Serendipities of Acquired Immunity.

Tasuku Honjo[1]

1.Kyoto University, Nobel Prize laureate in Physiology or Medicine in 2018 (Japan)

In 1992, we started working on PD-1 and found that this acts as a brake in the immune system. Then, in 2002, we discovered that PD-1 inhibition could be effective in treating cancer in animal models. After 22 years of study, this idea has borne fruit in a new, breakthrough immunotherapy that is being hailed as a 'penicillin moment' in cancer treatment. I believe that, just as a number of antibiotics developed in the wake of the discovery of penicillin now protect humans against threats of infectious diseases, this discovery will play a leading role in advancement of cancer immunotherapy so that in the future the fear of dying from cancer will cease to exist. Through evolution, vertebrate animals have developed immunity against infection by microorganisms. In the process, they incidentally acquired a sophisticated system for diversifying genomic information by combining gene fragments. It was doubly fortunate that the success in cancer treatment via PD-1 inhibition brought the realization that immunity, a “weapon” against infectious diseases, could also serve as a “shield” against cancer. It has been said that, whereas humankind's greatest enemies in the 20th century were infectious diseases, cancer is the major foe in the 21st century. It is a pleasant surprise to discover that the acquired immunity system holds the keys to overcoming both of these difficult medical challenges.

Keyword: PD-1, cancer immunotherapy

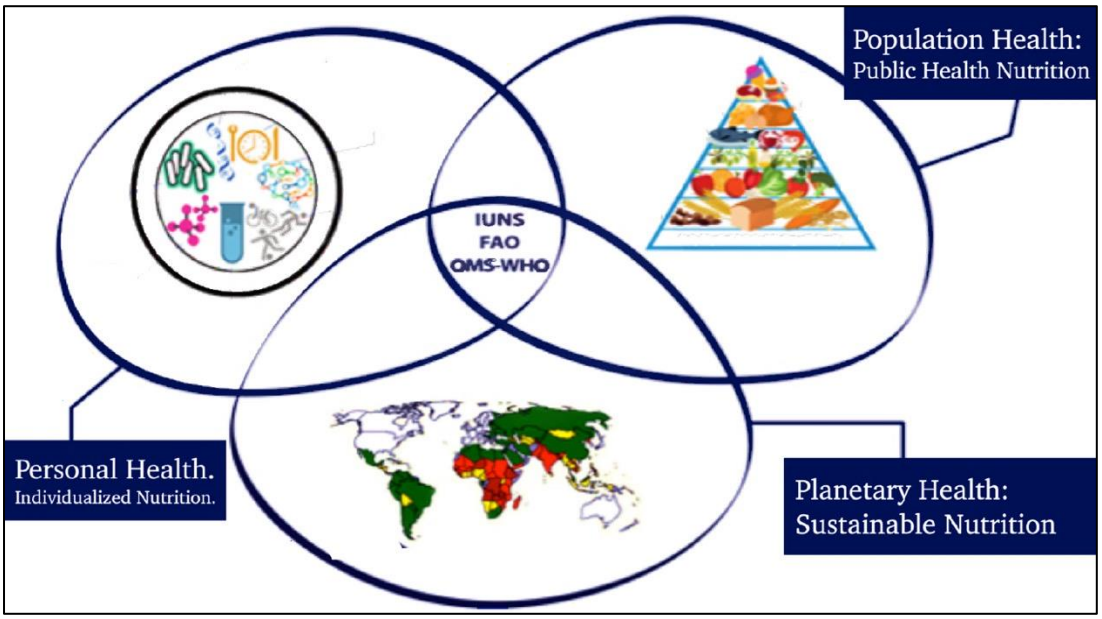
Personalized, Population and Planetary Nutrition: A Health world.

J. Alfredo Martinez[1,2,3]

1. University of Navarra (Spain), 2. IMDEA-CSIC-UAM (Spain), 3. IUNS (Spain)

Nutrition is a global science that originally analyzed and integrated those processes transforming food components contributing to body homeostasis to ensure life and wellbeing, nowadays nutritional interests are additionally being focused on mankind wellness involving physical, emotional, intellectual, civical, spiritual, environmental and occupational facets. Moreover, according to the emerging health settings, food intake should be screened concerning social, satisfactory, secure, safe and sustainable expressions, while that global updated public health and precision nutrition arms should be planetary harmonized, emphasizing on personalized participative, preventive and predictive directions in order to maintain health as well as to prevent and manage diseases at global level (Figure 1).



Precision nutrition not only consider individual´s genomic backgrounds, but also phenotypically related traits including family and personal clinical features, perinatal feeding information and a wide spectrum of data concerning metabolic pathways. Indeed, the conceptual framework describing precision nutrition is based on evaluating the inter-personal diversity caused by genetic/epigenetic differences, the environmental and lifestyle exposome heterogeneity, metagenomic variations in microbiota, and objective behavioral/psychological features with evident consequences for conjoint personal and population public health-related precision challenges and applications.

A number of endeavors and efforts are being currently devoted to generate evidence for health promotion and disease risk reduction based on food-based dietary guidelines (FBDG) in order to instruct population about healthy dietary habits. Interestingly, nutritional advises in different regions seem to be similar across countries such as to consume a variety of foods; fruits and vegetables, legumes with controlled animal-source foods; and to limit high calorie diets, sugar, fat, and salt intakes. Information sourced from the FBDG repository of the FAO or WHO reveals that FBDG are currently available for about 100 countries, where the incorporation of environmental sustainability information, climate change data and considerations to sustainability sociocultural factors and swiftly varying dietary tendencies are being slowly incorporated. Epidemiological investigations concerning the impacts of Japanese, Nordic and Mediterranean diets or plant-based nutritional patterns on chronic diseases have evidenced remarkable benefits in health outcomes.

Nutrition improvement anywhere in the world is a societal, household and individual right. Indeed, a major focus of Planetary nutrition is to fight against the etiological roots and hazardous consequences on health concerning the double burden of malnutrition, which involve not only undernutrition, stunning , underweight and wasting, but also includes hidden deficiencies affecting micronutrients such as iron and Vitamin A, as well as excessive body weight and obesity, which are associated to a highly prevalent impact non-communicable diseases across the Globe These wellbeing endeavors should also assimilate concepts of sustainability, food security plus environmental climate change monitoring , which are receiving support and resources from important organizations and institutions such a UN agencies, FAO, IUNS, and specifically via the sustainable Development Goals Declaration *in* order to match the planetary needs for nutrients intake considering socio-economic and political concerns controlling food distribution, aided by capacity building and online learning strategies.

AL1:
Healthier food environments: experience and lessons from Chile and Latin-America

Camila Corvalán[1]

1. University of Chile (Chile)

Worldwide, obesity and nutrition-related chronic diseases have reached epidemic proportions. At a population level, prevention is the most effective way of addressing these conditions. Individual preventive actions have shown limited impact and thus, policies that aim to improve food environments (i.e., physical, economic and policy conditions that influence people's food behaviors) have been suggested as a more cost-effective alternative. Interventions such as sweetened-sugared beverages tax, food marketing restrictions, and school policies have been implemented in Latin-American countries with promising results. However, larger impacts might be achieved by interventions that address different aspects of the food environment at the same time. In 2016 Chile implemented the Food Labeling and Marketing Law considered the most comprehensive package of food environment policies implemented to date to promote healthier food environments. This law considers the use of a front-of-package warning message to signal unhealthy foods (i.e., foods or beverages with high content of calories, sugars, total fats, or sodium), comprehensive marketing restrictions of unhealthy foods to children, and promotion of healthier school environments by banning the selling, promotion, and distribution of unhealthy foods. In this talk we will present results of the impact of the regulation on the food environment; consumers perceptions, attitudes, and behaviors; and food industry responses, including discourse framing, food reformulation, and employment. We will also discuss the challenges; the lessons learned and provide some insight on future directions for the research in this area.

Human brown fat: A tissue preventive against obesity and metabolic diseases

Masayuki Saito[1]

1.Hokkaido University (Japan)

We are now facing a worldwide increase in obesity and associated metabolic disorders such as diabetes mellitus and cardiovascular diseases. As obesity is a result of prolonged imbalance between energy intake and energy expenditure (EE), it can be treated by reducing energy intake and/or increasing EE. For the latter, while increasing physical activity is usually recommended, but sustained change in physical activity is rather difficult to achieve in our daily life. Adaptive non-shivering thermogenesis (NST) is another component of daily EE. NST is defined as an increase in EE above baseline levels in response to various environmental changes including cold exposure and food intake. NST is associated with the activation of brown fat, a unique adipose tissue of which primary function is to dissipate energy in the form of heat. Although brown fat research has long been limited mostly to small rodents, the rediscovery of metabolically active brown fat using radionuclide imaging technique in adult humans has dramatically accelerated the translational studies on brown fat in health and diseases. Now there is lots of evidence to show that brown fat takes parts in the regulation of whole-body EE, body fatness, and systemic metabolism in humans. For example, brown fat is activated after acute cold exposure and/or meal intake, in parallel with increased EE. The amount and activity of brown fat are inversely correlated with body fatness and insulin resistance. Moreover, repeated cold exposure re-activates and recruits brown fat to increase EE, reduce body fat content and improve glucose tolerance. Although cold exposure is undoubtedly the most physiological and effective regimen to activate and recruit brown fat, it would be difficult and uncomfortable to increase human exposure to cold temperatures under well-controlled conditions with the presence of clothing and heating systems. The stimulatory effects of cold exposure are mediated through transient receptor potential (TRP) channels and the sympathetic nervous system (SNS). Most TRP members also function as chemesthetic receptors for various food ingredients, and indeed, agonists of TRP vanilloid 1 such as capsaicin and its analog capsinoids mimic the effects of cold exposure to decrease body fatness through the activation and recruitment of brown fat. The anti-obesity effect of other food ingredients including tea catechins may be attributable, at least in part, to the activation of the TRP-SNS-brown fat axis. Thus, brown fat is a promising target to treat obesity and related metabolic disorders. In this lecture, I summarize evidence for the thermogenic and metabolic effects of brown fat, particularly focusing on regimens activating and recruiting brown fat in humans.

PL(T2)01
Signaling Pathways Through Which Leucine and Glucose Act to Stimulate mRNA Translation.

Scot R. Kimball[1]

1.Penn State College of Medicine (USA)

Amino acids are not only substrates for protein synthesis, but also act to regulate the process. For example, refeeding a protein-containing meal to a fasted animal, but not one lacking protein, stimulates protein synthesis in skeletal muscle. Similarly, consumption of a mixture of essential, i.e., indispensable, amino acids by a fasted person upregulates skeletal muscle protein synthesis. Interestingly, consumption of a mixture of branched-chain amino acids, or even leucine by itself, leads to upregulation of muscle protein synthesis to an extent similar to the effect of a complete mixture of amino acids. Leucine-induced upregulation of protein synthesis is mediated by the protein kinase mechanistic target of rapamycin (mTOR). When mTOR is present in a complex referred to as complex 1 (mTORC1), it phosphorylates key regulators of mRNA translation including eukaryotic initiation factor 4E (eIF4E) binding proteins (4EBP) 1 and 2 and the 70 kDa ribosomal protein S6 kinase (p70S6k). Phosphorylation of 4EBP1/4EBP2 and p70S6k by mTORC1 promotes the assembly of the active mRNA cap-binding complex consisting of eIF4A, eIF4E, and eIF4G that meditates cap-dependent mRNA translation. Thus, by upregulating mTORC1 activity leucine stimulates the translation of most mRNAs. Leucine activation of mTORC1 is mediated by a family of proteins referred to as Sestrins, as in cells lacking all three Sestrins mTORC1 is insensitive to leucine deprivation or readdition. The Sestrins act to inhibit mTORC1 by binding to a GTPase-activating protein complex referred to as GATOR2. Leucine binds directly to Sestrins 1 and 2 and promotes their dissociation from GATOR2, leading to activation of mTORC1. Leucine also acts to promote dephosphorylation of Sestrin2. Interestingly, mTORC1 activity in cells lacking the Sestrins is insensitive not only to changes in leucine availability but is also insensitive to glucose deprivation or readdition. However, unlike leucine, glucose does not promote dissociation of the Sestrin•GATOR2 complex or dephosphorylation of Sestrin2. Moreover, glucose does not appear to directly bind to the Sestrins. Instead, hexokinase 2 is required for glucose to activate

mTORC1. Thus, hexokinase 2, but not hexokinase 1, associates with the Sestrins in a glucose-dependent manner, and cells lacking hexokinase 2 are resistant to glucose-induced activation of mTORC1. Notably, the effect of glucose on mTORC1 appears to be independent of the AMP-activated protein kinase, AMPK, as glucose readdition to cells lacking either the Sestrins or hexokinase 2 downregulates AMPK activity but fails to activate mTORC1. Overall, the signaling pathways through which leucine and glucose regulate mTORC1 activity appear to converge at the Sestrins, but may deviate downstream of them.

PL(T3)01
Nutrition through the life course and lifelong health

Sian M. Robinson[1]

1. Newcastle University (UK)

While links between diet and health have long been recognised, innovative epidemiological investigations conducted in the 1990s, using retrospective (historical) cohorts, highlighted the need to take a lifecourse approach to understanding the importance of nutrition as an influence on lifelong health. These studies linked non-communicable diseases (NCDs), such as diabetes and cardiovascular disease, in older populations to early experience - specifically to differences in patterns of fetal and infant growth. The findings led to new thinking about the origins of these leading causes of morbidity and mortality, focusing mechanistic research on understanding the role of nutrition during critical periods in the lifecourse, as well as effects of accumulation of risk over the lifespan - also rapidly embedded in policy to recognise key life stages and the opportunity for early intervention. Over the intervening quarter of a century much has been achieved, extending research beyond NCD outcomes to other public health priorities, including obesity and ageing, and identifying how and why nutrition is important. This presentation provides an overview of that progress and considers some of the implications of this learning for dietary recommendations and the design, timing and aims of future strategies to promote lifelong health.

