Singapore); 2. WIL@NUS labs (Singapore)

Background: Legumes are naturally rich in plant protein, dietary fibre and various phytonutrients. While previous studies have indicated beneficial effects of legume rich diets on metabolic health, whether they provide additional benefits as part of a calorie restricted diet is not known.

Objective: To investigate the effects of a legume rich, lower calorie, low glycemic index (GI) diet, with added spices and healthy oil blends on metabolic outcomes, as compared with a lower calorie animal protein diet.

Methods: A 16-weeks, parallel-design, randomized controlled trial was undertaken in 127 Chinese prediabetics (aged 62.3 ± 6.4 years, BMI 24.2 ± 2.5). Participants were randomized to 2 groups: a low-GI, legume-rich plant protein with healthy blended oil treatment group (n = 63); or a high-GI, animal protein with refined corn oil control group (n = 64). Both groups were provided with calorie restricted meals, twice a day, while the remaining third main meal was chosen freely, with guidance from research dietitian to ensure total calorie compliance within range. Baseline and post-intervention glycemic and lipid profiles were assessed once every 4 weeks. Linear mixed effects model was used for analysis on the change from baseline values with treatment, time and the interaction as fixed effects variables.

Results: Compared with baseline, at the end of 16 weeks, there were significant reductions in body weight, LDL cholesterol, total cholesterol, HbA1c and HOMA-IR (all $p<0.05$). Those in treatment group had significantly greater reduction in LDL (mean difference: -0.14 mmol/L, $p = 0.02$) and total cholesterol (mean difference: -0.21 mmol/L, $p = 0.006$) from baseline overall as compared to control group, although there were no differences between the two groups on markers of glucose homeostasis.

Conclusions: Consumption of a low calorie, low GI, legume-rich diet with healthy blended oil can improve cardiometabolic risk factors in a prediabetic Chinese population. Calorie restriction *per se*, controlling for meal sizes, may be a greater predicator to improve glucose homeostasis, than dietary quality alone. Food based intervention forms an important strategy to reduce risk of type 2 diabetes and cardiovascular diseases in Asia.

Multimorbidity and its behavioural risk factors in Japanese community-dwelling older people: A cross-sectional analysis in the Nagasaki Islands Study (NaIS)

Wenbo Song[1,2], Hirotomo Yamanashi[1], Mika Matsuzaki[3], Shogo Akabame[1], Yukiko Honda[1], Judith Lieber[2], Poppy Mallinson[2], Sanjay Kinra[2], Takahiro Maeda[1]

1. Nagasaki University (Japan); 2. London School of Hygiene and Tropical Medicine (UK); 3. Johns Hopkins University (USA)

Background and objectives: Population ageing in Japan is leading to rapid and substantial increases in the prevalence of multimorbidity. More attention should be paid to its patterns and risk factors. The objectives of this study were to examine the prevalence and patterns of multimorbidity and investigate how the prevalence and patterns of multimorbidity are associated with behavioural risk factors (BRFs) among Japanese community-dwelling older people.

Methods: The study sample comprised residents aged over 60 who participated in the Nagasaki Islands Study (NaIS) between 2017 and 2019 in Goto city, Nagasaki prefecture, Japan. Multimorbidity (2 or more chronic diseases) was coded according to the chapters of the International Classification of Diseases (ICD-10) from a list of 24. Multimorbidity patterns were extracted conjointly using hierarchical cluster analysis (HCA) and exploratory factor analysis (EFA). Five BRFs were evaluated: 1) alcohol consumption, 2) smoking habit, 3) physical activity, 4) sleep duration, and 5) eating habit. Each BRF was given a score of 1 (unhealthy) if recommended behavioural targets were not achieved or 0 otherwise. The accumulative effect of unhealthy BRFs was evaluated using the total sum of scores. Logistic regression was used to examine the association of multimorbidity with BRFs. Analyses were stratified by gender, and models were adjusted by age.

Results: A total of 2,815 older participants (62.2% females; 84.2% had multimorbidity) were analysed. We identified 3 multimorbidity patterns (2 for females and 1 for males). Mean number ± standard deviation (SD) of unhealthy BRFs were 0.93 ± 0.79 for females and 1.68 ± 0.93 for males. For females, no association of multimorbidity with BRFs was found. For males, multimorbidity was associated positively with smoking habit [1.51 (1.05-2.19)] and with accumulative unhealthy BRFs [1.96 (1.03-3.71)].

Conclusions: This is the first study to quantify multimorbidity and to examine its associated BRFs for Japanese community-dwelling older people. These results highlight the emerging concern about multimorbidity and underpin the need to develop effective public health interventions to prevent and manage multimorbidity.

User-profiles, barriers and facilitators in adherence to the dietary pattern in diabetes. Functionalities needed in SMARTCLOTH, a digital tablecloth for people with diabetes

Guillermo Molina-Recio[1,4], Rafael Molina-Luque[1,4], María García-Rodríguez[1,2], María-Pilar Villena-Esponera[1], María-Dolores Aguilera-López[3], Manuel Romero-Saldaña[1,4], Beatriz Méndez-Serrano[3], Jorge Martínez-de la Iglesia[1,3], Fernando León-García[1,4], Sandra Zafrilla-Sánchez[1]

1. Maimonides Biomedical Research Institute of Cordoba (Spain); 2. Universidad Europea (Spain); 3. Andalusian Public Health System (Spain); 4. University of Cordoba (Spain)

Background and objectives: Diabetes mellitus (DM) affects all countries and represents a challenge for their healthcare systems. Besides, the lack of adherence to the diet is one of its most significant weaknesses. For this reason, we are developing a device (hardware) called SMARTCLOTH. It consists of a digital cloth for helping people with diabetes follow the recommended diet and, consequently, ensure greater adherence. Therefore, the main objective of this initial research was to identify the different user profiles, the barriers and the most frequent facilitators in this type of patient and, based on them, to define the main functionalities that this hardware should present to facilitate the follow-up of the diet for these patients.

Methods: We followed an end-user-centred design through an agile methodology known as Design Thinking. Various qualitative techniques (focus groups and in-depth interviews) were used with patients and professional experts in diabetes education (n=15) to identify patient profiles and explore barriers and facilitators.

Results: Four types of potential users were identified: (i) adolescent insulin-dependent (DM1), (ii) adults with DM2, (iii) aged patients with DM2 and (iv) women with gestational diabetes. In addition, we identified as main barriers: difficulty in understanding the relationship between intake and glycemia, monotony in the diet, lack of time for health professionals to carry out health education, and lack of motivation or ineffective emotional management of patients. Access to weekly menus and recipes, immediate feedback on the nutritional value of the food eaten, and family or caregiver support have been highlighted as facilitators.

Conclusions: The variability of potential users of SMARTCLOTH requires that the handling of the device be very intuitive basic and ensure high usability without requiring a high degree of technological literacy. SMARTCLOTH must identify different types of foods groups, include a weighing system, and report the amounts of macronutrients, being exceptionally accurate on carbohydrates. The development of inexpensive and straightforward recipes could also increase its efficiency.

Keywords: Diabetes Mellitus, Diet Adherence, eHealth

Conflict of Interest Disclosure: None. This research is framed within the project "SMARTCLOTH.Design, implementation and study of the effectiveness of a digital tablecloth for diet self-management in diabetic patients" [PI21/01602] funded by the Instituto de Salud Carlos III in the call 2021 of the Strategic Action in Health 2017-2020 (Government of Spain).

PAB(T4)-90
Nickel deficiency hypertension is stronger than salt hypertension in female rats

Katsuhiko Yokoi[1], Aki Konomi[2], Miwa Oki[1], Mayu Kitagawa[1]

1. Seitoku University (Japan), 2. Yasuda Women's University (Japan)

Background and objectives: Although vegetables and beans are well-known by their hypotensive effects, the responsible factors are not well identified. Vegetables and beans are rich in the ultratrace element nickel (Ni). Therefore, we tested a hypothesis that nickel may have a physiological role in blood pressure regulation using experimental rats.

Methods: Forty-eight four-week-old female Sprague-Dawley rats were divided into four groups and fed four different diets for nine weeks. Control diet, supplemental Ni 0.5 mg/kg and no additional sodium chloride (NaCl); Ni-deficient diet, no supplemental Ni and no additional NaCl; NaCl-excess diet, supplemental Ni and additional 4%(w/w) NaCl; Ni-deficient/NaCl-excess diet, no supplemental Ni and additional 4% NaCl. Blood pressures were measured by the tail-cuff method a day before the start of the regimen (baseline) and then biweekly later. Increments of blood pressures from baseline were statistically analyzed by Dunnett's test (two-tailed). P values less than 0.05 were considered significant.

Results: At two weeks on dietary regimen, systolic blood pressure of the rats fed Ni-deficient diet was significantly higher than that of the rats fed control diet. At four weeks, systolic blood pressure of the rats fed Ni-deficient diet was significantly higher than that of the rats fed control diet. At six weeks, systolic and mean blood pressures of the rats fed Ni-deficient diet and Ni-deficient/NaCl-excess diet were significantly higher, and diastolic blood pressure of the rats fed Ni-deficient diet was significantly higher compared to the rats fed control diet. At eight weeks, all systolic, mean and diastolic blood pressures were significantly higher in the rats fed Ni-deficient diet and Ni-deficient/NaCl excess diet, while only systolic and mean blood pressures were significantly higher in the rats fed NaCl-excess diet compared to the rats fed control diet.

Conclusions: These results suggest that Ni deficiency causes hypertension, and the hypertensive effect of Ni deficiency is stronger than NaCl excess of 4%(w/w).

A longitudinal analysis of insulin resistance in children, 2–8 years old, living in the Pacific Region, the Children's Healthy Living Program

Douglas Taren[1,2], Halimatou Alaofe[2], Ashley Yamanaka[3], Patricia Coleman[4], Travis Fleming[5], Tanisha Aflague[6], Leslie Shallcross[7], Carol Boushey[3], Lynne Wilkens[3], Rachel Novotny[3]

1. University of Colorado (USA), 2. University of Arizona (USA), 3. Univeristy of Hawai'i at Mānoa (USA), 4. Northern Marianas College (Northern Mariana Islands), 5. Samoa Community College (American Samoa), 6. University of Guam (Guam), 7. University of Alaska (USA)

Introduction: The global prevalence of childhood obesity has significantly increased, putting children at a greater risk for type 2 diabetes mellitus (T2D). Acanthosis nigricans (AN), a dark, velvety discoloration of skin often occurring on the neck is a sign for insulin resistance. There are limited longitudinal studies on how changes in body mass index (BMI) and diet are associated with AN. This study determined how changes in BMI z-scores and diet over a 2-year period for children 2-8 years old living in the Pacific region were associated with AN.

Methods: Children (n=693) assessed at baseline and at follow-up for BMI, food intake, and the presence of AN were included in this analysis. Food intake records were collected from caregivers for two randomly assigned non-consecutive days at each time-period to assess nutrient, and food group intakes and adjusted for within child variation. Multiple regression and multinomial regression were used to determine factors associated with AN at follow-up and 2-year changes in AN status.

Results: The baseline prevalence of AN was 5%. All children who developed or maintained AN were overweight or became overweight. No children who went from overweight or obese to not being overweight had AN at follow-up. Controlling for age, sex, study group, baseline BMI, change in BMI z-score, and time between assessments, each teaspoon increase in added sugar or refined carbohydrate serving significantly increased the risk for the presence of AN at follow-up by 9% and 7%, respectively ($p < 0.01$); an increase in added sugar (OR: 1.16, $p<0.05$) or refined carbohydrate food servings (OR: 1.15, $p<0.01$) also increased the risk for developing AN. Increased servings of citrus (OR: 0.05, $p<0.01$) and fruit (OR: 0.29 ($p<0.05$) were protective for AN. No nutrients were associated with the presence of AN.

Conclusions: Added sugar and refined carbohydrate foods independently increased the occurrence of AN suggesting the source of carbohydrates is a factor for the development of AN. Obtaining a healthy weight and decreasing the intake of refined carbohydrates are critical to preventing AN in young children.

PAB(T4)-92
An investigation into the impacts of early access to a dietitian-led multimodal cancer cachexia intervention in metastatic cancer (CACHEXIA-CARE): an RCT protocol

Erin Stella Sullivan[1,2], Clodagh M Scannell[1,2], Derek G Power[2,3], Aoife M Ryan[1,2]

1. School of Food & Nutritional Sciences, University College Cork, Cork (Ireland), 2. CancerResearch@UCC, University College Cork, Cork (Ireland), 3. Department of Medical Oncology, Mercy University Hospital, Cork (Ireland)

Background and Objectives: The management of cancer-related malnutrition (CRM) and cachexia (CC), remains challenging due to its multifactorial aetiology. While multimodal interventions have been proposed to target the complex aetiology, further pragmatic trials are required to demonstrate efficacy. Moreover, while efficacy of interventions is reported to be poor in advanced CC, there is no validated means of identifying patients early in the CRM trajectory who might benefit from intervention.

Methods: This RCT will recruit 70 patients with incurable pancreatic, oesophageal, gastric or lung cancer due to begin first-line systemic treatment. To achieve 80% power for the primary outcome, n=30 is required, while n=70 allows for greater variation in secondary outcomes. Patients will be randomised 1:1 (open-label) to intervention or control arms. The personalised 12-week multimodal intervention (initial consultation with a registered dietitian (RD) + weekly follow-up) includes dietary counselling (ESPEN targets), symptom management, exercise prescription (population targets) and 2 daily servings of a novel powdered oral nutritional supplement for reconstitution (46 g + 150 ml whole milk provides 264 kcal, 26 g protein (incl. 3.5 g Amino L40© (leucine-rich amino acid blend)) & 7.5 mcg vitamin D_3). The control group receive no routine dietetic input. All patients receive standard oncological care and written resources on diet and cancer.

Results: Assessments at weeks 0, 2, 4, 8 and 12 will use a variety of simple and gold-standard techniques (including anthropometry, bioelectrical impedance & CT body composition analysis) to comprehensively monitor nutritional, functional and clinical status. The primary outcome is CC prevalence in intervention vs. control at week 12, according to the 2011 International Consensus Criteria. Analyses will be conducted on an intention-to-treat basis. Secondary & exploratory outcomes include intervention feasibility, relative efficacy according to CRM severity at recruitment, intervention impact on quality of life, physical activity level, overall survival and clinical complications as well as the diagnostic validity of various nutritional assessment methods.

Conclusions: This RCT will add to the emerging evidence-base for multimodal interventions in advanced cancer, and will examine the validity of currently available assessment techniques in appropriate selection of patients with potential to benefit from such interventions.

Keywords: Cancer, Malnutrition, Cachexia, RCT, Dietetics

Conflict of Interest Disclosure: ESS is an IRC Enterprise Partnership Scheme Fellow, whose research is funded by the

Irish Research Council and Nualtra Ltd. Nualtra Ltd. are providing the oral nutritional supplement for use in this trial at no cost, and the novel ingredient (Amino L40©) is an Ajinomoto product. Nualtra Ltd. is a wholly owned subsidiary of Ajinomoto.

Conflict of Interest Disclosure: Authors declare no conflict of interest.

PAB(T4)-93
Effect of an online nutritional intervention on anthropometric parameters of overweight and obese adults

Yolanda Elizabeth Perez[1], Karina Gonzalez[2], Ingrid Rivera[2], Sonia Guadalupe Sayago[1], Edgar J. Mendivil[3]

1. Instituto Nacional de México, Instituto Tecnológico de Tepic (Mexico), 2. Universidad de Guadalajara (Mexico), 3. Instituto Tecnológico y de Estudios Superiores de Occidente (Mexico)

Background and objectives: Obesity and dyslipidemia are risk factors that predispose to the development of cardiovascular diseases. The pathogenesis of these diseases involves environmental and genetic factors, such as polymorphisms associated with alterations in lipid metabolism. Adequate and precise nutrition is essential for preventing, treating, and controlling these pathologies. However, considering the consequences of social distancing generated by the pandemic, online nutritional counselling is a potential tool for nutritional care that should be provided to the population. This study assessed the effect of online nutritional counselling on anthropometric parameters of overweight or obese adults using two dietary patterns.

Methods: Sixty overweight or obese Mexican adults were recruited and randomly assigned to follow for eight weeks, into two groups accordingly to two previously created nutrigenetic patterns: a) low fat-low glycemic index-high protein pattern, or b) low saturated fat-high unsaturated fat-low carbohydrate pattern. Monitoring of participants was carried out remotely through a virtual platform, and multimedia teaching material was created and provided for the orientation and adherence of participants to the treatments. Results were collected at baseline, in the middle, and at the end of the intervention.

Results: 52% (n= 32) of the recruited population were women (30.2± 8.2 YO). At the beginning of the intervention, 57% (n=34) of the participants were obese and 43% overweight (n=26). At the end of the intervention, significant weight loss and decreased BMI were observed in patients of both groups (35% obesity, 51% overweight, 14% normal weight), as well as a reduction in waist and hip circumference. The entire population reported improvement in their dietary habits due to online nutritional advice. Loss to treatment follow-up was 38%.

Conclusion: Online nutrition is a viable and feasible tool for nutritional care during confinement and posterity. Developing virtual strategies for adherence to the diet and the motivation to change habits is essential. Both eating patterns evaluated were beneficial to promote weight loss and the reduction of anthropometric measurements of the participants.

Effects of citrate synthase insufficiency on nutrient and energy metabolism in pressure overloaded heart

Chihiro Ono[1], Reina Takahashi, Naoko Wada, Kaoruko Iida[1,2]

1. Graduate School of Ochanomizu University (Japan), 2. The Institute for Human Life Innovation, Ochanomizu University (Japan)

Background and objectives: The heart is flexible in substrate selection, utilizing lipids as oxidative substrates under normal conditions and carbohydrates as oxidative substrates under loading conditions such as pressure overload. In recent years, it has been suggested that the decrease in mitochondrial function induced by chronic stresses, such as aging and pressure overload, may contribute to the decline of cardiac function. However, the effects of mitochondrial dysfunction on metabolic flexibility remain unclear. In this study, we investigated the metabolic changes in the hearts of mice with hetero knockout (KO) of citrate synthase (CS), an important mitochondrial enzyme.

Methods: Male CSKO mice aged 16 to 20 weeks and their wild-type (WT) siblings were injected with Angiotensin Ⅱ (Ang Ⅱ, 800 ng/kg BW/min) using a subcutaneously implanted osmotic pump. On the 8th day of treatment, the mice were dissected and the hearts were harvested to examine ATP content and the expression of genes related to the substrate utilization. In addition, immunostaining was performed for histological examination, and anabolic and catabolic signals were also examined.

Results: When the mice were loaded with Ang Ⅱ, myocardial ATP content tended to be decreased in CSKO mice compared to WT mice. The expression of genes involved in the uptake and utilization of various substrates, such as glucose, lipids, lactate, and amino acids were significantly upregulated in the CSKO group. The cardiac expression of genes related to mitochondrial respiratory chain complex was also elevated in CSKO mice. Histological examination showed a significant decrease in the cross-sectional area of myocardial fibers in the heart of CSKO mice. The protein analysis revealed a decrease in Akt signaling activity and induction of autophagy in CSKO heart, as assessed by the specific marker LC3.

Conclusions: In this study, it is suggested that the hearts with impaired mitochondrial function adapt to pressure overload by using variety of energy substrate, but are unable to generate sufficient ATP, leading to myocardial atrophy induced via autophagy.

A longitudinal attempt to accumulate higher peak bone mass in Japanese adolescents in order to prevent osteoporosis in later life

Takako Hirota[1], Kenji Hirota[2,1]

1. Institute of Hirota Antiaging Research (Japan), 2. Nanko Clinic (Japan)

Background and objectives: Bone mass is determined by the amount of bone accumulated at the completion of skeletal growth, known as peak bone mass (PBM), and by the amount of bone lost during the remainder of life. It is estimated that a 10% increase in PBM could reduce the risk of osteoporotic fracture by 50% in later life. This study attempted to elucidate whether PBM can be increased through education for adolescents on dietary habits and a physically active lifestyle.

Methods: The subjects were adolescent girls (10 to 12 years old) in the 5th to 6th grade of elementary school, and from the 1st to 3rd grade in high school (12 to 15 years old). Bone mass was measured at os calcis by quantitative ultrasound (GE: A1000 InSight) in spring every year from 2013 to 2017 and also in autumn of 2016 and 2017. Subjects were instructed in the importance of prevention of osteoporosis, and in the age-appropriate improvement in calcium and vitamin D intake together with physical activity. Questionnaires regarding food intake, physical activity and other lifestyle factors from childhood were carried out at the time of bone measurement. Informed consent was obtained from subjects, and the study was approved by the Ethical Committee of their educational institution.

Results: Based on cross-sectional observation, PBM was presumed to be reached at around 12 to 13 years, and subjects' bone mass was associated with menarche age, body mass index, calcium intake from childhood, and physical activity. However, after instruction regarding osteoporosis, longitudinal study shows that PBM developed continuously till the age of 15 years, and that PBM increased by over 10%. Subjects had increased their daily food intake (40%), vitamin D intake (10%), and physical activity (30%) after osteoporosis education. Most students had discussed bone mass and osteoporosis with their family and friends (80%).

Conclusion: Appropriate timing of education on osteoporosis prevention with measurement of bone mass in adolescents could increase PBM over 10%, thereby effectively decreasing the occurrence of osteoporosis in later life.

Keywords: Bone measurement, Calcium intake, Vitamin D, Physical activity, Education

PAB(T4)-96
High LYRM4-AS1 predicts poor prognosis and correlates with immune efficacy in patients with glioma

Haiyue Wang[1], Ying Xie[1], Hongzhen Du[1], Bin Luo[1], Zengning Li[1]

1. The First Hospital of Hebei Medical University (China)

Background and objectives: Long non-coding RNAs are proved to be involved in the development of glioma. Our previous research screened the differentially expressed genes through The Cancer Genome Atlas (TCGA) database and identified the molecule LYRM4-AS1.As a lncRNA, the expression level and biological function of LYRM4-AS1 in glioma are unclear. Therefore, we attempted to assess the expression, clinical significance and related mechanisms of LYRM4-AS1 in glioma.

Methods: RNA-seq data with clinical information were obtained from TCGA datasets. The LYRM4-AS1 expression level was evaluated. Kaplan-Meier method was used to constructed survival curves. Independent variables were analysed by Cox regression analysis. The median LYRM4-AS1 expression value in glioma tissues was used as cut-off value to divide patients into high and low expression groups. The RNA-seq data were compared between high and low LYRM4-AS1 expression groups to identify differentially expressed genes (DEGs) using the DESeq2 R package. Then, gene set enrichment analysis (GSEA) was performed by clusterProfiler R package. Next, the single-sample Gene Set Enrichment Analysis (ssGSEA) was done by GSVA R package to quantify the immune infiltration of 24 types of immune cells in glioma tissues and the relative enrichment score of every immune cell was quantified from gene expression profile for each glioma tumor tissues. Spearman correlation analysis was used to analyze the correlation between LYRM4-AS1 and biomarkers of immune cells as well as immune checkpoints in glioma. All statistical analyses were performed using R (v.3.6.2).

Results: We found that LYRM4-AS1 was upregulated and related to the grade and malignancy of glioma. Survival analyses showed that patients with high LYRM4-AS1 expression had worse clinical outcomes. Cox regression analyses demonstrated that LYRM4-AS1 was an independent risk factor for OS in patients with glioma. Enrichment analysis and immune infiltration analysis showed interferon signaling and cytokine-cytokine receptor interaction enriched in the LYRM4-AS1 high-expression phenotype, and LYRM4-AS1 showed significantly positively correlated with immune infiltration and immune checkpoints.

Conclusions: These findings indicated that the increased LYRM4-AS1 might be a potential biomarker for the diagnosis and prognosis of glioma and might participate in the immune efficacy of patients with glioma.

Difference of sterol metabolism between mice and rats in response to a high-fat diet or diet supplemented with cholic acid

Wakana Iwasaki[1], Ryo Yoshida[1], Shota Hori[1], Yasutake Tanaka[2], Masao Sato[2], Satoshi Ishizuka[1]

1. Hokkaido University (Japan), 2. Kyushu University (Japan)

Background and objectives: Diagnosis of simple fatty liver, an early manifestation of metabolic dysfunction-associated fatty liver disease, is useful for prevention of hepatic diseases that includes hepatitis or cirrhosis. We found that the ratio of 12α-hydroxylated (12αOH) bile acids (BAs)/non-12αOH BAs in enterohepatic circulation of rats and mice positively correlates hepatic lipid accumulation. In addition, the changes in 12αOH BA were more prominent in rats than that in mice upon high-fat (HF) diet. Therefore, we tried to clarify difference of neutral and acid sterol metabolism between rats and mice under HF- or cholic acid (CA)-supplemented conditions.

Methods: C57BL/6JJmsSlc male mice and WKAH/HkmSlc male rats were fed a HF diet or a CA-supplemented diet at 0.5 g/kg diet for several weeks and analyzed sterol metabolism with regard to lipid metabolism including neutral sterols and BAs.

Results: In mice, the proportion of non-12αOH BAs was higher than that of 12αOH BAs. In contrast, the proportion of 12αOH BAs especially in enterohepatic circulation was higher than that of non-12αOH BAs in rats. In rats, HF-diet increased portal 12αOH BA concentration that correlated hepatic triglyceride concentration in HF-fed rats. On the other hand, such simple correlation was not observed in mice, and it is required to calculate the proportion of 12αOH/non-12αOH BAs to find a significant correlation with hepatic triglyceride concentration upon HF diet. Hepatic 7α-hydroxycholesterol was found to be increased in rats fed HF diet. On the other hand, major oxysterols were increased in the liver of HF-diet-fed mice. Also, mice excreted cholesterol directly into feces at a high amount under HF diet. Basically, feed efficiency was 10 times higher in rats than mice, indicating an enhanced energy expenditure in mice than in rats. The CA-supplementation developed hepatic steatosis in rats whereas there was no apparent such symptom was observed in mice.

Conclusions: This study clearly demonstrated the difference of cholesterol metabolism between mice and rats fed HF diet that reflected hepatic responses to CA supplementation. Significant roles of 12αOH BAs in hepatic triglyceride concentration became obvious both mice and rats under careful evaluation of metabolism especially in neutral and acid sterols.

Association between nutritional status, physical function, and physical activity in patients with rheumatoid arthritis

Mieko Shimada[1], Nobuko Hongu[2], Michiyo Asai[1], Yuya Narita[1], Taro Okamura[1]

1. Chiba Prefectural University of Health Sciences (Japan), 2. Osaka Metropolitan University (Japan)

Background and objectives: The muscle loss in patients with rheumatoid arthritis (RA) is affected not only by abnormal immunity but also by pain-induced deterioration of physical activity and nutritional status. However, it is not clear to what extent nutrition and physical activity will affect the muscle loss. The purpose of this study is to clarify the association between nutritional status, physical function, and physical activity in patients with RA, and to obtain basic data for constructing reasonable lifestyle guidance for patients with RA.

Methods: Nine RA female patients (mean age 67.6 ± 8.6 years) with low Disease Activity Score in 28 joints were included. The duration of RA was asked. Body composition by biometric impedance scale were measured. Physical function was measured with the modified Health Assessment Questionnaire (m-HAQ) and grip strength. Physical activity was assessed daily steps using an activity monitor. Mini Nutritional Assessment (MNA) was used to assess nutritional status. Those with an MNA score of less than 23.5 points were classified as "suspected undernutrition". We compared it with the data released by the National Health and Nutrition Examination Survey.

Results: The average duration of illness in 9 patients was 22.2 ± 9.7 years. The average BMI was 22.2 ± 2.4 kg/m^2, and the body fat percentage was 31.6 ± 5.2%. Three patients taking 7 different medications were judged to be suspected undernourished. All but these three were judged to be in remission by m-HAQ. The grip strength was 12.8 ± 6.2 kg, and the number of steps per day was 5248 ± 1390 steps.

Conclusion: There was no difference in the daily step counts and BMI between the RA patients of this study and the National Survey. The grip strength was about 50% of the national average value except for 1 person. Therefore, it was clarified that the amount of physical activity in terms of the number of steps does not directly affect physical dysfunction. Undernutrition in RA patients represent a novel and under-researched topic and further studies are warranted to understand whether improved nutritional status would be associated with improved physical function and physical activity.

Green coffee bean extract protects muscle capillary regression via decreased oxidative stress under disuse condition

Hao Ji Xing[1], Han Pan[1], Hao Lin[1], Ryosuke Nakanishi[1], Takumi Hirabayashi[1], Qi Xiao Ma[1], Kazuya Iwai[2], Noriaki Maeshige[1], Hiroyo Kondo[1], Hidemi Fujino[1]

1. Kobe University (Japan), 2. UCC Ueshima Coffee Co., Ltd. (Japan)

Background and objectives: Inactivity causes muscle atrophy and capillary regression in skeletal muscle. Green coffee bean contains a significant amount of chlorogenic acid which has an antioxidant capacity and may prevent capillary regression. Therefore, the protective effects of chlorogenic acid on inactivity-induced capillary regression in rat soleus muscle were investigated.

Methods: Twenty male Wistar rats were randomly divided into four groups: control (CON), chlorogenic acid supplementation (CGA), 2-week hindlimb unloading (HU), 2-week hindlimb unloading plus chlorogenic acid supplementation (HU+CGA). The rats in CGA and HU+CGA groups were orally administrated chlorogenic acid (850 mg/kg/day). The soleus muscle was removed and made into sections for histochemical analyses.

Results: Unloading resulted in a decrease in capillary number, oxidative capacity, and an increase in oxidative stress of the soleus muscle, whereas chlorogenic acid supplementation prevented the capillary and metabolic changes resulting from unloading by reducing oxidative stress.

Conclusions: In conclusion, chlorogenic acid supplementation may qualify as an effective treatment to reduce capillary regression in skeletal muscle caused by the inactive condition.

Keywords: Inactivity, Oxidative stress, Chlorogenic acid

Fermented Composite Cereals Promote Healthy Gut in Sleep-Deprived Epileptic Rats

Kayode Ajayi[1], Edem Ekpenyong Edem[1]

1. Afe Babalola University, Ado-Ekiti, Nigeria (Nigeria)

Background and objectives: Probiotics in fermented cereals are capable of suppressing potentially pathogenic microorganisms in the gut, enhance immune system, improve resistance to infection and prevent various chronic diseases like epilepsy. This study evaluates the impact of fermented composite cereals (Ogi) and its supernatant (Omidun) on the gut of sleep-deprived epileptic rats.

Methods: A composite consisting of 500g each of maize, sorghum and millet were allowed to ferment for 72 hours in water. The same portion of each cereal were soaked individually (non-composite) and allowed to ferment for the same number of hours. The composite and non-composite cereals were wet-milled after fermentation by adding 250g of ginger to the composite only. All the samples were sieved and allowed to further ferment for another 48 hours. Male wistar rats were randomly distributed into five groups of six rats per group. Control (CTRL) received normal saline, epilepsy (EPL) group were kindled using pentylenetetrazol, Sleep deprived (SD)+EPL+Diazepam treatment, SD + EPL + Ogi treatment, lastly SD + EPL + Omidun treatment. Ogi of the composite and non-composite were oven dried at 65oc for 20 hours and packaged properly for chemical analysis including selected minerals and vitamins using standard methods of AOAC. Mean difference between the groups were significant at $p<0.05$. Results: Treatment with composite ogi (residue) and omidun (supernatant) produced an increase in gastrointestinal tract (GUT) Triglycerides levels, low density lipo-protein level, total cholesterol and decrease in high density lipo-protein following kindling in sleep-deprived rats compared with SD and EPL groups. Treatment with diazepam and ogi produced significant reduction in gut Interleukin-17 (IL-17) level. However, treatment with omidun following status epilepticus in sleep-deprived rats did not show any significant difference in gut Il-17 level. The composite ogi contained in (ug/100g) vitamin A (7.23), vitamin D (16.40), vitamin E (13.47), vitamin K (8.67) respectively and for the non-composite ogi, vitamin content in (ug/100g) ranges from (5.81-7.39), (9.83-12.68), (7.67-11.91) and (6.5-11.2).

Conclusion: The composite Ogi was richer in nutrient composition compare to the non-composite and could impact positively on the gut microbiota.

Prebiotics, partially hydrolyzed guar gum, improved the defecation status via changes in the fecal microbiota and short-chain fatty acids in hemodialysis patients

Makoto Miyoshi[1], Hiraku Kadoguchi[2], Makoto Usami[3], Yuichi Hori[1]

1. Kobe University Graduate School of Health Science (Japan), 2. Suzuran Hospital (Japan), 3. Konan Women's University (Japan)

Background and objectives: Hemodialysis patients frequently complain severe constipation with decreased dietary intake and quality of life. However, increase of vegetable and dietary fiber intake may cause hyperpotassemia in those patients. We hypothesized that some prebiotics improve defecation status with improvement of intestinal environment in hemodialysis patients.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: Fifteen patients received prebiotics as partially hydrolyzed guar gum, 12 g/day that contain 10 g dietary fiber, during four weeks. The defecation status was assessed using both the Bristol Stool Form Scale and the Japanese version of the Constipation Assessment Scale. Satisfaction with prebiotics ingestion was evaluated using a visual analog scale. The fecal status, microbiota measured by a terminal restriction fragment length polymorphism analysis, and fecal short-chain fatty acid concentrations by gas chromatography were compared before and after prebiotics ingestion.

Results: Based on the Bristol Stool Form Scale, some subjects showed extremely disordered properties, such as type 1, separate hard lumps, type 2, lumpy, type 6, mushy stool, or type 7, watery stool, before ingestion. Prebiotics improved the stool form in most subjects to type 3-5, from 60.0% to 66.7%. Type 3-5 stool forms are thought to be ideal in Japan. Prebiotics ingestion also decreased the Constipation Assessment Scale from 5.1 to 3.0. The satisfaction of ingestion increased from 5.8 to 7.3 cm after ingestion. Prebiotics increased the ratio for *Bifidobacterium*, *Bacteroides*, and *Lactobacillales* to 2.4-, 3.2-fold, and 1.9-fold, respectively. Furthermore, the concentration of short-chain fatty acids significantly increased (1.6-fold). The major short-chain fatty acid of acetic acid, propionic acid, and butyric acid increased more than 1.5-fold. After ingestion, total short-chain fatty acids as well as acetic acid and propionic acid showed a positive correlation with *Bifidobacterium*. The individual dendrogram distribution after ingestion was changed in 8 participants (53.3% of the subjects). In 5 participants (33.3% of the subjects), the clusters were even more noticeably different.

Conclusions: Prebiotics improved the defecation status in hemodialysis patients due in part to the composition of intestinal microbiota and short-chain fatty acid concentrations. Improvement of the stool form by prebiotics could relieve constipation, thus improve the quality of life in hemodialysis patients.

Keywords: Hemodialysis, Defecation, Prebiotics, Microbiota, Short-chain fatty acid

Betaine, a regulator of mitochondrial-endoplasmic reticulum (MAM) interactions in the hepatocyte

Béatrice Morio[1], Frederic Lamarche[2], Emmanuelle Meugnier[1], Sandra Pesenti[1], Emmanuelle Loizon[1], Christophe Moinard[2], Anais Alves[1]

1. CarMeN Laboratory (France), 2. LBFA (France)

Background and objectives: Interactions between mitochondria and the endoplasmic reticulum (ER), called MAMs, are impaired in the liver of obese mice, with insulin resistance (IR) and steatosis. As certain nutrients can regulate MAMs, we tested whether betaine (a methylated amino acid derived from glycine) could modulate the structure and function of hepatocyte MAMs.

Methods: Primary hepatocytes from Wistar rats (male, 3 months, n=5) were incubated in the presence or absence of betaine (5mM). The structure of MAMs was explored by electron microscopy (TEM) and by in situ proximity ligation assay (PLA) for the functional unit formed by IP3R1 (inositol 1,4,5-trisphosphate receptor) at the ER and VDAC1 (voltage dependent anion channel) at the mitochondrion. Mitochondrial respiration was measured by oxygraphy in permeabilised cells. Gene expression and protein content of key actor at the MAMs (VDAC1, mitofusin 2: Mfn2, chaperone Grp75) were analysed. The results were analysed with Student's t-test.

Results: Betaine promoted MAM integrity vs. control. The length of MAMs measured by TEM relative to the mitochondrial circumference was increased by 4.7 points under betaine vs. control (16.2 vs. 11.5%, $p<0.05$). The number of VDAC1/IP3R1 interactions per nucleus analysed by in situ PLA was increased by 16.7% under betaine vs. control ($p<0.05$). These adaptations were associated with an increase in glutamate (5mM)/malate (2.5mM) cellular respiration (+48%, $p<0.01$). Furthermore, the gene expression and protein content of Mfn2, the protein most commonly found at MAMs, were increased by 26.2 and 15.2% vs. control ($p<0.001$ and $p=0.052$), respectively.

Conclusions: Our results evidenced that betaine regulates the integrity of MAMs. This could be explained by a specific effect on the expression of the structural protein Mfn2. The increase in cellular respiration indicates a beneficial effect of improved MAM integrity on mitochondrial oxidative function.

Flaxseed Oil Supplement Inhibited Lung Cancer Metastasis via Alpha-Linolenic Acid Regulat

Szu-Hua Pan[1], Tan-Ching Wang[1], Yuan-Ling Hsu[1], Wan-Chun Chiu[2]

1. National Taiwan University, College of Medicine (Taiwan), 2. Taipei Medical University (Taiwan)

Background and objectives: In lung cancer therapy, patients usually become weak owing to their severe clinical symptoms or the therapeutic side effects. This lets patients be more willing to use some nutritional supplements as adjuvant therapies; and believing that can help to improve their clinical phenomena. Recently, studies that the tumor growth rate could be significantly suppressed when mice feeding with flaxseed oil. However, the detail mechanism about how flaxseed oil acting in inhibiting tumor progression still remains unclear. As flaxseed oil is composed with approximately 58% alpha-linolenic acid (ALA), one of the essential fatty acids called omega-3 C18 natural fatty

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

acid; and generally, the dietary ALA can be stored in tissues; this let us hypothesize that the anti-cancer activity of flaxseed oil may owing to its good bioavailability from its' component ALA. Here, we conduct a pilot study to systematically dissect the details about the role of ALA supplement in suppressing lung cancer metastasis.

Methods: First, the appropriate dosage of ALA supplements in affecting cancer invasion and migration were determined in vitro by several human lung adenocarcinoma cells (CL1-2, CL1-5, Hop62, and A549), and the normal lung fibroblast (MRC-5) will be used as the control. Further, cell morphological changes and the dynamics of cytoskeleton rearrangement were examined by immunoblotting and immunofluorescence staining. In addition, total proteomic analyses were utilized to reveal the potential mechanism involved in ALA-induced effects on cancer progression.

Results: The results indicated that ALA treatment could induce the occurrence of mesenchymal- epithelial transition in highly invasive lung cancer cells, and have end result in inhibiting cell migratory and invasive abilities.

Conclusions: Our present study may indicate the role of ALA in tumor metastasis and help ensure the chemoprevention is as safe and effective as possible for lung adenocarcinoma patients.

Incidence of oral allergy syndrome and pollen allergy in Japanese university students

Nobue Takamatsu[1], Masaru Kubota[2], Izumi Hayashidera[2], Kumiko Nakai[3], Yukie Higashiyama[4], Takashi Kusunoki[2]

1. Beppu University (Japan), 2. Ryukoku University (Japan), 3. Hagoromo University of International Studies (Japan), 4. Aichi Shukutoku University (Japan)

Background: Recent reports from various countries demonstrated an increase of oral allergy syndrome (OAS) in patients with food allergy. In addition, OAS is reported to be complicated with pollen allergy. However, the exact prevalence of OAS with pollen allergy has not been well elucidated in adolescents. The aim of the present study is to elucidate the prevalence in Japanese university students.

Methods: Our own self-reported questionnaire was made after discussion among authors who participated in this study. The questionnaire consisted of questions including positivity of food allergy, if positive, main symptoms especially the presence of OAS, causative foods, and the experience of consultation, the positivity of pollen allergy, if positive, possible causative pollen, and the experience of consultation. Participants were students attending to either Ryukoku, Beppu, Hagoromo International or Aichi Shukutoku universities during April and May in 2019. After excluding the incomplete answers, 1100 students (male 418, female 682, mean age 19.1 yr) were enrolled. This study was approved by the ethical committee of Ryukoku University.

Results: (i) Totally, 221(20.1%) students had food allergy. Male showed 14.1% positivity, whereas female showed 23.8% ($p<0.001$). (ii) Among students with food allergy, 21 males (35.6%) and 84 females (51.9%) had OAS ($p=0.032$). (iii) Approximately, half students with food allergy consulted the physicians, and approximately 40 students were diagnosed as food allergy without any sex difference. (iv) Kiwi, melon, pineapple and peach are representative causative foods in OAS. The number of causative foods tended to be higher in females. (v) Totally, 587(53.4%) students had pollen allergy, but there was no sex difference. (vi) The overall rate of complication of OAS and pollen allergy was 80 (7.3%) students.

Discussion: This large scale study on OAS and pollen allergy in adolescents clearly indicates that the prevalence of OAS, and OAS plus pollen allergy is increasing. However, since the number of students who consulted the physicians is limited, a further study is necessary to delineate “true food allergy” from “food hypersensitivity”.

Arctium lappa Lam and its related lignans reduce blood glucose and triglyceride levels in diabetic rodent models: Meta-analysis

Shihori Watanabe[1], Shizuko Yamabe[1], Masako Shimada[1]

1. Sagami Women's University (Japan)

Background and objectives: Plant-derived phytochemicals have been interested in as nutraceuticals for preventing onset and progress of diabetes mellitus and its associated complications. *Arctium lappa* L. is a rich source of plant polyphenols with beneficial properties against various diseases including diabetes mellitus. Arctigenin and its glucoside, arctiin, are characteristic lignans in *Arctium lappa* L., whose contents are found to be the highest in Fructus Arctii; these lignans have been studied for their anti-diabetic effects in recent years. Yet, few clinical studies on *Arctium lappa* L. and diabetes mellitus written in English have been reported to this day. Therefore, this study aimed to examine an effect of *Arctium lappa* L. on diabetic hyperglycemia and dyslipidemia by meta-analyzing the current evidence of diabetic rodent models.

Methods and Results: Peer-reviewed studies written in English from two databases, PubMed and Embase, were searched to February 1, 2022. Studies reporting blood glucose or lipid levels in diabetic rodents with and without receiving extracts of *Arctium lappa* L. or its related lignans, are included. Sixteen studies enrolling 160 diabetic rodents treated with extracts of *Arctium lappa* L., and 160 diabetic controls reported blood glucose levels. The pooled effect size was -1.30 (95% CI: -1.65 to -0.94) with a substantial heterogeneity (I^2=66.3%). This effect was, at least in part, modified by types of DM models and

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

doses of arctigenin-related compounds. Moreover, diabetic hypertriglyceridemia was also significantly improved in diabetic rodent models treated with *Arctium lappa* L. Ten studies enrolling 92 diabetic rodents treated with extracts of *Arctium lappa* L., and 92 diabetic controls reported triglyceride levels. The pooled effect size was -1.49 (95% CI: -2.40 to -0.57) with a substantial heterogeneity (I^2=87.3%). This effect was likely to be, at least partially, modified by types of DM models. No effect was observed on HDL-cholesterol levels.

Conclusions: The present meta-analyses demonstrated that blood glucose and triglyceride levels were significantly reduced in diabetic rodent models treated with extracts of *Arctium lappa* L. or its related lignans.

Keywords: *Arctium lappa* L., diabetic rodent models, blood glucose levels, lipid levels, meta-analysis

PAB(T4)-106
Relationship between pancreatic exocrine status and survival in patients with cystic fibrosis in Japan

Shiho Kondo[1], Kotoyo Fujiki[2], Miyuki Nakakuki[3], Yuka Kozawa[3], Akiko Yamamoto[3], Yoshifumi Takeyama[4], Satoru Naruse[5], Hiroshi Ishiguro[3]

1. Nagoya Women's University (Japan), 2. Nagoya University of Arts and Sciences (Japan), 3. Nagoya University Graduate School of Medicine (Japan), 4. Kindai University (Japan), 5. Miyoshi Municipal Hospital (Japan)

Background and aim: Cystic fibrosis (CF) is the most common genetic disease in Europeans. It's very rare in East Asian population including Japanese. Although the median survival time of CF patients is ~24 years in Japan, a small group of patients survive longer. Since the relationship between pancreatic exocrine status and survival is not understood in CF patients in Japan, in this study, we have compared the clinical features of pediatric and adult CF patients.

Subjects and Methods: Fifty patients (23 male and 27 female, 0~47 years old; median age 9 years) with definite CF were evaluated. Fecal pancreatic elastase (PE) was measured by ELISA.

Results: Twenty eight of 38 pediatric (<18 years of age) patients was pancreatic insufficient (PI) (fecal PE < 200µg/g,) and 10 pediatric patients was pancreatic sufficient (PS) (fecal PE ≧ 200 μg/g). Two of 12 adult (≧18 years of age) patients was PI and 10 adult patients was PS. These 10 adult PS patients had chronic pulmonary disease or high levels of sweat [Cl^-] (≧60 mmol/L). The ratio of PI and PS was significantly different between pediatric and adult patients (p<0.01).

Conclusion: These data suggest that the existence of PI is one of the risk factors for mortality of CF patients in Japan. Malnutrition caused by pancreatic insufficiency is known to be related to impaired lung function. Intensive nutritional management is necessary to improve nutritional status and survival.

Keywords: Cystic fibrosis, Pancreatic insufficiency

PAB(T4)-107
Ad libitum dietary intake in young people with craniopharyngioma: a feasibility study of eating behaviour

Fiona Lithander[1,2], Becca Ellsworth[3], Nimra Naeem[2], Ruth Elson[4], Katherine Hawton[4], Tashunka Taylor Miller[4], Kruthi Narayan[4], Julian Hamilton Shield[4,3], Elizabeth Crowne[4,5], Elanor Hinton[3]

1. University of Auckland (New Zealand), 2. University of Bristol (UK), 3. NIHR Bristol BRC Nutrition Theme (UK), 4. Bristol Royal Hospital for Children (UK), 5. University Hospitals Bristol and Weston NHS Foundation Trust (UK)

Background and objectives: Craniopharyngiomas are rare benign suprasellar tumours near the pituitary-hypothalamus region. Obesity often results from surgical and/or radiotherapy treatment or due to the tumour itself. Mechanisms leading to obesity, hyperphagia and altered energy homeostasis are largely understudied. The aim was to assess the feasibility of measuring energy and macronutrient intake of patients with craniopharyngioma and control participants using an *ad libitum* buffet-style meal.

Methods: Participants attended the research facility once, accompanied by a parent/guardian after an overnight fast. They underwent tests relevant to eating behaviour followed by an *ad libitum* lunch comprised of hot, cold, sweet, savoury, food and beverages. Each item was covertly weighed before and after the lunch was served. Lunch provided ~30MJ and 37, 49 and 11% energy from fat, carbohydrate and protein, respectively. Patients and controls ate alone, remained in a room for approximately 30 minutes and were asked to eat to appetite. Data are presented as mean and standard deviation (sd). Hedge's g was used to measure effect size (*g*) between the two groups.

Results: Eleven patients (5F/6M) with childhood-onset craniopharyngioma age 15(4.6)y, BMI SDS 1.2(1.9) and 11 controls (5F/6M) matched for age and pubertal stage, 15(4.9)y, BMI SDS -0.62(0.9) took part. One control participant did not consume lunch due to previously undisclosed allergies. The remaining participants reported acceptability of the lunch. Lunch intake was 4.79(1.92) and 4.93(1.6)MJ, 51(21) and 53(17)g fat, 138(57) and 135(55)g carbohydrate and 29(15) and 34(11)g protein by patients and controls, respectively. When intake was expressed as a percentage of total energy, patients consumed more carbohydrate (*g*=0.42) and less fat and protein than controls (*g*=0.26, *g*=0.58, respectively).

Conclusions: These preliminary results demonstrate the acceptability and usability of *ad libitum* lunch methodology to assess energy and macronutrient intake in childhood-onset craniopharyngioma. These data are a subset examining eating behaviour in this patient group and given that hyperphagia and obesity in children and young people with craniopharyngioma causes substantial personal and parental distress, this highlights the importance of further investigation with a view to the development of future novel interventions.

Low-carbohydrate diet containing plant-derived fat ameliorate heart failure via PPARα activation

Satoshi Bujo[1], Haruhiro Toko[1], Kaoru Ito[2], Masato Ishizuka[1], Masahiko Umei[1], Jiaxi Guo[1], Bowen Zhai[1], Risa Kishikawa[1], Mutsuo Harada[1], Issei Komuro[1]

1. The University of Tokyo (Japan), 2. RIKEN Center for Integrative Medical Sciences (Japan)

Background and objectives: Cardiovascular disease (CVD) is a global health burden that could be prevented by dietary intervention. Although low-carbohydrate diets (LCDs) have beneficial effects on CVD risk factors (obesity, diabetes, dyslipidemia, and hypertension), their preventive effects on CVD remain elusive. Recent clinical studies have suggested that the effects of LCDs depend on the difference of macronutrients replaced for carbohydrate. We aimed to investigate whether LCDs with animal-derived fat (LCD-A) or plant-derived fat (LCD-P) ameliorate heart failure (HF) using a murine model of pressure overload.

Methods: Using wild-type male mice, we performed transverse aortic constriction surgery to generate a pressure overload model of HF. Mice were subjected to either control standard diet, LCD-A or LCD-P for 4 weeks and cardiac function was evaluated by echocardiography. Based on RNA-sequencing results from mouse hearts, we used cardiomyocyte-specific peroxisome proliferator-activated receptor alpha (PPARα) conditional knockout mice and pemafibrate, a selective PPARα modulator, for loss- and gain-of-function experiments to elucidate the roles of PPARα in HF development. We also examined the fatty acid composition in the sera and hearts of LCD-fed mice and tested PPARα activation by fatty acid in cultured cardiomyocytes.

Results: LCD-P ameliorated HF progression, while LCD-A aggravated inflammation and cardiac dysfunction. In hearts of LCD-A-fed mice, inflammation-related and cell cycle-related gene expressions were upregulated. On the other hand, fatty acid oxidation-related genes were highly expressed in the hearts of LCD-P-fed mice, and PPARα, which regulates lipid metabolism and inflammation, was activated. After pressure overload, cardiomyocyte-specific *Ppara* conditional knockout mice exhibited more severe cardiac dysfunction and inflammation than control mice, which was not inhibited by feeding LCD-P. However, pemafibrate ameliorated pressure overload-induced cardiac dysfunction and inflammation in wild mice. Stearic acid, which was more abundant in the sera and hearts of LCD-P-fed mice, activated PPARα target genes in cultured cardiomyocytes. PPARα target gene expression reduced by phenylephrine, which is known to induce cardiomyocyte hypertrophy, was restored by stearic acid stimulation.

Conclusions: Our study highlights the importance of substituting fat sources for reduced carbohydrates in LCDs and suggests the LCD-P-stearic acid-PPARα pathway as a novel therapeutic target for HF.

Effects of dehulled adlay on modulating nonalcoholic fatty liver disease

Hsuan-Chih Huang[1], Hsin-Yi Yang[1], I-Ting Wu[1], Pei-Ni Lee[2]

1. Department of Nutritional Science, Fu Jen Catholic University (Taiwan), 2. Department of Nutrition, Taipei Hospital, Taipei Hospital, Ministry of Health and Welfare (Taiwan)

Background and objectives: Nonalcoholic fatty liver disease (NAFLD) is the most common liver diseases worldwide and diet modification may be useful in retarding the progression of NAFLD. Adlay and its bran was reported to show potential in anti-oxidant and anti-inflammatory activity. Thus, the aim of this study was to investigate the effects of dehulled adlay on modulating NAFLD.

Methods: 24 male Sprague-Dawley (SD) rats were randomly divided into control group (C), NAFLD group (N) and NAFLD + adlay group (NA) for a 16-week experimental period. Rats in control group were fed with chow diet. N and NA group were fed with a high-fat-high-sucrose (HFHS) diet with or without dehulled adlay powder.

Results: At the end of the study, we found no significant difference in body weight among groups, but both N and NA group had more significant fat accumulation in the liver. We also found that NA group showed less steatosis and had higher GSH/GSSG ratio than the N group. Although the expression of the toll-like receptor 4 (TLR4) and myeloid differentiation primary response 88 (Myd88) in N and NA group were lower than C group, no difference in hepatic pro-inflammatory cytokines and circulatory endotoxin levels among groups were found. In the analysis of gut microbiota, Firmicutes/Bacteroidetes ratio (F/B ratio) and the abundance of *Actinobacteriota, Verrucomicrobiota, Clostridia, Clostridium* was higher in both groups fed with HFHS diet. In addition, *Clostridiaceae* in group NA were more abundant than in group N.

Conclusions: Our result suggested that ingesting dehulled adlay as part of the diet may improve liver steatosis, oxidative stress modulating gut microbiota.

Fatty acid biomarkers of dairy fat consumption, gut microbiome and cardiovascular health

Menglei Shuai[1], Chang Gao[1], Congmei Xiao[1], Xinxiu Liang[1], Yu-ming Chen[2], Ju-Sheng Zheng[1]

1. Westlake University (China), 2. Sun Yat-sen University (China)

Background and objectives: To investigate the prospective associations of circulating odd-chain fatty acids (OCFA) pentadecanoic acid (15:0) and heptadecanoic acid (17:0), as

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

biomarkers of dairy fat intake, with gut microbiome. We further examined whether the gut microbiome could modify the association between OCFA and cardiovascular health.

Methods: We measured the baseline plasma OCFA of 1220 participants from the Guangzhou Nutrition and Health Study. The gut bacterial and fungal composition over a median follow-up of 6.9 years were profiled using 16S rRNA (n=1129) and ITS2 (n=720) sequencing, respectively. The carotid intima-media thickness (IMT) and carotid artery plaques (CAPs) at follow-up were determined by ultrasound examination. Using multivariable-adjusted linear regression analyses, we examined the associations between OCFA and gut microbiome features. We further explored the interaction between OCFA and gut microbiome on host cardiovascular disease risk.

Results: After adjustment for potential confounders, higher levels of 15:0, 17:0 and their sum were positively associated with a higher gut bacterial α-diversity, while negatively associated with the fungal α-diversity. The overall gut bacterial composition, but not fungal composition could be distinguished by the levels of OCFA (all p=0.001). Specific taxonomic components, such as *Prevotella 9*, *Butyricimonas* were enriched in individuals with the higher levels of plasma OCFA. Furthermore, we observed that the protective associations between 17:0 and carotid IMT and plaques varied depending on the microbial abundance. In particular, elevated levels of 17:0 was associated with lower incidence of CAPs (RR=0.74, 95% CI: 0.59-0.93) in participants with lower abundance of *Alistipes* (p<0.05), but not in high-abundance *Alistipes* carriers.

Conclusions: Plasma levels of odd-chain fatty acids (15:0, 17:0) were associated with gut bacterial and fungal community. The gut microbiome might modify the interaction between dairy fat biomarkers and cardiovascular health.

The relationship between dietary calorie intake in the Medicine ICU first week and the prognosis within 28 days

Ting Hsuan Tu[1,2], Shwu-Huey Sherry Yang[2]

1. Sijhih Cathay General Hospital (Taiwan), 2. Taipei Medical University (Taiwan)

Nutritional support to critically ill patients' is very important for medical treatment, especially in the first week of intensive care unit (ICU). The accumulated energy unbalance at the end of the first week of ICU is a strong predictor of prognosis. Aim: This study's purpose is to investigate the relationship between the calorie and protein intake in the Medical ICU first week and the prognosis within 28 days of a regional teaching hospital in northern Taiwan. Study design: A retrospective observational study was conducted on patients, aged 20-80 years, admitted to the Medical ICU of Sijhih Cathay General Hospital from 2018/01/01 to 2020/12/31 and we obtained patients' data from hospital information system (HIS system). We divided ICU patients into ≧ 60% energy group (≧ 60% ε) and & <60% energy group (<60% ε) of calorie requirement according to their actual caloric intake in first ICU week. We analyzed their 7 days, 28 days mortality of those patients. Results: It is significant higher 7 days mortality in <60 % ε group than ≧ 60 % εgroup. Conclusion: Early nutritional care in ICU is extremely important and we recommend that to maintain patient's caloric intake at least 60% energy requirement.

Keywords: nutritional support, intensive care unit, dietary calorie, mortality

Ketogenic Diet Therapy (KDT) and Nutritional Status in a Glut 1 Deficiency Syndrome (G1DS) Chilean Cohort

Cecilia Baeza[1,2], Valentina Parga[1], Francisco Cabello[1,3], Claudia Castiglioni[3], Loreto Rios[4], Jose Marin[2], Carmen Perez[5], Veronica Cornejo[1]

1. Instituto de Nutricion y Tecnologia de los Alimentos Universidad de Chile (Chile), 2. Complejo Asistencial Dr Sotero del Rio (Chile), 3. Clinica Las Condes (Chile), 4. Centro Integral de la Epilepsia (Chile), 5. Hospital Las Higueras Talcahuano (Chile)

Background: GLUT1DS is an early onset childhood epileptic encephalopathy caused by impaired glucose transport across the blood brain barrier with subsequent brain energy failure symptoms, primarily seizures, cognitive impairment, and movement disorders. Since its initial description in 1991, the number of affected individuals has increased with age specific symptoms across lifespan. KDT has been proven as an effective treatment that should be initiated as early as possible, providing the developing brain with alternative metabolic fuel (ketones).

Objective: Describe anthropometric and biochemical status of patients with GLUT1DS on KDT.

Methods: Medical records of all patients on our GLUT1DS follow-up program were reviewed. Patients were appointed for anthropometric and biochemical evaluation. Lipid profile, serum ferritin and 25OHvitD was obtained. Insufficient D vitamin status was defined with levels between 20-30ng/ml and deficiency with levels below 20ng/ml. In children <5y, weight for length(WFL)z-score were used for anthropometric evaluation, in >5y, BMIz-score was used. Height adequacy was evaluated with height for age (HFA)z-score.

Results: 20 patients (11 male), with a median age of 7.9y who had been on KDT for a median of 2.7y (range 3m-21y) were evaluated. All of them with adequate supplementation. In 9 subjects, KDT was initiated within the first 7d since diagnosis; 9 were started within 1m and only 2 were started at 3m since diagnosis due to family issues. After KDT initiation, all patients responded with >50% reduction of seizure activity, 12 of them becoming seizure-free. However, accurate diagnosis was delayed

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

a median of 3y since the first seizure episode (range 15d-13y). Ratio of KDT was between 2-2.7:1 in 11 subjects; 3 were following a MAD diet, 3 had a ratio of 1.5:1 and 2 had a ratio >3:1. Ketone levels (BOHB) were between 0,5-2 mmol/lt in MAD diet users, and between 2-3.9 mmol/lt in the rest of subjects. Six patients were classified with normal weight, 8 with overweight, 3 with obesity and 2 underweight. Two patients had short stature (z-score: -2.65 /-2,4). All subjects had normal iron deposits. Three subjects had insufficient vitamin D levels and 3 had deficiency status. 4 patients had elevated LDLc (range 116-130 mg/dl), 3 had low HDLc (34-38 mg/dl) and 4 had elevated triglycerides (137-165 mg/dl).

Conclusions: KDT is an effective nutritional medical therapy for GLUT1DS which renders a good seizure control with limited impact on micronutrient status and low risk of undernutrition.

Differences in urinary phosphorus excretion after animal or plant protein intake in healthy young Japanese women

Sayuki Hashimoto[1], Tomomi Asano[2], Kunihiro Sonoda[2], Ayako Minematsu[2], Akihiko Kato[3], Junko Ishida[2]

1. Kobe Shoin Women's University (Japan), 2. Kinjo Gakuin University (Japan), 3. Hamamatsu University Hospital (Japan)

Background and objectives: Among patients with chronic kidney disease undergoing dialysis, phosphorus intake needs to be reduced while maintaining the necessary consumption of protein. However, it is known that phosphorus and protein content in foods are correlated, thus dietary planning that balances protein consumption while restricting phosphorus intake is a difficult issue. Urinary phosphorus excretion is known to be reflective of phosphorus absorption. Therefore, in this study, we investigated the effect of dietary intervention with animal, plant, or restricted protein intake on phosphorus excretion by analyzing 24-hour collected urine and dietary surveys.

Methods: Healthy young Japanese women were divided into four groups: normal (no dietary intervention), animal (animal protein sources), plant (plant protein sources), and low-protein (protein restriction), and were subjected to a 3-day dietary intervention. Vegetable intake was limited in the animal, plant, and low-protein groups to eliminate the effects of their constituent minerals. Based on the 3-day dietary records and 24-hour collected urine on day 3 of the intervention, the nutritional value, food group intake, and urinary components were evaluated.

Results: There were no significant differences in the protein and phosphorus intake between the normal, animal, and plant groups. However, urinary phosphorus excretion was significantly lower in the plant and low-protein groups than that in the normal and animal groups; there was no significant difference between the plant and low-protein groups, with similar levels of phosphorus excretion. The primary protein source for the plant group was soy products, therefore, legume intake was significantly higher in the plant group compared to the other groups. Furthermore, soybeans are high in magnesium, thus, the plant group also showed significantly higher magnesium intake than the other groups.

Conclusions: We showed that the plant protein diet reduced urinary phosphorus excretion to levels similar to that of the protein-restricted diet, while ensuring the protein intake was comparable to that of the animal protein diet. We hypothesize that phytin and magnesium, which are related to the form of phosphorus in foods, are the factors that may explain these findings. Plant protein may therefore be useful for phosphorus limitation while maintaining adequate protein intake.