PL(T4)01
Nutrition Epidemiology-Methodology and its Future Aspects

Walter Willett[1]

1. Harvard T.H. Chan School of Public Health (USA)

Early ecologic associations between dietary fat and risks of many cancers, and inverse associations between intakes of fruits and vegetables and risks of these cancers in retrospective case-control studies, were not supported in prospective cohort studies, raising questions about the validity of dietary questionnaires used in these cohorts. However, in validation studies using detailed assessments of intake and biomarkers of diet as comparisons, these questionnaires have been sufficiently sensitive to intakes of dietary fat, other nutrients, specific foods, and dietary patterns to detect the hypothesized associations. Also, important effects of dietary fat on risks of breast and other cancers have not been supported by large randomized trials. The early associations with fruits and vegetables in case-control studies appear to be due to recall and/or selection bias, but some consistent inverse associations have been seen in cohort studies for specific fruits and vegetables and specific subtypes of cancers, such as ER-negative breast cancer. Long latencies and diet during childhood have only been possible to examine recently, and the limited evidence suggests important associations. In contrast to cancer incidence, many consistent associations between dietary factors and risks of diabetes and cardiovascular disease have been documented, including specific types of fat, sources of carbohydrate, fruits and vegetables, and overall dietary patterns. These findings, many of which have been supported by short term randomized trials with intermediate risk factors as outcomes, may be more easily seen because of a close temporal relation between diet and disease incidence.

Biomarkers of diet can be useful in nutritional epidemiology, especially for aspects of diet that can otherwise difficult to assess, such as additives, contaminants, and effects of food processing. However, biomarkers will usually playa complementary role because they can be affected by factors other than diet, including absorption and metabolism, some of which may be genetically determined. Other technologies for dietary assessment, such as imaging of meals, have been of long-standing interest, but the validity of these methods relative to available methods remains to be documented. Even a perfect assessment of short term intake can be a weak measure of long term intake, and any method should be sufficient inexpensive and practical to be repeated over time in long term follow-up studies to capture changes in food availability and personal choices.

Because randomized trials are not feasible to evaluate most hypotheses relating aspects of diet to disease risk, observational studies will continue to play a key role. Going forward, dietary questionnaires are likely to remain the core method for dietary assessment, complemented with biomarkers of intake for specific aspects of diet and possibly by new technologies. Prospective studies including assessment of early life diets, long follow-up, and repeated measures of intake will be especially important. High levels of certainty can be obtained when

findings are consistent with short term randomized trials with intermediate outcomes or Mendelian randomization analyses.

PL(T5)01
Large-scale regulatory and fiscal policy for tackling obesity and creating healthier diets

Barry Michael Popkin[1], Shu Wen Ng[1], Lindsey Smith Taillie[1]

1. University of North Carolina at Chapel Hill Gillings School of Global Public Health (USA)

We are still at a nascent level in learning the best ways to promote a healthy diet. We have learned that exercise is not the answer and we must focus on improving global diets. We have also learned how deleterious ultraprocessed foods are on our health and require policies to reduce consumption. Also we have learned how difficult it is to institute effective public policies due to the interference of the food industry. Globally the diets of the impoverished are much poorer than those of higher-income subpopulations. In most major countries people with lower incomes and educations are more likely to be obese or overweight compared to higher-income or higher-education populations. In all cases we will focus on these large disparities in the policies we review.

Despite industry obstructions, at least 44 countries have instituted sugar-sweetened beverage taxes, and a growing number has introduced effective front-of-the-package warning labels to draw attention to foods high in energy density and added sugar, sodium, and saturated fats or trans fats. In addition, a few countries have banned marketing to children and are moving forward to restrict marketing unhealthy ultraprocessed foods and beverages to the entire population. We present and review evidence of the impacts of these policies on food purchases and diets at the population and subpopulation levels in key countries such as Mexico, South Africa, Chile and Brazil.

We go on to review some of the food industry forces in our midst and across the globe that are attempting to stop these public health nutrition policies. While many government officials, advocates, and politicians push for efforts to improve diets and food choices, the adverse actions of the food and beverage industries create delays. The industries could be part of the solution, but they rarely are. Most if not all of the policies the food industries promote are ineffective. Industry self-regulation and corporate responsibility do not work. At the same time, the industries contradict the broader literature and advance research they have funded to argue that proposed restrictive policies do not work and have adverse results. We present some of the key elements that can advance understanding of this topic and fill the gaps in our knowledge.

PL(T6)01
Prevention of cardiovascular disease focusing on nutrition and eating habits

Pekka M. Puska[1]

1. Finnish Institute for Health and Welfare (THL) (Finland)

CVDs cause globally every year some 18 million and all noncommunicable disease (NCD) some 41 million deaths. The scientific evidence on their causal risk factors is very strong. Dietary factors are closely related to CVD risk and risks of NCDs as a whole. Global Burden of Disease (GBD) Study (2019) lists dietary risks as most important factor behind NCD deaths (responsible for over 11million annually). Among them the most important are high sodium, low whole grains, low fruit, low nuts and seeds, low vegetables, low omega 3, low fiber and low polyunsaturated fats. Based on this evidence numerous prevention strategies have been formulated, both internationally and within countries. After the UN Political Declaration (2011) WHO developed Global Action Plan with global behavioural targets, especially to reduce global sodium intake and to halt obesity increase, but also with broader nutrition indicators. These were in 2015 linked with the 2015 UN Global Development Goals. Prevention of CVDs and NCDs by influencing population nutrition calls for comprehensive strategies, of which the WHO Global Strategy on Diet and Physical activity in 2004 was a good basis. Although interventions on high risk individuals is important in reducing their risk, interventions targeting the populations a whole and their social and physical environments have the greatest public health potential. Such interventions include measures to change people's dietary habits through both broad health promotion and by changing food environments through political decisions. Providing health information to people is only the basis for changes in eating habits. It is important to give people specific advices and change skills and to try to provide social and environmental support. Policy interventions relate, among other things, to taxation, marketing, public procurements and agricultural policy. Now that the evidence on the role of several dietary factors and also on the effectiveness of many intervention measures is very strong, the big question is how to implement these measures. The big obstacle is the implementation gap, due to both inertia in lifestyle changes and to difficulties in needed policy changes. Successful health promotion to change population eating habits calls for health promotion with correct theory and good intensity. Policy decisions to change the food environment have a great potential, but are often not easy. There are many reasons for the resistance, like public costs, private interests with lobbying, other public consequences and often even public opinion. It is

good to remember that “no pain, no gain”! Understanding the process of political decision making is crucial for progress. It calls for different measures, preferably mobilizing public support and with innovative use of media. Many examples, like the North Karelia Project/Finland, show that big positive changes in population nutrition are possible with comprehensive, intensive and theory-based work, and can, indeed, lead to considerable reduction in CVD rates. Thus the potential for CVD/NCD prevention through changes in nutrition and other lifestyles in the population is great.

Functional foods in the near future for realization of the society toward healthy and powerful longevity

Keiko Abe[1]

1. The University of Tokyo (Japan)

In Japan as a super-aged country, the construction of a society for healthy longevity and improvement of quality of life (QOL) is of presenting importance. It is thus an inevitable theme is SDGs. Healthy is closely associated with maintenance of good QOL and its further improvement. These states are necessarily coming out from homeostatic bodily conditions. However, the state of pre-illness is expected to even normal people, preferably by proper food consumption. Recalling the case in about 30 years before, we know that Japan proposed the name of functional food and its concepts together with the commercialization of some functional food products. These have been globally accepted. The products as well as the concepts have actually contributed to the “food for health” science and industry. These states have targeted the so-called metabolic syndrome, as a report was publicized with a headline “Japan explores the boundary between food and medicine (*Nature*, 1993). Meanwhile, a Cabinet Project, SIP, “The Next Generation Agricultural and Fisheries Projects and Functional Food Products” (2014-2019; Represented by K. Abe, The University of Tokyo) was available. Closely relate states of pre-illness in this project were exemplified by gut-brain coordination, locomotive risk recovery, homeostatic risk avoidance, time-dependent nutrition and sports, as seen in spotlight on food science in Japan (*Nature*, 2017). In this context, research activities as well as coming into being which target stress reduction, mental normalization, proper feedings, full sleeping, memory-cognition normalization. Also, locomotion, frail and other bodily problems are included. These may be applicable even to health people and their some abnormality if any. With them as backgrounds, “pre-illness marker” has been interested in industries, ministries and academic regions. Particularly, Committee on “food and pre-illness marker” (2020-2025) as the JSPS University-Industry Research Cooperation Societally. These activities of the Committee will make it possible to innovate Japan as a world-top runner for healthy longevity in the next generation.

PL(T8)01
Prospects and challenges of cultured meat

Mark Post [1,2]

1. Maastricht University (Netherlands), 2. Mosa Meat, B.V. (Netherlands)

In the coming 30 years, the FAO anticipates that meat demand will rise by 70% due to the global population growth and increase in wealth of India, China, South America and Africa. To ensure food security and to diminish the environmental and animal welfare burden of current beef production, we envisioned an alternative by culturing meat from bovine muscle-specific stem cells. Since 2013, when we presented the first proof of concept, cultured meat has undergone exponential growth in funding, number of people working on it and number of startups trying to commercialise the technology. In December 2020, we have witnessed the first cell-cultured chicken being approved for consumption in Singapore. Undoubtedly, in the coming two years, we will see more small scale market introductions of cultured meat products. For serious scaling up however, important hurdles need to be taken, such as industrial cell and tissue production, making products cost-effective and resource-efficient, setting up a scalable supply chain of ingredients, generating consumer acceptance and regulatory approval for each regional market. Major advances have been made in all these areas in the last years. None of these hurdles is unpassable, but together they form an intense challenge, that can only be successfully addressed with the involvement of a large number of stakeholders in different industries. For instance, we have seen more than a dozen more startups that are starting to produce low-cost growth factors, necessary to replace serum. We are also seeing different approaches to cultured meat, ranging from recombinant meat proteins to tissue engineering of complex full thickness meat and all of that across various species. At the same time, advances are made in plant-based and single cell protein alternatives and it will be interesting how these alternative protein sources will develop in the market either by themselves of in various combinations. Nutrition-wise, cultured meat will has the potential to mimic conventional meat better that the other alternative protein sources. However, with that mimicry also comes the unhealthy components of meat, i.e. saturated fat and, although not entirely proven, heme-iron in myoglobin. Examples will be shown how this can be avoided. State of the art and intermediate future perspectives of cultured meat will be discussed. Cultured meat is a multifaceted technology that will provide insight into many fascinating biological, psychological, societal and economical questions. At the same time, we urgently need to find solutions for the upcoming surge in meat consumption.

SL(T1)1
Homeostatic versus hedonic control of carbohydrate selection -from studies of AMPK in the hypothalamus

Yasuhiko Minokoshi[1]

1.National Institute for Physiological Sciences (Japan)

Food selection is influenced by food palatability, nutritional state, and social factors such as stress. However, the mechanism responsible for selection between a high-carbohydrate diet (HCD) and a high-fat diet (HFD) remains unknown. In rodents, fasting and glucose deprivation increase the intake of an HCD when they are presented with both an HFD and an HCD in two-diet choice experiments. This is associated with a rapid recovery of whole-body metabolism during refeeding of carbohydrates compared with that of fat in diets.

We recently found that activation of a subset of corticotropin-releasing hormone (CRH)–positive neurons in the rostral region of the paraventricular nucleus of the hypothalamus (PVH) is necessary to induce the selection of an HCD over an HFD in mice during refeeding after fasting. These neurons manifested activation of a metabolic sensor, AMP-activated protein kinase (AMPK) during food deprivation. Studies with DREADD technology and expression of constitutively active AMPK or shRNA for AMPK in PVH CRH neurons revealed that the activation of AMPK in CRH neurons of the PVH is necessary and sufficient for the selection of an HCD over an HFD during refeeding after fasting. Furthermore, the effect of AMPK is mediated by a neuron type of carnitine palmitoyltransferase 1, CPT1c. Activation of isolated AMPK-regulated CRH neurons by AMPK activator increased cytosolic calcium level in the neurons depending on their cellular AMPK and CPT1c levels. A single nuclear RNA analysis revealed that a subpopulation of PVH CRH neurons expresses AMPK catalytic subunits (alpha1 and 2) abundantly, compared with those in non-CRH neurons in the PVH. We also found that the CRH neurons are involved in HCD selection after social defeat stress. In contrast, diet-induced obese mice impaired AMPK activation in the PVH, increasing HFD selection during fasting.

Glucose deprivation by 2-deoxyglucose (2DG) increases carbohydrate as well as fat intake in rodents. In two-diet choice experiments in mice, systemic injection of 2DG first increased HCD selection and then increased HFD selection. Interestingly, suppression of PVH CRH neurons inhibited the HCD selection, while it increased the HFD selection. Total calorie intake did not change. The 2DG-induced HCD selection but not HFD selection was mediated by NPY neurons regulating PVH neurons.

Together, AMPK-regulated CRH neurons in the PVH regulate selection between carbohydrate and fat in diets. Our results identify the specific neuron in the hypothalamus and intracellular signaling pathway responsible for the regulation of the complex behavior of selection between carbohydrate and fat in diets. Given that mice prefer an HFD in two-diet choice experiments under a normal metabolic condition, AMPK-regulated CRH neurons in the PVH increase HCD selection overcoming a hedonic feeding for an HFD, dependent on a homeostatic need.