Maternal consumption of eggshell membrane during pregnancy and lactation influences offspring colitis symptoms and dysbiosis in mice

Xuguang Li[1], Ke Li[1], Yukio Hasebe[2], Huijuan Jia[1], Hisanori Kato[1]

1. The University of Tokyo (Japan), 2. ALMADO Inc. (Japan)

Background and objectives: Dietary habits can affect the gut microbial community, thus influencing disease susceptibility in offspring. Although the effects of maternal nutritional status on offspring development have been documented, much less is known regarding the effects of maternal functional food consumption on offspring. Our previous study suggested that eggshell membrane (ESM) consumption could inhibit intestinal inflammation against inflammatory bowel disease (IBD). In this study, we further explored the effects of maternal ESM consumption during pregnancy and lactation on the gut inflammation, microbial structure, and composition in interleukin-10 knockout (IL-10 KO)-induced IBD offspring mice.

Methods: The pregnant mice were divided into three groups (WT: wild type C57BL/6J mice, basal diet; KO: IL-10 KO mice, basal diet; KOE: IL-10 KO mice, 8% ESM diet during pregnancy and lactation). The female pups were kept with their own mothers until postweaning to receive basal diet conditions. After 61 weeks of treatment, transcriptome analysis and microbiota analysis were performed on IL-10 KO-induced IBD offspring mice.

Results: Administration of ESM significantly increased the body weight of female offspring mice. Gene profile results indicated that with maternal ESM consumption, the female offspring mice exhibited enhanced serum response factor (Srf) expression which might assist in keeping normal macrophage phagocytosis to improve inflammation conditions.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Concomitantly, microbiota analysis established an essential role of ESM in improving dysbiosis characterized by affecting the relative abundance alterations of bacteria composition including reductions in immune-related Parapedobacter, Gramella, Parabacteroides distasonis, increased Muricauda as well as increased organic acid concentration especially enhanced butyrate to protect against IL-10 KO-induced microbiota dysbiosis cooperatively.

Conclusions: Our findings provided evidence that ESM serving as a maternal functional food contributes to the improvement of offspring colitis symptoms and dysbiosis in mice, which provides new perspectives from maternal dietary consumption for preventing the development of offspring colonic inflammation. Further investigation is needed to demonstrate the impact of the maternal gut microbiota, as well as short-chain fatty acids, on embryonic development and disease susceptibility late in life.

Effectiveness of Mediterranean diet on daytime sleepiness among individual with type 2 diabetes mellitus in Oman

Najwa Salim AlAufi[1], Yoke Mun Chan[1], Yit Siew Chin[1], Norliza Ahmed[1], Barakatun Nisak Mohd Yusof[1], Mostafa I Waly[2], Noor Al Busaidi[3], Sulaiman Al-Shuriqi[3], Khadija Al Amri[3]

1. Universiti Putra Malaysia (Malaysia), 2. Sultan Qaboos University (Oman), 3. National Diabetic and Endocrine Center (Oman)

Background: Excessive daytime sleepiness is a major complaint among individual with diabetes mellitus, which may be augmented with dietary intervention. The objective of this randomized controlled trial was to determine the effectiveness of Mediterranean diet intervention on daytime sleepiness among Type 2 Diabetes Mellitus (T2DM) patients in Oman.

Methods: A total of 134 eligible T2DM patients (61 and 73 respondents in the intervention and control group, respectively) were recruited. The intervention respondents underwent a six-month Mediterranean diet intervention comprising of individual dietary counselling, cooking classes, phone calls and social media messages while the control group continued with standard diabetes care. Daytime sleepiness was assessed using the Epworth Sleepiness scale. All data were analyzed using SPSS.

Results: Approximately 30% of the respondents experienced daytime sleepiness, with no significant difference between control and intervention respondents at baseline. There was significant reduction in daytime sleepiness in both intervention and control groups after 6 months, with daytime sleepiness was significantly lower in the intervention respondents, at a modest difference of 42.56% ($p < 0.001$).

Conclusion: Adherence to Mediterranean diet is effective in reducing daytime sleepiness among individual with T2DM.

Keywords: Mediterranean diet, Daytime sleepiness, Diabetes mellitus

Effects of muscle mass retention in morbidly obese patients after bariatric surgery on body composition in different genders in Taiwan

I-Chi Cheng[1], Pei-fen Lee[2], Wayne Hsu[2,3], Weu Wang[3], Yu Hsin Chang[1], Jo Hsuan Wang[1], Shyh Hsiang Lin[1], Sung-Ling Yeh[1]

1. School of nutrition and health sciences, Taipei Medical University (Taiwan), 2. Comprehensive weight management center, Taipei Medical University Hospital (Taiwan), 3. Division of general surgery, department of surgery, Taipei Medical University Hospital (Taiwan)

Background and objectives: Bariatric surgery is an effective method to control morbid obesity. The number of sleeve gastrectomy (SG) has increased recently. Their body weight can be decreased rapidly in the first 3 months, especially lean body mass. Muscle mass retention and intervention rate are important for patients who want to lose weight. This study aims to investigate the association between body composition and follow-up rate in patients with sleeve gastrectomy.

Methods: A retrospective clinical study conducted in Taipei Medical University Hospital, Taiwan. This study included 1062 morbid obese patients who have been SG for enrollment from 2010 to 2014. The final follow-up was in 2019 (TMU-JIRB201203002). Patients needed to measure body weight, muscle mass, fat mass, and waist-hip ratio (WHR) before and after surgery using BIA measurement. After surgery, a registered dietitian visited the patients, and gave the diet recommendations based on ASN and ASMBS guidelines. The interventions include counseling (15 sessions in 5years) and modification on dietary, physical activity, and behavioral approach in visit time.

Results: Of 1062 patients (713 [67.1%] women; mean age 35.3±9.1 years, weight 112.3±23.6 kg, BMI 40.4±6.8 kg/m^2, length of stay 3.9±1.2 days). Data showed that body weight, body fat mass and WHR significantly decreased within a year (weight between male(M) and female(F): 91.8±17.7kg, 73.5±12.9kg), and to third year (M and F: 92.8±22.1kg, 73.0±12.6kg), by the end of fifth year body weight increased (M and F: 100.6±17.7kg, 75.2±11.6kg). Patients with lower change in muscle mass positively related to weight maintenance. Compared the follow-up rate and body composition, patients with higher follow-up rate showed a trend on higher change in body weight.

Conclusions: The present study suggests that higher weight loss in the first 3-months, especially combined muscle mass retention, and a more follow-up rate relates to better weight loss.

Optimal protein intake for inpatients with type 2 diabetes

Chinatsu Yamagami[1], Chihiro Kugumiya[1], Megumi Honma[1], Yasuko Isaki[1], Yoko Tanaka[1], Michiko Ikemoto[2], Tetsuya Kawahara[1]

1. Shinkomonji Hospital (Japan), 2. Kyushu Nutrition Welfare University (Japan)

Background: In the previous study, we demonstrated that a one-week diet of 25 kcal x ideal body weight (IBW) to inpatients with type 2 diabetes resulted in significant weight gain in the underweight group (BMI <18.5 kg/m^2) and significant weight loss in the overweight group (BMI> 25.0 kg/m^2). However, we did not investigate whether this is due to the increase or decrease in muscle and fat.

Methods: We performed a Randomized Controlled Trial on patients in diabetes educational admission. Men and women over the age of 20 with type 2 diabetes and without renal dysfunction were randomly assigned to the standard-protein group (1.0g x IBW <= protein <1.3g x IBW) or the high-protein group (1.3g x IBW & <= protein <=1.6g x IBW). All participants were provided with a diet of 25 kcal x IBW for one week. In addition, an average of 3.4 Exercise/day rehabilitation was performed in both groups. During hospitalization, their blood glucose was corrected with intensive insulin therapy. A body composition analyzer (InBody®) was used to measure muscle and fat mass. The primary endpoint was the changes in muscle and fat mass (rate) between the two groups. The secondary endpoint was the amount of protein that changes muscle mass (rate) from decreasing to increasing.

Results: From March 2021 to March 2022, twenty-seven patients who met the eligibility criteria participated in this study. After one week of intervention, the change in muscle mass (rate) was +0.3 kg (+1.0%) and fat mass (rate) was -1.3 kg (-6.0%) in the standard-protein group. The change in muscle mass (rate) was +1.9 kg (+4.9%) and fat mass (rate) was -4.1 kg (-22.6%) in the high-protein group. Compared with the standard-protein group, a significant increase in muscle mass (P =0.04) and a decrease in fat mass (P < 0.001) were observed in the high-protein group. The protein intake at which muscle mass changed to increase was 1.2 g x IBW.

Conclusion: It was demonstrated that a large amount of protein diet (> 1.2 g x IBW) to patients with type 2 diabetes in educational hospitalization significantly increased muscle mass and decreased fat mass.

Effect of Japanese fermented rice malt beverage on defecation status in home-care patients with disabilities including severe motor and intellectual disabilities

Suzumi Kageyama[1], Rikako Inoue[2], Tetsuzo Tagawa[3], Natsuko Shiomi[4], Michiko Sakamoto[5], Miki Doi[1], A. Yasmin Syauki[1], Masahisa Funato[4], Toshisaburo Nagai[6], Yasuyuki Irie[2]

1. Graduate School of Okayama Prefectural University (Japan), 2. Okayama Prefectural University (Japan), 3. Asashio Clinic (Japan), 4. Osaka Children's Rehabilitation Hospital (Japan), 5. Toyonaka City Support Center for Children with Developmental Disabilities (Japan), 6. St. Andrew's University of Education (Japan)

Background and objectives: Constipation is a frequent complication in patients with severe motor and intellectual disabilities (SMID), therefore it is important to monitor the defecation status on a daily basis. The aim of this study was to investigate changes in defecation status associated with the intake of a Japanese fermented rice malt beverage (FRMB) in home-care patients with disabilities including SMID.

Methods: Ten patients (6.9 ± 5.6 years old, four males, six females) consumed FRMB (35 g/day) for six weeks and their physical condition, dietary and medication status, and defecation status, including constipation assessment scale (CAS), Bristol stool scale (BSS), and flowchart to classify defecation patterns of revised version (FCDP-RV) were investigated. For CAS, the score rate was calculated. Patients with a score of 31.3% or higher were evaluated as constipation-prone.

Results: CAS showed a decreasing tendency from 25.6 ± 13.0% to 13.8 ± 15.5% after the intervention (p = 0.064). BSS was classified into three categories: hard stools (type 1-2), normal stools (type 3-5), and soft stools (type 6-7), and the percentage of the three categories of BSS in the frequency of defecation during the week before the intervention and the sixth week was analyzed. The results showed a decreasing tendency in hard stools from 21.0 ± 34.7% to 8.1 ± 21.1% (p=0.066) and a significant increase in normal stools from 28.6 ± 22.6% to 54.1 ± 31.4% (p= 0.038). FCDP-RV is a tool for classifying defecation patterns into six categories based on stool shape and defecation days, and the percentage of patients falling into each category was examined. Diarrhea class, Observation-required class, and Constipation I class decreased from 30% to 10%, 10% to 0%, and 20% to 10%, respectively, and Constipation II class and Normal class increased from 0% to 20% and 30% to 50%, respectively.

Conclusions: After six weeks of FRMB intake in home-care patients with disabilities including SMID, changes in CAS suggested the possibility of reducing constipation symptoms. This may be accompanied by a change in stool shape. However, further validation with a larger sample size and a control group is needed.

Keywords: Fermented rice malt beverage, constipation, defecation status, patients with severe motor and intellectual disabilities

PAB(T4)-119
Effect of dietary intake and training of heavyweight male athletes on blood ALT and γ-GTP

Yukika Yoshizawa1, Jun Konnno[2], Hidehiko Kushi[2], Megumi Matsumoto[2]

1. Graduate School of Nihon University (Japan), 2. Nihon University of Humanities and Sciences (Japan)

Background and objectives: Heavyweight athletes may eat more and strain the liver in order to grow larger. In addition, the accumulation of fatigue from daily training can lead to a chronic decline in liver function. Therefore, among athletes, heavyweight athletes are considered to have a high risk of decreased liver function. However, few studies have objectively observed diet and training as factors that influence blood test data, which is an indicator of liver function, and no conditioning method has been established for athletes to restore liver function. Therefore, in this study, we decided to analyze in detail the factors related to the deterioration of blood test intake status, physical activity, liver function, and blood test data of track and field thrower and judo heavyweight athletes.

Methods: The subjects were 20 college students track and field thrower and 9 college students judo heavyweight (90 kg or more). We performed body composition measurement using impedance method, training survey, semi-quantitative diet survey for 3 days, and blood test.

Results: Examination of blood test data and influencing factors showed that there was a positive correlation between carbohydrate intake and ALT, energy ratio and triglyceride in blood in track and field thrower (r = 0.478, r = 0.519). There was a positive correlation between the amount of physical activity of track and field throwers and judo heavyweight athletes and γ-GTP (r = 0.605, r = 0.712).

Conclusions: For heavyweight athletes, it was suggested that excessive consumption of energy, especially carbohydrates and overtraining may synergistically worsen liver function. From this, it was considered necessary to adjust the dietary balance and the amount of training in order to improve liver function.

Keywords: ALT, γ-GTP, Track and field thrower, Judo, Meal

The effect of healthy eating index for hemodialysis patients on body composition

Yun Han Chen[1], Peng Sheng Zeng[2], Yung-Ho Hsu[3], Tso-Hsiao Chen[4], Hsi-Hsien Chen[5], Shwu-Huey Yang[1]

1. Taipei Medical University (Taiwan), 2. Cathay general hospital (Taiwan), 3. Shuang ho hospital (Taiwan), 4. Wanfang hospital (Taiwan), 5. Taipei medical university hospital (Taiwan)

Background: Dietary quality is an important factor to maintain the body composition which may further improve the clinical outcomes in hemodialysis patients. Health eating index for hemodialysis (HEI-HD) is established of 16 items include nutrient and food for hemodialysis patients in 2020. Aim: To investigate the relationship between dietary quality and body composition in hemodialysis patients.

Study design: A quasi experimental design was conducted in the four hemodialysis centers in northern Taiwan from May 2019 to April 2021. Total 94 subjects were included for analysis. Muscle and fat mass were assessed by bioelectrical impedance analysis and dietary quality was assessed by HEI-HD.

Results: The mean age, HEI-HD score, skeletal muscle mass (SMM) and appendicular skeletal muscle mass (ASM) of the subjects was 58.3 ± 10.1 years, 65.6 ± 8.3, 26.3 ± 5.7 kg, 19.4 ± 4.7 kg, respectively. The results of linear regression showed that the HEI-HD score, and total protein were positively correlated with SMM/Wt and ASM/Wt. The HEI-HD score was negatively associated with body fat mass, body fat percentage, and visceral fat mass. We divided subjects into 2 groups according to the median of SMM/Wt 40.53%, analyzed the binary logics regression model with the generalized estimating equation showed that with one piont increment of total protein, the risk of low muscle mass reduced by 12%.

Conclusion: It is recommended to use HEI-HD to evaluate the dietary quality of hemodialysis patients. Promoting dietary quality is highly suggested to improve the patient outcomes.

PAB(T4)-121
An increase in enterohepatic 12α-hydroxylated bile acid circulation alters iron balance in an early phase and induces subsequent stable reduction of hepatic iron concentration in rats

Natsuki Kubota[1], Shota Hori[1], Satoshi Ishizuka[1]

1. Hokkaido university (Japan)

Background and objectives: We previously found an increase 12α-hydroxylated (12αOH) bile acids (BAs) correlates liver triacylglycerol in rats fed a high-fat diet, and a cholic acid (CA)-supplemented diet develops simple hepatic steatosis. The CA feeding markedly reduced the hepatic iron concentration without change in food intake. In this study, we compared iron balance between the rats fed CA-supplemented diet and marginal iron deficiency (MID) diet to understand iron homeostasis.

Methods: WKAH/HkmSlc male rats (3-week-old) were divided into four groups, and fed either a control diet, a diet supplemented with CA (0.5 g/kg diet), a diet with a half concentration of iron in AIN-93G-based mineral mixture (MID), or diet in combination with CA and MID for two weeks. We measured iron balance and hepatic iron concentration. Also,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

iron-related parameters and hepatic gene expressions were analyzed.

Results: As shown in our previous study, CA diet specifically reduced hepatic iron concentration also in the 2-week study. Notably, CA diet enhanced fecal iron excretion, but such enhancement was not observed in our previous 13-week study. On the other hand, reductions were found in hepatic iron concentration, hematocrit, and aortic plasma iron parameters in MID-fed rats regardless of no difference in iron balance. Also, there was no anemia-related symptoms, such as reduction of food consumption, body weight, and whole blood hemoglobin concentration in MID-fed rats. In gene expression analysis, there were significant differences in iron transporters in MID-fed rats, but such difference was not observed in CA-fed rats. These results suggest that an increase in enterohepatic 12αOH BA circulation selectively reduces hepatic iron concentration by alteration of iron balance in the early phase. The mechanism underlying in this condition is obviously different from that in MID-fed rats.

Conclusions: Sufficient energy intake induces an increase in 12αOH BAs, which is possible to reduce hepatic iron concentration selectively by enhancement of iron excretion in an early phase. Such a liver-specific reduction of iron concentration may be involved in liver-specific lipid accumulation.

The effect of dietary fat quality on cardiovascular disease risk factors in hemodialysis patients

Wan-Lin Liu[1], Chien-Yin Chen[1], Hsi-Hsien Chen[2], Tso-Hsiao Chen[3], Yung-Ho Hsu[4], Sheng-Jeng Peng[5], Shwu-Huey Yang[1]

1. Taipei Medical University (Taiwan), 2. Taipei Medical University Hospital (Taiwan), 3. Taipei Municipal Wanfang Hospital (Taiwan), 4. Taipei Medical University-Shuang Ho Hospital,Ministry of Health and Welfare (Taiwan), 5. Cathay General Hospital (Taiwan)

Background and objectives: Cardiovascular disease (CVD) is the most common complication in hemodialysis (HD) patients. The dietary cholesterol-saturated fat index (CSI) is a measure of dietary fat quality and is associated with CVD risk in obese patients. The aim of this study was to investigate the correlation between CSI and CVD risk factors in HD patients.

Methods: A quasi-experimental design was conducted in the four hemodialysis centers (one group in one center) in northern Taiwan from May 2019 to April 2021. The educational handbook is given to both subject patients and nurses, and the Non-C group is not given nutrition education courses; Nutrition education for nurses in the CN group; nutrition education for patients in the CP group; nutrition education for nurses and patients in the CPN group. We collected the patient's characteristics, biochemical parameters, dietary intake. The CSI value was calculated. A total of 119 HD patients were included in the analysis.

Results: It showed that in comparison with the Non-C group, the CP group had significantly improved CSI, serum total cholesterol, homocysteine, and albumin. CSI was positively correlated with serum total cholesterol and high-sensitivity C-reactive protein.

Conclusions: Nutritional education could improve patients' dietary fat quality, and CVD risk factors. CSI could be used as a predictor of serum total cholesterol and high-sensitivity C-reactive protein.

Keywords: Cardiovascular disease, Dietary fat quality, Dietary cholesterol-saturated fat index (CSI), Nutritional education

The effects of adapted renal dietary guidelines on adherence in hemodialysis patients

Talita Du Plooy[1], Zarina Ebrahim[1], Nazeema Esau[1]

1. Stellenbosch University (South Africa)

Background: Renal dysfunction and chronic kidney disease (CKD) is known to affect as much as 10% of the population worldwide.[1] The annual mortality rate of hemodialysis patients is as high as 20%, with poor nutritional status being one of the biggest influencers of poor outcomes.[2] There is currently an increased awareness of the importance of optimal nutrition and early intervention to address malnutrition.[3] Despite the known advantages of nutritional intervention for dialysis patients, the CKD diet remains one of the most complex therapies to teach, understand and moreover, adhere to. Better adherence may be achieved by adapting and simplifying the dialysis patient's dietary prescription.[4] This study assessed whether simplifying the current renal dietary guidelines would have a positive effect in terms of patient adherence to the dietary guidelines and improve nutritional status.

Methods: A Quasi-experimental study including 75 hemodialysis patients from 4 dialysis units in Pretoria, South Africa. Adult hemodialysis patients undergoing dialysis 3 times per week between the ages of 18–70 years were included. Each participant's nutritional status was determined using anthropometrical measurements (body mass index (BMI)), waist circumference, triceps skinfold, mid-upper arm circumference (arm muscle area (AMA)) and biochemical parameters. Dietary intake was determined using a food frequency questionnaire (FFQ). Statistical tests were performed to analyse the stated objectives.

Results: Seventy-five participants were enrolled; 42 participants in the intervention group and 33 in the control group. The mean age of the population was 55 years (± 10.90). Fifty-five of the participants (73%) have been on dialysis for longer than 2 years. In terms of gender, 52 (69.33%) of the study population were male and 23 (30.67%) female. The majority of participants were well educated with a high household income. The most prevalent chronic illness reported was hypertension in

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

66 (88%) of the participants. The average BMI of the population at baseline was 26.6kg/(m²) (± 5.40) with 42 (56%) participants being overweight or obese. The majority of participants, 52 (69.33%), presented with an average AMA. The average protein intake of the group was within the recommendation at 1g/kg/day. The population showed a high intake of saturated fats and refined sugar. The average fiber intake was 20.68g/day (± 10.86), which is lower than the recommendation of 25g/day. An improvement in adherence to the renal dietary guidelines was seen in all aspects in both the intervention and the control group. After the intervention, the total adherence for the population improved by 15%, although adherence remained poor in terms of fruit, vegetables and fiber intake. When comparing the improvement in adherence to the renal dietary guidelines between groups, no statistically significant difference was found between the traditional vs simplified guidelines (p = 0.341).

Conclusion: Both the control and the intervention group received in-depth dietary education which might explain an equal improvement in terms of adherence. Given the high prevalence of overweight and obesity in end-stage renal disease, the management thereof should form an integral part of the nutritional intervention. Further intervention should focus on weight loss and increasing fruit, vegetable and fiber intake.

Hyperinsulinemia- An early marker to detect risk of metabolic dysfunction and prediabetes in adolescents and young adults in India

Jagmeet Madan Madan[1], Shobha Udipi Udipi[2], Soumik Kalita Kalita[3], Sharvari Malashe Malashe, Panchali Moitra Moitra, Rama Ashok Vaidya

1. Sir Vithaldas Thackersey College of Home Science (Autonomous), SNDT Women's University, Mumbai (India), 2. Kasturba Health Research Society, Medical Research Centre, Vile Parle, Mumbai (India), 3. Fam Phy, Gurgaon , Delhi (India)

Background and Objectives: Hyperinsulinaemia in the absence of impaired glucose tolerance and normal HbA1c may provide the earliest detection for metabolic disease risk and is considered indicative of pre-diabetes or occult diabetes. Very few Indian studies have focused on hyperinsulinemia particularly in adolescents and young adults. The present study examined the fasting and 2-hour stimulated glucose and insulin levels vis-à-vis their glycosylated hemoglobin levels in adolescents and young adults (16-25 years of age) living in Mumbai, India.

Methods: The study screened 1313 subjects in the age group of 16-25 years for Height, Weight, BMI, Waist Circumference, Body Fat percentage , Fasting and 2 hour blood glucose and insulin levels and glycosylated haemoglobin using standardized techniques.

Results: Among this young population (n=1313), 4.2% (n=55) of the participants were found to be prediabetic by ADA criteria and 19.7% of the participants were found to have HbA1c levels between 5.7%-6.5%. However, almost, 30.5% of adolescents had hyperinsulinemia in spite of normal blood glucose levels. Among those with normal HbA1c (<5.7), 56 participants had fasting insulin> 15 mIU/L and a higher percentage of participants (39.4%, n=260) participants had stimulated insulin above 80 mIU/L. Among those with normal HbA1c, mean values for BMI, WC, WHtR, percent body fat as well as visceral fat were significantly higher when their fasting and/or stimulated insulin was high as compared to those with normal fasting and/or stimulated insulin, whereas muscle mass was lower.

Conclusions: These findings highlight the need to use insulin levels as a screening tool along with commonly used blood glucose markers in young population, particularly for the overweight/obese who may beat-risk of progressing to diabetes in near future.

High Protein and Ready-to-eat Rice for Elderly with Dysphagia

Gladys Chu[1], Lina Tan[1], Daisy Cheong[1], Jessie Tan[1]

1. Nanyang Polytechnic Singapore (Singapore)

Background and objectives: Singapore is facing an increase in ageing population with dysphagia a growing concern. Study showed that one in two Singapore people aged 50 and older do not meet the daily protein requirement. Additionally, about 15% of the Singapore elderly population is affected by swallowing difficulty. Dysphagia in the elderly population is associated with increased risk of malnutrition and pneumonia. Traditionally, rice has been a staple food for people in Singapore and across Asia. At present, dysphagia friendly protein fortified ready-to-eat cooked rice is not available in the local food market. This project aimed to produce high-protein and ready-to-eat rice suitable for the community elderly especially those with dysphagia.

Methods: For swallowing safety, a highly efficient size reduction machine Comitrol® Processor Model 1700 was used to size reduce the rice into consistent size that meets the International Dysphagia Diet Standardization Initiative (IDDSI) Level 5 minced and moist consistency requirements. The nutrient properties of the dysphagia rice were improved through fortification with protein during the preparation process. The nutrient analysis was performed, and protein content was analysed using Dumas method. Speech therapist evaluation of the rice was conducted to further approve the texture and consistency that meet swallowing safety requirements.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Results: The outcomes this project were three types of protein fortified ready-to-eat dysphagia rice products namely white, pumpkin, and sweet potato rice which met the requirement of IDDSI Level 5 minced and moist consistency. The protein content for the rice products were 10.6g/100g for white rice, 11g/100g for pumpkin rice, and 10.2g/100g for sweet potato rice; as compared to the standard cooked white rice with only 2.8g/100g protein. The fortification has significantly increased the protein content of the rice products by approximately 260-290%.

Conclusions: These high protein dysphagia rice products will help to increase protein intake of not only the dysphagic individuals but elderly in general. With 50% of the Singapore elderly in need of an increased of protein intake, fortifying the rice staples with protein can be a cost effective and achievable method to help enhancing protein consumption.

PAB(T4)-126
Association between nutritional status and chemotherapy interruption in outpatients with ovarian cancer

Naoko Nomoto[1], Shinichi Tate[2], Makoto Arai[3], Chisato Mori[4,5], Kenichi Sakurai[6]

1. Chiba University Graduate School of Medicine (Japan), 2. Division of Gynecology, Chiba University Hospital (Japan), 3. Department of Medical Oncology, Chiba University Hospital (Japan), 4. Department of Sustainable Health Science, Center for Preventive Medical Sciences, Chiba University (Japan), 5. Department of Bioenvironmental Medicine, Graduate School of Medicine, Chiba University (Japan), 6. Department of Nutrition and Metabolic Medicine, Center for Preventive Medical Sciences, Chiba University (Japan)

Background and objectives: Discontinuation of cancer chemotherapy has been reported to worsen the prognosis of patients. However, few studies have examined the role of nutritional status before the start of treatment in chemotherapy interruption. The aim of this study was to determine the relationship between nutritional status at the start of chemotherapy and chemotherapy discontinuation in ovarian cancer including fallopian tube cancer and primary peritoneal cancer.

Methods: This was a retrospective case-control study. One hundred and forty-six patients with ovarian cancer, fallopian tube cancer, or primary peritoneal cancer were enrolled. They underwent postoperative chemotherapy as weekly Carboplatin and Paclitaxel therapy at the outpatient chemotherapy center of hospital X between April 2016 and March 2020. Patients were classified into two groups according to whether they had completed chemotherapy or not. Baseline characteristics and nutritional indicators were compared between the groups. Nutritional indicators included serum albumin level (ALB) and Prognostic Nutritional Index (PNI). In addition, the patients were divided into two groups according to ALB (cut off 3.1 g/dl) or PNI (cut off 50.1). The two groups were compared in terms of the number of times they received chemotherapy. Analysis was performed with JMP Pro 15 with statistical significance level of $p< 0.05$. This study was conducted with the approval of the Ethics Committee of Graduate School of Medicine, Chiba University. ALB and PNI were significantly higher and age was significantly lower in the completed group than in the incomplete group. The times of chemotherapy conducted was significantly lower in the low ALB group than in the non-low ALB group. Similarly, the times of chemotherapy conducted in the low-PNI group was significantly lower than that in the non-low-PNI group.

Results: ALB and PNI were significantly higher and age was significantly lower in the completed group than in the incomplete group. The times of chemotherapy conducted was significantly lower in the low ALB group than in the non-low ALB group. Similarly, the times of chemotherapy conducted in the low-PNI group was significantly lower than that in the non-low-PNI group.

Conclusions: ALB and PNI were associated with chemotherapy interruption and the times of chemotherapy which patients can be accepted. These results suggested that low nutritional status may play a role in chemotherapy discontinuation.

Docosahexaenoic acid suppresses the generation of reactive oxygen species in endothelial cells: a role for retinoid X receptor RXR

Ayasa Tajima[1,2], Gregory C. Shearer[2], Hiroshi Yoshida[3], Senya Matsufuji[1], A. Catharine Ross[2]

1. The Jikei University School of Medicine (Japan), 2. The Pennsylvania State University (USA), 3. The Jikei University Kashiwa Hospital (Japan)

Background and objectives: Docosahexaenoic acid (DHA) is known to play an important role in several physiological functions. However, clinical evaluations of DHA for arteriosclerosis prevention have not been conducted conclusive and molecular mechanisms underlying DHA's effect remain unclear. To fill this research gap, we investigated molecular mechanisms for DHA's effect on endothelial cells using human umbilical vein endothelial cells (HUVEC).

Methods and results: High levels of reactive oxygen species (ROS) were generated following oxidative stress generated by irradiation of cells with light and the ROS thus produced diffused from the nucleus to the cytoplasm. We found that DHA (as low as 10 nM) strongly suppressed endothelial ROS generation, more so than eicosapentaenoic acid (EPA). We also noted that HUVEC showed a large variation in the reactivity of DHA depending on individual differences of donors. The effect of DHA was canceled by HX531, a retinoid X receptor (RXR)-selective antagonist. Additionally, bexarotene as an RXR-selective agonist similarly

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

suppressed endothelial ROS. We also found some DHA-insensitive HUVEC, from different donors, in which DHA does not suppress ROS generation even with high doses of DHA. However, when these cells were pretreated with LE 540 as a retinoid A receptor (RAR)-selective antagonist, then DHA suppressed ROS generation. When the DHA-insensitive HUVEC strains were cultured in a medium without retinol acetate, vitamin D_2 and cholesterol, the ROS inhibitory effect of DHA was restored. These factors are ligands of nuclear receptors that dimerize with RXR.

Conclusions: These results indicate that DHA suppresses the generation of endothelial ROS through interaction with RXR. Thus, the difference in reactivity to DHA may be determined by the amount of RXR available to bind to DHA.