Chrono-nutrition

Shigenobu Shibata[1]

1. Waseda University (Japan)

Circadian clock systems play important roles in clock-related physiological functions including energy, protein, and mineral metabolisms. This clock system also has an important role in microbiota diversity, because impairment of circadian clock such as shift work caused not only obesity but also less diversity of fecal microflora. The increase in adiposity is related to significant changes in the human environment and lifestyle, including less physical exercise and high-energy dietary choices. This lifestyle is also related to locomotive syndrome, such as sarcopenia, osteoporosis, and joint problems. Thus, reducing fat and/or sucrose and increasing protein, minerals and dietary fibers in the diet and increasing physical exercise represent the primary methods for prevention of and/or recovery from lifestyle-related diseases such as obesity and locomotive syndrome especially in middle and old age persons. However, the best timing of nutrients/functional food intake is still unknown. After discovery of molecular mechanism of circadian rhythm, research field of chrono-biology has influenced on many other research fields such as pharmacology, nutrition science and sports /exercise science. Inulin rich breakfast compared to dinner reduced colon pH according with increase of short chain fatty acids and increased the diversity of fecal microflora in mice. In human experiments, artichoke powder (5g) was given at breakfast or

dinner. It is well known that blood glucose level by same meal is dependent on the meal time; glucose at dinner is higher than glucose at breakfast. Here, we monitored 24-hr interstitial glucose levels (GL) by freestyle libre Pro. Artichoke powder at breakfast in human experiments lowered the 24-hr GL, and lunch- and dinner-induced GL, as a "second meal effect". Artichoke intake at breakfast time improved the constipation, and increase of fecal *Bacteroidetes* and decrease of *Firmicutes* corresponding with reduction of GL in comparison to artichoke intake at dinner time. Thus, artichoke at breakfast has a good health effect on both small intestinal and large intestinal function. Cellobiose, water soluble dietary fiber and short chain fatty acids mixture food provided phase-resetting effects on mouse peripheral clocks. Protein rich food at breakfast increase the skeletal muscle volume in mice, and 10g milk protein intake at breakfast but not at dinner causes muscle volume and sarcopenia index marker increases in human intervention experiments. Web survey of the relationship of protein intake at 3 meal times and physical activity (Mets) demonstrated the strong positive relationship between protein volume/protein ration at breakfast and physical activity. These data suggest the importance of protein rich food at breakfast. Blood pressure is positively related to the ratio of Na/K at lunch, but not at breakfast and dinner, suggesting low intake K rich foods such as vegetable and fruits at lunch time. Blood pressure is negatively related the physical activity (Mets) at 18:00-21:00, but not other clock times. The present results strongly suggest that the timing of feeding and functional food is critical for protection of lifestyle related diseases. We are interested in elucidating how new approach such as chrono-nutrition and -exercise helps to promote health science using animal and observation/intervention human experiments.

Modulation of SREBPs activation, and functional food factors that prevent their activation

Ryuichiro Sato[1]

1. The University of Tokyo (Japan)

SREBPs (SREBP-1 and SREBP-2) are membrane-bound transcription factors that control the transcription of lipogenic genes involved in the biosynthesis of fatty acids or cholesterol. These proteins interact with the dedicated associating protein SCAP and are primarily localized to the endoplasmic reticulum (ER). This complex forms a heterotrimeric with another ER membrane protein INSIG and remains on the ER membrane without transducing signals as a transcription factor in the nucleus. Under the sterol-depleted condition, the SREBP-SCAP complex detached from INSIG is transported from the ER to the Golgi apparatus where the N-terminal region, the active form of the transcription factor, is generated by sequential proteolysis by two types of cleavage enzymes, S1P and S2P. Finally, the active transcription factors translocated to the nucleus enhance the expression of target genes such as the LDL receptor. The C-terminal region of SCAP with the WD40 repeat, which contributes to the protein-protein association, interacts with the C-terminal region of either SREBP-1 or SREBP-2, despite they share only 49% amino acid homology. Based on this fact, we hypothesized that SCAP has unidentified associating proteins other than SREBPs, which may affect SREBP activation. To identify novel SCAP interacting proteins, the Flag-tagged C-terminal portion of SCAP was expressed in HEK293 cells and the interacting proteins were found by the immunoprecipitation (IP) method using anti-Flag antibodies. The mass spectrometry analyses revealed that heat shock protein 90 (Hsp90) is the most possible interacting protein of SCAP. Several types of IP experiments verified the formation of the HSP90-SCAP-SREBPs complex, thereby stabilizing SCAP and SREBPs, and elevating SREBP target gene expression. Overexpression of exogenous Hsp90 in HepG2 cells increased the intracellular triglyceride and cholesterol accumulation, whereas an Hsp90 inhibitor 17-AAG or Hsp90 knockdown reduced their accumulation. In the presence of 17-AAG, SCAP and SREBPs were rapidly degraded, which was hampered by a proteasome inhibitor, suggesting the involvement of the ubiquitin-proteasome pathway. When another type of Hsp 90 inhibitor was injected intraperitoneally into mice, the same effects observed in cultured cells were observed in the liver. Aiming at searching for food factors that mitigate SREBP activation, a luciferase assay system was established using the human fatty acid synthase (FAS) promoter. A stable human hepatoma cell line (Huh7) expressing the luciferase was cultured with various types of purified food factors (approximately 100 agents) to find out the potential candidates that suppress the FAS promoter activity. One of the potent suppressors was xanthohumol (XN), the most abundant prenylated flavonoid in hops. When wild-type Huh7 cells were cultured with XN, SREBP target gene expression was suppressed in a dose-dependent manner, thereby reducing fatty acid and cholesterol *de novo* synthesis. Western blot analyses revealed that XN inhibits proteolytic activation of SREBPs and that isoxanthohumol and 8-prenylnaringenin, XN derivatives, were less potent inhibitors. The detailed mechanism by which XN inhibits SREBP activation will be discussed in the talk.

Recent progress of research and evidence on Health Emergency and Disaster Risk Management (Health EDRM): call for global and interdisciplinary collaboration

Emily Ying Yang Chan[1]

1. The Chinese University of Hong Kong (Hong Kong)

For the recent few decades, increasing number of natural disasters has been observed. Globalization, urbanization, health inequity, and global ageing have been affecting the increased

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

vulnerability and exacerbated the impact of emergencies and disasters. More recently COVID-19 pandemic and sporadic conflicts and other types of disasters also caused operational and implementation challenges for global societies.

The Sendai Framework for Disaster Risk Reduction 2015-2030, the resulting document of the 3rd UN World Congress for Disaster Risk Reduction, proposed strategic direction of global societies for disaster risk reduction with a paradigm shift from event-based to risk-based and human-centered approach. It highlights the imperative of health, and for the first time, health is clearly indicated as part of the objectives of disaster risk reduction. In line with this progress, WHO developed Health Emergency and Disaster Risk Management (Health EDRM) Framework in 2019, which support the Sendai Framework. Reliable scientific evidence is essential for effective policy and programs that support the implementation of these global frameworks and other regional, national, and local strategies and guidelines.

The 2016 WHO expert meeting on Health EDRM research identified fundamental gaps in knowledge and evidence, as well as the challenges in coordination and collaboration among stakeholders. WHO Thematic Platform for Health EDRM Research Network (Health EDRM RN), officially launched in 2018, is a global expert network supported by WHO HQ and Regional Offices, which aims to strengthen the scientific evidence on Health EDRM and to foster global collaboration among academia, government officials and other stakeholders for a harmonized approach to produce, disseminate and apply knowledge and evidence into policy and practice in regions and countries. The Health EDRM RN facilitated multiple global collaborative activities for the improvement of scientific evidence and knowledge dissemination, which includes the development of the WHO Guidance on Research Methods for Health EDRM and establishment of WHO Health EDRM Knowledge Hub. Along with the development and implementation of these global initiative, scientific evidence on Health EDRM has been also improved, as demonstrated by the series of publications of thematic special journal editions on Health EDRM (e.g. Special editions by Prof. Emily Chan for International Journal of Environmental Research and Public Health).

The 2022 Core Group Meeting of the Health EDRM emphasized the strong requirement for interdisciplinary collaboration, as well as further global, regional, national, and local knowledge dissemination to deliver the key evidence-base messages to be applied for better policies and programs.

As the co-chair of the Health EDRM RN, this special lecture will introduce the recent progress of scientific evidence on Health EDRM and related research areas linking with the development of multiple global initiatives on Health EDRM research. The lecture also highlight the latest research frontiers of Health EDRM and policy implications on disaster risk reduction in future extreme events.

Keyword: health emergency and disaster risk management, Health EDRM, interdisciplinary research, disaster risk reduction

SL(T2)1
Arginine as a functional amino acid in human nutrition and health

Guoyao Wu[1]

1.Texas A&M University (USA)

As a functional amino acid, L-arginine serves not only as a building block of protein but also as a crucial substrate for the synthesis of nitric oxide (NO), creatine, polyamines, homoarginine, and agmatine in mammals (including humans). NO (a major vasodilator) increases blood flow to tissues. L-Arginine and its metabolites play important roles in metabolism and physiology. L-Arginine is required to maintain the urea cycle in the active state to detoxify ammonia. This amino acid also activates cellular mechanistic target of rapamycin (MTOR), focal adhesion kinase, and redox cell signaling pathways in mammals, thereby stimulating protein synthesis, inhibiting autophagy and proteolysis, enhancing cell migration and wound healing, promoting spermatogenesis and sperm quality, improving conceptus survival and growth, and augmenting the production of milk proteins. Although L-arginine is formed from glutamine/glutamate and proline in humans, these synthetic pathways do not provide sufficient L-arginine in infants or adults. Thus, humans and other animals do have dietary needs of L-arginine for optimal growth, development, lactation, fertility, immunity, and health. Much evidence shows that oral administration of L-arginine within the physiological range can confer health benefits to both men and women by increasing NO synthesis and thus blood flow in tissues (e.g., skeletal muscle and the corpora cavernosa of the penis). NO is a vasodilator, a neurotransmitter, a regulator of nutrient metabolism, and a killer of bacteria, fungi, parasites, and viruses [including coronaviruses, such as SARS-CoV and SARS-CoV-2 (the virus causing Covid-19)]. Thus, L-arginine supplementation can enhance immunity, anti-infectious and anti-oxidative responses, embryonic survival, fetal growth, wound healing, ammonia detoxification, nutrient digestion and absorption, lean tissue mass, and brown adipose tissue development; ameliorate metabolic syndromes (including dyslipidemia, obesity, diabetes, and hypertension); and treat individuals with erectile dysfunction, sickle cell disease, muscular dystrophy, and pre-eclampsia.

Sarcopenic obesity

Rocco Barazzoni[1]

1. University of Trieste (Italy)

Obesity prevalence has reached epidemic proportions worldwide, posing unprecedented individual, social, and medical challenges, by increasing risk for metabolic diseases, chronic organ failures and cancer, as well as their acute complications. Reducing excess adiposity remains the fundamental treatment for obese individuals. However, complex metabolic and lifestyle abnormalities as well as weight reduction therapies per se may compromise the ability to preserve muscle function and mass. Indeed loss of skeletal muscle mass and function (sarcopenia) is common in individuals with obesity due to metabolic changes associated with sedentary lifestyle, adipose tissue derangements, comorbidities and the ageing process. Strong evidence indicates that low muscle mass and function have a major negative health impact in persons with obesity, leading to disabilities and increased morbidity and mortality. Awareness of the importance of skeletal muscle maintenance in obesity is however unfortunately still low among clinicians and researchers alike. The term 'sarcopenic obesity' has been introduced to identify obesity with low skeletal muscle mass and function, but its utilization is limited and consensus on its definition and diagnostic criteria has also been low. Knowledge on the prevalence of sarcopenic obesity in various clinical conditions and patient subgroups, on its clinical impact in patient risk stratification, and on effective prevention and treatment strategies remains therefore an unmet clinical priority. Optimal lifestyle approaches and potential nutritional care support strategies to preserve muscle mass in persons with obesity are particularly important, and optimization of body composition should become an additional key target in obesity treatment.

SL(T2)3
Eating behaviors as a future direction in nutrition research: what we have known and not known about the association between eating speed and obesity

Satoshi Sasaki[1]

1. The University of Tokyo (Japan)

Health effects of ingredients and nutrients in foods have long been of main interest in nutrition researches, especially in nutritional epidemiology. This is based on the knowledge of nutritional biochemistry. In addition to this, nutritional physiology is also important determinant of our health. For example, in obesity, “percentage of energy taken from carbohydrate, fat, or protein” has long been paid a great attention. However, no matter which nutrient is taken for energy, “speed of taking energy” may affect to energy intake, and consequently to obesity status and to occurrence of some diseases. Self-reported rate of eating speed is probably the dietary factor that has ever shown the strongest association with body mass index in both sexes and across ages in many cross-sectional studies. The consistent association was shown in a meta-analysis. This association was shown also in prospective studies. In addition, self-reported rate of eating speed was statistically and positively associated with subsequent incidence of diabetes in a Japanese population. The question and the predefined answer is quite simple and well validated. Among the questions of dietary behaviors, this may be relatively rare and precious for studies. In this presentation, how eating behaviors is attractive as a future direction for human nutrition research is introduced and discussed by taking the association between eating speed and obesity as an example.

Keyword: nutritional epidemiology, obesity, eating behavior

SL(T2)04
Trends for cardiovascular disease in Japan, and its prevention through nutritional assessment and improvement

Hiroyasu Iso[1]

1. National Center for Global Health and Medicine (Japan)

In the 1960s, Japan had the highest mortality from stroke and the lowest mortality of ischemic heart disease (IHD) in the world. Since then, stroke mortality has decreased substantially and IHD mortality has declined moderately along with a large decline in blood pressure levels and for men a moderate decline in smoking albeit an increase in blood cholesterol levels. More recently, stroke mortality in Japan is still two-fold higher and IHD mortality is one-fourth compared with that in the US and UK. The large difference in cardiovascular disease profiles may be due to a material difference in profiles of cardiovascular risk factors, attributable to differences in diets. Higher sodium, lower calcium, and lower meat intakes, and for men higher alcohol consumption may have contributed to the higher prevalence of hypertension leading to a higher risk of stroke, while higher physical activity, higher n3 polyunsaturated fat (fish) intake, lower saturated fat (meat) intake contributed to the lower prevalence of obesity, diabetes, and dyslipidemia leading to a lower risk of ischemic heart disease. Albeit the moderate decline in IHD mortality, there has been an increasing trend for IHD incidence among urban middle-aged men (workers and residents) in Japan. This incidence trend is worth noting because of a potential future problem for public health and clinical practice. In such situations, the nutritional assessment is crucial to perform health counseling for nutritional improvements in the prevention of cardiovascular disease. The nutritional assessments are composed of 1) dietary assessment *per se*, i.e.,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

by different methods such as dietary records, 24-hour recall, and food frequency questionnaire, and 2) assessment of biomarkers such as blood lipids, fatty acids, protein, amino acids, vitamins, and inflammation markers. Japan is unique among the developed countries where IHD mortality has been low and continued to decline. However, careful surveillance is needed to examine whether the complex changes in lifestyles, i.e., lowering sodium and rice intakes, recent lowering fish intake and smoking while increasing animal protein and saturated fat intakes, and physical inactivity may affect the future trend in cardiovascular disease.

Health effects of dietary risks – evidence from the global burden of disease study

Shuhei Nomura[1,2,3]

1. Keio University (Japan), 2. The University of Tokyo (Japan), 3. Tokyo Foundation for Policy Research (Japan)

Comparable evidence on disease-specific deaths, disabilities, and their causal risk factors is essential for policy-making and designing health interventions. The Global Burden of Disease (GBD) study is one of the largest systematic scientific efforts in the world: it provides a data-rich framework for comparing the importance of various diseases, injuries, and risk factors that cause death and disability over time and space. All estimated data are publicly available, and the value of the GBD lies not only in the data, but also in the critical discussion made possible by its comprehensive, longitudinal nature.

Chronic diseases are becoming more prevalent worldwide. Further public health efforts to curb the increase in potentially preventable risk factors can make the global population more resilient to public health crises such as COVID-19. This presentation will provide comprehensive data on various dietary risk factors, including dietary risks for death and disability in countries and regions of the world based on the latest GBD findings.

This presentation will also provide results from recent studies that projected future changes in the burden of disease in Japan attributed to dietary risk factors under a variety of future intake scenarios. Large gaps in future burden of disease estimates across scenarios were identified. This implies that policies targeting dietary risk factors in a given population may have a significant impact on the future trajectory of the risk factor profile and associated burden of disease within that population.

The influence of diet on fertility and outcomes of assisted reproductive technologies

Audrey Jane Gaskins[1]

1. Emory University Rollins School of Public Health (USA)

The literature on the relation between diet and human fertility has greatly expanded over the last decade. At present, antioxidant supplementation does not appear to offer benefits to women undergoing infertility treatment, but it may be beneficial when it is the male partner who is supplemented. It is, however, unclear which specific antioxidants and which doses are responsible for this benefit. Maternal intake of supplemental folate, particularly at doses higher than those recommended for the prevention of neural tube defects, has been consistently related to lower frequency of infertility, shorter time to pregnancy, lower risk of pregnancy loss, and greater success in infertility treatment. Higher intake of other vitamins involved in one carbon metabolism, such as B12, may also be associated with enhanced fertility. On the other hand, vitamin D supplementation does not appear to play an important role in fertility in the absence of deficiency. Male and female intake of long chain omega 3 fatty acids (particularly from seafood) and fruits and vegetables (particularly from produce with low levels of pesticides) may improve fertility although it remains unclear to what extent contamination with environmental toxicants can dampen this benefit. Dairy and soy, once proposed as reproductive toxicants, have not been consistently related to poorer fertility in men or women. In fact, newer evidence suggests that soy foods and supplements could be beneficial for women undergoing infertility treatment. As more rigorous studies continue to be published, the evidence of a potentially deleterious effect of moderate alcohol and caffeine intake on the fecundability, pregnancy loss, and ART outcomes seems less solid than previously hypothesized. Overall, in women, adherence to a diet prioritizing intake of supplemental folic acid, vitamin B12, vitamin D, low pesticide fruits and vegetables, whole grains, seafood, dairy, and soy foods and limiting intake of high pesticide fruits and vegetables appears to be the most optimal pre-conception guidance. In men, adherence to a Mediterranean diet characterized by high intake of low pesticide fruits and vegetables, seafood, whole grains and limited intake of red and processed meat, refined grains, high-energy drinks, and sweets appears to be the best recommendations to enhance semen quality and fertility. While a complete picture of the role of nutrition on fertility is far from complete, the current state of the evidence stresses the importance of providing specific pre-conception guidance to couples planning pregnancy above and beyond general recommendations for chronic disease prevention.

SL(T3)3
The importance of nutrition for dementia and frailty: Evidence from epidemiological studies in aging

Sara Hagg[1]

1. Karolinska Institutet (Sweden)

Keeping a healthy diet throughout life is important for a healthy aging. However, at old ages, many individuals suffer from malnutrition due to a reduced food intake and disturbed metabolic regulation. Being malnourished is tightly intertwined with sarcopenia – loss of muscle mass and strength – and with frailty – a geriatric syndrome characterized by increased vulnerability and reduced ability to cope with stressors. In addition, these factors are also associated with an increased risk for the development of dementia. Hence, the mechanisms are connected and difficult to disentangle.

Observational studies have shown that vitamin B and E intake as well as poly-unsaturated fatty acids are beneficial for the prevention of frailty and dementia. Saturated fatty acids have an opposite effect. The evidence for effects from different diets have been mixed. However, saturated fatty acids typically reflect adherence to Western diets with relatively high amounts of animal fat. A neuroprotective effect is suggested from intake of vegetables, fruits, berries and sea-food, of which some components are found in different Mediterranean diets. However, for old frail individuals, it is important to have a high protein intake to counteract sarcopenia.

There are some RCTs conducted in pre-frail and frail individuals that show beneficial effects from protein supplementation and physical exercise. Another way of finding causal evidence for possible interventions is to use a Mendelian Randomization study, which is nature´s own version of an RCT. Then, genetic variants are used as proxies for an exposure to provide unbiased estimates with frailty and dementia outcomes. For example, genetic variants that explain part of the circulating serum albumin level can be used to analyze if high or low albumin levels are good or bad for frailty without bias from unmeasured confounders. In this way, epidemiological studies can provide clinical guidance of nutritional interventions that should have the potential to prevent against frailty and dementia.

Keyword: nutrition, frailty, dementia, epidemiology, Mendelian Randomization

SL(T3)4
Food insecurity and child growth and development

Edward A. Frongillo[1]

1. University of South Carolina (USA)

Background and objectives: Children and adolescents are sensitive to their environments and vulnerable physically, psychologically, and socially to stressors in their environments. From developmental, life course, cumulative disadvantage, and intergenerational theoretical perspectives, stressors in the environments of children and adolescents can have substantial immediate and long-term consequences. Food insecurity is a common stressor in the environments of children and adolescents in all countries, with the prevalence of moderate or severe food insecurity in 2020 among individuals aged 15 years or above being 30% in the world, 60% in Africa, 26% in Asia, and 41% in Latin America and the Caribbean. The aim of this lecture is to summarize evidence on the consequences of food insecurity for children and adolescents with particular attention to growth and development.

Methods: The literature on food insecurity, how children experience it, and its consequences for children and adolescents was reviewed.

Results: Children and adolescents experience food insecurity cognitively, emotionally, and physically in ways that are different from adults. Children who experience food insecurity can live adult roles prematurely such as by participating in adult strategies to ensure adequate food, helping to generate resources by doing chores and participating in labor, and reducing their own food consumption to protect their parents and siblings from food insecurity. Food insecurity in families leads to distress and adverse family and social interactions, worry and anxiety, and feelings of deprivation and alienation. For children and adolescents, these experiences result in greater likelihood or intensity of behavioral problems, disrupted social interactions, compromised school performance, poor dietary intake, low physical activity, low physical function in daily activities and exercise, poor general physical health and illness, poor mental health, shame, and compromised growth and development.

Conclusions: Food insecurity is experienced by children despite attempts from adults to protect them from it. Food insecurity is a powerful stressor that harms children directly and through disruptions in parenting and family life. The consequences of food insecurity for children and adolescents are likely to have long-term effects that are cumulative throughout the life course and to be passed to the next generation. Therefore, continued efforts to prevent food insecurity and mitigate its consequence are needed and will result in long-term benefits for individuals.

Keyword: Food insecurity, Child growth, Child development, Stress, Health

SL(T4)1
Epidemiological evidence on nutrition, metabolome and cardiometabolic risk.

Paul Elliott[1]

1. Imperial College London (UK)

Geographical and temporal trends in disease rates – such as the declines in coronary heart disease mortality in many countries since the 1960s and 1970s and the current worldwide obesity and diabetes epidemics -- indicate the importance of the environment (including lifestyle, dietary and nutritional factors) in the development of cardiometabolic diseases. In this regard, the 'exposome' paradigm has been proposed as a means of representing the totality of exposures (including lifestyle, dietary and nutritional factors) that lead to an individual's risk of disease over the lifecourse. The exposome involves both exposure to 'external' stressors such as occupational, lifestyle and dietary factors and the 'internal' (biochemical) exposome which captures (among others) the biological imprints of these external stressors. Increasingly these biochemical signatures can be measured through use of omic technologies, among which metabolomics -- the measurement of small molecule metabolites in blood or urine by nuclear magnetic resonance (NMR) spectroscopy and/or mass spectrometry (MS) -- is key since it is the most proximal of the omic technologies to the phenotype. Specifically, metabolomics captures in high-resolution the end-products of metabolic pathways of the organism, from both physiological and pathophysiological processes, as well as providing direct measures (biomarkers) of lifestyle exposures including dietary intakes (1). The concept is that, against a background of genetic susceptibility, the external and internal stressors (represented by their associated molecular signatures) interact at a cellular and systems level to determine the trajectory of health or disease over the lifecourse. Agnostic (untargeted) analyses, including the metabolome-wide association study (MWAS) approach applied to epidemiological cohorts, have been utilised, for example, to reveal novel signatures of perturbations in metabolic pathways associated with adiposity (2), as well as targeted metabolomic analyses of specific pathways. Identification of nutritional biomarkers using such methods may lead to development of objective markers of dietary intakes and diet quality for use in epidemiological studies, and potentially in clinical practice. However, new methods of working involving a multi-disciplinary approach are required to address the computational and interpretational demands of the metabolomic approach.

Food, Nutrition and Cancer Risk: Pros and Cons of the Japanese Diet

Shoichiro Tsugane[1]

1. National Institutes of Biomedical Innovation, Health, and Nutrition (Japan)

World Cancer Research Fund International evaluated obesity (colorectum, liver, breast, kidney, etc.), alcohol consumption (esophagus, colorectum, liver, breast, etc.) and processed meats (colorectum) to be "convincing" diet-related factors, and foods preserved by salting (stomach) and red meats (colorectum) to be "probable" factors that increase the risk of cancer. On the other hand, the fund evaluated physical activity (colorectum) as only "convincing" and fruits and vegetables (aerodigestive cancer and some other cancers aggregated), whole grains (colorectum), dietary fiber (colorectum), dairy products (colorectum), and coffee (liver, endometrium) as "probable" to lower the risk of cancer.

According to Global Burden of Disease Study 2019, the global excess mortality attributed to diet-related factors was estimated to be 6.1% of total cancer death world-wide aged 25 year and over. The breakdown is as follows: insufficient intake of whole grains (1.7%), milk (1.7%), calcium (1.4%), fruits (1.3%), vegetables (0.2%), and dietary fiber (0.2%), and excessive intake of red meat (0.8%), sodium (0.7%), and processed meat (0.3%). Except for fruit being esophageal and lung, vegetable being esophageal and sodium being stomach, all the rest are defined as attributing to excess colorectal cancer deaths.

The age-standardized cancer mortality rate in Japan is the lowest among the G7 countries, especially for breast and prostate cancer. On the other hand, stomach and colorectal cancers are relatively high.

The Japanese diet generally consists mainly of plant based-foods such as vegetables and soybeans and seafood and is eaten with sugar-free drinks such as green tea. They are low in calories and less lead to obesity (its prevalence is extremely low in Japan compared with the other G7 Countries), and in this aspect, they may be beneficial in cancer prevention. On the other hand, higher salted foods consumption such as salt pickled vegetables and salt preserved seafoods, raises the risk of stomach cancer, whereas low in calcium intake due to low milk and dairy products may increase the risk of colorectal cancer.

Soybeans are consumed predominantly in Asian countries, including Japan, and are the only source of isoflavones, which are similar in chemical structure to estrogen, a female hormone. It is thought to bind to estrogen receptors with weak estrogenic function in reproductive women and inhibit estrogen-induced tumor growth. Although evidence is limited in Western countries, consumption of isoflavones in the amounts consumed in Asian countries is associated with a lower risk of breast and

prostate cancer, and high soy intake may be associated with low mortality rates for breast and prostate cancer in Asian countries.

The current international evidence on food, nutrition and cancer risk will be introduced, as well as the relationship with Japan's unique diet.

SL(T4)3
Dietary strategy for diabetes and sarcopenia in the longevity society

Yutaka Seino[1] , Yuji Yamazaki[1]

1. Kansai Electric Power Hospital (Japan)

In the longevity society, diabetes and sarcopenia have significant impacts on the quality of our elderly life. Dietary therapy is a basic way to maintain our health and to make our health better. In general, a protein, fat, carbohydrate (PFC) balanced meal is recommended for health together with an appropriate total daily calory intake. Dietary therapy is also fundamental for prediabetes, diabetes, and obesity. Accumulated evidence has shown that “how we eat and what we eat” are closely associated with glucose homeostasis, due to various physiological factors such as gastric emptying and incretin effects and so on. Gastric emptying impacts on an intestinal absorption of nutrients, which is associated with postprandial blood glucose excursion in an insulin-independent manner. Nutrients absorption in gut stimulates the secretion of incretins in the intestinal endocrine cells, glucose-dependent Insulinotropic peptide (GIP) and glucagon-like peptide 1 (GLP-1), which enhance insulin secretion from pancreatic beta cells in a glucose dependent manner. Not only their insulinotropic effects, but they also play various roles in gastric emptying, the feeding center in brain, and others. Incretin signaling orchestrates glucose metabolism along with meal ingestions. While carbohydrate is associated with glucose homeostasis, protein intake is relevant for the prevention of sarcopenia, particularly, in the elderly people. A daily change of muscle mass is determined by a net balance of muscle protein synthesis and muscle protein degradation. Muscle protein synthesis is elevated a certain period after meal ingestion. Muscle mass is increased in a period of the time that the rate of muscle protein synthesis exceeds the rate of degradation. The duration of muscle synthesis per day are also incremented by several principles related to “how we eat and what we eat”. Here, I'll discuss about dietary strategy for diabetes and sarcopenia.