A case definition for thiamine responsive disorders: results from a prospective cohort study among infants and young children in Lao PDR

Taryn J Smith[1], Charles D Arnold[1], Philip R Fischer[2], Indi Trehan[3,4], Laurent Hiffler[5], Dalaphone Sitthideth[6], Xiuping Tan[1], Sengchanh Kounnavong[6], Sonja Y Hess[1]

1. University of California Davis (USA), 2. Mayo Clinic (USA), 3. University of Washington (USA), 4. Lao Friends Hospital for Children (Laos), 5. Cellular Nutrition Research Group (France), 6. Lao Tropical and Public Health Institute (Laos)

Background and objectives: Thiamine deficiency disorders (TDD) describes the broad clinical conditions associated with thiamine deficiency, of which beriberi is best known. Due to the non-specific manifestations and the observation that infantile TDD can present in the context of acute infections, TDD may go unrecognized and untreated. Therefore, this study aimed to develop a case definition for thiamine responsive disorders (TRD) to determine among hospitalized children which clinical features and risk factors identify those who positively respond to therapeutic thiamine.

Methods: Children (aged 21 days – <18 months) were eligible for participation in this prospective cohort study if they presented to hospital with symptoms suggestive of TDD. Children were treated with parenteral thiamine (100mg daily) for ≧3 days alongside other treatments. Physical examinations and recovery assessment were conducted 0, 4, 8, 12, 24, 36, 48 and 72 hours after administration of the initial thiamine dose. Individual case reports were generated for each child and independently reviewed by three pediatricians who assigned a TRD score (TRD or non-TRD), that was used as the dependent variable in logistic regression models to identify predictors of TRD. Clinical prediction model performance was quantified by empirical area under the receiver operating characteristic curve (AUROC).

Results: In total, 449 children (mean±SD age 4.3±3.4 months; 60.8% male; 70.3% exclusively/predominantly breastfed) were enrolled. The majority of children presented with signs of cardiac and respiratory distress (70.8% difficulty breathing; 61.7% tachycardia; 45.2% tachypnea). Children were hospitalized for a median (Q1, Q3) of 3 (2,6) days. There was a high prevalence of TRD (60.8%). The AUROC (95% CI) was 0.82 (0.78, 0.86), indicating excellent discriminative capacity. Variables selected as most predictive of TRD were exclusive/predominant breastfeeding, hoarse voice/loss of voice, cyanosis, child not making eye contact and no diarrhea in the previous 2 weeks.

Conclusions: In this study population, there was a high prevalence of TRD, and the consensus recommendation would be that all children presenting with clinical signs/symptoms suggestive of TDD in this and similar settings with high risk of thiamine deficiency should be treated with thiamine. The usefulness of the case definition in other contexts requires further exploration.

Can a new diet tracking app, myfood24 healthcare, support tier 3 weight management and gastroenterology surgery patients? A feasibility randomised controlled trial

Diane Threapleton[1], Janet Cade[1], Sarah Beer[3], Sarah Trevillion[2], Dermot Burke[1], Darren Greenwood[1]

1. University of Leeds (UK), 2. York and Scarborough Teaching Hospitals NHS Foundation Trust (UK), 3. Dietary Assessment Ltd (UK)

Background: Healthcare professionals regularly see patients requiring dietary support, however, they do not have all the tools needed to easily track food and nutrient intakes. Monitoring nutritional intake is of clinical value but few existing tools offer electronic dietary recording, instant nutritional analysis and a platform connecting healthcare teams with patients, providing timely, personalised support. This feasibility randomised controlled trial tests 'myfood24 Healthcare', a dietary assessment app and healthcare professional website in two clinical populations.

Methods: Two patient groups were included. Patients from a weight management programme in York and gastroenterology

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

surgery outpatients, Leeds (UK). They were randomised into three groups: standard care, myfood24, or myfood24+diet optimisation (automated suggestions for dietary improvement). Participants were asked to record diet with the app at least four times over eight weeks. Healthcare professionals viewed patient dietary information linked to targets. Participants provided feedback on usability and acceptability.

Results: 21 weight management patients and 27 gastroenterology surgery patients were recruited and 16 randomised to each of 3 groups. Patient mean age was 51y and self-rated internet ability was only 'fair'. Compliance in app users (n 32) was good, with 25 (78%) using it at least once. Among users the mean (SD) days recorded was 14.0 (17.5). Mean daily energy intake for weight management patients was 1060 (SD 513) kcal; with energy from 29% fat, 52% CHO; 20% protein; and for gastroenterology patients 1209 (SD 675) kcal; with energy from 37% fat, 50% CHO; 13% protein. Feedback questionnaires were completed by 50%. Despite small numbers, some patients said symptoms had improved by using myfood24 and that it could help them manage their condition. The mean System Usability Score was 59 (95% CI, 48 to 70). Patient and healthcare professional feedback indicates that patients found the tool easy to use, but needed more user training at the start and improvement of some key app features such as the search function.

Conclusions: This feasibility study shows that myfood24 Healthcare app is acceptable for patients and healthcare professionals. These data have informed app refinements, which are now in place.

Amino Acid-Amadori Products Affect Protein Synthesis of Fibroblasts and Myotubes Derived from Chicken Embryos

Miyu Sugita[1], Kazumi Kita[1]

1. Iwate University (Japan)

Background and objectives: Glycation is a non-enzymatic chemical reaction in which proteins and amino acids form Schiff base with reducing sugar like glucose. Schiff base undergoes Amadori rearrangement to form Amadori products (APs). A chicken is known to be one of hyperglycemic animals, and we found 7 types of amino acid-APs (Ile/LeuAP, LysAP, PheAP, TrpAP, TyrAP and ValAP) in the plasma of chickens. (Kita, K. et al., unpublished result). But physiological functions of amino acid-APs have not been clarified so far. In this study, therefore, the influence of amino acid-APs on protein synthesis of fibroblasts and myotubes derived from chicken embryos was examined.

Methods: Skin and breast muscle were excised from chicken embryos incubated for 19 days, and fibroblasts and myotubes were prepared, respectively. Amino acid-APs were synthesized from Ile, Leu, Lys, Phe, Trp, Tyr and Val, and added into culture medium. Final concentrations of amino acids-APs were 200 µM and 500 µM. ^{3} H-labeled amino acid, which is the substrate of amino acid-AP, was added into culture medium as a tracer for measuring protein synthesis. After overnight incubation, proteins were precipitated with TCA and the supernatant was collected. The radioactivity in protein and supernatant was measured with a liquid scintillation counter and used as indicators of protein synthesis and amino acid uptake into embryonic cells, respectively.

Results: In fibroblasts, amino acid-APs except for TrpAP, TyrAP and ValAP suppressed protein synthesis. Conversely, ValAP increased protein synthesis of fibroblasts. The decrease in protein synthesis by amino acid-APs was significantly correlated to the decline of amino acid uptake into intracellular fluid of fibroblasts. In myotubes, only LysAP and TyAP significantly suppressed protein synthesis. Interestingly, amino acid uptake into intracellular fluid of myotubes was increased by adding amino acid-APs into culture medium.

Conclusions: It was concluded that some of amino acid-APs would decrease protein synthesis of fibroblasts accompanied with a decline of amino acid uptake. On the other hand, ValAP may have different function to increase protein synthesis of fibroblasts. Some of amino acid-APs also decrease protein synthesis of myotube but not accompanied with a decrease of amino acid uptake.

Plant foods consumption and its association with cardiovascular disease risk profile in South Africans at risk of diabetes

Tatum Lopes[1,2], Annalise E. Zemlin[1,3], Jillian Hill[2], Zandile J. Mchiza[2], Nasheeta Peer[2,4], Rajiv T. Erasmus[1], Andre P. Kengne[2,4]

1. University of Stellenbosch (South Africa), 2. South African Medical Research Council (South Africa), 3. National Health Laboratory Service (NHLS) (South Africa), 4. University of Cape Town (South Africa)

Background and objectives: Plant foods differ in their nutrient content and can be classified as healthy (i.e., fruits and vegetables) or less healthy (i.e., sugar-sweetened beverages). Nutrient-rich plant foods are healthier and contain bioactive compounds such as polyphenols with antioxidant properties that may protect against cardiovascular disease (CVD). We assessed the distribution of healthy plant foods and its association with CVD risk factors in South African adults at high risk of diabetes.

Methods: This cross-sectional study utilized baseline screening data from the South African Diabetes Prevention Programme (SA-DPP). Participants identified as being at high risk of diabetes underwent data collection including a non-quantified 24-hour dietary recall, physical examination, and biochemical analysis. Group comparisons used appropriate statistical tests to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

explore differences in the distribution and associations of common CVD risk factors by plant foods consumption.

Results: Among 693 participants (81% females), the mean age was 51 years (SD=8.95). The prevalence of obesity was higher in consumers of cereals than in non-consumers (86% vs. 14%, p=0.018). Compared with non-consumers, consumers of maize had lower fasting insulin (7.8 vs. 9.6 mIU/L, p<0.001), lower LDL-cholesterol (3.0 vs. 3.2 mmol/L, p=0.011), lower triglycerides (1.2 vs. 1.3 mmol/L, p=0.023) and lower fibrinogen (3.6 vs. 3.8 g/L, p=0.005) levels; consumers of yellow coloured vitamin A rich vegetables and tubers had lower systolic blood pressure (125 vs. 128 mmHg, p=0.030) and lower triglycerides (1.2 vs. 1.3 mmol/L, p=0.028), while consumers of vitamin A rich fruits had lower fasting plasma glucose (5.0 vs. 5.4 mmol/L, p=0.001). Regression analysis revealed a negative association between body mass index >30 kg/m^2 and white roots and tubers consumption (adjusted odds ratio: 0.64, p=0.048).

Conclusions: Significant differences were apparent in the distribution of some CVD risk factors between consumers and non-consumers of certain plant foods. The association of healthy plant foods consumption and CVD risk reduction needs further investigations in this setting.

PAB(T4)-132
Thiamin insufficiency as a risk for heart failure

Misora Ao[1], Kiyoshi Tanaka[2]

1. Osaka Shoin Women's University (Japan), 2. Kobe Gakuin University (Japan)

Background and Objectives: Vitamin deficiency causes such diseases as rickets (vitamin D) and beriberi (thiamin; vitamin B1), but even vitamin insufficiency, milder than deficiency, increases the disease risk. Most studies on vitamin insufficiency have been on vitamin D, and little attention has been paid on thiamin. Our hypothesis is that insufficiency of thiamin, indispensable in energy metabolism, would affect cardiac function, and be a risk for heart failure.

Study 1 Subjects and Methods: Institutionalized elderly were evaluated for their whole blood (WB) thiamin concentration and plasma brain natriuretic peptide (BNP) level, a sensitive marker for heart failure. Information was also obtained on anthropometry and prescribed drugs.

Results: WB thiamin concentration has exhibited a significant negative correlation with plasma BNP level. Multiple regression analysis has revealed that WB thiamin concentration is a significant negative contributor to plasma BNP level corrected by age, BMI, and eGFR. In two-thirds of the subjects, plasma BNP level was higher than 40 pg/mL, suggesting the possibility of heart failure. Decreased WB thiamin concentration was a significant contributor to plasma BNP level higher than 40pg/mL by the logistic regression analysis. In subjects with diuretics use, WB thiamin concentration was significantly lower than those without it.

Study 2 Subjects and Methods: Patients visiting cardiology clinic were evaluated for WB thiamin and plasma BNP level. Information was also obtained on anthropometry, prescribed drugs, and dietary intake using BDHQ.

Results: Significant negative correlation was observed between WB thiamin concentration and plasma BNP level in thiamin-deficiency/insufficiency group, but not sufficiency group. Multiple regression analysis has revealed that WB thiamin concentration and eGFR significantly and negatively contributed to plasma BNP level corrected by age and gender in thiamin-deficient/insufficient group. Patients with loop diuretics use had lower WB thiamin concentration and higher BNP level than those without it.

Conclusions: In both institutionalized elderly and patients visiting the cardiology clinic, thiamin insufficiency was suggested to be a modifiable risk for heart failure. Considering that elderly heart failure is markedly increasing in number, our results would be of possible clinical and societal significance.

Keywords: Thiamin, heart failure, vitamin insufficiency

PAB(T4)-133
Adherence to the World Cancer Research Fund/American Institute for Cancer Research Cancer Prevention Recommendations and risk of overall, breast, prostate, colorectal and lung cancer in the UK Biobank

Fiona Caroline Malcomson[1], Solange Parra-Soto[2], Liya Lu[1], Frederick Ho[2], Carlos Celis-Morales[2,3], Linda Sharp[1], John C Mathers[1]

1. Newcastle University (UK), 2. University of Glasgow (UK), 3. University Católica del Maule (Chile)

Background and objectives: Approximately 40% of cancers in the UK are attributable to modifiable, lifestyle risk factors such as smoking, overweight and obesity and low dietary fibre intake. The World Cancer Research Fund (WCRF)/American Institute for Cancer Research (AICR) published ten lifestyle-based Cancer Prevention Recommendations with the aim of reducing the risk of cancer and other non-communicable diseases worldwide. We investigated associations between adherence to these Cancer Prevention Recommendations and the risk of overall cancer and of the top four cancers (breast, prostate, colorectal and lung) in the UK.

Methods: We used data from 139,491 UK Biobank participants, mean age 55.9 years (range 40–72) recruited between 2006 and 2010 and without cancer at baseline. Scores for adherence to the Cancer Prevention Recommendations were calculated from dietary (food frequency questionnaire and 24-hour recall), physical activity (International Physical Activity

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Questionnaire) and body composition (body mass index and waist circumference) data using the standardised scoring system by Shams-White and colleagues. Scores ranged from 0 (lower adherence, unhealthier lifestyle) to 7 (higher adherence, healthier lifestyle) points. Incident invasive cancer cases were identified through linked population-based cancer registries. Cox proportional hazard models were used to investigate associations, adjusting for age, sex, ethnicity, Townsend deprivation index and smoking status.

Results: The mean adherence score was 3.57 (SD 1.04) points. Over a median follow-up time of 7.9 years (IQR 7.3 – 8.6), there were 10,756 incident cancers. We observed a 7% reduction in overall cancer risk per 1-point increment in score (HR 0.93; 95%CI 0.91-0.94, P<0.001). There were significant associations between total score and risk of breast (HR 0.90; 95%CI 0.86-0.94, P<0.001) and colorectal (HR 0.89; 95%CI 0.84-0.94, P<0.001) cancer, but not for lung (HR 0.94; 95%CI 0.87-1.02, P=0.126) or prostate (HR 1.00; 95%CI 0.97-1.04, P=0.888) cancers.

Conclusions: This is the first study to investigate associations between adherence to the WCRF/AICR Cancer Prevention Recommendations and the risk of overall, breast, prostate, colorectal and lung cancers in a UK cohort. Higher adherence scores were associated with reduced risk of overall, breast and colorectal cancer, supporting compliance to the WCRF/AICR Cancer Recommendations for cancer prevention.

Vitamins C and E supplementation alleviate oxidative stress and lipid peroxidation in pediatric patients with acute lymphoblastic leukemia receiving chemotherapy

Phanphen Phoonlapdacha[1], Samart Pakakasama[1], Ruchaneekorn W. Kalpravidh[2], Umaporn Suthutvoravut[1], Nalinee Chongviriyaphan[1]

1. Faculty of Medicine Ramathibodi Hospital, Mahidol University (Thailand), 2. Faculty of Medicine Siriraj Hospital, Mahidol University (Thailand)

Background and objectives: Oxidative stress is associated with cancers via lipid peroxidation and DNA damage. Antioxidants play roles in protection against cancers. The most common cancer in childhood is acute lymphoblastic leukemia (ALL). Many of the components given to treat leukemia are associated with free radical production. This study was conducted to evaluate the effect of vitamin C (VC) and E (VE) supplementation on the oxidative stress and antioxidant status in pediatric patients with ALL during chemotherapy.

Methods: Twenty-four pediatric patients diagnosed with ALL were recruited and divided into 2 groups using a randomized selection as the intervention group and the placebo group during chemotherapy for 6 months. The intervention group received VC (500 mg/d) and VE (200 IU/d) supplementation in addition to chemotherapy. Levels of erythrocyte reduced glutathione (GSH), plasma VC, VE:total cholesterol ratio (VE:TC ratio) were evaluated. The activities of erythrocyte superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx), malondialdehyde (MDA, a marker of lipid peroxidation), and 8-hydroxy-2'-deoxyguanosine (8-OHdG, a product of DNA damage) were assessed.

Results: At baseline, the levels of antioxidant enzymes, VC, VE, MDA, and 8-OH-dG of the intervention and placebo groups were not significantly different (p>0.05). At 6 months of chemotherapy, the mean levels of VC and VE:TC ratio in the intervention group were statistically higher than those in the placebo group (8.08±6.88 vs. 3.43±3.50 µg/dL, p=0.049 and 9.13±4.05 vs. 4.76±1.89 mg/g, p=0.004, respectively). The intervention group had the mean levels of SOD, GPx lower than the placebo group; however, the mean levels of CAT in the intervention group was higher than the placebo group without a significance. The intervention group had a significantly lower MDA levels than the placebo group (1.10±1.08 vs. 3.63±3.52 µM, p=0.027). The 8-OHdG levels were not significantly different between 2 groups.

Conclusions: Patients with ALL receiving chemotherapy in conjunction with VC and VE supplements had lower oxidative stress and lipid peroxidation.

Keywords: Acute lymphoblastic leukemia, Antoxidant, Lipid peroxidation, Oxidative stress, Vitamin C and Vitamin E

PAB(T4)-135
The Association between Rice Intake and Chronic Kidney Disease: the Toon Health Study

Jia Li[1], Koutatsu Maruyama[1], Kiyohide Tomooka[2], Takeshi Tanigawa[2], Isao Saito[1]

1. Ehime University (Japan), 2. Juntendo University (Japan)

Background and objectives: Almost one in eight Japanese adults have chronic kidney disease (CKD). Although rice intake may increase the risk of diabetes which is one of the major risk factors for CKD, the association between rice intake and CKD remained unknown. The objective of our study was to examine the association between rice intake and CKD in Japanese adults.

Methods: This cross-sectional study included 1665 Japanese men and women aged 30-84 years who participated in the Toon Health Study. We calculated estimated glomerular filtration rate (eGFR), and defined CKD as eGFR <60 mL/min/1.73 m^2. Furthermore, albuminuria was defined as urinary albumin in >=30mg/L. Rice intake was assessed by food frequency questionnaire, and adjusted for energy intake by residual method. The participants were divided into sex-specific quartiles according to rice intake. We calculated the multivariable-adjusted odds ratio (OR) and 95% confidence intervals (95%CIs)

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of CKD and albuminuria according to the quartiles of rice intake using the logistic regression model.

Results: We found no significant association between rice intake and CKD. The multivariable-adjusted OR of CKD was 0.87 (95%CI: 0.60-1.25, p for trend =0.44) for the highest quartile of rice intake compared with the lowest quartile. However, we found that higher rice intake tended to be associated with lower odds of albuminuria; the OR of albuminuria was 0.59 (95%CI 0.32-1.08, p for trend =0.09). After stratification by current drinking status, the OR of CKD for the highest quartile was 0.88 (95%CI 0.53-1.47, p for trend =0.63) and albuminuria was 1.00 (95%CI 0.41-2.49, p for trend =0.99) in the non-drinking group; but in the current drinking group, the OR of CKD for highest quartile was 0.82 (95%CI 0.48-1.39, p for trend =0.45) and albuminuria was 0.37 (95%CI 0.15-0.91, p for trend =0.03). This association in the current drinking group remained significant after further adjustment for ethanol intake.

Conclusion: Higher rice intake may be associated with a lower presence of albuminuria for individuals with a drinking habit (or who consumes alcohol).

Keywords: Rice intake, Chronic kidney disease, Albuminuria

PAB(T4)-136
The association between dietary macronutrients consumption and the prevalence of metabolic syndrome among male South African taxi drivers

Machoene Derrick Sekgala[1,2], Zandile Mchiza[3,2]

1. Human Sciences Research Council (South Africa), 2. University of the Western Cape (South Africa), 3. South African Medical Research Council (South Africa)

Background and objectives: Diet is a major modifiable lifestyle factor that can influence metabolic syndrome and its components. To examine the association of dietary carbohydrates, protein, and fat (including fatty acid subtypes) with the metabolic syndrome and its components, in a cross-sectional study of 237 male taxi drivers.

Methods: The associations between macronutrients (as determined by a 24-hour dietary recall) and the metabolic syndrome (defined by International Diabetes Federation (IDF)) were investigated using multivariate nutrient density substitution models. These models depict the effects of substituting one macronutrient for another while maintaining total energy intake constant.

Results: Increases in carbohydrates offset by isoenergetic decreases in either protein or fat were associated with a little increase in the prevalence of the metabolic syndrome (OR 1.001 (95 % CI 0.997-1.005); OR 1.001 (95 % CI 0.997-1.005)). Increased intake of dietary fat at the expense of dietary protein was also associated with little increased prevalence of the metabolic syndrome (OR 1.005 (95 % CI 0.973-1.038), per 5 % energy intake). Favouring fats over protein was associated with little odds of abnormal obesity, whereas favouring either carbohydrates or fats over proteins was associated with lower odds of the blood pressure component of the metabolic syndrome. There was no statistical difference between the relative proportions of dietary macronutrients or fatty acids and the presence of the metabolic syndrome.

Conclusions: A diet high in carbohydrates, either in low fat or protein, is associated with a slightly increased in the prevalence of metabolic syndrome. Therefore, the relative distribution of macronutrients may be related to metabolic syndrome.

Keywords: Metabolic syndrome, macronutrients intake, substitution model, taxi drivers, South African man

Effects of n-3 PUFAs on the generation and characteristics of EVs generated in vitro from washed platelets

Esra Bozbas[1], Ruihan Zhou[1], Keith Allen-Redpath[1], Parveen Yaqoob[1]

1. University of Reading (UK)

Background and Objective: Platelet-derived EVs (PDEVs) comprise the most abundant EV population in the circulation, at least in healthy individuals, and may contribute to the development and progression of cardiovascular diseases (CVDs) through their procoagulant activities, thus, serve as emerging biomarkers for cardiovascular health. PDEVs can potentially be modified by dietary fatty acids since they carry bioactive lipid mediators and their cell membrane fatty acid composition can be modified by dietary fatty acids, including n-3 polyunsaturated fatty acids (PUFAs), which are abundant in oily fish and fish oil and reported to reduce risk of cardiovascular diseases. This study investigated whether supplementation with n-3 PUFAs alters the generation and characteristics of PDEVs.

Methods: Forty subjects with moderate risk of CVDs were supplemented with either 1.8 g/d n-3 PUFA or control (high-oleic safflower oil) for a 12-week period. To isolate PDEVs in vitro, washed platelets, obtained before and after each intervention period, were incubated in the presence or absence of the stimulant, 30 µM Thrombin Receptor Activator Peptide-6 (TRAP-6), for 2h at 37°C. Platelets were then removed by centrifugation and EVs were pelleted and washed. The generation and characteristics of PDEVs were assessed by Nanoparticle Tracking Analysis (NTA) and flow cytometry. Total fatty acid composition of PDEVs was evaluated by gas chromatography.

Results: There was no effect of the intervention on the size and numbers of PDEVs generated in vitro, regardless of whether they were derived from unstimulated or stimulated platelets. Supplementation with fish oil significantly increased the content of EPA and total n-3 PUFA of EVs generated in vitro by either unstimulated or stimulated platelets, while decreasing that of arachidonic acid, compared with the control group. Fish oil significantly decreased the expression of PS by only EVs generated from unstimulated platelets.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: N-3 PUFA supplementation had no effect on the number or size of EVs generated in vitro from stimulated or unstimulated platelets, but altered their fatty acid composition and, in the case of EVs derived from unstimulated platelets, decreased their surface expression of PS.

Keywords: Cardiovascular disease, n-3 polyunsaturated fatty acids, fish oil, platelets, extracellular vesicles

The effect of fructose on impaired neutrophil differentiation caused by mitochondrial dysfunction

Ayako Tanimura[1], Taigo Horiguchi[2], Keiko Miyoshi[2], Hiroko Hagita2, Hisanori Minami[3], Takafumi Noma[4]

1. Prefectural University of Kumamoto (Japan), 2. Tokushima University Graduate School of Biomedical Sciences (Japan), 3. Kobe Gakuin University (Japan), 4. Hiroshima Jogakuin University (Japan)

Background and objectives: Mitochondrial dysfunction cause mitochondrial diseases with variety symptoms in organs and cells. Mitochondria has been reported to regulate cell differentiations via its functions such as ATP production and ROS generation. We have previously reported that disruption of adenylate kinase 2 (AK2), a mitochondrial energy metabolic enzyme, leads to mitochondrial dysfunction, including decreased ATP production, elevated oxidative stress, and impairment of ATP-dependent systems. And AK2 deficiency causes reticular dysgenesis, a severe combined immunodeficiency with neutropenia and sensory deafness. In this study, we tried to improve the impairment of neutrophil differentiation by enhancing glycolytic ATP production with fructose using AK2 deficiency model cells.

Methods: Human promyelocytic leukemia cell line HL-60 was differentiated into neutrophil with all-trans retinoic acid (ATRA). AK2 hetero-knockout HL-60 was generated using CRISPR/Cas9 genome-editing system. Unfortunately, we could not get complete KO cells. Fructose was added during induction of differentiation by ATRA, and we evaluated the effects of fructose treatment on the neutrophil differentiation rate and intracellular ATP amount in wild type (WT) and AK2 hetero-knockout HL-60.

Results: We confirmed that AK2 activity is decreased by about half in AK2 hetero-knockout HL-60. To evaluate neutrophil differentiation rate, we checked protein expression of CD11b, a differentiation marker expressed from the early stage to the mature stage of neutrophil differentiation, in WT cells and AK2 hetero-KO cells on day 4. CD11b was not changed between WT HL-60 and hetero-knockout HL-60. Therefore, we evaluated the proportion of differentiation stages morphologically. Undifferentiated cells were more and matured neutrophils were less in AK2 hetero-knockout than those in WT significantly in the absence of fructose. Also, fructose treatment restored the percentage of mature neutrophils in AK2 hetero-KO HL-60. Then, ATP production during neutrophil differentiation was measured, and no significant difference was observed between WT and AK2 hetero-knockout HL-60 with and without fructose treatment.

Conclusions: From these results, fructose may recover neutrophil differentiation not by glycolytic ATP production under condition of impaired mitochondrial ATP production.

Keywords: Neutrophil differentiation, Fructose, Mitochondria, ATP

Degradation of Lys-Amadori Product in the Extract Derived from Kidney of Chickens

Motomi Toyama[1], Kazumi Kita[1]

1. Iwate University (Japan)

Background and objectives: Non-enzymatic chemical reaction of amino acids with reducing sugars such as glucose generates amino acid-Amadori products (APs), which can be intermediates of advanced glycation end products (AGEs). We found seven amino acid-APs in the plasma of chickens (Kita, K. et al., unpublished results), which are known to be hyperglycemic animals. Fructosamine-3-kinase (FN3K) is an enzyme identified in human erythrocytes can degrade APs using ATP. In our previous study, gene expression of FN3K was observed in several tissues (brain, heart, liver, kidney and muscle) of chickens. But it has not been clarified whether tissue FN3K can degrade amino acid-APs or not. In this study, therefore, we examined the degradation of Lys-AP by the extract derived from kidney of chickens.

Methods: Animals - Newly hatched male chickens (single comb White Leghorn) were purchased from a local hatchery and fed with a commercial starter feed for 20 days. Sample – Under anesthesia, blood was collected by heart puncture, and then kidney was removed and cut into 300 mg pieces. Tissue Extract – Kidney pieces was homogenized with 500 µl DPBS. Then, homogenate was centrifuged at 4 ℃, 8000 x g for 20 minutes. The supernatant was collected and passed through a 0.22 µm sterile filter. Degradation Experiment – The 3 ml of filtrated supernatant was transferred into a 15 ml centrifuge tube and added Lys-AP with final concentration of 300 µM. Samples were incubated at 37 ℃ overnight in the presence or absence of 1-deoxy-1-morpholinofructose (DMF), which is an inhibitor of FN3K. After incubation, samples were defatted and deproteinized, and Lys-AP concentration was measured by LC/MS.

Results: After incubating Lys-AP with extract derived from chicken kidney, the concentration of Lys-AP in the presence of DMF was significantly higher than that in absence of DMF. The lower concentration of Lys-AP in the absence of DMF would be resulted by the degradation of Lys-AP by FN3K existed in the extract derived from kidney.

Conclusion: It was concluded that FN3K exists in the kidney would degrade Lys-AP generated in vivo.

Keywords: Amadori products, Amino acid, chicken, FN3K, Glycation

PAB(T4)-141
A national survey of Japanese medical facilities to consider promoting the implementation of nutritional diagnosis

Ryo Shimizu[1], Chotoku Saito[1], Yusuke Tando[2]

1. Aomori University of Health and Welfare (Japan), 2. Hirosaki University (Japan)

Background and objects: Almost no reports exist regarding the implementation of Nutrition Diagnosis (ND) at hospitals and its effectiveness in Japan. This study focuses on ND among nutrition care processes and uses a survey of hospitals in Japan to investigate the awareness and implementation of ND, its benefits, and reasons for non-implementation. It also considers how to support for the wider implementation of ND.

Methods: The objects were supervisors of registered dietitians and dietitians at the 2,482 hospitals. The requests to cooperate with the surveys were mailed to the objects at the targeted facilities at the beginning of September 2021 and respondents were asked to fill them out and return them by the end of the month. IBM® SPSS® Statistics 26 (IBM Japan, Ltd.) was used for the statistical analysis. Chi-square tests were used to determine significance, with a significance of $p<0.05$.

Results: Responses were received from 732 hospitals (29.5%). Of them, 13.8% were implementing ND. Regarding employment of registered dietitians at their facilities, 10.8% had one or fewer and 31.8% had 6 or more. The benefits that facilities realized most often from implementing ND were, “ND make patients' nutrition issues clear,” at 83.2%. The most frequent reason for not implementing ND was “It is hard to have a common understanding among the staff,” at 40.1%, followed by “We did not have the opportunity to learn it,” at 39.0%. For the desired support for implementation, the most frequent response was “Opportunity to learn ND at a training session,” at 75.8%, followed by “An easy-to-understand ND manual,” at 73.9%. “An easy-to-understand ND manual” was 69.1% in the group with six or more registered dietitians belonging to the hospital and 84.5% in the group with one or fewer. It should be noted that the group of with 1 or fewer was significantly more common than the group of 6 or more ($p=0.008$).

Conclusions: The percentage of hospitals implementing ND is 13.8%. It was suggested that support considering the difference in the number of registered dietitians may be effective in disseminating nutritional diagnosis.