SL(T4)4
Nature, Nurture, and Type 2 Diabetes from a Nikkei Perspective

Wilfred Y. Fujimoto[1]

1. University of Washington (USA)

Prior to the 1970's, diabetes prevalence was reported to be very low in Japan. Thus it was commonly believed that diabetes prevalence would also be low in Japanese Americans (Nikkei). However, a 1963 report demonstrated diabetes to be much more prevalent in Japanese Americans than in Caucasians on the island of Oahu in Hawaii. Furthermore, the Ni-Hon-San Study and the Hiroshima University Study pointed out in the 1970's that diabetes prevalence was higher among migrant Japanese populations in Hawaii and the San Francisco Bay area of California than in Japan. Thus the Japanese American Community Diabetes Study was begun in 1983 in Seattle, Washington to examine why this was the case by exploring the etiology and pathogenesis of type 2 diabetes among Japanese Americans who were Nisei (second generation) and Sansei (third generation) descendents of immigrants to the United States from Japan. This epidemiologic investigation was planned as a metabolic, longitudinal, population-based study that assessed lifestyle factors, insulin sensitivity, insulin secretion, and adiposity, including measurements of body fat distribution by anthropometry and computed tomography. An early important contribution from this research was the demonstration that visceral adiposity was a powerful risk factor for type 2 diabetes in Japanese Americans. In addition, among susceptible Japanese Americans lifestyle factors appeared to lead to weight gain, especially in visceral fat depots, that in turn led to decreased insulin sensitivity that in conjunction with reduced β-cell reserve, resulted in hyperglycemia and type 2 diabetes. This process can be retarded by dietary and exercise intervention. The lessons learned from studying migrant Japanese in Seattle may in many ways be applicable to the epidemic of diabetes that has been observed among other populations of Asian origin.

Measures against obesity and metabolic syndrome in Japan: Findings from the specific health checkups and specific health guidance system

Kazuyo Tsushita[1]

1. Kagawa Nutrition University (Japan)

Prolonging healthy life expectancy and preventing disparities in health status are major challenges in Japan. Health checkups and subsequent health guidance have played a key role in combating lifestyle-related diseases.

All health insurers in Japan are mandated to provide Specific Health Checkups and Specific Health Guidance focusing on metabolic syndrome in middle-aged adults, beginning in 2008. People who are abdominal obesity and have more than two metabolic risk factors are eligible for Intensive Health Guidance (HG). This program includes individual counseling or group sessions to give information about how to change lifestyle and set individual goals, with follow-up by e-mail, phone or interviews for six months, with a final evaluation.

We analyzed the examination data of 3,480 participants enrolled in the Intensive HG. Significant weight reduction and concomitant improvements in measurements associated with obesity-related diseases were observed in one year. In the group exhibiting a 1% to <3% weight reduction, TG, LDL-C, HbA1c, AST, ALT and γ-GTP decreased significantly, and HDL-C increased significantly compared to the control group. Significant reductions in SBP, DBP, FPG and UA were observed in the group with a 3% to <5% weight reduction. Based on these findings, setting goal of 3% weight reduction is thought to be feasible and effective.

We compared changes of risk factors and initiation of pharmacological therapy over three years between participants (n=31,790) and non-participants (n=189,726) who were eligible for HG in 2008. Participants in HG showed greater improvements in MetS profiles with proportionally smaller pharmacological treatment initiations than non-participants for three years. In the Intensive HG group, waist circumference, BMI, body weight, BP, TG and HDL-C were significantly improved in comparison to the corresponding control groups. Although selection bias may be present, this study suggests SHG would be a feasible strategy to prevent MetS and its sequelae.

The implementation rate of health guidance was 23.2%; meaning that in 2019 around 1.2 million individuals received SHG out of an eligible population of 5.2 million. The government is introducing incentives for insurers and seeking more efficient implementation methods in order to increase the implementation rate.

Since face-to-face guidance has become difficult due to the COVID-19, the number of cases of health guidance through online interviews and the use of apps is increasing. It has been reported that health guidance using the app makes it easier to understand changes in the subject's behavior and raises motivation. In this lecture, I will introduce new initiatives in Japan.

Ultra-processed foods, diet quality and health: evidence and policy implications

Carlos Augusto Monteiro[1]

1. University of Sao Paulo (Brazil)

All over the world, long-established dietary patterns based on a variety of unprocessed or minimally processed foods and freshly prepared meals made with these foods using processed culinary ingredients and some processed foods, are being displaced by ultra-processed foods (concepts and terminologies according to the Nova food classification system). Meta-analyses of data from large, long-duration, well-conducted cohort studies have shown that displacement of unprocessed or minimally processed foods and freshly prepared meals by ultra-processed foods increases the risk of obesity, diabetes, dyslipidaemias, cardiovascular diseases, stroke, depression, and also of earlier all-cause mortality. Other disorders and diseases prospectively associated with ultra-processed food intake include increased adiposity accumulation from childhood and adolescence to adulthood, hypertension, and gastrointestinal and liver diseases. A randomized controlled cross-over trial has demonstrated that ultra-processed diets cause passive dietary energy overconsumption and huge body fat mass accumulation. Part of these studies also show that the ill-effects of ultra-processed foods do not depend only on the use of high amounts of fat, sugar or salt in their manufacture. Other likely mechanisms are due to ultra-processing itself such as the destruction of the food matrix and the loss of the synergy existing in the original foods between nutrients and other bioactive compounds. Or the presence of harmful substances created by high temperatures and compression or released by synthetic packaging material. Ultra-processing also depends on the use of a myriad of additives whose effects on health, cumulatively and in combination, are unknown. This is why ultra-processed foods reformulated with less salt, sugar or fat remain harmful to health. Official national and international dietary guidelines should all emphasise a great diversity of unprocessed or minimally processed foods, mostly plants, and freshly prepared meals, and clearly state that ultra-processed foods should be avoided. National dietary guidelines already do so in Brazil, in other Latin-American countries, and also in France, Israel, and Malaysia. This is also the orientation of the 2021 American Heart Association Scientific Statement on Dietary Guidance to Improve Cardiovascular Health. Having a great variety of unprocessed or minimally processed foods, balanced across food groups, while restricting highly(ultra-) processed food and drink products is one of the FAO/WHO guiding principles for sustainable healthy diets. The emphasis on unprocessed or minimally processed foods and the avoidance of ultra-processed foods will also have social, cultural, economic and environmental benefits, including the support of local cooperative and family farming, retailing and catering

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

businesses, and protection of authentic food cultures, non-renewable natural resources, and biodiversity. Statutory policies and programs to reduce the consumption of ultra-processed foods should now be put in place, approximating to those used with success to limit smoking and use of tobacco. Policies and programs are also needed to support, protect and encourage the production, distribution and consumption of unprocessed and minimally processed foods, and the preparation and enjoyment of fresh meals at home, schools, workplaces, hospitals, community facilities, and in affordable restaurants.

Health literacy, public policy and nutrition: Making healthy food choices, easy choices

Don Nutbeam[1]

1. University of Sydney (Australia)

Access to timely, accurate and reliable information is a fundamental determinant of health. The internet and digital communications have provided unprecedented access to information about food and nutrition. An overwhelming volume of information on food and nutrition is now accessible to many people, but much of it is presented in a form that is hard to understand, and in some cases, it is deliberately misleading – often designed to advance commercial interests. The challenge for many today is to find trustworthy information that is easy to understand and can be used in a practical way to inform decisions about food choices. In response to this challenge governments in many countries have implemented codes and regulations to help provide consumers with consistent and accurate information. Disappointingly, in most examples these regulations provide information that is difficult to interpret and hard to act on for many consumers. These interventions to improve access to trustworthy information have to be continuously monitored and refined, and need to be matched by improvements in people's skills to obtain, process, and understand health information. These personal skills and capacities are referred to as health literacy. This presentation examines approaches to improving health literacy by both changing the quality and accessibility of information on food choices, and improving individual's skills and capacity to obtain, understand and act on trustworthy information – to make health food choices, easy choices.

Healthy longevity and the nutrition with AI computing technologies

Teruo Miyazawa[1]

1. Tohoku University (Japan)

Currently, various technologies that use AI are being developed in the fields of food and nutritional science. There is great hope that AI can make a significant contribution to the field of food and nutritional science. AI will not only accelerate the efficiency of food production and processing but will also be of great help in developing better food products that include the immunomodulatory function of dietary components, dietary assessments, health claims in immune systems, dietary components that also affect the intestinal microbiota, and safety assessment of foods. Research has also begun to focus on the development of related technologies, such as the "AI Diatrofi", which aims to establish predictive models for the interaction between the simultaneous intake of multi-molecular food products and human health. Such studies have only recently begun to be conducted. Continued research is required to obtain reliable information in the future. The fields of food and nutritional science, food analytical methods, and AI will continue to complement each other. This is not limited to either nutrition or nutritional science, food analytical methods, or AI, but is intended to be of interest to people in both fields and to build a bridge for healthy longevity.

Salt

Feng J He[1]

1. Queen Mary University of London (UK)

There is strong evidence for a causal relationship between salt intake and raised blood pressure which in turn is the leading cause of deaths, responsible for more than 10 million deaths a year worldwide. The World Health Organization has recommended a reduction in salt intake from the current level of ≈10 g/d in most countries to less than 5 g/d. This has been challenged by several cohort studies which suggested a J-shaped relationship between salt intake and cardiovascular disease (CVD). However, these studies have methodological issues, e.g. reverse causality, biased estimations of salt intake. Methodologically robust studies with accurate measurement of salt intake have shown a direct linear association with CVD events and mortality, down to an intake of 3 g/d. Indeed, a

reduction in population salt intake is one of the most cost-effective measures to prevent CVD.

The question now is how to effectively reduce salt intake. In many developed countries, most of the salt in the diet is from processed food, i.e. added by the food industry. A key strategy is to set incrementally lower salt targets for the industry to achieve within a clear timeframe. Such a target-based approach has been shown to be effective in reducing salt levels in foods and leading to a reduction in population salt intake. In many developing countries, most of the salt in the diet is added by the consumers during cooking or in sauces. Public health campaign plays a key role in encouraging individuals to reduce the amount of salt they use. Changing individual's dietary behavior is very difficult, however, new approaches have shown promising results. Studies have shown that schoolchildren could play a key role in helping the family to reduce salt intake. m-Health technology could be used to sustain salt reduction education. Replacing the usual salt with salt substitutes, which are made with reduced sodium and increased potassium, have been shown to lower blood pressure and CVD and total mortality. Every country should develop and implement a coherent, workable strategy to reduce salt intake. Even a modest reduction in population salt intake will have enormous health and economic benefits.

An apple a day to keep the doctor away? Fruit and vegetable consumption and links with chronic disease

Nita G. Forouhi[1]

1. University of Cambridge (UK)

The massive global burden of non-communicable chronic diseases such as cardiovascular disease, type 2 diabetes and cancer poses a serious crisis for which urgent solutions are needed. Diet and nutrition are critical to this goal.

As part of this strategy, the public health recommendation of “five-a-day” has been around for decades, promoting the consumption of at least five portions daily of fruits and vegetables for good health and longevity. By now this message is widespread worldwide and has gained even greater prominence because of the increasing interest in plant-based diets for human health and planetary sustainability.

This session will examine dietary guidelines on fruit and vegetable promotion, where are we with achieving the public health goal, what the barriers and facilitators are, and consider how quantity and variety of dietary intakes are relevant for human health but how it has been challenging to study this link. As well, we will examine the wider influences on fruit and vegetable consumption including the impact of the COVID-19 pandemic.

We will also consider how the use of nutritional biomarkers and new ‘omics technologies are offering the objective assessment of fruit and vegetable consumption with greater precision to overcome the limitations of subjective assessment using dietary self-report and how this can help with the potential for personalised nutrition.

SL(T6)3
Improving nutrition in Japan and its factors

Teiji Nakamura[1]

1. Kanagawa University of Human Services (Japan)

The traditional Japanese diet is being considered healthy by people around the world. However, this is not necessarily true. Around 150 years ago, the diet of most Japanese people was simple and suffered from many nutritional deficiencies. Meiji government introduced nutrition science from Europe to make the nation wealthy and strong. Around the end of World War II, the country was burnt to the ground and there was severe hunger with no food and no money.

In 1945, the year the war ended, Japanese dietitians were created by national license and in 1952 the “Nutrition Improvement Law” enacted and full-scale nutritional improvement began as a national policy. A distinctive feature of Japan's nutritional improvement is that nutrition policy have been drawn up based on scientific evidence, and dietitians who serve as practical leaders, have been placed as professionals in group feeding facilities such as infant hospitals, kindergartens, schools, hospitals, welfare and other facilities.

In other words, based on the principle of Universal Health Coverage (UHC), a system of improved nutrition have been created for the entire life course of the population, creating a society where no one is left behind and everyone has access to healthy diets and nutrition education. In traditional Japanese diets of low nutrition, and Western diets of over-nutrition is reasonably mixed, and then healthy Japanese diets that balanced nutrition has been formed. Comprehensive nutritional improvement based on adequate supply and distribution of food, as well as nutrition education have been effective not only in preventing post-war undernutrition, but also non-communicable diseases caused by over-nutrition after economic development.

While food and economic assistance can be effective in providing nutritional support in emergencies caused by war and hunger, these alone can make it difficult to improve nutrition once international assistance ends, leaving people suffering from the double burden of malnutrition, where obesity and undernutrition coexist. The Japanese experience of building a healthy and long-lived nation, starting from post-war hunger and building a society where all people have access to healthy food and nutrition through aggressive nutritional improvements, is collectively known as “Japan nutrition”.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

In recent years, it has become clear that nutrition is not only related to health, but also to education, labor, the economy, gender and the environment, and that improved nutrition is fundamental to achieving the SDGs. We want to make use of this "Japan nutrition" to make an international contribution to developing countries in Asia, Africa and elsewhere by promoting practical nutrition research, training people in nutrition improvement, and supporting the establishment and development of nutrition policy and dietitian systems.

Improving access to healthy local and traditional foods within First Nations communities in Canada

Rhona M. Hanning[1], Louise W. McEachern[1], Ashleigh Domingo[1], Renata F. Valaitis[1], Barbara Zupko[1], Jennifer Yessis[1]

1. University of Waterloo (Canada)

Introduction: Ongoing impacts of colonization and Indian residential schools have contributed to the higher prevalence of food insecurity and chronic disease within First Nations communities in Canada relative to the general population. However, Indigenous communities are increasingly reclaiming local and traditional foods and food skills to improve food security and advance food sovereignty and holistic health. Learning Circles: Local Healthy Food to School (LC:LHF2S) used Learning Circles (LC), a community capacity-building model, to bring together diverse stakeholders (including Indigenous knowledge keepers, community members, hunters, gatherers, farmers, food producers, teachers, school administrators, students and parents) to participate in an iterative cycle of planning, prioritizing, implementing and assessing actions to support their local school community food system. Building on initial experience in Haida Gwaii, BC, the model was also evaluated across three First Nations school communities in the provinces of BC, Saskatchewan and Manitoba that varied in context, including governance, geography, size and food systems. An LC facilitator was hired in each community to oversee and support food activities and evaluation.