Challenges of Dietary Management of Diabetes Mellitus in the African Setting

Anselimo Makokha[1], Sheila Kilonzi[2]

1. Jomo Kenyatta University of Agriculture and Technology (Kenya), 2. Karatina University (Kenya)

Background and Objective: The incidence and prevalence of Type 2 Diabetes Mellitus continues to rise rapidly, and is of great public health concern. About 500 million people are living with the condition globally, and this poses both disease and economic burdens. The condition is not usually curable, and has to be managed in various ways. Proper dietary management is of great importance in delaying and avoiding the onset of complications associated with the conditions. The complications increase the risk of morbidity and mortality. The main objective of this study was to evaluate the challenges encountered in dietary management of Diabetes Mellitus in the African Setting.

Methods: The method employed in the study is a review of literature using search engines, including Google Scholar.

Results: Most of the African diets include starchy staples that are consumed with an accompaniment of vegetable or meat stews. The starchy staples are predominantly cereals- maize, sorghum millets and rice. Other starchy staples include cassava, yams, and sweet potatoes. Among the key challenges is that these starchy foods are converted to glucose in the body, contributing to high blood glucose levels. There are many varieties of each of these staple foods. For instance there are over 30 varieties of sorghum, and over 20 varieties of finger millets. These varieties differ significantly in their nutritional and anti-nutrient composition, and also in their digestibility. The same applies, to a less extent, to cassava and sweet potatoes, and the other staples. There is little information on the glycemic index and glycemic load of these foods which will differ among these varieties. Different food preparation methods will also affect the glycemic index. Yet the dietary recommendations provided for Diabetes Mellitus do not take into account these differences.

Conclusion: The many varieties of the staple foods in African diets that differ in nutrition composition, digestibility and glycemic index pose a big challenge in providing guidelines for dietary management of Diabetes Mellitus in the African setting.

Obesity is associated with greater prevalence of perimenopausal symptoms: findings from the ZOE Health study in 25,570 participants

Kate M Bermingham[1], Satya Penamakuri[2], Anna May[2], Joan Capdevila[2], Christina Hu[2], Somesh Selvachandran[2], Louise R Newson[3], Jonathan Wolf[2], Tim D Spector[1], Sarah E Berry[1]

1. Kings College London, London (UK), 2. Zoe Ltd, London (UK), 3. Newson Health Research and Education, Stratford-upon-Avon (UK)

Background and objectives: The menopause or perimenopause, is a challenging time for midlife females that is often marked by multiple somatic, psychological, and urogenital symptoms caused by changes in key hormone levels. Here we investigate the impact of body weight on menopausal symptoms in 25,570 perimenopausal females from the smartphone-based ZOE Health App.

Methods: Self-reported menopausal symptoms (vaginal dryness, vasomotor (hot flashes, chills, night sweats), sleep disturbances, mood, thinning hair or dry skin and loss of breast fullness) and baseline characteristics (age and body mass index (BMI)) were assessed in self-reported perimenopausal females (n=25,570). Females taking menopausal hormone therapy (MHT) were excluded from analysis. The relationship between BMI groups (healthy 20-25 kg/m^2 and obese 30-35 kg/m^2) and the prevalence of menopausal symptoms was investigated using binomial logistic regression.

Results: The most commonly reported menopausal symptoms included sleep problems (68% of women), night sweats (60%), mood changes (60%) and hot flashes (59%). In this perimenopausal cohort, 57% of women had an unhealthy BMI (overweight 25-30 kg/m^2; 30%, obese; 16% and morbidly obese >35 kg/m^2; 11%) while 43% had a healthy BMI. The number of symptoms experienced was associated with BMI (r; 0.08, p<0.001), and higher in obese versus normal weight females (4.0 *vs* 3.7 symptoms). The top symptom for both healthy weight and obese women was sleep problems (66% and 71%). Logistic regression was performed to ascertain the effects of BMI on the likelihood that a woman experienced menopausal symptoms. Chills, thinning of hair or dry skin, hot flashes, mood changes, and sleep problems are (RR with 95% CI) 38% [28-49], 23% [18-29], 17% [14-20], 8% [5-11] and 7% [4-9] more likely, respectively, in obese women compared to healthy weight women.

Conclusion: This study shows that obese women are more likely to experience menopausal symptoms. Higher BMI and lower oestradiol levels can lead to insulin resistance and increased risk of type 2 diabetes. Future studies are needed to understand how oestradiol can reduce weight gain, insulin resistance and menopausal symptoms experienced post-menopause.

The protective effect of glycyrrhizin, a natural sweetener, on the incidence of early puberty

Nam Nhat Nguyen[1], Chia-Yuan Lin[1], Yang-Ching Chen[1]

1. Taipei Medical University (Taiwan)

Background and objectives: Precocious puberty (PP) is characterized by the early development of secondary sexual characteristics, which may lead to many adverse outcomes. Gonadotropin-releasing hormone analog (GnRHa) is currently the first-line treatment for PP. However, it is a costly and invasive medication that may create an unpleasant experience for patients. Therefore, in this animal model, we aimed to investigate the protective effect of oral glycyrrhizin (as monosodium salt - MAG), a commonly used natural sweetener, against early puberty in female rats.

Methods: We divided 25 young female Sprague-Dawley rats into Control, Danazol, Low MAG (100 μg/kg/day), and High MAG (200 μg/kg/day) groups. A PP model was established by injection of danazol on postnatal day (PND) 5, and the MAG had been administered daily since PND 13. The time of vaginal opening (primary outcome), the day of setup of regular cycle, and the day of establishment of 3 regular cycles (secondary outcomes) were observed. Blood was taken to confirm the safety of MAG. We also collected their stool samples for microbiome and short-chain fatty acid (SCFA) analyses to explore the mechanistic pathways.

Results: High MAG significantly delayed vaginal opening day compared to the Danazol group (27.86±5.31 vs. 23.00±0.00, p=0.029). We observed similar effects for two secondary outcomes (p=0.008 and <0.001, respectively). Meanwhile, Low MAG only delayed the day of establishment of 3 regular cycles (44.29±3.95 vs. 38.00±0.82, <0.001). There is no significant difference in body weight during puberty, body weight and weight of reproductive organs on sacrifice day. Routine laboratory tests were comparable among groups. Regarding gut microbiome, High MAG rats showed a significantly different beta-diversity compared to the Danazol group. We identified enriched taxa in the High MAG group, including *Ruminococcaceae UCG-008*, *Lachnoclostridium*, and *Muribaculaceae*, and in the Low MAG group, including *Ruminococcus gnavus* and *Clostridium innocuum*. They tended to be negatively correlated with SCFA levels, especially butyric acid, which is often linked with early puberty.

Conclusions: MAG protected rats against PP in a dose-response manner. MAG exerted its benefits by reducing butyrate-producing gut bacteria. MAG may serve as a complementary therapy to GnRHa in treating PP.

Keywords: Glycyrrhizin, precoccious puberty, gut microbiome, short-chain fatty acid

Body fat is associated with higher mortality in patients with hemodialysis

Pei-Yu Wu[1], ShwuHuay Yang[2]

1. China Medical University (Taiwan), 2. Taipei Medical University (Taiwan)

Background and objectives: Patients with hemodialysis (HD) have higher premature mortality. Higher BMI is related to lower mortality in this population. However, body weight is poor obesity indicator. Therefore, this study tried to find out the association between body fat and mortality in HD patients.

Methods: This was a multiple-center prospective study. Maintenance HD patients were recruited in this study. All subjects were aged 20 years and above, who had received three hemodialysis treatment per week for at least 3 months, and were equilibrated Kt/V more than or equal to 1.2. Patients excluded from the study were those diagnosed with one or more medical conditions including cancer or malignancy or hepatic failure. All data and information were collected at baseline, then the information of all-causes mortality was collected at followed up period. Body fat was assessed by the same bioelectrical impedance analysis device using multiple operating frequencies.

Results: 318 patients with HD treatment were recruited in this study with completed information. During the median follow-up of 1.4 years, 59 patients were dead. Comparing with dry body weight in normal range, both overweight and obesity did not increase mortality. Besides, there was no association between body mass index (BMI) and mortality. Higher percentage of body fat was significantly related to increased mortality after adjust for age, sex, diabetes, and hemodialysis duration (odds ratio was 1.05, 95% confidence limits was 1.01-1.09, p=0.01). Both C-reactive protein (CRP) and Homeostatic Model Assessment for Insulin Resistance (HOMA-IR) did not adjust the association between body fat and mortality.

Conclusions: Among these patients with HD treatment, there is a positive association between body fat and mortality. Higher CRP and HOMA-IR may not be the reason. More researches with high quality are needed.

Keywords: Hemodialysis, Body fat, Mortality

PAB(T4)-146
Evidence for the Protein Leverage Hypothesis in Young Children Prone to Obesity: A Cohort Analysis From the 'Healthy Start' Study

Hanyue Zhang[1,2], Alistair M Senior[3], Christoph Saner[4,5], Nanna J Olsen[1], Sofus C Larsen[1], David Raubenheimer[3], Stephen Simpson[3], Berit Lilienthal Heitmann[1,2,3]

1. Bispebjerg and Frederiksberg Hospital (Denmark), 2. University of Copenhagen (Denmark), 3. University of Sydney (Australia), 4. University of Bern (Switzerland), 5. The Royal Children's Hospital (Australia)

Background and objectives: The protein leverage hypothesis (PLH) proposes that the rise in obesity has been caused partly by a shift towards diets with reduced protein energy/non-protein energy ratios relative to the set point for protein intake, which is strictly regulated in people. Evidence for the PLH comes from studies in animals and adult humans, while studies in children are few. Thus, the aim is to test the PLH in young children prone to obesity.

Materials and methods: Data were from the 'Healthy Start' intervention study of young children prone to obesity. Dietary information was measured by a 4-day dietary record. Body mass index (BMI) *z* scores, fat mass percentage (FM%), waist-height (WHtR) and hip-height ratio (HHtR) were measured by trained health professionals. The strength of leverage (L coefficient) for protein was tested by fitting the power function to the relationship between energy intake and protein (%). Multiple linear regression analyses were carried out for the association between total energy intake and anthropometrics. The energy composition of dietary macronutrients (%) with total energy intake and each anthropometric was presented using the Nutritional Geometry, visualized through response surfaces, and analyzed through mixture models.

Results: A total of 553 individuals aged 2-6 years were included and followed for 1.3 years. At baseline, total energy intake (Mean [SD]) was 4.8 (1.0) MJ/day, energy proportion from protein (%) was 15.7 (2.3) %, carbohydrate (%) 54.8 (4.7) %, and fat (%) 29.5 (4.5) %. At baseline, there was an inverse relationship between dietary protein (%) and total energy intake, which followed a power function (L coefficient -0.19; P< 0.01). Higher total energy intake (per unit [MJ/day]) was associated with an increase in BMI z scores (b [CI 95%]: 0.04 [0.01, 0.07]), and FM% (0.93 [0.09, 1.77]) over 1.3 years. Notably, a diet lower in protein (%) at baseline was associated with a subsequent increase in BMI *z* scores, WHtR, and HHtR after 1.3-year follow-up, in support of the PLH.

Conclusion: Evidence for the PLH was found in young children prone to obesity, showing that children with dietary protein diluted by carbohydrate or fat had higher energy intake, later weight gain and adiposity risk over 1.3 years.

Impact of early enteral nutrition in patients with COVID 19 under invasive ventilation

Edith Gutierrez Vargas[1], Cesar Ramos Garcia[1]

1. Universidad Montrer (Mexico)

Background and objectives: Nutritional support is particularly important on the patient with COVID 19 under mechanical ventilation as it strengthens the immune system. This research seeks to relate the implementation of enteral nutrition with the reduction of invasive mechanical ventilation time and mortality rate.

Methodology: A study was carried out at the Guanajuato General Hospital, 89 patients (49 women and 41 men with COVID 19 pneumonia under mechanical ventilation were included. The population was divided into three groups. Those who received early enteral nutrition (<36 hours), late enteral nutrition (>36 hours) and those who did not receive nutrition. Acute phase reactants (leukocytosis, CPR, DHL, Lymphocytes), length of hospital stay and days of ventilation were evaluated using Student`s T analysis, mortality in each of the groups using X^2 and Odds Ratio. Survival was calculated from Kaplan Meier with long rank test.

Results: Early enteral nutrition (NTE) was administered in 19 patients, 17 patients received late enteral nutrition (NTA) and 53 patients did not receive enteral nutrition (NN). The days of mechanical ventilation with NTE a mean of 11.11 $\pm$ 12.351 was established, for patients with NTA with a mean of 16.29 $\pm$ 7.523 and for those NN 4.64 $\pm$ 3.552. And OR of 3.22 was obtained for death as an outcome in the group of patients who did not receive enteral nutrition and an OR of 0.15 for the group that received early enteral nutrition. OR of 5.75 for death as an outcome for patients who received delayed nutrition. The was no significant difference in the gender variable regarding the decrease in acute phase reactants with $p<0.05$ who received NTE was 18.73 and for the group of NN patients ii was 8.41

Conclusion: The start of early enteral nutrition was associated with a lower risk of mortality and an increase in days of interhospital stay is explained in the study as greater survival.

The effects of upper- and lower-body exercise on postprandial triglycerides in healthy young men

Zhentao Zhong[1], Haixin Wen[1], Kayoko Kamemoto[1], Waris Wongpipit[2], Chihiro Nagayama[1], Ge Li[1], Yusei Tataka[1], Ayano Hiratsu[1], Yoshie Yoshikawa[1], Masashi Miyashita[1]

1. Waseda University (Japan), 2. Chulalongkorn University (Thailand)

Background and objectives: Over one-third of Japanese adults aged between 20 and 29 consumed daily meals containing over 30% of energy as fat. Elevated non-fasting triglycerides (TG) is associated with an increased incidence of cardiovascular disease. Ample evidence supports the notion that acute aerobic exercise, weight-bearing exercise in particular (i.e., walking and running), mitigates the elevation of TG concentrations after a meal. Arm cranking and cycling exercises are characterised as non-weight-bearing exercises and are often recommended as replacement strategies for those who have any condition/preference with limited ability to run. Nevertheless, it remains unclear whether the similar reduction in postprandial TG could be obtained as demonstrated by weight-bearing exercise if healthy individuals perform arm cranking or cycling exercises. Furthermore, it is not clear whether a similar benefit, if any, on a reduction in postprandial TG between these non-weight-bearing exercises. Therefore, this study aimed to examine the effect of an acute bout of upper- and lower-body exercise on postprandial TG concentrations in young men.

Methods: Fifteen healthy young men (aged 22±2 years, mean±standard deviations) underwent three, 2-day laboratory-based trials in random order: control, upper-body exercise and lower-body exercise. On day 1, participants rested from 0900 to 1600 and performed upper-body exercise or lower-body exercise at a workload predicted to elicit 70% of maximum/peak oxygen uptake for pre-determined exercise duration which was designed to induce a net energy expenditure of 1255 kJ (300 kcal), or rested between 1600 and 1700. On day 2 of each trial, participants rested and consumed standardised test meals for breakfast (1000) and lunch (1300). Venous blood samples were collected in the fasted state (0900), at 1000, 1100, 1300, 1500 and 1700 on day 2.

Results: Postprandial TG concentrations were higher throughout day 2 in the control trial (1.62±0.74 mmol/L) than the lower-body exercise (1.34±0.50 mmol/L) and upper-body exercise (1.37±0.62 mmol/L) trials ($P<0.001$). There was no difference in postprandial TG concentrations between exercise trials.

Conclusions: The present study demonstrated that an acute bout of upper- and lower-body exercise matched for the total energy expenditure attenuates postprandial TG concentrations in healthy young men.

Nutrition intake among children with cow's milk allergy according to the degree of elimination

Yuie Motoyama[1], Yuzuna Tanaka[1], Ayu Kawabata[1], Tomiyo Nakamura[2], Takashi Kusunoki[1,3]

1. Laboratory of Child Health and Nutrition, Department of Food Science and Human Nutrition, Faculty of Agriculture, Ryukoku University, Shiga (Japan), 2. Laboratory of Public Health Nutrition, Department of Food Science and Human Nutrition, Faculty of Agriculture, Ryukoku University, Shiga (Japan), 3. Department of Pediatrics, Shiga Medical Center for Children, Shiga (Japan)

Background and objective: Children with cow's milk allergy (CMA) have lower bone mineral density and shorter height than children without CMA or non-food allergy (FA), and their final height in adolescence is also affected. Thus, there is a need for appropriate nutritional guidance for CMA children. The purpose of this study was to conduct a dietary survey of CMA children and to compare their characteristics according to the degree of elimination.

Methods: A dietary survey of FA children attending the allergy clinic at Shiga Medical Center for Children, Shiga, Japan was conducted using the brief-type self-administered diet history questionnaire for Japanese children and adolescents (BDHQ15y). Additionally, the intake of soy milk, a common alternative food for CMA, was also determined using the same question format as for CM. To objectively assess the intake of vegetables and fruits, skin carotenoid levels were measured using the Veggie Meter®.

Results: Regarding the degree of CM elimination, of the 147 FA children recruited, 38, 27, and 82 children were in the complete-, partial-, and non-elimination groups, respectively. Significantly more intake of vegetable proteins, β carotene, α tocopherol, vitamin C, and polyunsaturated fatty acids, as well as significantly higher levels of skin carotenoids, were observed as the degree of CM elimination increased. On the other hand, significantly lower intake of calcium, animal proteins, vitamin B2, and saturated fatty acids were observed as the degree of CM elimination increased. In the complete-, partial-, and non-elimination groups, 16.7% (6/36), 40.0% (10/25), and 0.0% (0/74) drank more than one glass of soy milk per day, respectively.

Conclusions: The intake of many nutrients with antioxidant and anti-inflammatory effects was higher as the degree of CM elimination increased, presumably reflecting the caregiver's effort in identifying alternative foods. However, calcium intake was still inadequate, indicating the need for further encouragement of calcium intake for CMA children.

Arab Women Adherence to the Mediterranean Diet and Insomnia

Ayah Talal Zaidalkilani[1], Omar Amin AlHaj[1], Mohamed F. Serag El-Dine[2], Feten Fekih-Romdhane[3,4], Maha M. AlRasheed[5], Haitham A. Jahrami[6,7], Nicola L. Bragazzi[8]

1. University of Petra (Jordan), 2. Menofia University (Egypt), 3. Razi Hospital (Tunisia), 4. Tunis El Manar University (Tunisia), 5. King Saud University (Saudi Arabia), 6. Ministry of Health (Bahrain), 7. Arabian Gulf University (Bahrain), 8. York University (Canada)

Background and objectives: Sleeping difficulties affect overall health, nutrition, and wellbeing. The Mediterranean diet has proven effective in improving the quality of life and overall health of people of all ages. Therefore, this study aimed to determine whether adherence to the Mediterranean diet (MD) is linked to reduced insomnia in Arabic-speaking female adults in Jordan.

Materials and Methods: A self-administered, cross-sectional survey was used to detect the relationship between MD and sleep quality in Arabic-speaking female adults. Data were collected from 917 Arabic-speaking female participants of 14 Arab nationalities in Jordan between March and May 2021 via social media. All participants answered the whole questionnaire, including questions on sociodemographic aspects, Mediterranean diet adherence, sleeping habits measured with the Athens Insomnia Scale (AIS), and lifestyle components such as smoking and dietary patterns.

Results: The mean age of the 917 Arabic-speaking female participants was 36±10 years. Most participants were unemployed (85%) single females (64%) with an undergraduate degree (74%). Most of them (86%) were non-smokers. More than half of the participants were Jordanians (57%). The BMI was normal for 52% of the participants, whereas 26% of them were overweight, and 12% were obese. One-way ANCOVA showed a statistically significant difference between MD adherence score categories and AIS, F (2, 914) = 3.36, p = 0.015. Among the MD adherence score categories, we found that between groups, MD scores above or equal to 10 were associated with a statistically significant difference in AIS. Cohen's value was calculated for the three MD score categories and indicated a 'small' effect size association between all adherence scores of the MD categories and AIS.

Conclusions: In conclusion, our findings provide preliminary evidence that participants' adherence to the MD was significantly associated with better sleep and reduced insomnia symptoms, highlighting the need for further research.

Nutritive value, zinc bioavailability and glycemic index of “chin-chin,” bread and biscuit made from composite flours made from African yam beam, orange-fleshed sweet potato, plantain, maize, and wheat

Lilian Chinelo Aburime[1], Henrietta Nkechi Ene-Obong[1], Essien David-Oku[1]

1. University of Calabar (Nigeria)

Background and objectives: The combination of legumes and cereals/tubers in a single meal or snack can help promote better nutrition and reduce the development of some chronic Non-Communicable Diseases (NCD), especially diabetes. The aim of this work was to determine the nutritive value, zinc bioavailability, and glycemic index of “chin-chin” bread and biscuit made from composite flours from indigenous.

Methods: *Sphenostylis stenocarpa* seeds were fermented in a citric acid medium (0.5%) for 24hrs at room temperature (28^{o}C) in a seed water ratio of 1:4 (w/v). *Zea mays* were sorted and fermented for 48hrs at room temperature (28^{o}C) in a seed water ratio of 1:3 (w/v). The fermented grains were separately dried and milled into flour for further use. Green matured *Musa paradisca* fruits were peeled, and sliced into a thin thickness of about 2 cm, and then dried in a food dehydrator (40- 50°C) for 24hr and milled into fine flour. Biscuits, ‘chin-chin' and bread were developed from the composite flours using standard methods. Standard laboratory methods were used for chemical analysis. Using 50g of anhydrous glucose as the reference food and 50g of available carbohydrate for the test food, the Glycemic Index (GI) of each food was determined by feeding them to 12 healthy subjects after an overnight fast. The incremental Area Under Curve (AUC) was used for the calculation of the GI of foods.

Results: The ranges of the chemical composition of the products were; α-carotenoid 612 -1042 mcg/100g, β-Carotene 646- 1146 mcg/100g, vitamin A (RAE) 69- 129mcg/100g. The phytate- zinc molar ratio of the products was low (0.00). The contributions of the 100g of the products to the Recommended Nutrient Intake (RNI) of adults ranged as follows: iron 7-99%, zinc 10-65%, phosphorus 38-51%, sodium 5-13%, vitamin A 11-18%, protein 21-30%, dietary fibre 13-39%, fat 4-12, available carbohydrate 33-52%. The Glycemic index (GI) of the products ranged from 15-63.

Conclusions: Availability and consumption of low GI foods made from indigenous raw food materials will enhance healthy diets and this might lower the number of health problems arising from poor dietary practices that leads to chronic non-communicable diseases.

INFINITE - Institute for Translational Research in Inflammation, University of Lille (France), 6. Centro de Investigación Biomédica en Red de Fisiopatología de la Obesidad y la Nutrición (CIBERObn), Instituto de Salud Carlos III, (Spain), 7. Institut Pasteur de Lille, University of Lille (France)

Background and objectives: An increased prevalence of hypertension (HTA) has been observed in children and adolescents. In recent years, several single nucleotide polymorphisms (SNPs) have been associated with blood pressure levels. Therefore, a genetic risk score (GRS), combining a number of SNPs, could be a useful genetic tool to identify the predisposition to HTA from early life. For this reason, the aim of our study was to build a GRS being able to predict the genetic predisposition to hypertension in European adolescents. Methods: Data were extracted from the Healthy Lifestyle in Europe by Nutrition in Adolescence (HELENA) cross-sectional study. A total of 869 adolescents (53 % female), 12.5-17.5 years were included, with complete genetic and blood pressure (BP) information. BP levels were measured and cut-off points (≧ 130 mmHg for systolic and/or ≧ 80 mmHg for diastolic) were established for hypertension according to the recommendations. From a genome-wide association study all available SNPs from 57 BP-related genes were selected to construct a GRS. Moreover, Linkage disequilibrium (LD), (r2>0.8), Hardy-Weinberg equilibrium (<0.05) and Major Allele Frequency (MAF) (>0.9) filters were applied, to obtain a final number of 1534 SNPs available for the present analysis. First, a screening of SNPs univariately associated with BP (p<0.10) was established, obtaining a final number of 16 SNPs significantly associated to BP (p< 0.05) in the multivariate model. The unweighted GRS (uGRS) and weighted GRS (wGRS) were calculated.

Results: The area under the curve (AUC) was calculated and validated using ten-fold internal cross-validation for uGRS (0.7631) and wGRS (0.7659). When other covariates of interest were added to the analyses, the AUC obtained increased their predictive ability (uGRS: 0.8102; wGRS: 0.8127 for z-BMI; uGRS: 0.8644; wGRS: 0.8711 for z-BMI plus pure fructose from non-natural foods). Furthermore, there were significant differences between AUC with covariates, BMI-z alone and BMI-z plus pure fructose from non-natural foods, and without them (p<0.001).

Conclusions: Both GRSs, the uGRS and wGRS could be used to evaluate the predisposition to HTA in European adolescents. Moreover, the inclusion of z-BMI and pure fructose from non-natural foods increased the predictive ability of the BP specific GRSs.

Aryl hydrocarbon receptor-mediated modulation of the body clock and wasting syndrome

Hinako Iki[1], Takuya Nomura[1], Tomoya Kitakaze[2], Hitoshi Ashida[1]

1. Kobe University (Japan), 2. Osaka Metropolitan University (Japan)

Background and objectives: The circadian rhythm of living organisms is regulated by oscillations of the expression of clock genes. Abnormal expression of clock genes leads to disturbance in the circadian rhythm. Aryl hydrocarbon receptor (AhR) is a transcription factor whose ligands are environmental pollutants including benzo[a]pyrene (B[a]P), and it has been reported that activation of AhR induces wasting syndrome and disrupts the biological clock. However, the effect of AhR on circadian rhythms in adipose tissue has not been clarified. Therefore, the aim of this study is to clarify the relationship between disruption of clock gene expression and AhR-induced wasting syndrome.

Method: 3T3-L1 cells were differentiated into mature adipocytes and used this study. Adipocytes were synchronized to circadian rhythms by serum stimulation, and B[a]P was treated to the cells for 60 hours. mRNA and protein expression levels of clock genes were measured by qPCR and Western blotting, respectively. A dual-luciferase assay was used to examine the involvement of DNA-binding sequences that regulate the expression of clock genes. Lipid accumulation was estimated by Oil Red O staining.

Results: B[a]P decreased both mRNA and protein expression of Brain and muscle arnt-like protein-1 (BMAL1), and Circadian locomotor output cycles kaput (CLOCK). B[a]P reduced the transcriptional activity of BMAL1 and CLOCK through the RORE region. B[a]P did not alter the expression level of REV-ERBα, a transcription factor of BMAL1 that binds to the RORE region, but it did increase the nuclear accumulation. B[a]P decreased lipid accumulation into the cells as symptom of wasting syndrome. Furthermore, B[a]P suppressed fatty acid uptake, fatty acid synthesis, and differentiation of adipocytes, but knockdown of AhR and BMAL1 by siRNA cancelled them.

Conclusion: Activation of AhR increases the nuclear accumulation of REV-ERBα, causes RORE-mediated transcriptional repression of BMAL1. In addition, AhR activation causes dysfunction of lipid metabolism such as fatty acid synthesis, its uptake, and differentiation of adipocytes via reduced BMAL1 expression. Taken together, these results indicate that disruption of clock gene expression is involved in the onset of wasting syndrome.

Utilizing stockpiled foods for Preparing Therapeutic Foods in Disasters

Tomoko Hirouchi[1], Yuka Nabae[1], Tomomi Hoshikawa[1], Haruno Shiraki[1], Risa Nakao[1]

1. University of Kochi (Japan)

Background and objectives: In the event of a large-scale disaster, it is difficult to obtain special nutritional foods due to the disruption of distribution channels, and there is concern that the health status of people requiring special care will deteriorate. This is particularly true for those with chronic diseases requiring special nutritional foods. These foods, however, have short expiration dates and few local governments stockpile them. To remedy this, the Ministry of Agriculture, Forestry and Fisheries recommends stockpiling these foods at people's homes. However, depending on the timing of the disaster, it is possible that there will not be any food stocks. Therefore, we examined whether it is possible to make therapeutic foods at home using foods that stored at room temperature and have a best-by date of one year or more.

Methods: We considered four therapeutic diets, low-salt diet, low-protein diet, energy-control diet and lipid-control diet. The cooking method is to put the ingredients and seasonings in a heat-resistant plastic bag and boil them in a water bath. First, a general diet was prepared using the intake target amounts set by the Ministry of Health, for each therapeutic diet.

Results: Even when there was no stock of special foods at home, it was possible to make therapeutic foods at home using foods that could be stored at room temperature. The low-protein diet was deficient in vitamins B_1 and B_2 because it excluded the use of canned mackerel, which is high in protein. Since protein was restricted, energy was also reduced, so cookies were added to provide energy and improve pfc balance.

Conclusions: Therapeutic foods can be made at home, but in the event of a disaster, vitamins B_1 and B_2 are deficient due to lack of vegetables. Then this can be supplemented by using canned foods rich in vitamins B_1 and B_2. Furthermore, it is desirable to prepare sweet snacks or desserts to adjust energy.

Genetic hemoglobin disorders and their association with biomarkers of nutritional anemia: A review

Brock A Williams[1,2], Aviva I Rappaport[3], Crystal D Karakochuk[1,2]

1. The University of British Columbia (Canada), 2. BC Children's Hospital Research Institute (Canada), 3. McGill University (Canada)

Background and objectives: Genetic hemoglobin disorders are autosomal recessive conditions that can result in a decreased production of hemoglobin or structurally variant forms of hemoglobin. Certain genetic hemoglobin disorders are thought to cause higher red blood cell turnover, due to chronic hemolysis and increased erythropoiesis. Requirements of nutrients involved in erythropoiesis, including iron, zinc, folate, vitamins B6 and B12, and riboflavin are therefore thought to be increased in individuals with genetic hemoglobin disorders, especially if dietary intake is marginal. Conversely, deficiencies of these micronutrients can contribute to significant alterations in erythropoiesis. We aimed to systematically review the literature for studies that measured ferritin, soluble transferrin receptor (sTfR), zinc, folate, vitamin B12, vitamin B6, and riboflavin concentrations in individuals with genetic hemoglobin disorders as compared with controls.

Methods: A systematic scoping review of English-language observational studies, with no limit on year of publication, was conducted.

Results: Findings from 167 studies were included. In study populations with genetic hemoglobin disorders, concentrations of mean or median ferritin and sTfR were higher compared with control study populations, and concentrations of zinc were lower than compared with control study populations. Vitamins B12 and B6 tended to be either lower or similar in those with genetic hemoglobin disorders as compared to control populations. For folate, discrepancies in the literature were found as to whether concentrations differed among those with and without genetic hemoglobin disorders, which may be attributable to the routine use of prophylactic high-dose folic acid supplementation in some populations, especially among those with sickle cell disease. Erythrocyte glutathione reductase activation coefficients (EGRac), an indicator of functional riboflavin deficiency, tended to be either higher or similar in those with genetic hemoglobin disorders as compared to control populations; however, data on this nutrient are limited to only four studies.

Conclusion: In individuals with some genetic hemoglobin disorders, biomarkers of nutritional anemia may not accurately represent an individual's nutritional status, and nutritional deficiency prevalence may be falsely underestimated or overestimated.

The physiological function ZIP14 in manganese metabolism

Caitlin Fung[1], Ningning Zhao[1]

1. The University of Arizona (USA)

Background: Manganese is an essential nutrient. Manganese homeostasis needs to be tightly controlled to prevent the adverse effects caused by its deficiency or overload. In this control, both the intestine and the liver play important roles—The intestine regulates dietary manganese absorption; whereas the liver clears manganese from the blood and secretes manganese into the bile for subsequent intestinal reabsorption or fecal excretion. As a newly identified manganese transporter, ZIP14 is abundantly expressed in the liver and small intestine. In humans, loss-of-function mutations in *ZIP14* result in severe neurodegeneration due to manganese hyper-accumulation in the brain; similarly, mice with whole-body *Zip14* knockout display manganese overload in the blood and brain, indicating an indispensable role for ZIP14 in regulating systemic manganese homeostasis. However, our knowledge on the transport of manganese by ZIP14 is limited and the functions of ZIP14 in the intestine and liver are not well understood.

Study objective: The current study aims to determine the tissue specific function of ZIP14 in the intestine and liver.

Methods: To establish the tissue-specific function of ZIP14 in manganese homeostasis, we generated mice with intestinal or/and hepatic *Zip14* knockout. Immunoblot analyses were used to confirm liver- and intestine-specific deletion of ZIP14. Inductively coupled plasma mass spectrometry (ICP-MS) analysis was used to measure tissue manganese content.

Results: In liver-specific *Zip14* knockout mice, hepatic manganese was significantly reduced, but brain manganese level was similar to that of the control animals, suggesting that although required for the liver to acquire manganese, hepatic ZIP14 is not essential for the maintenance of systemic manganese homeostasis. In contrast, in mice with ZIP14 deletion in the intestine, or in both the intestine and the liver, the brain manganese content increased significantly, indicating that loss of ZIP14 in the intestine increases body manganese loading.

Conclusions: Our study identified the critical role of intestinal ZIP14 in regulating systemic manganese homeostasis, and provided novel insights into how manganese homeostasis is regulated and how individuals lacking functional ZIP14 develop manganese overload.

Effectiveness of a Locally Produced, Fish-Based Ready-to-Use Therapeutic Food on Weight gain and Micronutrients status among Cambodian Children in the Treatment of Acute Malnutrition; A randomized Controlled Trial

Sanne Sigh[1,2], Nanna Roos[1], Chhoun Chamnan[2], Arnaud Laillou[3], Frank T. Wieringa[4]

1. Department of Nutrition, Exercise, and Sports, University of Copenhagen (Denmark), 2. Department of Fisheries Post-Harvest Technologies and Quality Control, Fisheries Administration (Cambodia), 3. Department of Child Survival and Development, UNICEF (Cambodia), 4. UMR-204, Institut de Recherche pour le développment/Université Montpellier/SupAgo (France)

Background and objective: Acute malnutrition (AM) remains a global health concern associated with low weight and micronutrient deficiencies in Cambodia. Low acceptability was found for standard ready-to-use-therapeutic-food (RUTF) products. Therefore, NumTrey, a locally-produced fish-based RUTF, was developed. The objective was to evaluate the effectiveness of NumTrey compared to an imported milk-based RUTF for weight gain and micronutrient status among 6-59-months-old children for home treatment of acute malnutrition.

Methods: Effectiveness was assessed in a single-blinded randomized controlled trial with weight gain as the primary outcome. Anthropometry was measured at baseline and bi-weekly follow-ups until endline (week 8). Biomarkers of vitamin A status (retinol-binding-protein (RBP)), iron status (ferritin and soluble transferrin receptor (sTfR)), and inflammation (C-reactive protein (CRP) and alpha-1 acid glycoprotein (AGP)) were collected at admission and discharge. Vitamin A deficiency was defined as RBP <0.70 µmol/L, low body iron as body iron (BI) <0 mg/kg, and deficient iron stores as ferritin <12 µ/L.

Results: In total, 121 children were randomized to BP-100 (n=61) and NumTrey (n=60). There was no statistical difference in weight gain between the groups (1.06 g/kg/day</95% CI (0.72, 1.41) and 1.08 g/kg/day; 95% CI (0.75, 1.41) for BP-100TM and NumTrey, respectively). Although the ability to conclude was limited by lower weight gain than the desired 4 g/kg/day in both groups, no superiority was found for any RUTFs. There was no significant difference in haemoglobin, ferritin or sTfR concentrations between admission and discharge. Body iron was 0.2 mg/kg lower at discharge, and there was a tendency towards a lower RBP. Prevalence of low BI increased significantly during the treatment (15% *vs* 16%, OR=23, *P*=0.000), but there was no impact on iron stores. RBP increased from 1.2 µmol/L to 1.4 µmol/L (*P*=0.566), and marginal vitamin A deficiency was reduced by 5.2%. Vitamin A deficiency prevalence was moderate at admission and discharge (6% and 3%, respectively). The prevalence of inflammation was high (>30%).

Conclusions: A locally produced fish-based RUTF effectively treats AM; however, more research is needed to improve the micronutrient status during SAM treatment among children.

Effects of Asian-based oil blends made from refined rice bran, flaxseed and sesame seed oils on lipoprotein particle size distribution

Yi Ning Yong[1], Kat Long Hui Wong[2], Shalini Ponnalagu[1], Farhana Osman[1], Shia Lyn Tay[1], Christiani Jeyakumar Henry[1,3], Sumanto Haldar[1]

1. Singapore Institute of Food and Biotechnology Innovation (Singapore), 2. Wil@NUS Corporate Laboratory (Singapore), 3. National University of Singapore (Singapore)

Background and objective: Low density lipoprotein (LDL) cholesterol particle size distribution have implications on atherosclerosis risk. As part of a dietary intervention trial where volunteers consumed either one of two vegetable oil blends made with different proportions of refined rice bran, flaxseed and sesame seed oils, or refined olive oil (control), the objective of this study was to determine the effects of consuming these oils on the distribution of the LDL subfractions.

Methods: This secondary analysis was undertaken using serum samples collected as part of the 8-week, three-arm, parallel design, randomised controlled trial in 135 borderline hypercholesterolemic older Chinese adults. LDL subfractions analysis were conducted using the Lipoprint LDL system.

Results: There were significant reductions in intermediate density lipoprotein (IDL) cholesterol concentration in all three intervention groups over time (-6.07%; <0.001), though this was accompanied by a corresponding increase in small, dense LDL-C (sdLDL-C) (+24.7%; <0.05) and non-significant changes in large, buoyant LDL-C (lbLDL-C) (p=0.77). The concentration of VLDL-C was also reduced in all three interventions over time (-8.23%; <0.0001), whereas no significant changes in mean LDL particle size nor high density lipoprotein (HDL) cholesterol were observed. None of the treatment or time x treatment comparisons were significant.

Conclusions: The effects of the two oil blends on LDL subfractions were comparable to that of refined olive oil, with LDL-cholesterol lowering effects elicited mainly through the reduction of IDL-C. Given the preferential reduction of cholesterol from larger, buoyant lipoproteins alongside a small but significant increase in sdLDL-C, with minimal changes in overall LDL particle size, the long-term cardiovascular impacts of these dietary interventions remain to be determined.

Taipei Medical University- Shuang Ho Hospital (Taiwan), 5. Cathay General Hospital (Taiwan), 6. Taipei Tzu-Chi Hospital (Taiwan), 7. Lotung Poh-Ai Hospital (Taiwan), 8. Wei Gong Memorial Hospital (Taiwan), 9. Taipei Medical University (Taiwan)

Background and objectives: The cardiovascular cause of death in end stage of renal disease (ESRD) patients is 10-20 times higher in the healthy population and accounted for more than half of all death. Insulin resistance (IR) is with high prevalence in the ESRD patients. IR is a risk factor for CVD and strongly associates with other CVD risk factors, such as: dyslipidemia, hypertension, and inflammation. The homeostatic model assessment of insulin resistance index (HOMA-IR) is used to assess IR. This study objective is to investigate the association between body phenotype and cardiovascular disease (CVD) risks of hemodialysis patients.

Methods: We conducted a cross-sectional study between 2013 and 2017, on 383 hemodialysis patients (male: n = 222, 58%) from seven hospital-based-dialysis centers, Taiwan. The patients' medical records were reviewed and body composition data, blood samples were collected at the first dialysis session in monthly examination. Body phenotype is classified according to BMI (normal weight:18.5-24.9) and fat mass percentage (FM %, male: 25%, female: 35%) into underweight (UW) (BMI <18.5), Normal weight/ nonobese (NW), Normal weight/ obsess (NWO), overweight-obese (pre-OB). We analyzed the traditional and nontraditional CVD risk factors among different body phenotype by using Student's t-test and ANOVA post hoc Tukey's test, Spearman rank correlation to evaluate the correlation between BMI, body composition and other clinical variables.

Results: Both NOW group and pre-obese group have higher triglyceride and HOMA-IR, lower high-density-lipoprotein cholesterol than UW group and NW group. NOW group has higher AC sugar than others. There are positive correlation between FM% and total cholesterol, low-density-lipoprotein cholesterol, triglyceride, AC sugar, insulin, HOMA-IR, high sensitivity C reactive protein.

Conclusion: Both NOW group and pre-obese group have higher cardiovascular disease risks than NW and UW patients.

Keywords: Hemodialysis, obesity, obese phenotype, cardiovascular disease

Blood levels of some nicotinamide adenine dinucleotide-related metabolites correlate with hearing acuity in healthy older men

Yoshiko Nakagawa-Nagahama[1], Masaki Igarashi[1], Masaomi Miura[1], Yuichiro Fukamizu[2], Toshiya Sato[2], Takanobu Sakurai[2], Takashi Nakagawa[3], Toshimasa Yamauchi[1]

1. The University of Tokyo (Japan), 2. Mitsubishi Corporation Life Sciences Limited (Japan), 3. University of Toyama (Japan)

Background and Objectives: Age-related hearing loss (ARHL) is one of typical phenomena observed during aging. Although nicotinamide adenine dinucleotide (NAD+) metabolism is known to be associated with a variety of age-related disease, there are few findings in relation between ARHL and NAD+ metabolism.

Methods: This study is conducted as a sub-analysis in the Nicotinamide mononucleotide supplementation clinical trial. Blood levels of NAD+-related metabolites at the first visit of 42 older men were correlated with their hearing ability. In the hearing test, only air conduction was measured, and the pure tone hearing was evaluated at frequencies of 125, 250, 500, 1000, 2000, 4000 and 8000 Hz. Correlations were analyzed by the Spearman's rank correlation.

Results: Positive associations between nicotinic acid (NA) and right-ear hearing ability (indicating correlations between NA and hearing loss) in frequencies of 1000 Hz ($r = 0.480$, $p = 0.001$) and 2000 Hz ($r = 0.507$, <0.001) were observed. Moreover, positive associations between NA and left-ear hearing ability in frequencies of 1000 Hz ($r = 0.422$, $p = 0.003$), 2000 Hz ($r = 0.629$, <0.001) and 4000 Hz ($r = 0.366$, $p = 0.029$) were identified. In contrast, a negative association between nicotinic acid riboside (NAR) and right-ear hearing ability (indicating correlations between NAR and improving hearing ability) in frequencies of 125 Hz ($r = -0.396$, $p = 0.009$) was observed. Furthermore, NAR was positively correlated with left-ear hearing ability at frequencies of 1000 Hz ($r = 0.335$, $p = 0.030$) and 2000 Hz ($r = 0.390$, $p = 0.011$). There are also positive associations between nicotinamide (NAM) and left-ear hearing ability in the frequencies of 250 Hz ($r = 0.356$, $p = 0.021$) and 2000 Hz ($r = 0.371$, $p = 0.016$).

Conclusions: There is a positive correlation among the blood concentrations of NA, NAR and NAM and hearing loss at mainly 1000 Hz and 2000 Hz. This finding suggests that the NAD+ metabolic pathway could be associated with the onset and progression of ARHL.

Keywords: Nicotinamide adenine dinucleotide (NAD+), NAD+ metabolites, nicotinic acid, age-related hearing loss (ARHL), aging

Food is medicine: pilot testing a 'Produce Prescription' program in Australia

Jason Wu[1], Kathy Trieu[1], Daisy Coyle[1], Liping Huang[1], Dariush Mozaffarian[2], Freya MacMillan[3], Ted Wu[4], Stephen Twigg[4], Jencia Wong[4], Bruce Neal[1]

1. The George Institute for Global Health, Faculty of Medicine, University of New South Wales (Australia), 2. Tufts Friedman School of Nutrition Science and Policy (USA), 3. Diabetes, Obesity and Metabolism Translational Research Unit, School of Medicine, Western Sydney University (Australia), 4. Diabetes Centre, Royal Prince Alfred Hospital (Australia)

Background and objectives: There is growing interest in *Food is medicine* programs to provide healthy foods as a treatment for patients, particularly those experiencing food insecurity. We aimed to test the feasibility of a healthy 'Produce Prescription' program and its impact on diet quality for people with type 2 diabetes (T2D) and consistently high blood glucose experiencing food insecurity in Australia.

Methods: A pre-post intervention study with n=50 participants recruited from a major public hospital in Sydney, Australia. Adults experiencing food insecurity with T2D and HbA1c ≧8% at the most recent clinical assessment, were eligible. Once enrolled, participants received healthy food boxes delivered weekly free of charge, with the contents sufficient to create 2 meals per day, 5 days per week for the entire household, over 12 weeks. Participants were also provided with tailored recipes that could be prepared using the contents of the boxes and behavioral change support from dietitians fortnightly. The primary outcome was change from baseline to week 12 in diet quality assessed by 24-hour diet recalls. Secondary outcomes included differences in cardiovascular risk factors; blood micronutrient status; body weight; and feasibility and acceptability indicators.

Results: Participants varied by ethnicity, with mean±SD age 63±9 years, HbA1c 9.8±1.5%, BMI 33.8±7.5 kg/m^2 and 46% were female. Overall, 92% completed the study. Compared to baseline, diet quality improved at week 12, with an increase in the mean overall diet quality (the Alternate Healthy Eating Index score) of 12.9 (95% CI: 8.7 to 17.1, *P*<0.001), driven by significant improvements in vegetables, fruits, whole grains, red/processed meat, trans fat, sodium, and alcohol consumption. Blood lipids also improved (total: HDL cholesterol ratio, -0.48, 95% CI -0.72 to -0.26, *P* <0.001), and there was significant weight loss (-1.74, 95%CI -2.80 to -0.68 kg, *P*=0.002), but no substantial changes in other clinical outcomes. Participants reported high levels of satisfaction with the Produce Prescription program.

Conclusions: These findings provide strong support for an adequately powered randomized trial to assess longer term effects of Produce Prescription as an innovative approach to improve clinical management of T2D.

Association of the inflammatory balance of diet and lifestyle with colorectal cancer among Korean adults: a case–control study

Shinyoung Jun[1], Jeonghee Lee[1], Jae Hwan Oh[2], Hee Jin Chang[2], Dae Kyung Sohn[2], Aesun Shin[3], Jeongseon Kim[1]

1. National Cancer Center Graduate School of Cancer Science and Policy (Korea), 2. National Cancer Center (Korea), 3. Seoul National University College of Medicine (Korea)

Background and objectives: Dietary and lifestyle exposures may affect the risk of colorectal cancer (CRC) by promoting chronic inflammation. In this study, we assessed the separate and joint associations of dietary and lifestyle inflammation scores (DIS and LIS, respectively) with CRC.

Methods: Data from 919 pathologically confirmed CRC cases and 1846 age and sex-matched controls recruited at National Cancer Center Korea were analyzed. We calculated DIS and LIS that characterize the collective contributions of 19 food groups and 4 lifestyle components, respectively, to systematic inflammation by applying weights based on high-sensitivity C-reactive protein. Higher score indicates greater proinflammatory exposure. Unconditional logistic regression models were used to estimate the ORs and 95% CIs for CRC risk by DIS and LIS tertiles with adjustment for potential confounders. The lowest tertile served as the reference group.

Results: The highest DIS tertile group had significantly increased odds of having CRC (OR 2.67, 95% CI 2.11–3.38) and the odds increased with increasing DIS. The highest LIS tertile group had higher odds of having CRC (OR 1.28, 95% CI 1.03–1.58). In the cross-classification analysis, the odds of having CRC increased as DIS and LIS jointly increased until DIS reached the highest tertile, where the risk was very high (3-fold or more) regardless of LIS.

Conclusions: Higher balances of pro- relative to anti-inflammatory dietary and lifestyle factors, especially dietary factors, were associated with higher CRC risk among Korean adults.

Keywords: diet, lifestyle, inflammation, colorectal cancer

Survey on the preparation of low-salt diets in Chubu region hospitals

Yukie Higashiyama[1], Miyu Kuzushima[2], Suzu Kawamura[3]

1. Aichi Shukutoku University (Japan), 2. G H Hospitality Food Service Chubu Co., Ltd (Japan), 3. Sugi Holdings Co., Ltd. (Japan)

Background and objectives: High sodium intake is related to many diseases, such as cardiovascular disease, and providing a

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

low–salt diet to patients in medical facilities is often necessary. The purpose of this study was to examine the methods used to adjust and prepare low-salt diets at hospitals in Japan.

Methods: In 2016, we mailed a questionnaire to 252 general hospitals with ≧200 beds in 8 prefectures in the Chubu region; central region in Japan; Seventy-seven facilities were analyzed ‹response rate of 30.6%›.

Results: The average number of meals served at the facilities was 259.3±119.8, and average percentage of low-salt meals to total number of meals ratio was 20.8±11.7%. The most common method for reducing salt was, "using low-salt seasonings"‹58 facilities›. We divided the methods for salt reduction into two: "simple" ‹e.g.,removing ingredients, reducing the amount of each serving› and "complex" ‹e.g.,changing the cooking method›. The average length of hospital stay was significantly shorter in facilities using simple methods ‹n=31› than in those using complex methods ‹n=46, 14.0±5.6 d,32.1±60.5 d; <0.001›. In addition, patients tended to highly rate the diets of facilities that used various salt reduction methods.

Conclusions: A low-salt diet was provided at all facilities; however, the cooking methods were diverse. It was noted that the methods for adjusting the salt content of the diet varied across the facilities, especially in those with long-term inpatients. Furthermore, it was observed that the use of diverse methods for preparing the low-salt diet received high ratings in the preference survey. However, there are few facilities that measure salt content on a regular basis, suggesting that objective evaluation is necessary to provide properly rationed meals.

Effects of mild magnesium deficiency on depressive-like behavior and metabolome of urine and plasma in rats

Shozo Tomonaga[1], Takashi Futami[1,2]

1. Kyoto University (Japan), 2. Institute of Food Research, National Agriculture and Food Research Organization (Japan)

Background and objectives: Epidemiological studies suggest that low magnesium (Mg) intake increased the risk of various diseases such as diabetes and depression. In addition, reliable method to identify mild Mg deficiency has not been established yet. For the biomarker discovery, we speculate that metabolomic analysis will be effective because Mg can affect various metabolism in the body. In the present study, we evaluated whether mild Mg deficiency could affect depressive-like behavior and metabolome of urine and plasma in rats.

Methods: Male Wistar rats (five-week-old) were fed a control diet formulated according to AIN-93G or low Mg diet containing 25% or 50% of Mg compared with the control diet. One-day's urine was collected on days 7, 14, 21, and 28. Open field test and forced swim test were conducted on days 29-35 to evaluate effects on locomotor activity and depressive-like behavior, respectively. On day 35, plasma was collected. The urine and plasma were subjected to untargeted and semi-quantitative metabolomics by gas chromatography-tandem mass spectrometry.

Results and discussion: Locomotor activity and depressive-like behavior were not affected by the treatments. Urinary excretion of Mg and plasma Mg level were decreased by low Mg diet while body weight and feed intake were not affected. In the urine, 29 out of the 122 annotated metabolites were affected by the diet. At all-time points from 7 to 28 days, there was a marked decrease of the excretion of some TCA cycle organic acids, especially citrate. In the plasma, only glycyl-glycine out of the 93 annotated metabolites were moderately affected.

Conclusion: Depressive-like behavior were not affected by mild Mg deficiency in rats. The deficiency clearly affects the urinary excretion of some metabolites. Further study should be done to evaluate whether these urinary metabolites can be the biomarker for mild Mg deficiency.

Statins for hypercholesterolemia tend to decrease plasma ACBP/DBI concentrations

Mitsue Miyazaki[1], Masashi Yanagimachi[1], Wataru Miyazaki[1], Yusuke Tando[1]

1. Hirosaki University Graduate School of Health Science (Japan)

Background and objectives: ACBP (Acyl-CoA Binding Protein)/DBI (Diazepam Binding Inhibitor), a highly conserved 10-kDa polypeptide, has been implicated in various physiological processes including acyl-CoA binding and transport, g-aminobutyric acid type A receptor binding, steroidogenesis, and peptide hormone release. It was reported that the plasma concentration of ACBP/DBI is positively correlated with BMI, and it is known that plasma ACBP/DBI concentration is significantly higher in severely obese patients and conversely decreases in loss of appetite. These reports indicate that ACBP/DBI may be considered a new appetite-promoting factor, but the evidence is still insufficient.

Methods: In this study, we measured plasma ACBP/DBI concentration in type2 diabetic patients visiting Hirosaki University Hospital (16 males, 12 females; 72.7±9.4 age) and investigated the association with statins, a therapeutic drug for hypercholesterolemia with DBI (Human) ELISA kit (Abnova).

Results: As a result, there was no correlation between the ACBP/DBI plasma concentration and the patient's body weight (statin-treated; 70.2±12.9 kg, statin untreated; 72.3±14.1 kg), body fat percentage (34.7±10.1%, 36.5±9.6%, respectively), LDL-Cho (109.1±30.7, 112.8±19.2 mg/dL, respectively) nor BMI (27.2±5.5, 28.5±4.1, respectively). Furthermore, plasma ACBP concentrations tended to be lower in the statin-treated group (144.2±29.8 ng/mL) than in the untreated group (173.6±54.3

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

ng/mL), although Welch's t-test results showed no significant differences (*P*=0.055).

Conclusions: This study found that in patients with type2 diabetes, those taking statins tend to have lower plasma ACBP/DBI concentrations than those not taking statins. The number of patients in this study was small, and future studies with larger numbers of subjects are needed to clarify the relationship between statins and ACBP/DBI. In addition, patients were taking multiple medications, so further investigation is required to determine if this is due to statins alone.

Keywords: ACBP/DBI, type2 diabetes, cholesterol

PAB(T4)-166
Effect of hyperglycemia during pregnancy on brain neurons in infants

Ritsuko Kawaharada[1], Haruka Okami[2], Hitomi Yoshizaki[3], Akiyo Toriumi[4], Akio Nakamura[3]

1. Takasaki University of Health and Welfare (Japan), 2. Gunma University (Japan), 3. Jissen Women's University (Japan), 4. Tokyo Medical and Dental University (Japan)

Background and objectives: Child from the gestational diabetes mellitus (GDM) with hyperglycemia during pregnancy develop neonatal complications such as macrosomia, myocardial hypertrophy, and neonatal hypoglycemia. Furthermore, it has been already reported that when infants of GDM grow up, they have a higher incidence of learning disabilities and attention-deficit/hyperactivity disorder (ADHD), and an increased rate of neurological dysfunction. In this study, we examined the effects of hyperglycemia during pregnancy on infant using a rat animal and cell model of GDM. We further examined whether n-7 unsaturated fatty acids ameliorate the effects of hyperglycemia using GDM cellular model.

Methods: GDM animal model rats were prepared by tail vein administration of streptozotocin to Wistar rats on day 2 of gestation. The cerebrum of infants of GDM rats (IDM rats) and infants of control mother rats (ICM rats) were examined. In addition, the rat pheochromocytoma cells (PC12 cells) were cultured in 500 mg/dL glucose to create GDM cellular model. Control cells were cultured with 200 mg /dL glucose. The effect of fatty acids on the PC12 cells was examined by adding the GDM model cells with the cis - palmitoleic acid (CPA) and the trans - palmitoleic acid (TPA), structural isomers of palmitoleic acid, an n-7 unsaturated fatty acid that has been reported to improve insulin resistance.

Results: The advanced glycation end-products (AGEs) generation was enhanced in the cerebrum of IDM rats on postnatal day 2 and the expression level of the receptor (RAGE) for AGEs was increased. The phosphorylation level of Akt was decreased in IDM rats. In GDM cellular model, the generation levels of AGEs were enhanced, the phosphorylation levels of Akt and JNK were inhibited. In GDM cellular model exposed to hyperglycemia, cleaved caspase and Bax were increased and the number of apoptotic cells increased compared to control cells. However, the induction of AGEs and inflammation was suppressed, and the number of apoptotic cells decreased by treated with CPA or TPA. However, CPA was cytotoxic in a concentration dependent manner.

Conclusions: Hyperglycemia during pregnancy increases AGEs and induces apoptosis on brain neurons, suggesting that dairy products containing TPA may ameliorate these abnormalities by feeding during pregnancy.

Keywords: Intrauterine hyperglycaemia, advanced glycation end products, n-7 unsaturated fatty acids, infants, apoptosis

Vitamin E intake and Paraoxonase 1 (*PON1*) rs662 genetic polymorphism associated with colorectal cancer risk in a Korean population

Anh Quynh Bui[1], Madhawa Gunathilake[1], Jeonghee Lee[1], Jae Hwan Oh[2], Hee Jin Chang[2], Dae Kyung Sohn[2], Aesun Shin[3], Jeongseon Kim[1]

1. National Cancer Center Graduate School of Cancer Science and Policy (Korea), 2. National Cancer Center (Korea), 3. Seoul National University College of Medicine (Korea)

Background: Vitamin E and paraoxonase 1 (*PON1*) have essential roles in reducing oxidative stress, which may contribute to cancer development. However, their interaction on the risk of colorectal cancer (CRC) was inconclusive. We conducted a hospital-based case-control study to determine whether PON1 affects the antioxidant activity of vitamin E in CRC occurrence.

Methods: Total study sample comprised with 923 CRC cases and 1846 controls matched by age and sex at the National Cancer Center, Korea. Based on the genotype data, 589 cases and 810 controls were selected to perform interaction analysis. Dietary information was collected using a semiquantitative food frequency questionnaire (SQFFQ). Genotyping was carried out using an Illumina MEGA-Expanded Array. Unconditional logistic regression models were used to observe the associations and likelihood ratio tests were applied to observe the interaction.

Results: There was an inverse association between vitamin E intake and CRC risk (odds ratio (OR) = 0.26; 95% confidence interval (CI) = 0.21–0.33; *p* for trend <0.001) after adjusting for confounders. We identified a lower risk of CRC among homozygous CC carriers of the *PON1* rs662 polymorphism than participants having the T allele (CT+TT) (OR = 0.72; 95% CI=0.55–0.94; p=0.017). Among the individuals carrying the minor allele (T), the highest vitamin E intake was associated with a 70% reduced CRC risk compared to the lowest level (OR = 0.30; 95% CI = 0.19–0.49). The protective effect of dietary vitamin E against CRC development was stronger among CC individuals (OR = 0.11; 95% CI = 0.06–0.21; *p* for interaction=0.029).

Conclusions: The study supported the evidence that vitamin E intake was associated with CRC risk reduction. Furthermore, the activity of vitamin E was strengthened among homozygous CC carriers of the *PON1* rs662 polymorphism.

Ann Nutr Metab 2023;79(suppl 1):14–1172

All-trans retinoic acid induces lipolysis via activation of autophagy in mouse adipocytes

Yuki Mori[1], Masashi Masuda[1], Risa Yoshida-Shimizu[1], Saki Aoyagi[1], Yuichiro Adachi[1], Kohta Ohnishi[1], Hirokazu Ohminami[1], Koichiro Hamada[2], Yutaka Taketani[1]

1. Tokushima University Graduate School (Japan), 2. Saga Nutraceuticals Research Institute, Otsuka Pharmaceutical Co., Ltd (Japan)

Background and objectives: Lipophagy is the new pathway of lipolysis that is defined as the breakdown of lipid droplets (LDs) via autophagy, a cellular homeostasis mechanism, in adipose tissue and liver. All-trans retinoic acid (atRA), a metabolite of vitamin A, has been thought to induce lipolysis by hormone-sensitive lipase (HSL) in mouse adipocytes. However, it is unclear whether atRA can be involved in lipophagy. In this study, we investigated the effects of atRA on autophagy in the epididymal fat of mice and on lipolysis through the activation of autophagy in mouse adipocytes (3T3-L1 cells).

Methods & Results: C57BL/6J mice were intraperitoneally administered 10 mg/kg body weight/day of atRA for 4 weeks. We confirmed that the epididymal fat mass and adipocyte size in atRA-treated mice were smaller than in DMSO-treated mice as a control. Western blotting analysis showed that atRA increased the expression of LC3B-II protein, but decreased the expression of p62 protein in the epididymal fat of mice. Oil Red-O staining indicated that lipid accumulation in differentiated 3T3-L1 cells treated with atRA (100 nM) for 10 days was lower than DMSO-treated cells. The treatment of Torin1, an autophagic inducer, or atRA for 24 h increased the release of fatty acids from LDs in differentiated 3T3-L1 cells. Furthermore, we verified that atRA activated autophagy flux in mature 3T3-L1 cells using the autophagy flux assay probe, GFP-LC3-RFP-LC3ΔG. Inhibition of autophagy using siRNA of autophagy-related gene 5 (ATG5) partially suppressed the atRA-induced release of fatty acids from LDs in differentiated 3T3-L1 cells.

Conclusions: These results suggest that atRA partly may induce lipolysis via activation of autophagy in adipocytes.

Keywords: All-trans retinoic acid (atRA), autophagy, lipolysis, adipocyte, obesity

PAB(T4)-169
Associations between polyunsaturated fatty acid intake and risk of dyslipidemia

Seoeun Ahn[1], Soo Hyun Kim[1], Jina Chung[1], Yejin Park[1], Hyojee Joung[1]

1. Seoul National University (Korea)

Background and objectives: cardiovascular diseases are the leading cause of death in Korea. Thus, efforts are needed to improve the lipid profile, a risk factor for cardiovascular diseases. Previous studies show the inverse relationship between the intake of polyunsaturated fatty acids (PUFA) and lipid levels, but studies conducted on Koreans are insufficient. Therefore, this study aimed to investigate the association between PUFA intake with the incidence of dyslipidemia and its components in Korean adults.