Objectives: The objectives of the evaluation across 2016-2019 were to 1) document local food system actions, 2) examine the LC model of food system capacity building as scaled up across diverse contexts, and 3) document perceptions of annual cross-community project team gatherings as an integrated knowledge mobilization approach.

Methods: This community-based participatory action research used Indigenous and Western methods to gather and thematically analyze data from documents (community reports, tracking sheets), conversational interviews (n=52) and open-ended responses on two student surveys (n=171). The process of scale-up was guided by Foster-Fishman and Watson's ABLe Change Framework (2012).

Results: Food systems action was evident in each context and included development of local and traditional food pantries, school gardens, school nutrition programs and land-based learning from Indigenous knowledge keepers. Initiatives ranged from "quick wins", like a healthy community feast to raise funds for school food projects, to improving infrastructure to support local and traditional food access. Across communities, the LC facilitated a process to: 1) identify and build on strengths to increase capacity to reclaim traditional and local food systems; 2) strengthen connections to land, and traditional ways of knowing and doing; 3) foster relationships, community-level action and multi-sector collaboration; and 4) improve access to and perceived value of local healthy and traditional foods in school communities. Local champions supported community readiness for food-related action and Spirit of Collaboration research protocols helped decolonize research processes. Annual gatherings of community members, partners and research team facilitated relationship building, knowledge sharing and cross-community support of food project and evaluation processes.

Conclusion: The LC model helped to engage and empower community members across diverse First Nations contexts to drive actions to enhance local and traditional food access and food skills among youth. Ultimately, the actions advance food sovereignty and holistic wellness for Indigenous communities. Respectful, reciprocal partnerships between community members, researchers and partners contributed to a process of learning and action towards reconciliation and decolonization.

Biochemical mechanisms of the health benefits of curcumin

Claus Schneider [1]

1. Vanderbilt University (USA)

Curcumin, prepared as an extract from the rhizome of the turmeric plant, is one of the most widely consumed dietary supplements. Curcumin is best known for its anti-inflammatory effects, with frequent use of curcumin dietary supplements by consumers seeking relief for arthritis, pain, and other persistent inflammatory conditions. The ever increasing popularity of curcumin as a treatment for inflammatory conditions by the general public has, for a long time, lacked support by evidence from well-designed and executed clinical trials. Our interest has

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

been to elucidate the chemical and molecular mechanisms of how curcumin exerts biological activity, using its anti-inflammatory activity as example. Curcumin is unstable in aqueous solution at physiological pH, resulting in rapid degradation. We have identified the degradation products and their mechanism of formation and characterized the overall degradation reaction as an autoxidation. Autoxidation is initiated by hydrogen abstraction from the phenolic hydroxyl and proceeds via radical-driven cyclization reactions and the incorporation of molecular oxygen to yield a final bicyclopentadione derivative of curcumin. Among the intermediates in the degradation reaction are unstable and reactive electrophiles featuring quinone methide and epoxide moieties. We hypothesized that the electrophiles may exert biological effects via protein adduction at redox-active cysteine residues of curcumin target proteins. We characterized binding of electrophilic curcumin degradation products to a cysteine residue of IkB kinase b (IKKb), the kinase that activates NF-kB, a transcription factor involved in inflammation and cancer. The final and stable product of curcumin (bicyclopentadione) did not inhibit NF-kB, and the activity of synthetic curcumin analogues correlated with their chemical stability. The chemically more unstable analogues that more readily underwent autoxidation to electrophilic products were also more potent inhibitors of NF-kB. This supported the hypothesis that curcumin serves as a pro-drug and that its anti-inflammatory effects on NF-kB are mediated by its electrophilic degradation products. This was further confirmed upon analysis of covalent binding of the degradation products to a peptide containing the target cysteine within the redox-regulatory domain of IKKb. Our studies identified curcumin as a pro-drug requiring activation by metabolic oxidation in order to exert anti-inflammatory effects. Insufficient activation of curcumin in vivo may be contributing to a lack of showing clear therapeutic benefits in human clinical trials.

Keyword: turmeric, pro-drug, metabolic activation, electrophile, protein adduction

SL(T7)2
Food Bioactive Peptides -Past, Today and Future Perspective.

Yoshinori Mine[1]

1. University of Guelph (Canada)

Nowadays, food is recognized as a source of dietary substances and biologically active compounds that improve human health beyond traditional nutrient's source. In recent years, numerous reports have been published describing bioactive peptides/hydrolysates produced from various food sources. Bioactive peptides generated from food proteins have great potential as functional foods and nutraceuticals. These peptides are inactive within the sequence of parent protein and can be released during gastrointestinal digestion or food processing. The production of food-derived bioactive peptides is mainly through the hydrolysis of digestive enzymes and proteolytic enzymes or microbial fermentation. Most bioactive peptides range between two (dipeptides) and 20 amino acid residues and have a molecular mass of 0.4–2 kDa. Depending on the amino acid sequence, bioactive peptides possess several significant functions, such as antioxidative, anti-inflammatory, anticancer, antimicrobial, immunomodulatory, and antihypertensive effects in the living body. We highlight the history of food derived bioactive peptide research (plant and animal), extraction of bioactive peptides, bioassay of bioactive peptides, peptides analytical tools, bio accessibility and bioavailability testing in ex-vivo and in vivo, and clinical aspect of these peptides. We also introduce the application of bioactive peptides in functional food development, pharmaceutical and cosmetic industry as well as challenges, and prospects of food-derived bioactive peptides.

SL(T7)3
Food function on disease

Takeshi Nikawa[1]

1. Tokushima University Graduate School (Japan)

Nowadays, humankind is entering the Age of Discovery in the 21st century. The space environment causes various physical changes. One of the changes is muscle atrophy (sarcopenia). We aim to elucidate the mechanism of this weightless muscle atrophy and devise a nutritional treatment for it. Previous studies have shown that ubiquitin ligase Cbl-b, of which expression is increased by microgravity, induced IRS-1 ubiquitination and degradation, resulting in impaired IGF-1 signal and muscular atrophy. However, it remains unclear how cells sense weightless stress and enhance Cbl-b expression. Therefore, to clarify the mechanism of gravity sensing by these cells, we conducted “Myolab” and “Cell Mechanosensing” space experiments, and 3D-Clinorotation, which is a simulated microgravity culture device on the ground. First, in the Myolab space experiment, we performed metabolome analysis of space samples cultured under microgravity conditions for a week. Then we found that microgravity accumulated oxidative stress in cells and changed the expression of proteins localized in mitochondria related to energy metabolism. It was also found that the oxidative stress regulates the expression of ubiquitin ligase Cbl-b via Egr1 / 2 and ERK1 / 2 pathways. Thus, we considered ubiquitin ligase Cbl-b and oxidative stress as targets for functional foods that can prevent muscle atrophy due to weightlessness.

1) Soy protein (anti-ubiquitinating effect): We discovered a DG (p) YMP peptide (named Cblin peptide) that has an inhibitory activity on the binding of IRS-1, which is the target molecule of ubiquitin ligase Cbl-b. Furthermore, it was found that the soy protein glycinin has a similar sequence. These suppressed the ubiquitination of IRS-1 by Cbl-b and increased muscle mass in *in vitro* and *in vivo* experiments. In addition, the soy protein-added

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

diet was also effective in suppressing muscle weakness in bedridden patients.

2) **Polyphenol (antioxidant effect**): Polyphenols are attracting attention as a dietary ingredient that can reduce antioxidant stress. Antioxidant nutrients such as soy isoflavone and quercetin have been shown to suppress muscular atrophy due to tail suspension.

Because of the usefulness of these functional ingredients of soybeans for such muscle atrophy, we are advocating the construction of a plant factory that can make soybeans self-sufficient in the space environment.

Keyword: oxidative stress, ubiquitin ligase, anti-oxidative nutrients, soy protein, muscle atrophy

SL(T7)4
Branched-chain amino acids as functional foods.

Yoshiharu Shimomura[1]

1. Chubu University (Japan)

Branched-chain amino acids (BCAAs: leucine, isoleucine, and valine) are indispensable amino acids for mammals, and the catabolic system for BCAAs is equipped in mammalian cells to dispose of excess BCAAs. The main BCAA catabolic pathway is localized in the mitochondria of almost all tissues. The first 2 steps of the catabolic pathway are common to the three BCAAs. The first step reaction is the transamination of BCAAs to form branched-chain α-keto acids (BCKAs), which is a reversible reaction catalyzed by branched-chain aminotransferase (BCAT). Two isozymes of BCAT have been reported; one is a mitochondrial type (BCATm or BCAT2) that is expressed in all of the peripheral tissues except for liver, and the other one is a cytosolic type (BCATc or BCAT1) that is unique to cerebral tissues, placenta, and ovaries. The second step reaction is the oxidative decarboxylation of BCKAs to form CoA esters, which is catalyzed by BCKA dehydrogenase (BCKDH) complex. Since this reaction is irreversible, it is thought that BCKDH complex is a primary regulator of the BCAA catabolism. Furthermore, BCKDH complex is regulated by covalent modifications: the complex is inactivated by phosphorylation of the complex and reactivated by dephosphorylation. BCKDH kinase (BDK) and BCKDH phosphatase are responsible for these modifications, respectively. These reactions allow the rapid conversion of the activity state of BCKDH complex in response to alterations in the nutritional and physiological conditions of the animals. BDK, compared to BCKDH phosphatase, is tightly bound to the complex and its activity is inversely related with the complex activity, suggesting that BDK is a main regulator of the BCKDH complex. Although the concentrations of free BCAAs in blood and tissues at the postabsorptive state in humans are relatively stable due to the strictly regulated catabolic system described above, the plasma concentrations are rapidly elevated by ingestion of free BCAAs. This elevation of the plasma concentrations of BCAAs (especially leucine) promotes protein synthesis and inhibits protein degradation in tissues. Due to the anabolic effects of BCAAs, a mixture of BCAAs is used as a pharmaceutical for liver cirrhotic patients to increase the plasma albumin concentration. It has been reported that liver cirrhotic patients suffered from frequent muscle clamp and that BCAA supplementation to the patents markedly decreases frequency of the muscle clamp. It has also been demonstrated that BCAA supplementation right before exercise significantly decreases delayed-onset muscle soreness (DOMS), probably due to decreasing muscle damage caused by the exercise and promoting recovery of the muscle after exercise. Recent studies demonstrated that BCAAs are used in the brain tissues to produce glutamate as a neurotransmitter. It was found that mice deficient for BDK significantly reduced the BCAA concentrations in plasma and brain due to the activation of BCKDH complex and showed neurological abnormalities. Subsequently, patients with homozygous BDK mutations were identified and it was found that the patients showed markedly low levels of plasma BCAAs and presented with autism, intellectual disability, and epilepsy. These findings indicate that BCAAs are effective supplements for skeletal muscle and brain.

The benefits of a colourful diet

Cathie Martin[1], Jie Li[1], Ronan Broad[1], Eugenio Butelli[1]

1. John Innes Centre (UK)

The appreciation of the challenges of achieving global food security has matured to include nutritional security, as scientists have realized that not only calorie content but also food composition impact our health and well-being, dramatically. The ways that the nutrients we consume affect our health are highly complex due to the diversity of what we eat, the varying digestibility of what we eat, the changing composition and functioning of each individual's gut microbiota, the differences in absorption and bioavailability of the nutrients we eat, the differences in responses between individuals to what they eat and the multi-fold mechanisms of action that nutrients have on our health. However, one generic conclusion is possible: it has been accepted for more than 50 years that diets rich in plants, particularly fruit and vegetables, protect health. Yet over this same period diets have declined, with lower fruit and vegetable content replaced by more cheap, sugary, oily processed foods. These dietary shifts are having a marked impact on the incidence of chronic diseases; obesity, metabolic diseases, type2 diabetes and cardiovascular diseases. By understanding which nutrients from plants confer greatest benefits and how they protect against specific diseases (a process termed comparative nutrition) we hope to achieve dietary improvements at all levels in society. I hope to illustrate the potential of dietary improvement using plant-based foods to improve our health and

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

quality of life and to reduce the economic burden on our health-care systems.

Keyword: Fruit, Vegetables, Polyphenols, Vitamins

SL(T8)2
Protein and amino acid need in health and disease: new knowledge and discoveries

Rajavel Elango[1]

1. University of British Columbia, BC Children's Hospital (Canada)

Introduction: Dietary protein is a key nutrient which modulates our long-term health. Adequate intake of protein through all stages of life from conception to aging ensures that our body maintains ideal muscle mass, and overall body functions. In humans body proteins are made of 20 amino acids, among which 9 are considered essential to be obtained from diet. Thus, dietary reference intakes (DRI) are provided for protein and the 9 essential amino acids. The most recent recommendations are from the 2005 DRI's and the 2007 Food and Agriculture Organization (FAO)/World Health Organization (WHO) guidelines. However, the recommendations are predominantly based on young adult men, with a factorial determination for other life-stages.

Protein and amino acid requirements: We have embarked on a re-assessment of protein and amino acid requirements using novel stable isotope-based techniques during key life-stages including young children, pregnancy, elderly and in disease. Our new discoveries include estimated average requirements (EAR) for adult men (0.9g/kg), children (1.3g/kg), early pregnancy (1.2 g/kg), late pregnancy (1.5g/kg), elderly 65-80y (0.85-0.96g/kg), malnourished children (1.55g/kg) and children with in-born error of metabolism, Phenylketonuria (1.85g/kg). These values all differ substantially from current recommendations by 30-50% and have implications for the maintenance of 'optimal' health in healthy individuals, and to ensure recovery from disease in patients. We have also made significant discoveries on amino acid requirements, including the finding that key essential amino acids lysine, phenylalanine requirements are higher in late pregnancy compared to early stages, and that glycine, a non-essential amino acid is conditionally-essential in late stages of human pregnancy. In elderly men and women, we showed that the essential amino acid leucine requirements are nearly doubled compared to young adults (80 mg/kg vs 39 mg/kg, respectively). We also showed that supplementing both young and elderly men is safe with a tolerable upper intake level (UL) of 500mg/kg.