Methods: Data were obtained from the Korean Genome and Epidemiology Study (KoGES), a community-based prospective cohort study. Korean adults aged 40-69 years who did not have dyslipidemia components, hypertension, type 2 diabetes, cardiovascular diseases, or cancer at baseline and who participated in the diet survey using a semi-quantitative food frequency questionnaire were selected as subjects. The data of 2,629~6,270 subjects were utilized for final analyses. The new cases of dyslipidemia were defined as satisfying one or more of the following conditions: hypercholesterolemia, defined as total cholesterol ≧ 240 mg/dL; hyper-LDL-cholesterolemia, defined as LDL-cholesterol ≧ 160 mg/dL; hypo-HDL-cholesterolemia, defined as HDL-cholesterol <40 mg/dL for men and <50 mg/dL for women; hypertriglyceridemia, defined as ≧ 200 mg/dL; or have been diagnosed with dyslipidemia or taking lipid-lowering medications during follow-up. Subjects were classified into quintiles according to the PUFA intake. Cox proportional hazard model was used to analyze relative risks (RR) and 95% confidence intervals (95% CI) for incident dyslipidemia according to PUFA intake.

Results: During a maximum follow-up of 15.6 years, 1607, 1230, 1375, 1555, and 1233 cases were newly identified as dyslipidemia, hypercholesterolemia, hyper-LDL-cholesterolemia, hypo-HDL-cholesterolemia, and hypertriglyceridemia, respectively. After adjusting for confounders, subjects with the highest quintile of PUFA intake had a significantly lower risk of hypercholesterolemia (RR=0.77, 95% CI=0.61-0.96, P for trend=0.0081) and hyper-LDL-cholesterolemia (RR=0.74, 95% CI=0.60-0.92, P for trend=0.0087) than those who with the lowest quintile. However, there was no significant difference in risk of dyslipidemia, hypo-HDL-cholesterolemia, and hypertriglyceridemia according to PUFA intake.

Conclusions: The findings of this study imply that a higher PUFA intake may affect improving lipid profile among middle-aged Korean adults.

Keywords: Polyunsaturated fatty acids, Dyslipidemia, Korean adults, Cohort study

Effect of phosphate on intestinal zinc absorption in 5/6 nephrectomized rats

Yosuke Okumura[1], Hirokazu Ohminami[1], Kohta Ohnishi[1], Masashi Masuda[1], Yutaka Taketani[1]

1. Tokushima University (Japan)

Background and objectives: Zinc is an essential trace element and maintains several important biological processes in human body by serving as a component of various enzymes and transcription factors. In chronic kidney disease (CKD), more than 80% of the patients show hypozincemia. Hypozincemia is one of the adverse prognostic factors of CKD. However, the pathogenesis of hypozincemia in CKD remains unclear and its treatment is not well established. Zinc homeostasis is mainly regulated by intestinal absorption. In this study, we aimed to elucidate the pathogenesis of hypozincemia in CKD, focusing on intestinal zinc absorption.

Methods: We performed experiments in normal rats and in a rat model of CKD generated by 5/6 Nephrectomy. To evaluate intestinal zinc absorption capacity of rats, the area under the plasma zinc concentration-time curve (AUC) was measured after administration of $ZnSO_4$ solution with or without phosphate. The solubility of zinc in the solution was examined using a 0.22 µm filter.

Results: CKD rats had lower plasma zinc levels and higher phosphate levels than those of control rats. The AUC in CKD rats after administration of $ZnSO_4$ alone was significantly decreased compared to control rats, suggesting that intestinal zinc absorption may be reduced in CKD. Renal dysfunction often leads to excess accumulation of phosphate in the body, including intestinal lumen. To explore the mechanisms of reduced AUC in CKD rats, we examined the relationship between phosphate and zinc metabolism. In rats fed a high-phosphate diet, plasma zinc levels significantly decreased compared to rats fed a control diet. Furthermore, we found that the AUC in normal rats decreased as increase in phosphate concentration of the administered solution. The solubility of zinc in the solution decreased in a phosphate concentration-dependent manner, which was also seen in the physiological intraluminal pH range (pH 6~8).

Conclusions: This study suggests that hypozincemia in CKD may be, in part, induced by excess phosphate, which reduces the solubility of intraluminal zinc and inhibits its absorption. Therefore, dietary phosphate restriction may help to ameliorate hypozincemia as well as hyperphosphatemia in CKD patients. Further clinical investigation will be needed.

Evaluation of impact of nutritional counseling on nutritional status of post-operative coronary artery bypass graft surgery patients

Oshadhi Warunika Meegoda[1], A. M. N. Thakshila Adikari[1], Amal Zaffroon Firouse[2]

1. Wayamba University (Sri Lanka), 2. Asiri Surgical Hospital (Sri Lanka)

Background and objectives: Modifying the diet via nutritional counseling is an emerging concept used to intervene nutrition imbalances that lead to malnutrition, chronic diseases, and other clinical conditions. In surgical patients, nutritional counseling supports fast recovery and reduces complications after surgery. Coronary artery bypass graft (CABG) surgery is used to treat cardiovascular diseases, which are increasing in Sri Lanka. However, studies determining effect of nutritional counseling for CABG patients in Sri Lanka are limited. Therefore current study employed a pre-post design to evaluate the impact of nutritional counseling on the nutritional status of post-operative CABG patients.

Methods: Thirty post-operative CABG patients (Males; 20, Females; 10), age >18 years were recruited from a private hospital. Post-operative nutritional counseling was provided at the hospital by a registered dietitian. Observations on nutritional counseling, patients' information sheets available with the dietitian, and a pre-tested interviewer-administered questionnaire via telephone were used for data collection. At baseline, data were collected on patients' general characteristics, medical information, nutritional status-related biochemical parameter information, and dietary information. At the first hospital visit after surgery, patients' length of wound healing period and biochemical parameters were obtained. Patients' pre-operative biochemical parameter information and dietary information were compared with post-operative biochemical parameter information and dietary information.

Results: Findings confirmed improved biochemical parameters from high levels to healthy range for random blood glucose level and serum albumin level in 6 (20%) and 5 (16.7%) patients respectively. Serum albumin level of 10 (33.3%) patients was improved from low level to healthy range. Length of wound healing period (Mean 3.07$\pm$1.2 weeks) was less than two weeks for 11 (36.7%) patients. After nutritional counseling, vegetable consumption of 10 (33.3%) patients was increased from <2 servings to 2-4 servings per day. Majority, 26 (86.7%) patients have changed their usage of coconut milk type from first milk to second milk for cooking meals.

Conclusions: According to the results, nutritional counseling positively impacted on nutritional status of post-operative CABG patients. Further studies are required on nutritional counseling for CABG patients in both government and private hospitals and the impact of nutritional counseling on other surgical procedures.

MMS Process Evaluation in 10 Districts in Indonesia

Nurzakiah Hasan[1,2], Veni Hadju[1,2], Djunaidi M. Dachlan[1,2], Nurhaedar Jafar[1,2], Healthy Hidayanty[1,2], Abdul Salam[1,2], Akmal Novrian Syahruddin[1,2], Sabaria Manti Battung[1,2], Marini Amalia Mansur[1,2]

1. Indonesian Center for Nutrition Studies (ICONS) (Indonesia), 2. Department of Nutrition Science, Faculty of Public Health, Universitas Hasanuddin (Indonesia)

Background and objectives: Micronutrient deficiencies are common among pregnant women especially in LMICs. Multiple micronutrient supplement (MMS) has been shown to improve pregnancy outcomes and the World Health Organization (WHO) has provided a context -specific recommendation for MMS. This study examines inputs, processes, and outputs related to the implementation of MMS in 10 health office districts level in Indonesia.

Methods: An online ANC facility-based survey was conducted in 10 districts in Indonesia. Online forms were socialized with, and then sent to head of facility. Inputs examined included provision of existing MMS storage area, program implementation team, program operations manuals, and provision of broader MMS program awareness and socialization within district ANC system. Processes examined included feedback from pregnant women (e.g., MMS related questions, complaints, and side effects). Outputs included MMS distribution data in each districts.

Results: Most district (80%) had a well-managed storage facility for MSS. While few had a specific MMS implementation team (10%) and operations manual (20%), half (50%) had socialized the importance of MMS within broader health system. Across all district, no monitoring system existed to collect data on beneficiary feedback, however some recipients of MMS could report their questions or concerns to midwives via a previously established WhatsApp group. The amount of MMS distributed was recorded monthly at the level of 70% (based on number of doses allotted for each district).

Conclusions: District health facilities are distributing MMS to pregnant women via the ANC system. Improving s monitoring and evaluation protocols and efforts to better understand the strengths and weaknesses of current MMS implementation efforts will help health care providers (e.g., midwifes) within district-level health facilities improve the delivery of MMS.

Factors influencing depressive disorder in late adulthood, Korea

Soo Jin Lee[1], Ho Kyung Ryu[2]

1. Pusan National University (Korea), 2. Pusan National University (Korea)

Background and Objectives: Depressive Disorder (DD) is the most common mental illness. It is known that the possibility of suffering from DD in the elderly attempted suicide is high. To improve the symptoms of DD, this study was conducted how dietary status works among factors, such as socio-economic characteristics, health behaviors, chronic diseases, and dietary behaviors (DB) affecting DD.

Methods: This study was conducted using data from KNHANES. The subjects were adults 65 years of age or older. Those diagnosed with DD by a doctor or had a PHQ-9 score of 10 or higher were classified as DD group. And normal group with the same gender and age were chosen using the Propensity Score Method, and all of 528 subjects were analyzed. Decision Tree method was used to predict factors influencing the prevalence of DD.

Results: The 1st factor influencing the prevalence of DD was quality of life, the second factor was stress recognition, current smoking status, and income level. The third factor was age, rheumatoid arthritis, folate intake ratio, mixed-grains intake, perception of nutritional labeling (NL), and food security (FS). Particularly, the probability of DD occurrence increased to 100% when the NL of food was not recognized even if stress was hardly recognized. In terms of DB, the first factor was FS. Even if FS is secured, if the mixed grain intake score was under 1.2 points, the probability of DD was increased. And when the intake of meat, fish, eggs, and beans was under 1.3 points, the probability of DD to 100%. If FS is mildly insecure, if the iron intake ratio is poor, the probability of DD was increased. And when the intake of n-6 intake ratio is poor, the probability of DD was also increased. The probability of DD occurrence increased when the NL of food was not recognized even if iron intake ratio was good.

Conclusions: It was found that various environmental factors had more influence on DD in late adulthood. However, DB is a factor that can be improved, and confirmed that recognizing NL and properly consuming foods affects the prevalence of DD.

PAB(T4)-174
Maternal vitamin D deficiency may be a risk factor for enamel hypomineralization in permanent teeth of the fetus.

Takashi Nakamura[1], Hannah M Nakamura[2], Minoru Wakamori[1]

1. Tohoku University (Japan), 2. Tohoku Medical and Pharmaceutical University (Japan)

Background and objectives: Vitamin D is one of the essential nutrients and especially important for hard tissue development such as bone and teeth, which require mineral deposition. The principal function of vitamin D in calcium and phosphate homeostasis is to increase those mineral absorptions from the intestine. Thus, its deficiency results in rickets and osteomalacia. In recent years, the number of rickets patients has been increasing not only in Japan but also in other countries. In dentistry, hypomineralization of a permanent tooth at 1st molars and/or incisors known as MIH is increasing, which could be related to vitamin D deficiency.

Methods: We analyzed the role of 1,25-Dihydroxyvitamin D3 in the differentiation of dental epithelial cells into ameloblasts and in the mineralization of the enamel matrix in vitro and tooth bud organ culture system.

Results: The expression of ameloblast marker genes were induced by 1,25-Dihydroxyvitamin D3 in dental epithelial cells and cultured tooth buds. Mineralization of enamel matrices secreted from ameloblasts was induced by 1,25-Dihydroxyvitamin D3, but was necessary in the presence of sufficient calcium.

Conclusions: Vitamin D as well as sufficient calcium is essential for enamel calcification. One key point of this presentation is that the bone phenotype of rickets patients improves and heals with active vitamin administration, but the calcification defects of the enamel cannot be corrected once the enamel has formed. This is because, unlike bone, teeth cannot be remodeled. In addition, vitamin D intake in pregnant and nursing women is important because the induction of ameloblast and the enamel mineralization of permanent teeth begin in the late phase of pregnancy. We believe that breastfeeding is wonderful, thus we would like to establish a system to check the nutritional composition of breast milk like a formular milk and if there is excess or deficiency, it can be improved with supplements for mothers.

PAB(T4)-175
The association of dietary potassium intake and the *TNF*-α rs1800629 polymorphism with gastric cancer risk: A case-control study in Korea

Tao Thi Tran[1], Madhawa Gunathilake[1], Jeonghee Lee[1], Il Ju Choi[1], Young-Il Kim[1], Jeongseon Kim[1]

1. National Cancer Center (Korea)

Background: Dietary mineral intake has been suggested to have an impact on gastric cancer (GC) prevention; however, a protective effect against gastric carcinogenesis of potassium remains understudied. The causal link between inflammation and cancer was well established. Notably, potassium and potassium channels may have certain roles in the regulation of tumor necrosis factor-α (T*NF*-α) production. We determined whether dietary potassium intake has a beneficial effect on GC prevention and whether the effect of potassium on GC risk is modified by *TNF*-α rs1800629 single-nucleotide polymorphism.

Method: We designed a case-control study with 377 cases and 756 controls to investigate the association of dietary potassium intake with GC risk. A semi-quantitative food frequency questionnaire was used to identify dietary potassium intake. We used the Affymetrix Axiom Exom 319 Array platform to genetic analyze *TNF-α* rs1800629. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated based on logistic regression models.

Results: Dietary potassium intake was found to be inversely associated with GC risk (OR=0.63, 95% CI=0.45-0.89, *P* for trend=0.009). We observed an insignificant association of *TNF-α rs1800629* with GC risk (OR=1.01, 95% CI=0.68-1.49). Notably, the protective effect of potassium against gastric carcinogenesis may be modified by *TNF-α rs1800629*; in detail, potassium seemed to have a greater effect among females with GG homozygotes (OR (95% CI)=0.40 (0.20-0.78), *P* interaction=0.041).

Conclusion: Our study emphasized a beneficial effect of potassium intake on GC prevention. However, this effect depended on *TNF-α rs1800629* genotype. A greater effect was exhibited for females with GG homozygotes.

Longer-term mixed nut consumption improves not only cardiometabolic risk markers, but also regional insulin action in the brain: Results of a randomized, controlled crossover trial in older adults

Kevin MR Nijssen[1], Ronald P Mensink[1], Peter J Joris[1]

1. Maastricht University (Netherlands)

Background and objectives: Improving brain insulin sensitivity is considered a promising approach in the prevention and treatment of age-related metabolic and cognitive diseases. This study therefore investigated the longer-term effects of mixed nuts on regional cerebral blood flow (CBF) responses to intranasal insulin in older adults. Furthermore, more traditional cardiometabolic risk markers were assessed.

Methods: In a randomized, single-blinded, cross-over trial, twenty-eight healthy adults (65±3 years; BMI: 27.9±2.3 kg/m^2) received either daily 60 g mixed nuts (15 g of walnuts, pistachio, cashew, and hazelnuts) or no nuts (control) for 16 weeks, separated by an 8-week washout period. Throughout the whole study, participants were requested to adhere to the Dutch food-based dietary guidelines. During follow-up, brain insulin action was assessed by quantifying acute effects of nasal insulin on regional CBF using arterial spin labeling MRI. Furthermore, peripheral insulin sensitivity using an oral glucose tolerance test (OGTT) and other cardiometabolic risk markers were assessed.

Results: Body weight and composition did not change during the study. Mixed nut consumption significantly affected regional insulin action in eight brain clusters. Four clusters were located in the left (Δ-4.5±4.7 mL/100g/min; <0.001; Δ-4.6±4.8 mL/100g/min; <0.001; and Δ-4.3±3.6 mL/100g/min; P=0.007) and right occipital lobe (Δ-4.3±5.6 mL/100g/min; P=0.028). Another cluster was part of the left frontal lobe (Δ-4.9±4.6 mL/100g/min; <0.001), while three other cortical clusters were located in the left and right parietal lobe (Δ-4.2±3.6 mL/100g/min; <0.001; Δ-4.7±3.7 mL/100g/min; <0.001; and Δ-3.9±4.9 mL/100g/min; P=0.028). Post-load concentrations during the OGTT and fasting glucose and insulin concentrations were however not affected. Finally, serum LDL-cholesterol concentrations (Δ-0.24 mmol/L; 95%CI: -0.44 to -0.04; P=0.019), and systolic blood pressure (Δ-5 mmHg; 95%CI: -8 to -1; P=0.006) and mean arterial pressure (Δ-3 mmHg; 95%CI: -6 to -1; P=0.020) were lower after the intervention as compared to the control period.

Conclusions: Longer-term mixed nut consumption as part of a healthy diet may improve in older adults insulin responsiveness in brain regions involved in the modulation of metabolic and cognitive processes. LDL-cholesterol concentrations and blood pressure levels also improved, but beneficial effects on peripheral insulin sensitivity were however not observed.

Keywords: Nuts, Brain, Insulin Sensitivity, Cerebral Blood Flow, Cardiometabolic Risk

Conflict of Interest Disclosure: This study was supported by a grant from the International Nuts and Dried Fruit Council (INC). The INC was not involved in the design, implementation, analysis, and interpretation of the study.

Unsaturated fatty acid supplementation maintains a healthy liver and improves intestinal morphometry in an animal model at an early age

Ivonne Gutierrez Zorrilla[1], Nataly D. Bernuy Osorio[1], Otto Zea Mendoza[1], Carlos Vílchez Perales[1]

1. Universidad Nacional Agraria La Molina (Peru)

Background and objective: Obesity in children promotes an inadequate formation of adipocytes that would have repercussions in adulthood; this generates the need to look for new foods or components that favor the adequate establishment of adipocytes in early childhood, where oils are a great alternative due to their composition. Therefore, the objective was to evaluate the influence of the consumption of different sources of fatty acids such as quinoa oil (QO), fish oil (FO) and vegetable shortening (VS), on liver and intestinal morphometry in an animal model at an early age.

Methods: 76 Cobb 500 male chicks were used, divided into four treatments. The diets were provided for seven days, T1: basal, T2: basal+1% QO, T3: basal+1% FO and T4: basal+1% VS. At the end, all the animals were sacrificed to extract the liver for its weight and evaluation of macroscopic (MaC) and microscopic (MiC) characteristics, in addition to samples of the small intestine to determine its morphometry (length, width, area and depth of the crypt). Data were analyzed by Kruskal-Wallis considering P<0.05 as statistically significant, using the R Studio 4.1.1 program.

Results: The weight of the liver was greater in the T4 group compared to the other treatments (P<0.05), this is confirmed by the MaC and MiC, which indicated moderate injury and accumulation of fat globules in the hepatocytes, respectively. Whereas, the groups fed with QO or FO had normal and similar characteristics to T1. In reference to the intestinal morphometry, the animals fed with T2 and T3 obtained greater villus length compared to those fed with T1 and T4 (P>0.05); regarding the width and area of the villi, values were obtained in favor of the T2 treatment compared to the other treatments; however, there were no significant differences in crypt depth.

Conclusions: The consumption of diets supplemented with fatty acids from quinoa oil or fish oil improves intestinal morphometry, compared to vegetable shortening and basal diet. In addition, quinoa oil and fish oil help maintain the normal characteristics of the liver compared to vegetable shortening, which causes injuries and promotes the accumulation of fat in hepatocytes.

Keywords: Fatty acids, quinoa oil, liver, intestinal morphometry, early age

The effects of pre-exercise high and low glycaemic index meals on substrate metabolism in inactive middle-aged women

Miki Sakazaki[1], Yoshie Yoshikawa[1], Kayoko Kamemoto[1], Zhentao Zhong[1], Ge Li[1], Yusei Tataka[1], Masashi Miyashita[1]

1. Waseda University (Japan)

Background and objectives: Unhealthy diet and physical inactivity are the major risk factors for non-communicable diseases. Glycaemic index (GI) is an indicator of glucose absorption into the systemic circulation after ingestion of the same amount of carbohydrates from different foods. Given that lowered postprandial insulin after consuming low GI foods, the consumption of low GI foods has been shown to enhance fat oxidation and reduce carbohydrate oxidation compared with high GI foods during subsequent exercise. However, few studies have examined the influence of pre-exercise meal with different GIs in untrained adults performed feasible exercise. Thus, the aim of this study was to investigate the effect of high and low GI meals before exercise on substrate metabolism in inactive middle-aged woman.

Methods: Ten inactive middle-aged women (aged 42±6 years, mean ± standard deviation) completed two trials, high GI and low GI, in a randomised crossover design. Each participant consumed an isocaloric high GI or low GI breakfast (1.5 g/kg body mass carbohydrate) with GI values of 73 and 41, respectively 120 minutes before a 60-minute walk at 50% of maximum oxygen uptake. After performing a 60-minute walk, participants rested for 60 minutes. Expired gas samples were collected every 30 minutes for 15 minutes prior to walking, and further samples were collected continuously throughout the walking session and the entire 60-minute post-walking period.

Results: The pattern of fat oxidation response was different between trials (trial-by-time interaction, $P<0.0005$). Post hoc tests revealed that there was a tendency toward increased fat oxidation at 15 minutes into the waking period in the low GI trial ($P=0.117$). The pattern of carbohydrate oxidation response was different between trials (trial-by-time interaction, $P<0.0005$). Post hoc tests revealed that there was a tendency toward decreased carbohydrate oxidation at 15 minutes into the waking period in the low GI trial ($P=0.081$). These data were also confirmed by cumulative fat and carbohydrate oxidation analyses using data extracted from a 60-minute walk.

Conclusions: These findings may indicate that consuming a low GI breakfast have favourable effects on fat and carbohydrate metabolism during subsequent walking.

Effect of highly unsaturated fatty acid deficiency from birth on hepatic cholesterol accumulation and pathology

Natsuki Matsuoka[1], Yukina Yoshimoto[1], Yuri Hayashi[2], Tomoko Ishikawa[3], Yoko Fujiwara[1], Ikuyo Ichi[1]

1. Ochanomizu University (Japan), 2. University of Tsukuba (Japan), 3. Seitoku University (Japan)

Background and objectives: Highly unsaturated fatty acids (HUFAs), which are polyunsaturated fatty acids (PUFAs) with more than 20 carbons and three or more double bonds, are important components of biological membranes and are converted to lipid mediators that are important for the maintenance of homeostasis in the body. Fatty acid desaturase 2 (FADS2) is responsible for the conversion of C18 PUFA to C20 PUFA. We have previously reported that feeding adult FADS2-deficient mice a PUFA deficient-diet resulted in a marked decrease in HUFAs and accumulation of both triglyceride and cholesterol in the liver (FEBS letters, 2021). In this study, we examined cholesterol accumulation and pathology in the liver of FADS2-deficient mice fed a PUFA-deficient diet from birth.

Methods: The parental FADS2 heterozygous deficient mice were fed the experimental diet immediately after birth. Wild-type and FADS2-deficient pups were weaned at 4 weeks of ages. Each pup was fed the same diet as the mother and dissected at 12 weeks of ages. The experimental diets were a control diet with soybean oil and a PUFA-deficient diet with tripalmitin (TG-16:0).

Results: FADS2-deficient mice fed a PUFA-deficient diet from birth resulted in a marked decrease in HUFAs and a dramatic accumulation of cholesterol in the liver. The degree of increase in hepatic cholesterol in FADS2-deficient mice fed a PUFA-deficient diet from birth was greater than those from adulthood. However, the expression of genes involved in cholesterol synthesis, transport, catabolism, and efflux was not increased in FADS2-deficient mice. In addition, the gene expression of the inflammatory cytokines such as TNF-α and IL-6 and the fibrosis markers such as Col1a1 and TGF-β were increased in the liver of FADS2-deficient mice. Furthermore, Azan and Sirius red staining results confirmed that fibrosis was increased in FADS2-deficient mice.

Conclusions: These results proposed that FADS2-mediated production of HUFAs in the liver had an inhibitory effect on the progression of hepatic steatosis and NASH.

Coptidis Rhizoma and Evodiae Fructus Mixture Regulates Inflammation and Tight Junction Proteins in DGER rat

Jin A Lee[1], Mi-Rae Shin[1], Seong-Soo Roh[1]

1. Daegu Haany University (Korea)

Background and objectives: Gastroesophageal reflux disease (GERD) is a gastrointestinal disorder in which stomach contents reflux into the esophagus, causing complications such as mucosal damage. GERD accounts for more than 20% of the Western population and is a disease that is also increasing in incidence in Asian countries. This work aimed to assess the impact of Coptidis Rhizoma and Evodiae Fructus 1:4 mixture (CE) against esophageal mucosal injury with duodenogastroesophageal reflux esophagitis (DGRE).

Methods: After inducing DGRE through surgery, the group was separated (n=8) and the drug was administered for 2 weeks; normal rats (Normal), water-treated DGRE rats (Control), CE 100 mg/kg-treated DGRE rats (CE100), CE 200 mg/kg-treated DGRE rats (CE200). Thereafter, oxidative stress-related biomarkers were identified in serum and esophageal tissue, and the expressions of inflammatory cytokines in the lower esophageal sphincter and duodenum were analyzed through RT-PCR. Also, expressions of NADPH oxidase, inflammation-related proteins, and tight junction proteins were analyzed in esophageal tissue by western blotting.

Results: As a result, it was confirmed that ROS and MDA-related oxidative stress were decreased CE-treated. Also, in GERD-induced models, CE significantly reduced the inflammatory cytokine in the lower esophageal sphincter and duodenum and significantly regulated the expression of the NADPH oxidase in esophageal tissue. In addition, it not only modulated the MAPK and NF-κB pathways by modulating PI3K/Akt signaling but also significantly increased the expression of tight junction proteins.

Conclusions: Taken together, these findings indicate that CE alleviates inflammation by inhibiting oxidative stress and regulating PI3K/Akt signaling, thereby inhibiting the MAPK and NF-κB pathways. These results improve our understanding of the effect and the underlying mechanism of the CE in the management of DGRE.

Keywords: Coptidis Rhizoma, Evodiae Fructus, Duodenogastroesophageal reflux esophagitis, inflammation

PAB(T4)-181
Osteoarthritis Improvement Effect of *Pinus sylvestris* L.

Min Ju Kim[1], Mi-Rae Shin[1], Seong-Soo Roh[1]

1. Daegu Haany University (Korea)

Background and objectives: *Pinus sylvestris* L. (PS) has the largest geographical distribution among pine species and is the most widely distributed conifer in the world. PS has anti-inflammatory and antioxidant properties, but its effect on osteoarthritis (OA) has not been studied. Therefore, in this study, the effect of PS on cartilage degradation and inflammatory response in osteoclasts and monosodium iodoacetate (MIA)-induced OA rats model was analyzed.

Methods: In this study, the effect of PS on Metal regulatory transcription factor 1 (MTF1) and Collagen T2 in osteoclasts was analyzed by performing immunohistochemistry (IHC). In addition, hind paw weight distribution ratio analysis of MIA-induced OA rats orally administered with PS (200 mg/kg) for 2 weeks was performed, and inflammation and collagen protein expression in articular cartilage tissues were analyzed by Western blot.

Results: As a result of osteoclasts analysis, it was confirmed that collagen-related factors MTF1 and Collagen T2 were increased during PS treatment. Furthermore, PS decreased the expression of nuclear factor kappa B (NF-κB), cyclooxygenase-2 (Cox-2), and tumor necrosis factor-alpha (TNFα) which are inflammation-related proteins increased by MIA in articular cartilage tissue. Also the expression of metalloproteinases (MMP)-2, 3, 13 increased by MIA was significantly reduced.

Conclusions: PS increased collagen-related factors in osteoclasts and inhibited inflammation-related factors and MMPs in MIA-induced OA rats to promote articular cartilage damage recovery. Therefore, PS could be a potential candidate for OA treatment.

Metabolomics of cerebral cortex and cecal content in vitamin B_{12} deficiency-induced depression model rats

Rokuro Tanaka[1], Shozo Tomonaga[1]

1. Kyoto University (Japan)

Background and objectives: Some epidemiological studies indicate that vitamin B_{12} deficiency could be the risk of depression. However, their underlying mechanisms have not been well clarified. Some gut microbiota-derived metabolites affect brain function and most microbiota requires vitamin B_{12}. Therefore, it can be hypothesized that vitamin B_{12} affects gut microbiota-derived metabolites and consequently alters brain function. In the present study, we investigated metabolite levels of cerebral cortex and cecal content in vitamin B_{12} deficiency-induced depression model rats.

Methods: Twenty-eight male Wistar rats were divided into four groups and reared individually in metabolic cage. Control group fed the diet containing 50 μg/kg vitamin B_{12}, which meets the requirement based on the National Research Council. Other three groups were fed the diet containing vitamin B_{12} which were 50, 25, and 0 % of the control diet. All rats were fed for three weeks. Then, forced-swimming test were performed to confirm vitamin B_{12} deficiency-induced depressive-like behavior. After the euthanasia, cerebral cortex and cecal content were collected. Metabolite levels of these samples were analyzed by gas chromatography-tandem mass spectrometry-based metabolomics.

Results: Depressive-like behavior was increased by 0 % vitamin B_{12} diet compared with control. In cerebral cortex, of the 172 metabolites annotated, there was no metabolite related to both vitamin B_{12} intake and depressive-like behavior. In cecal content, of the 185 metabolites annotated, only asparagine was related to both vitamin B_{12} intake and depressive-like behavior, while acetic acid, butyric acid, and propionic acid were not related to them.

Conclusions: Relationships among vitamin B_{12}, gut microbiota, asparagine, and brain function should be investigated to clarify the mechanism of vitamin B_{12} deficiency-induced depression.

Improvement Effect of *Cotoneaster mongolicus* Extract on MIA-Induced Osteoarthritis Animal Model

Jeong Won Choi[1], Mi-Rae Shin[1], Seong-Soo Roh[1]

1. Daegu Haany University (Korea)

Background and objectives: Osteoarthritis (OA) is a chronic degenerative disease of articular cartilage, the most common joint disease worldwide. OA affects the bone of joints and induces pro-inflammatory and anti-inflammatory pathway dysregulation, leading to pain. This study evaluated the anti-inflammatory effects of *Cotoneaster mongolicus* Pojark. extract (CM) *in vitro* and *in vivo*.

Methods: Analyzed the antioxidant and radical scavenging activities of CM. OA models were induced via intra-joint injection of monosodium iodoacetate (MIA) 50 μL with 80 mg/mL in rats. The drug concentrations were indomethacin 2 mg/kg and AF 200 mg/kg and were administered orally once a day for 2 weeks. Western blot was carried out for the changes of the associated protein expressions on articulation tissue.

Results: The total phenolic contents (125.42 ± 0.55 mg gallic acid equivalents/g) and total flavonoids (27.45 ± 0.17 mg quercetin equivalents/g) values were observed. The group administered with CM showed a significant reduction of changes in relative hind paw weight distribution. Moreover, NF-κB activation by MIA led to the release of pro-inflammatory markers whereas CM treatment markedly decreased such an increase.

Conclusions: As a result, CM has a therapeutic and protective effect on OA by suppression of inflammation. Therefore, CM could represent a potential and effective candidate for OA treatment.

Keywords: Cotoneaster mongolicus Pojark., Osteoarthritis, monosodium iodoacetate, inflammation

Investigation of Refeeding syndrome-related substances for development preventive and treatment strategies

Nagisa Hashimoto[1], Sarasa Tanaka[1], Haruna Fujikawa[1], Hikari Miyake[1], Ema Matsumoto[1], Motoyoshi Sakaue[2], Mikiko Ito[1]

1. University of Hyogo (Japan), 2. Kobe Shoin Women's University (Japan)

Background and objectives: Refeeding syndrome (RFS) is the general term for a series of metabolic complications that develop when chronically malnourished patients are rapidly initiated on excessive nutritional therapy. Since details of the pathogenetic mechanisms of RFS are unknown, aggressive nutritional therapy should not be administered to malnourished individuals. Clarification of the metabolic status resulting from malnutrition prior to RFS might allow metabolic correction before nutritional therapy is initiated, and help to establish preventive and treatment strategies for metabolic correction before the onset of RFS. In this animal study, we investigated candidate preventive

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

and treatment substances for RFS using blood metabolome analysis prior to RFS.

Methods: We created a mild RFS animal model using rats that were fasted for 24-hours and refed with oral gavage using a 50% glucose solution and intraperitoneal administration of insulin. Identification of hypophosphatemia 24-hours after refeeding was used to confirm the development of mild RFS. 1. Metabolome analysis Blood samples were obtained from mild RFS model (fasted) and healthy rats (feed) for metabolome analysis to identify metabolic changes prior to the onset of RFS. Substances likely to have an association with the onset of RFS were evaluated, and candidate substances were extracted by %CV calculation and volcano plot analysis. 2.Prevention of hypophosphatemia by administration of candidate substances. In a separate experiment, mild RFS model rats were given the identified candidate substances prior to refeeding. Plasma phosphorus concentrations and other items related to RFS were measured and statistically analyzed before and after RFS.

Results: Blood metabolome analysis evaluated 711 substances. Of these, 160 substances were found to be lower in the mild RFS group before RFS than in the normal group. Statistical analysis revealed substances A, B and C as being associated with the onset of RFS. We are currently investigating the preventive effects of the candidate substances by administering them before refeeding.

Conclusions: These results suggest that any of the candidate substances prior to refeeding might prevent hypophosphatemia.

Keywords: Refeeding syndrome, blood metabolome analysis, hypophosphatemia, mild RFS animal model

PAB(T4)-185
Association between HIV and clinical outcomes of children aged 6-59 months diagnosed with growth failure: SAMAC sub-study

Martani Johanni Lombard[1], Robin Claire Dolman-Macleod[1], Arista Nienaber[1], cornelia Conradie[1]

1. North-West University (South Africa)

Background and objectives: Growth failure in sub-Sahara Africa remains a leading cause of death among children under five years of age. The high incidence of HIV exacerbates the severity of infection and growth failure. This contributes to increased mortality and adds additional burden on already struggling health systems. The objective of the SAMAC sub-study is to determine the prevalence of HIV and to compare clinical outcomes between HIV positive and negative children in South Africa, Ghana and Botswana.

Methods: SAMAC is a multi-country, multi-hospital study and is based on a retrospective observational study design with a quantitative, descriptive-comparative approach. Medical records of children diagnosed with SAM in hospitals from three sub-Sahara African countries have been retrospectively reviewed between January 2013 and December 2018. Data were tested for normality with Shapiro-Wilks's test in SPSS. Pearson correlation coefficients were determined between HIV status and length of stay (LOS), rate of weight gain (RWG) (g/kg/day) and number of co-morbidities. Chi-square tests were done for HIV status and death, and discharge.

Results: Of the 533 participants included, 410 (77%) were HIV negative and 123 (23%) HIV positive. For HIV negative children LOS was 13.5 (± 8.4) days, RWG 7.8 (± 14.9) g/kg/day while HIV positive children had a LOS of 17.1 (± 12.6) days, RWG 5.0 (± 8.0) g/kg/day. 42 (10%) of the HIV negative children passed away while 31 (25.2%) of the HIV positive children passed away. There were significant differences ($P<0.05$) between HIV status and LOS, RWG, number of co-morbidities (especially TB and sepsis) and death.

Conclusions: Results indicated that the outcomes of growth failure are worse for children diagnosed with HIV. They stay longer in hospital, have a poorer growth rate with a higher mortality rate. This is mostly because they present with more serious co-morbidities such as TB and sepsis. The WHO guidelines currently recommend the same treatment regime for HIV positive and negative children. However, more strenuous treatment measures should be considered for those with HIV to ensure better clinical outcomes.

Uses of dietary supplements and risk of non-alcoholic fatty liver disease in hypertensive adults in South Korea

Yoonmi Park[1], Dorgan F. Joanne[2], Smith-Warner A. Stephanie[3], Hyesook Park[1], Hyeah Lee[1], Seungyoun Jung[1]

1. Ewha Womans University (Korea), 2. University of Maryland School of Medicine (USA), 3. Harvard T. H. Chan School of Public Health (USA)

Background and objectives: Non-alcoholic fatty liver disease (NAFLD) is characterized by increased fat accumulation in the liver and has emerged as one of the most prevalent, rising hepatic metabolic disorders, affecting approximately 40% hypertensive adults worldwide. Deregulation of micronutrient metabolisms, partly due to insufficient intake, is increasingly found to be associated with development of NAFLD. Use of dietary supplement (DS) may lower NAFLD risk, a significant cause of hepatic and cardiovascular mortality, potentially improving clinical complications of hypertension. Thus, we aimed to examine the potential clinical benefit and the specific behavior of DS uses and NAFLD risk in hypertensive adults.

Methods: We analyzed nationally representative, cross-sectional data from 4,954 hypertensive adults aged >19y with 1,574 NAFLD cases in the Korea National Health Examination Survey 2005 and 2007-2009. Current users of DS were identified via questionnaire and interviewed for frequency, duration, and types of DS uses. NAFLD was defined by having a hepatic

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

steatosis index>36. To investigate the associations between DS use and NAFLD risk, multivariable-adjusted odds ratios (MVORs) and 95% confidence intervals (CIs) were calculated using logistic regression.

Results: Approximately 26% subjects were current users of DS, of which 81%were using vitamin/mineral supplements. Current use of DS was not significantly associated with NAFLD risk. The multivariable-adjusted OR (95% CI) was 0.94 (0.73-1.20) comparing current users vs nonusers of DS. When we explored associations according to specific behaviors of DS use, we also observed no associations with increasing frequency of use (MVOR [95% CI]$_{\geqq 2 \text{ times/day vs. no use}}$: 1.13 [0.75-1.68]), duration (MVOR [95% CI]$_{\geqq 16 \text{ months vs no use}}$: 1.06 [0.62-1.81]), and concomitant use of DS (MVOR [95% CI] $_{\geqq 2 \text{ supplements vs. no use}}$: 1.06 [0.73-1.54]). (all $P_{\text{trend}} \geqq 0.80$) These results were not significantly different across stages of hypertension, use of hypertensive medication, age, gender, obesity, and status of smoking and alcohol consumption (all $P_{\text{interaction}} \geqq 0.06$).

Conclusions: The use of DS was not associated with NAFLD risk in hypertensive adults, regardless of specific behaviors of DS uses or population characteristics examined. Though prospective studies are warranted, our results do not support DS use as alternative clinical therapies to prevent NAFLD in hypertensive adults.

Relationship between γ-GTP and dietary choline intake

Takeshi Ohkubo[1], Momoka Konno[1], Yuuki Ohta[1], Azusa Kanda[1], Hiroyuki Nishikawa[2], Takashi Miyawaki[3]

1. Sendai Shirayuri Women's College (Japan), 2. Rakuwakai Touji Minami Hospital (Japan), 3. Kyoto Women's University (Japan)

Background and objectives: The relationship between choline intake and liver function is already known. Choline deficiency exacerbates liver function markers. For this reason, the US Food and Drug Administration established AI (adequate intake, 550 mg / day for men and 425 mg / day for women) as Essential Nutrition in 2001. The European Food Safety Authority also set AI (400 mg / day for adults) in 2016. In particular in the United States, data on the content of choline compounds in food is published on the website of the United States Department of Agriculture. However, in Japan, these are not listed in the 2020 Japanese Dietary Intake Standards and Food Composition Tables (8th edition). We previously reported to the Society that the intake of choline compounds by university students was chronically deficient at around 60% of the intake standard in the United States. In our study, we report the results of comprehensive medical examinations and the frequency of intake of choline compounds from the diet.

Methods: A questionnaire survey was conducted on the frequency of intake of foods rich in choline compounds for those who underwent a comprehensive medical examination at Hospital A. The subjects were 517 respondents (424 males and 93 females) who had agreed to the experiment. Correlation with the test data was verified. This time, the statistical analysis performed was the Tukey's HSD test method, using JMP (ver14.2).

Results: Among the liver function markers, the value of γ-GTP showed a strong correlation with the frequency of choline intake. There was a significant difference even after excluding the factors involved in liver function such as drinking, medical history (liver disease), BMI, age, and medication (drugs related to lipid metabolism).

Conclusions: Statistically significant difference in the frequency of intake of foods rich in choline compounds were observed between high and normal of γ-GTP level. It was suggested that a gradual inadequate intake of choline compounds over a long period of time may have a negative effect on liver function.

Keywords: Choline, γ-GTP

PAB(T4)-188
Associations of food insecurity with dietary inflammatory potential and risk of low muscle strength in Korean adults

Su min Kim[1], Joanne F. Dorgan[2], Stephanie A. Smith-Warner[3], Kwang Suk Ko[1], Hyesook Park[1], Seungyoun Jung[1]

1. Ewha womans university (Korea), 2. University of Maryland School of Medicine (USA), 3. Harvard T. H. Chan School of Public Health (USA)

Background and objectives: Food insecurity is the disruption of food intake or eating patterns because of limited access for food and were associated with poor diet quality. Nutrient-poor diet disturbs lipids and glucose metabolism, aggravating oxidative stress and immune homeostasis. A higher inflammatory burden impairs skeletal muscle protein metabolism and muscle strength, which is recognized as a clinically important cardiometabolic marker associated with functional disability and early mortality. However, limited studies have examined the associations of food insecurity with dietary inflammatory potential and muscle strength. This study, thus, examined the associations between food insecurity and risk of low muscle strength and explored the potential role of diet as a mediator for the association.

Methods: Cross-sectional data from 9,595 adults aged >19y from the Korean National Health and Nutrition Examination Survey 2014-2015 were analyzed. The household food security status was assessed using an 18-item Food Security Survey Module. Dietary data were collected via 24-hr recalls assisted by trained interviewers. The pro-inflammatory potential of diet was estimated by calculating dietary inflammation index (DII). Low muscle strength was defined by having the maximally measured hand grip strength of dominant hand <28kg for men and <18kg for women. The associations of food insecurity with DII and risk of low muscle strength were examined using multivariable-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

adjusted linear regression and multivariable-adjusted logistic regression, respectively.

Results: Greater food insecurity was significantly associated with a higher DII. The multivariable-adjusted mean difference and 95% confidence intervals in DII, comparing "Moderate-to-severe" food insecurity group to "Food secure" group, was 0.31 (0.01-0.59) (P_{trend}: 0.02). "Moderate-to-severe" food insecurity group was also at greater risk of low muscle strength, compared to "Food secure" group. The multivariable-adjusted odds ratios and 95% confidence intervals was 2.08 (1.65-4.05) (P_{trend}: 0.03). These results were not heterogeneous by age, sex, physical activity, smoking, and obesity status.

Conclusions: In this nationally representative study of South Korea, food insecurity was associated with greater inflammatory diet potential and muscle weakness. Our results suggest diet-mediated alterations in pro-inflammatory conditions may exacerbate muscle strength, potentially increasing future risk of functional disability and cardiometabolic morbidity, among individuals at risk of food insecurity.

PAB(T4)-189
Impact of disease specific nutrition intervention on body composition and food intake in Head and Neck cancer patients

Namratha Pai K[1,2], Asna Urooj[1], Sathya M[3], Mukesh S[3]

1. University of Mysore (India), 2. Manipal Academy of Higher Education (India), 3. Mysore Medical College and Research Institute (India)

Background and Objectives: Head and neck cancers (HNC) are one among the top leading cancer sites in India. HNC patients are susceptible to malnutrition due to swallowing problems which worsens with the advancing stage. Chemotherapy and radiotherapy further deteriorate the condition. The food intake reduces drastically ultimately leading to malnutrition. Although, food formulations are available in the Indian market, not all them are disease-specific catering to patient needs. Thus, this study aimed at developing a high energy high protein food formulation specific to HNC and assess the impact of nutrition intervention on body composition and food intake in clinically diagnosed HNC patients.

Methods: This prospective, open labelled, randomized, nutrition intervention study was conducted in Krishna Rajendra Hospital attached to Mysore Medical College and Research Institute from July 2017 to March 2019. Subjects aged above 18years, with histopathologically confirmed HNC undergoing treatment who showed willingness to participate were included in the study. Thirty-eight patients who gave consent for participation were randomized into two groups viz., Control group (n=20) which received nutrition counseling alone and, Intervention group (n=18) which received nutrition supplementation of the formulation and nutrition counseling. The effect of nutrition intervention was evaluated on food intake and body composition. The patients were followed up on 15th, 30th and 45th day.

Results: The trajectory of weight loss was higher in control group as compared to intervention group. A significant difference was observed in the indicators of muscle mass between the control and intervention group on all days of follow up (Day 15: p=0.037; Day 30: p=0.026; Day 45: p=0.014). The mean values of fat free mass, fat mass, body cell mass, protein and muscle mass were significantly higher in the intervention group than the control group after the 1st follow up. The intake of food was better in the Intervention group than the control group by the end of the follow up.

Conclusion: Nutrition intervention of the disease specific food formulation with the right consistency and composition can significantly improve food intake and body composition in head and neck cancer patients.

Quantification, dietary intake adequacy and circulating levels of vitamin B9, vitamin B12, betaine and choline levels, in Chilean women with polycystic ovary syndrome

Francisca Salas-Perez[1], Veronica Sambra[2], Guiselle Villarroel[2], Valentina Monsalve[2], Danyela Morales[2], Daniela Vega[2], Yocelyn Rojas[2], Paz Martínez[2], Nicolás Crisosto-King[2]

1. University of OHiggins (Chile), 2. University of Chile (Chile)

Background and objectives: Polycystic ovary syndrome (PCOS) is a prevalent and multifactorial endocrine disorder, characterized by reproductive and metabolic alterations. Existing data is not conclusive to determine differences in vitamin B9, vitamin B12, betaine, and choline levels in PCOS women. The objective of this study was to assess the dietary intake of vitamin B complex and cofactors in women with PCOS and their relationship with their metabolic profile in comparison to control women.

Methods: A total of 15 Chilean women with PCOS (P) without hormonal contraception and 19 control women (C) with a BMI between 18 and 35 kg/m² (18-34 y.o.) were included. Anthropometric measurements were carried out using standardized techniques and blood samples were obtained. A modified food frequency questionnaire for chilean foods was applied for the assessment of vitamin B9 (folic acid), vitamin B12, betaine and choline, and Recommended Daily Allowances (RDAs) were calculated. To evaluate metabolic status, lipid and biochemical profiles, vitamin B12, serum and red blood cells folate (RBC) were measured. Student's t-test or Mann Whitney

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

test were applied, and Pearson or Spearman correlations were performed (p<0.05 significant).

Results: PCOS women exhibited a significant increment in BMI (P:29.7 ± 6.6; C:22.6 ± 4.3 kg/m²; p>0.05), accompained by elevated insulin (P:13.7±7.4; C:8.6±5.9 uUI/mL;p>0.05). RBC (P:391.9±157.6; C: 311.6 ± 80.9 ng/mL), serum folate (P:12.7 ±3.8; C:11.0 ±2.9 ng/mL) and vitamin B12 (P:322.6±125.7; C:303.7±80.2 pg/mL) did not shown differences. RDA was calculated for vitamin B9 (P: 80%; C:47,7%), vitamin B12 (P: 46.6%; C:57.8) and adequate intake reference for choline (P: 0%; C:10.5%), and betaine (P:13%; C:0%), however, vitamin B9 intake and RDA were increased in PCOS women (p<0.05). Moreover, there was a positive correlation between insulin and BMI (r=0.612;p=0.000) RBC and serum folate (r=0.610;p=0.000); RBC and insulin (r=0.518;p=0.002).

Conclusions: The significant difference in vitamin B9 intake can be explained due to a national food-fortification program with folic acid in wheat flour. PCOS women were overweight and had a higher intake through bread consumption. PCOS and control women do not achieve the daily dietary recommendations for choline and betaine, which should be studied due to their impact on hepatic dysfunctions.

Keywords: PCOS, Folic Acid, Vitamin B12

PAB(T4)-192
The influence of niacin on pregnancy status and outcomes: A systematic review and meta-analysis

Rina Agustina[1,2], Davrina Rianda[2], Faisal Muda[2], Nadhifa Nadhifa[2], Anuraj H Shankar[3,4]

1. Department of Nutrition, Faculty of Medicine, Universitas Indonesia – Dr. Cipto Mangunkusumo General Hospital, Jakarta (Indonesia), 2. Human Nutrition Research Center, Indonesian Medical Education and Research Institute (HNRC-IMERI), Faculty of Medicine, Universitas Indonesia, Jakarta (Indonesia), 3. Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford (UK), 4. Eijkman-Oxford Clinical Research Unit, Eijkman Institute for Molecular Biology, Jakarta (Indonesia)

Background and Objective: Maternal niacin intake may reduce the risk of birth defects and support fetal growth as seen in animal models. However, a comprehensive evaluation of the benefits of niacin on these outcomes has not been summarized across in-vitro, animal, and human studies. We performed an integrated systematic review and meta-analysis to compare pregnancy outcomes related to niacin intake or intervention in in-vitro, animal, and human studies.

Methods: We searched for human, animal, and in-vitro studies that assessed niacin intake or niacin intervention in pregnancy or pre-pregnancy, and related in-vitro outcomes, until June 2019 in Cochrane Library databases, PUBMED, SCOPUS, Proquest, and EBSCOhost (PROSPERO number: CRD42020140116 and CRD42020140111). The outcomes assessed were congenital malformations, fetal growth and loss, and related indicators. Two independent reviewers conducted the title and abstract screening and full-text eligibility assessment. The risk of bias and the quality of evidence were assessed according to the STROBE checklist, SYRCLE's risk of bias tool, and PRISMA checklist regarding the study type.

Results: After screening the title, abstract and duplicates, 166 out of 7,391 articles were selected, and eligibility after full text review included 12 in-vitro, 30 animal, and 12 human studies that were all observational, with no randomized controlled trials in humans. Higher maternal intake of niacin tended to be protective for birth defects in animal studies (pooled OR for random effect = 0.35; 95%CI 0.12–1.02, p=0.053), and intake or supplementation was protective against birth defects in human studies (random effect pooled OR 0.76, 95%CI 0.62–0.93; p=0.008). In animal models, maternal niacin intake also improved fetal growth (pooled standardized mean difference (SMD) = 2.7; 95%CI 2.45 – 2.96, p<0.001), tended to be protective for fetal death (random-effects pooled OR = 0.37; 95%CI 0.14–1.00, p=0.05), but did not affect breastmilk yield (pooled SMD = -0.07, 95%CI -0.25–0.09, p=0.38).

Conclusion: Maternal niacin intake provided a modest protective effect on birth defects in human observational studies consistent with animal models. Future clinical studies of niacin intake or supplementation on fetal outcomes are warranted to confirm these findings before establishing public health recommendations.

Eat-O'Clock: The Preliminary findings of the association between eating time with Body Mass Index (BMI) among Brunei Adults

Syahirah Marshidi[1], Satvinder Kaur[1], Hui Chin Koo[2], Vaidehi Ulaganathan[1]

1. UCSI University, Kuala Lumpur (Malaysia), 2. Tunku Abdul Rahman University College, Kuala Lumpur (Malaysia)

Background & Objectives: The obesity epidemic in Brunei has magnified the need to identify criteria for an optimal approach that promotes a healthy body weight. Chrononutrition is an emerging field in nutritional science that understands the role of meal timing with numerous evidence that have been linked to the improvement of weight status and health outcomes. However, to date, there is a paucity of research assessing the chrononutrition profile among Bruneian adults. This study aimed to determine the chrononutrition profile of Bruneian adults.

Methods: A cross-sectional study was conducted among 73 Brunei adults aged 18-59 years old. Subjects were recruited through voluntary participation throughout Brunei. Components of chrononutrition preferences and behaviors of breakfast

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

skipping, largest meal, evening eating, evening latency, nighttime eating, and eating window were assessed using an adapted questionnaire from the Chrononutrition Profile Questionnaire (CP-Q). Demographic and medical history was determined using a predesigned questionnaire, followed by anthropometric measurements of height, weight, and BMI.

Results: The participants included in the study consisted of 31 (42.5%) males and 42 (57.5%) females. The prevalence of BMI was 2.7% were normal weight, 36.5 % were overweight and 59.5% were obese. 66.3% skipped breakfast more than 5 days per week. Largest meal was lunch (70.3%), dinner (16.2%) and breakfast (12.2%) respectively. Consequently, 52.7% indulge in nighttime snacking after bedtime more than 5 days per week. The duration between the last eating before bed was 1 to 2 hours during workdays and free days were 38.1% and 35.9%, respectively. At least 32.4% wake up more than once a week to eat at night. Almost half practice more than 12 hours eating window during workdays and free days with 38.9% and 57.0%, respectively. There was a significant difference between breakfast skipping with BMI (r=0.222, p=0.050) and evening latency during workdays with BMI (p=0.028) respectively, whereby subjects who skip breakfast more than 5 days per week and shorter evening latency have higher BMI. However, there was no association between largest meal, evening eating, evening latency on free days, night time eating, and eating window with BMI.

Conclusions: These findings suggest that breakfast skipping and shorter evening latency on workdays were found to influence BMI. Further studies to explore the role of breakfast skipping and evening latency on workdays vs free days Further studies to explore the role of longitudinal effect of meal timing long could be included to understand the role of chrononutrition to BMI and disease prevention among Brunei adults.

Effect of a novel supplementary porridge on the nutritional status of infants and young children diagnosed with moderate acute malnutrition in Uganda: a cluster randomised control trial

Richard Bazibu Kajjura[1,2,3], Susanna Maria Kassier, Frederick Johannes Veldman

1. Makerere University (Uganda), 2. University of Kwazulu Natal (South Africa), 3. Safako Makgatho Health Sciences University (South Africa)

Background and Objective: Moderate acute malnutrition (MAM) and anaemia are prevalent among infants and young children (IYC) in Uganda. A lack of consensus regarding the most effective strategy for managing MAM among IYC resulted in the present study comparing the effect of malted sorghum-based porridge (MSBP) (an active malt, extruded maize and soy sorghum supplementary porridge developed for the purpose of the present study) as an intervention versus an extruded maize and soy micronutrient fortified blend (CSB+) as a control and current standard care. Outcome measures were anthropometric status and haemoglobin levels.

Methods: The study comprised a double-blind cluster randomised control trial with eight to 10 conveniently sampled consenting mother–IYC pairs per cluster who were randomly assigned to the intervention (n = 110) or control (n = 110) for 3 months. Weekly anthropometric measurements were taken. Haemoglobin levels were measured at baseline and end line. Mean length-for-age, weight-for-age, length-for-weight and mean haemoglobin levels of the treatment and control groups were compared using an independent t-test. The Z-test was used to compare proportions of the outcome indicators between the treatment and control groups.

Results: Difference in mean weight-for-age Z-scores in the treatment group improved compared to control (P= 0.010). The change in mean haemoglobin levels was lower in the treatment versus the control group (P= 0.010). The proportion of IYC recovering from MAM between treatment and control did not differ significantly (P=0.055).

Conclusions: Recovery rates after supplementation with MSBP versus CSB+ resulted in similar weight-for-length and haemoglobin levels. Therefore, MSBP has the potential for being scaled up in the management of IYC with MAM in Uganda.

Effects of cardiorespiratory fitness on appetite-related hormones in response to a standardised meal in young men

Yusei Tataka[1], Ge Li[1], Kayoko Kamemoto[1], Haixin Wen[1], Kazuna Yamanaka[1], Chihiro Nagayama[1], Masashi Miyashita[1]

1. Waseda University (Japan)

Background and objectives: Maximal oxygen uptake (VO2max) is an important determinant of aerobic capacity and it has been shown to be a strong predictor of all-cause and disease-specific mortality. Appetite-related hormones (acylated ghrelin; an appetite-stimulating hormone, peptide YY (PYY); an appetite-suppressing hormone) are important physiological factors involved in short-term appetite regulation. It has been suggested that habitual physical activity influences homeostatic appetite control by enhancing post-meal satiety, mediating energy intake to match energy expenditure in response to hunger and satiety signals. However, it remains unclear whether individuals with different levels of cardiorespiratory fitness differ in the meal

responses of appetite-related hormones. Thus, the purpose of the present study was to examine the effects of cardiorespiratory fitness on appetite-related hormones in response to a standardised meal.

Methods: Thirty young healthy males [23 ±2 years old (mean ±standard deviation)] underwent a 1.5-h laboratory-based experiment. They were divided into two groups according to median VO2max: above median (the high VO2max group (15 participants; [55.6 ±4.6 ml/kg/min])) and below median (the low VO 2max group (15 participants; [45.5 ±4.3 ml/kg/min])) evaluated by maximal exercise testing. Participants consumed a standardised meal at 1000 h. Venous blood samples (circulating concentrations of acylated ghrelin and PYY) and subjective appetite (hunger and fullness) were collected prior to 1000, 1030, 1100 and 1130 h.

Results: There were no differences in fasting circulating concentrations of acylated ghrelin, PYY or subjective appetite between groups (all for $p>0.05$). Regardless of VO2max level, acylated ghrelin was suppressed and PYY was elevated after the meal (all for $p<0.001$). Subjective feelings of hunger was suppressed and fullness was elevated after the meal regardless of VO2max level (all for $p<0.001$). There were no differences in the patterns of circulating concentrations of acylated ghrelin, PYY or subjective appetite over the course of the entire experiment between groups (all for $p>0.05$).

Conclusions: The present study demonstrates that the post-meal responses of appetite-related hormones were similar among healthy young men with different levels of cardiorespiratory fitness.

Keywords: Cardiorespiratory fitness, maximal oxygen uptake, appetite, appetite-related hormones, young men

PAB(T4)-196
Improvement of energy and protein intake after dietetic intervention among COVID-19 patients in a rehabilitation and convalescent hospital

Tiffany Hoi Man Lo[1], Winnie Wing Tung Lo[1], Terry Ho Yan Ting[1]

1. Shatin Hospital (Hong Kong)

Background and objectives: Malnutrition is frequently seen in hospitalized COVID-19 patients, and studies suggested malnutrition rate among COVID-19 patients ranged from 27.5% to 82.6%. Poor nutrition status often contributes to lower rehabilitation potential and poorer clinical outcome of the COVID-19 rehabilitation patients. The aims of this study are to investigate the nutrition status, energy and protein intake and the adequacy before and after dietetic intervention among COVID-19 patients in a rehabilitation hospital.

Methods: Total 93 COVID-19 patients admitted to the Shatin Hospital for rehabilitation purpose during the admission period from February to April 2022, were recruited for the analysis. Electronic dietetics records of patients who have seen a dietitian for nutrition support were retrieved. Information such as gender, age, weight, BMI and malnutrition risk were collected. Energy intake and protein intake were compared at the baseline and the follow-up dietetic assessment. Patients who has no nutrition intake at the follow-up assessment were excluded. The estimated energy and protein requirement for this patient group were used to calculate the energy and protein adequacy in percentage, and compared between baseline and post-dietetic intervention.

Results: There were 41 males and 52 females, the mean age was 81.4±12.3 years old, mean weight 48.4±11.3kg and BMI 18.9±3.7kg/m². There were 54% patient was underweight (BMI<18.5 kg/m²) at admission. Among this group, the overall prevalence of malnutrition risk was 94.6% (medium risk:66.9%; high risk:24.7%). The energy intake at baseline was 715±422kcal and increased significantly to 1021±387kcal after follow-up intervention ($p<0.001$). The baseline protein intake was 32±18g, and increased significantly to 47±18g protein afterwards ($p<0.001$). The percentage of energy and protein adequacy were improved from 53.2% and 57.2% during admission to 74.7% and 83.3% after intervention respectively, which both meeting the most part of their daily energy and protein requirement ($p<0.001$).

Conclusions: This review suggested high prevalence of malnutrition among COVID-19 hospitalized rehabilitation patients, with high percentage of underweight patient admitted to hospital. Their energy and protein intake greatly improved after dietetic intervention, with meeting most of the energy and protein requirement. Improvement of nutrition intake benefits on better clinical outcome and recovery at rehabilitation period.

The role of ultra-processed food intake and development of dyslipidemia and obesity in middle-aged and older adults: A longitudinal community-based study

Li-Juan Tan[1], Jialei Fu[1], Hyein Jung[1], Khongorzul Ganbat[1], Jiwon Jeong[1], Seok-jae Oh[1], Jun-Mo Kim[1], Sangah Shin[1]

1. Chung-ang University (Korea)

Background: Impact of ultra-processed foods (UPF) consumption is an emerging issue on nutrition and health. How to prevent and manage obesity and dyslipidemia better is still the topic that the publics concerned. The consumption of UPF has increased steadily in South Korea. However, the long-term effect of UPF consumption on the development of obesity or dyslipidemia in South Korea is unknown. Besides, compared to other well-known diet quality index, whether UPF consumption is a useful tool to assessed diet quality need to be confirmed.

Objective: We aimed to investigate the association between UPF intake and the risk of obesity or dyslipidemia and to evaluate the validity of UPF consumption in assessing the diet quality.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: We studied 17,310 adults aged ≧ 40 years in the Health Examinee cohort study from 38 community sites of South Korea. UPF consumption was classified by NOVA system. After an average five-year follow-up, we examined the incidence of obesity or dyslipidemia and investigated the association between UPF consumption and risk for incident obesity or dyslipidemia. To evaluate UPF validity in assessing the diet quality, we made a comparison using alternative Mediterranean Diet (AMED) Score which developed for Korean based on Mediterranean Diet Score.

Results: The incidence of dyslipidemia was 35.41% and 43.04% in men and women, respectively, and that of obesity was 8.28% and 7.39% in men and women, respectively. There was a positive association between the UPF consumption and the risk for dyslipidemia development: the Q4 group was almost 20% higher than the Q1 group (men, adjusted HR=1.209 [95% CI 1.039 – 1.407], women, adjusted HR=1.195 [95% CI 1.096 – 1.303]. For obesity, only women demonstrated a significant positive association (model 3, HR=1.360 [95% CI 1.072 – 1.725]). There was no significant association between other NOVA food group consumption and dyslipidemia was found. After calculating AMED scores, only UPF consumption showed a significant negative association with AMED score (*p* value<0001).

Conclusion: Higher UPF intakes were associated with increased incidence of dyslipidemia and obesity. Furthermore, UPF consumption showed the statistically significant negative association with AMED score indicating a poor diet quality.