Translating protein requirements – Protein Quality: Ultimately our findings from the requirement studies needs to be translated to human diets, and this requires an understanding of the quality of the protein in foods. Protein quality of foods is determined by several factors including the amino acid composition of the foods, digestibility and bioavailability in vivo for protein synthesis. In general plant-based protein are usually limiting in one or more essential amino acid, with lysine being the key limiting amino acid. Using novel stable-isotope based methods we have shown recently that in young men and children, lysine bioavailability varies across cereal grains such as rice, oats and pulses such as chickpeas and lentils. Furthermore, bioavailability is reduced due to heat treatment and food processing. Additional work is ongoing on devising better food-based recommendations to ensure human populations can meet sufficient protein and amino acid needs from diets, with an increased understanding of requirements and protein quality.

Conclusions: Protein and amino acid recommendations in health and disease are underestimated. To ensure that optimal body needs are met revision of current recommendations with an understanding of the bioavailability/protein quality of foods is necessary.

Keyword: protein, amino acids, requirements, pregnancy, elderly

SL(T8)3
New perspectives on the delivery of bioactive compounds through food structure design

Harjinder Singh[1]

1. Massey University (New Zealand)

All foods come from living organisms in which macromolecules, such as proteins and polysaccharides are synthesized, modified and assembled into complex hierarchical structures, such as organelles, cells and tissues. Many of the nutrients and bioactive compounds are contained within these structures, from which they must be liberated and converted into an absorbable form during digestion. It is now realised that the modification of these structures during digestion play a key role in determining the bioaccessibility and rates of absorption of bioactive compounds. Therefore, an understanding of the spatial organisation and interactions of the structure units in natural foods and how they change from raw material harvesting to processing and consumption is paramount. In the manufacture of fabricated foods, the concept of "food structure design" has emerged recently as a way of guiding new product development. This is based on the idea that specific food structures with tailored functionality can be developed through interactions and assembly of food biopolymers and ingredients through mixing, shearing, heating and cooling processes. While considerable research has been undertaken in developing food structures to control the perception of fat, salt and sugar in food products, the role of food structure as a variable in nutrient and bioactive delivery is relatively less understood. Understanding the architecture and structures of foods and how they interact within the physiological environment of the GIT could lead to new foods that provide optimal bio-accessibility and absorption of bioactive compounds. Recent work at our institute has demonstrated the importance of understanding the state and structures of food materials and biopolymer interactions in the environment in the GIT, in particular in the stomach, and the critical role of 'modified' structures on the kinetics of the release

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of nutrients and bioactive compounds from the food matrix (e.g. the rate, extent and type of released nutrients), gastric emptying and subsequent digestion of foods in the small intestine. The use of dynamic *in vitro* digestion in combination with *in-vivo* studies has provided new insights into the structural dynamics of complex food systems and subsequent interactions of food components during the gastrointestinal transit. This presentation will provide an overview of the approaches used for understanding the complex interactions in complex food systems within the environment of the GIT, with examples of recent work from our laboratory on the structural changes in natural and fabricated food systems during the digestion process.

SL(T8)4
Food Safety – Internationally Agreed Framework

Yukiko Yamada[1]

1. International Food Safety Consultant / National Institute of Health Sciences (Japan)

Food safety continues to be an important issue in the world for protecting the health of consumers. Foods are traded internationally and ensuring food safety is also important for facilitating trade. For these two objectives, we need to note one international agreement, the Agreement on the Application of Sanitary and Phytosanitary Measures (SPS Agreement) of the World Trade Organization (WTO), and one international body, the Codex Alimentarius Commission (CAC). The SPS Agreement covers measures for human, animal and plant life and health in relation to international trade. These measures are to be: "based on scientific principles" and "not maintained without sufficient scientific evidence"; based on "international standards, guidelines or recommendations, where they exist"; and "based on an assessment of the risks". For food safety, the SPS Agreement explicitly name the CAC as the international standard setting body. The SPS Agreement states that members of WTO shall play a full part in the CAC for food safety recommendations. The CAC is a joint FAO/WHO intergovernmental organization. Its major purpose is, among others, protecting the health of consumers and ensuring fair practices in the food trade. There are 189 members (including European Union), 243 observer organizations. Its first meeting was held in 1963. Under the CAC, which is supported by the Executive Committee, there are many subsidiary bodies: 10 general subject committees; 12 commodity committees (4 active and 8 adjourned *sine die*; and 6 regional committees. These committees are operated jointly by the Codex Secretariat and respective host countries. The CAC develops standards, codes of practice, guidelines and other recommendations through discussions among its members. For food safety and feed safety, the CAC takes science-based and risk-based approach. Since 1993, the CAC developed the definitions of the terms and working principles for risk analysis for use by itself and its members. The CAC works as risk manager. The Joint FAO/WHO Expert Committee on Food Additives (also on contaminants, natural toxins and veterinary drugs), Joint FAO/WHO Meeting on Pesticide Residues, and Joint FAO/WHO Expert Meetings on Microbiological Risk Assessment act as risk assessors. They are independent from the CAC and participated by individual scientists. The priority of risk assessment by these scientific bodies is determined by the respective Codex committees. Risk analysis concept is used not only in the areas of food safety (pathogenic microorganisms, contaminants and natural toxins, residues of pesticides and veterinary drugs, and food additives) but also in the area of nutrition where both malnutrition and overdose of nutrients may pose health risks. For developing safety standards, there is an absolute need for scientific data, such as occurrence data to which the ALARA principle is applied; and trial data following good practice, etc. The safety of the standards is checked by exposure assessment using the occurrence data/trial data and the model consumption data of related foods.

Policy and financial commitments to nutrition made through the Tokyo Nutrition for Growth Summit 2021 - anatomy of success

Francesco Branca[1]

1. World Health Organization (Switzerland)

Under the umbrella of the UN Decade of Action on Nutrition, In December 2021 the Government of Japan convened the Tokyo Nutrition for Growth Summit. The summit called for policy and financial commitments in three main focus areas: (1) Integrating nutrition into Universal Health Coverage (UHC); (2) Transforming the food system to promote safe, sustainable, and healthy foods to support people and planet; (3) Effectively addressing malnutrition in fragile and conflict affected contexts, supporting resiliency; in addition to promote data and monitoring of nutrition indicators and drive innovation in nutrition financing. The summit was prepared by the Government of Japan through intensive involvement of several stakeholders from the UN, governments, civil society, philanthropies and through the active role of the Scaling Up Nutrition Movement. At the Tokyo Nutrition for Growth Summit, national governments and various stakeholders reaffirmed their commitment to the Decade and to driving greater action on nutrition. Overall, 396 new nutrition commitments were made by a total of 181 stakeholders covering 78 countries across the thematic areas of health (67%), food (63%), resilience (41%), accountability (27%) and financing (27%). This includes 224 commitments to address all forms of malnutrition from 80 government departments/ministries in 66 countries. Donor governments and donor organizations committed new nutrition-specific and nutrition-sensitive financing of about US$ 27 billion to tackle malnutrition. In addition, four governments committed to increase national budget allocations to nutrition. Accountability to nutrition has been strengthened through the Nutrition Accountability Framework, a platform for assessing and tracking the nutrition financing landscape and the Nutrition for Growth commitments provided by the Global Nutrition Report. It is critical these commitments are implemented and lead to intensified action addressing the growing nutrition challenges

Current progress and challenges in sodium reduction in Brazil

Eduardo Nilson[1]

1. Oswaldo Cruz Foundation (Fiocruz) (Brazil)

Brazilians consume approximately double the World Health Organization (WHO) recommended maximum limit for sodium and excessive sodium intake causes over 47 thousand deaths from cardiovascular disease (CVD) in the country. About 40% of Brazilians' dietary sodium comes from industrialized foods, while 55% comes from added table salt, therefore sodium reduction policies in Brazil have incorporated a set of strategies. Current sodium reduction policies include health education campaigns based on the National Dietary Guidelines, especially targeted to the table salt added to foods and meals, food procurement and school meal standards limiting sodium in foods, improvement of nutritional labeling, and food reformulation strategies aimed at voluntarily reducing the sodium content of processed and ultra-processed products. From 2011 to 2017, all food categories have reduced their upper limits of sodium, and most have reduced their average sodium content, from 8 to 34% and these reductions may prevent or postpone approximately 2,900 deaths from CVD over the next 20 years. However, sodium reduction and health outcomes would be increased by implementing stricter mandatory sodium limits, effective front-of-package labeling, and possibly using low sodium table salt at the population level. Brazil's main challenges in sodium reduction are including other strategies to the existing multi-component policies and improving the current strategies, such as using the WHO Global Sodium Benchmarks for setting new targets for industrialized foods and transitioning to mandatory sodium limits in foods, improving communication and social marketing, and implementing effective front of package nutritional labeling for consumers.

United States Population Sodium Reduction: National Strategy, Progress and Surveillance

Douglas Balentine[1]

1. U.S. Food and Drug Administration (United States of America)

Americans consume on average 3,400 milligrams (mg) of sodium per day—nearly 50%more than the 2,300 mg limit recommended by federal guidelines for people 14 years and older. Too much sodium can raise blood pressure, which is a major risk factor for heart disease and stroke. More than 4 in 10 American adults have high blood pressure and that number increases to almost 6 in 10 for non-Hispanic Black adults. Additionally, about one in 10 children (8-12 years) and one in 8 teens (13-17 years) has elevated or high blood pressure. Reducing sodium intake has the potential to prevent hundreds of thousands of premature deaths and illnesses in the coming years. The FDA's goal to reduce sodium intake is consistent with the Dietary Guidelines for Americans, 2020-2025 and the 2019 National Academies of Sciences, Engineering, and Medicine Dietary Reference Intakes Report on Sodium and Potassium. External Link Disclaimer. To gradually reduce sodium across the food supply, the FDA is taking an iterative approach that includes establishing voluntary sodium targets for industry, monitoring and evaluating progress, and engaging with stakeholders. The FDA issued the final guidance with voluntary targets for reducing sodium in commercially processed, packaged and prepared food over the next 2.5 years. The approach supports sodium reduction efforts already made by industry, provides common targets for defining and measuring progress, and provides companies with the flexibility and time to meet these targets. The FDA's approach encourages a level playing field by setting voluntary targets for both processed and restaurant foods. To achieve a significant impact, the FDA is especially encouraging adoption by food manufacturers whose products make up a significant proportion of national sales in one or more categories and restaurant chains that are national and regional in scope. There are 16 overarching categories with individual sodium targets for 163 subcategories of food in recognition that a one-size approach does not fit all. The targets in the final guidance are designed to support decreasing average daily sodium intake by about 12 percent—from approximately 3,400 milligrams (mg) to 3,000 mg. The FDA will monitor the sodium content of the food supply, evaluate progress towards achieving the targets in the final guidance and engage with stakeholders on sodium reduction efforts and the targets. Dietary sodium intake will also be evaluated though the National Health and Examination Survey (NHANES). Preliminary evaluation finds that industry has made progress against the voluntary targets in many categories. Additional surveillance is in progress. The FDA expects to issue revised subsequent targets in the next few years to facilitate a gradual, iterative process to reduce sodium intake.

Methods for estimating the potential dietary and health impact of compliance with WHO global sodium benchmarks- case studies from Australia and India

Kathy Trieu[1]*, Daisy Coyle*[1]*, Emalie Rosewarne*[1]*, Maria Shahid*[1]*, Rain Yamamoto*[2]*, Chizuru Nishida*[2]*, Feng He*[3]*, Rachita Gupta*[4]*, Matti Marklund*[5]*, Jason HY Wu*[1]

1. The George Institute for Global Health, The University of New South Wales (Australia), 2. The World Health Organization (Switzerland), 3. Queen Mary University of London (UK), 4. The World Health Organization Country Office India, (India), 5. Johns Hopkins Bloomberg School of Public Health (United States of America)

Background and objectives: In 2021, the World Health Organization (WHO) set global sodium benchmarks for 58 packaged food categories, to help countries establish sodium reformulation programs for lowering sodium intake and preventing related diseases. The potential health impact of adopting the WHO sodium benchmarks differs in each country, largely due to different dietary intake and food supply. Therefore, having methods to estimate the potential effect of achieving the WHO sodium benchmarks is crucial for informing policy decisions. We describe the methods for estimating the potential reduction in sodium intake, and the number of deaths, new cases of diseases, and disability-adjusted life years (DALYs) that could potentially be averted if the WHO sodium benchmarks were adopted using Australia and India as case studies.

Methods: The reduction in sodium intake after reformulation towards the WHO benchmarks was estimated through five steps and then comparative risk assessment models were used to estimate the associated cardiovascular disease (CVD), chronic kidney disease (CKD) and stomach cancer deaths, incidence, and DALYs averted. First, pre-reformulation sodium intake from each WHO packaged food category was estimated using dietary intake and food composition data. Second, the pre-reformulation average sodium content of each food category was calculated using brand-specific sodium content data for packaged foods and sales weighting where possible. Third, the post-reformulation average sodium content for food categories was calculated with the assumption that targeted products with current sodium levels above the WHO sodium benchmarks were reformulated to the benchmark level, whereas products with sodium levels below the benchmarks remain the same. Fourth, the proportional reduction in sodium content for each food category was calculated by dividing the post-reformulation by the pre-reformulation average sodium content. Fifth, the post-reformulation sodium intake by food category was calculated by multiplying the pre-reformulation sodium intake (step 1) by the proportional reduction in sodium content (step 4) for each food category, and the sum across food categories is the overall sodium intake post-reformulation. The reduction in sodium intake post-reformulation is then used to estimate the effect on blood pressure, CVD, CKD and stomach cancer using data from the Global Burden of Disease and previous studies.

Results: In Australia, about 45% of average sodium intake (1527 mg/day) comes from the packaged foods targeted by the

WHO's sodium benchmarks. Compliance with the WHO's sodium benchmarks could lower average adult sodium intake by 404mg/day (12% of total sodium intake). This could prevent about 1,770 deaths/year (95% uncertainty interval 1,168 to 2,587), corresponding to 3% of all CVD, CKD and stomach cancer deaths in Australia, and prevent some 6,900 (4,603 to 9,513) new cases, and 25,700 (17,655 to 35,796) DALYs/year from CVD, CKD and stomach cancer. The potential health impact in India is to be determined.

Conclusion: Methods for estimating the potential health gains of sodium benchmarks for packaged foods are presented, providing a step-by-step process for countries to follow. In Australia, where packaged foods are a major source of sodium, adopting the WHO's strict and comprehensive sodium benchmarks can have substantial health gains.

SSY2-5

Reducing population salt intake in the WHO South- East Asia Region; Developing regional sodium targets and progress on other actions.

Angela de Silva[1]

1. WHO Regional office for South East Asia (India)

The 11 countries of WHO South-East Asia (WHO SEA) Region are undergoing vast health challenges in terms of noncommunicable diseases (NCDs). Hypertension and cardiovascular diseases (CVDs) account for a large proportion of morbidity and mortality attributed to NCDs.

Dietary salt intake, a key risk factor for hypertension far exceeds WHO recommendations. A modeling exercise across WHO SEA countries reported that doubling the proportion of population currently consuming ≦ 5 g salt/d (30%) will reduce associated CVD mortality by ≧ 4 deaths/100000 population. WHO advocated the implementation of the WHO SHAKE package to progress towards the global goal of 30% reduction in salt/sodium intake by 2025 and is providing technical support to countries for salt/sodium surveillance, labelling and marketing of foods, education to consume less salt and healthy settings. The results are encouraging; all countries have set timebound targets to reduce mean population salt/sodium intake, six countries have implemented national behaviour change campaigns to reduce discretionary salt, and three have implemented front-of-pack labelling with a fourth country finalizing draft regulations. Food procurement in public institutions and settings based actions are also implemented. While discretionary salt dominates, consumption through foods supplied by food manufacturers is increasing. Countries are therefore planning to set sodium benchmarks to encourage industry reformulation of foods to a lower sodium content.

WHO's Global sodium benchmarks are mostly based on data/thresholds from high income countries. No benchmarks were available from WHO SEA to contribute to the global report. While global benchmarks are useful and can be adopted for some foods, the regional/country context, food consumption patterns and the level of salt/sodium in foods will influence country adaptation. An initial scoping identified issues that would be best addressed through adopting the global sodium benchmarks where relevant and setting new regional benchmarks for some food groups. These included varied food consumption patterns, food groups specific to SEA Region, particular foods contributing significantly to salt/sodium intake, foods with very high levels of salt, and food technology concerns of microbial safety and stability considering climactic conditions.

Therefore, country information on dietary habits, salt/sodium content of foods, top food contributors of salt and market availability of products are being utilized to inform development of regional benchmarks, at present in early drafting stage. Six major food categories, aligned to food categories in the WHO SEA Region nutrient profile model to better facilitate regulatory processes are planned, and 46 sub-categories. The benchmarks will be set at the lowest maximum value for each sub-category. Interim benchmarks will be provided for selected foods/sub-categories with very high levels of sodium, to encourage gradual lowering of sodium. Simultaneously, WHO is supporting capacity building on monitoring food reformulation and other regulatory actions to promote healthy diets through an e-learning course. WHO is also offering technical assistance to countries interested in taking initial steps to reformulate products. A digital scorecard to assess and advocate country progress toward the global target of 30% reduction in salt/sodium intake by 2025 is also finalized and will help countries easily visualize their status on salt reduction.

Indigenous Peoples' food systems: How they cover Indigenous Peoples' dietary needs and can help broaden the current food base.

Yon Fernandez de Larrinoa[1]

1. Food and Agriculture Organization of the United Nations (Italy)

The Global-Hub on Indigenous Peoples' Food Systems is a knowledge platform that brings together Indigenous and non-Indigenous experts who co-create knowledge and share evidence on the sustainability and resilience of Indigenous Peoples' food systems. On the occasion of the United Nations Food Systems Summit in 2021, the Global-Hub coordinated the drafting of the collective White/Wiphala paper on Indigenous Peoples' food systems. The paper was accepted by the Scientific Group of the Summit and led to the recognition of Indigenous Peoples' food systems as game-changers. It hence played a fundamental role in the creation of the Coalition on Indigenous Peoples' food systems as major outcome of the Summit.

The White/Wiphala paper highlighted how Indigenous Peoples can make use of several hundred species of edible and nutritious flora and fauna found in their territories. This impressive inter- and intra- specific diversity is the result of centuries of territorial management practices that support the natural capacity of ecosystems to generate food while maintaining biodiversity. Those practices are rooted in their unique knowledge systems, values, language, and cosmogony.

Research carried out by Global-Hub's members have exemplified in several occasions the positive interlinkages between Indigenous Peoples' food systems, territorial management, biodiversity, food and nutrition security, and resilience. These results show in which measure the world has lot to learn from Indigenous Peoples and their sustainable approach to nature and territorial management.

In addition, the nutritional content of Indigenous Peoples' foods can contrast drastically with many other food commodities consumed worldwide. Food composition analysis of identical species can reveal high nutrient ratio within Indigenous foods compared to non-Indigenous foods. Moreover, 3 crops cover more than half of the humanity's energy intake. Indigenous Peoples' foods could hence help broaden the existing narrow food base, as long as free, prior and informed consent and Indigenous Peoples' intellectual property rights are respected.

As Indigenous Peoples can inform the global debate on sustainable food systems and sustainable diets as well as broadening the narrow food base (Opening remarks, Presentation 1), their food systems support their health and well-being (Presentation 2) in the meantime. Indigenous Peoples' knowledge systems ensure the positive interlinkages between sustainable management of the resources, nutrition and food preparation (Presentations 3, 4 and 5). This evidence contribute to the overall learning, preservation and promotion of Indigenous Peoples' food systems in research and policy-making, as well as to the Coalition's work.

Current status and challenges of under- and post-graduate education for registered dietitians in Japan: Toward a better future.

Narumi Nagai[1]

1. University of Hyogo (Japan)

The purpose of this presentation is to introduce the current status and challenges of under- and post-graduate education for registered dietitians (RDs) in Japan.

In Japan, approximately 10,000 people pass the national examination and obtain RD license each year. More than 90% (8,812, in 2021) of those who pass the exam are new graduates of four-year RD training facilities (n=152), many of which are universities (n=144).

One of the characteristics of RDs in Japan is the diversity of workplaces. The common places of employment for new graduates are hospitals (34%), companies (26%), food service companies (13%), long-term care insurance facilities (10%), child (6%) and social welfare facilities (4%), schools (3%), and governments (3%) (March 2022). The reason of such diversity is that Japan's dietitian system began at a time of worsening nutritional conditions at the end of World War II. The government established the status and duties of dietitians in the Dietitians Law and Nutrition Improvement Low, which mandated the assignment of dietitians to specific facilities, such as, schools, hospitals, and welfare facilities.

With the subsequent economic growth and the rapid aging of the population, the purpose of improving nutrition changed from malnutrition to prevention of lifestyle-related diseases, requiring the ability to manage within the health, medical care, welfare, and nursing care systems. In other words, the work of RD s has become more focused on addressing the "human itself", the individual's physical condition and nutritional status.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Therefore, education that fosters comprehensive competence in knowledge, skills, and attitudes to cover the diverse areas of expertise that RDs must fulfill has become a requirement. Revisions to relevant laws, educational content, and the national examination guidelines, as well as the creation of a model core curriculum and a competency model have been developed up to the present.

Regarding post-graduate education, since the RD license is not renewable, education to maintain professional knowledge and practical skills is necessary. In Japan, the Japan Dietetic Association (JDA) is responsible for this role. The JDA provide some educational programs and approve "Authorized RD/ Dietitian" in the8 areas and “Specially Certifies for RD/Dietitian” in the 5 specific fields (specialized health guidance, home-visiting, food allergy, parenteral and enteral nutrition, and certified sports nutrition). Moreover, under the commission of the Ministry of Health, Labour and Welfare, the "Certified Specialist of RD by Specialty Field" program is conducted in collaboration with related academic societies in the 5 fields: cancer, kidney disease, diabetes, dysphagia rehabilitation, and home nutrition management.

There are many issues in RD education. As for under-graduate education, a shorter period of super-vised professional practice has been conducted than those of foreign countries, and the priority of education is tended to be placed on passing the national examination rather than acquisition of higher level of professional knowledge and skills. As for post-graduate education, only Japanese dietitians (approximately 50,000) are eligible for this program, so it is desirable to enhance recurrent education at the university. Finally, with the development of digital transformation and AI technologies, RDs will be required to manage more personalized nutrition care and to create healthy food environments. The RD education may enter a new stage.

SSY4-2

Korean Dietitian Education from the Perspective of the Dietitian Licensing Examination

Kyoungsin Lee[1]

1. Korea Health Personnel Licensing Examination Institute (Korea)

As of December 2021, 167,307 people had been licensed as dietitian in Korea and 42,107 dietitians were working at the various sites. 87% of them were working at food service industry and 13% were working in such areas as education or research on food and nutrition. Korea's Dietitian education began in 1929 by establishing the department of Home-Economics in Ewha Woman's University and teaching a science-based nutrition. In Korea, “Dietitian” was first named to the hospital meal managers in 1950 who had graduated from the department of Home-Economics.

Then the dietitian licensing system was adopted in 1962 when [Food Sanitation Act] was activated. Since 1978, it has been necessary to pass a government-managing licensing exam to obtain a dietitian license. At that time, the Ministry of Health and Welfare organized the exam, and 868 people passed and received dietitian licenses at the first year. Later, since 1998, the dietitian licensing exam has been conducted by Korea Health Personnel Licensing Examination Institute (KHPLEI, hereinafter referred as Kuksiwon). Kuksiwon is the public institution in charge of all licensing exam for healthcare professionals including doctors, nurses, and dietitian etc.

The purpose of the dietitian licensing exam set by Kuksiwon is to evaluate whether they have a job competency as dietitians. The dietitian licensing exam is being conducted as a Paper Based Test consisting of multiple choices questions. The Kuksiwon is trying to secure the validity of the questions and the reliability of the evaluation results. To increase the job relevance with the exam, Kuksiwon leads job analysis of the dietitian and keeps improving the exam subjects based on the results from the research. In addition, Kuksiwon is steadily conducting researches on appropriate evaluation method.

As the healthcare environment changes rapidly, and food and nutrition related information overflows, it gets more difficult to people to find the exact information they need to improve their health and apply to their dietary life. In hence, the roles of dietitians demanded by society are expanding from the traditional role of food service provider to the sophisticated role of customized nutritional information provider. Furthermore, the dietitians should be the ones who teach and lead people how to take care of dietary life themselves, just like personal trainers.

Therefore, In the dietitian education, the direction of this change and society's specific requirements should be accurately grasped and reflected. In licensing exam, it is strongly important to discover and evaluate the effective core job competencies, which are also valid in future.

Keywords: Core Job Competencies, Dietitian Education, Dietitian Licensing Examination

U.S. Food and Nutrition Practice in the Time of Discovery and Disruption

Jasia Steinmetz[1]

1. Society of Nutrition Education and Behavior / University of Wisconsin-Stevens Point (USA)

The food and nutrition profession in the United States, which includes nutritionists, Registered Dietitians and nutrition educators, continues to show strong job growth and opportunities. It is an exciting time to practice within the field of food and nutrition that is seeing new research and technology expand our practice in new areas and yet, there has never been a more challenging time. This is an exciting time of discovery that

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

increasingly integrates new research and innovative technology that is changing our ability to monitor personal health and inform clinical practice. New research in genomics is increasing our ability to provide personalized nutrition that will integrate individualized healthy eating plans and personal genomes. Our increasing knowledge of human microbiomes as moderators of health and the role of chronic inflammation in the etiology of many of chronic diseases such as cardiovascular diseases, diabetes and some cancers reinforce and refine our long-standing recommendations for healthy eating patterns based on a variety of whole foods or minimally processed foods. U.S. health professionals are now recognizing what nutritionists and dietitians have long known-Food is Medicine. Longevity science and system science is challenging our approach to individual physical health independent of mental, emotional and social health or persons independent of families, community and the planet. Our excitement and enthusiasm for new knowledge and understanding of the human health and the role of food and nutrition in maintaining well-being across the lifespan is challenged by the global syndemic of obesity, undernutrition and climate change. Human activity on the planet is dismantling ecosystems with increasing rapidity. The disruptions of the pandemic, wildfires, drought and hurricanes within the U.S. and the concomitant social, economic and physical challenges have disproportionately affected the vulnerable populations. We have yet to address the social determinants of health that divide our nation and impact our practice. Emergency food systems such as food pantries have become permanent and expanding programs in communities, including schools. Overweight and obesity is rising in all age groups and chronic disease is occurring at younger ages. It is our challenge to support the people in our programs, provide the food and nutrition guidance to improve individual lives but also consider that since the 1970s we have created a society of increasingly unhealthy people and have yet to understand this from a system level. Progress has come at a cost and we have yet to unravel the mistaken directions in science or practice that have contributed to our declining longevity, increased chronic disease burden and environmental deterioration. Our profession is uniquely placed at the intersection of the food system and health system and we must discover new approaches in our practice to meet the disruptions.

3D Food Printing Technology in Sustainable Food and Nutrition Security

Mitsutoshi Nakajima[1]

1. University of Tsukuba (Japan)

Presently we have faced with many world-wide difficulties, such as an aging and declining population, extreme natural disasters, and global climate change. These issues should be addressed and resolved by science and technology so that we may bring a better future to our society. Against this background, Council for Science, Technology and Innovation of Japan has recently started the new "Moonshot Research and Development Program" aiming to create disruptive innovations and promoting challenging R&D based on revolutionary concepts that are not simply the extension of existing technologies. To realize "Human Well-being", nine Moonshot goals have been decided in the area of society, environment, and economics. The Bio-oriented Technology Research Advancement Institution has started the Moonshot Agriculture, Forestry and Fisheries Research and Development Program to realize the research and development concept, which was set forth by the Ministry of Agriculture, Forestry and Fisheries, Japan to achieve the Moonshot Goal #5 "Creation of the industry that enables sustainable global food supply by exploiting unused biological resources by 2050" decided by the Council for Science, Technology and Innovation. In order to realize the creation of a sustainable food supply industry on a global scale in 2050, it is essential to utilize food loss so that approximately 10 billion individuals, including an increasing number of 2 billion people, can consume food satisfactorily. We have proposed "Development of Innovative Food Solution for Simultaneous Food Loss Reduction and QoL Improvement". Our project is expected to build an innovative solution system that provides tasty/healthy personal foods suitable for each individual using AI-driven 3D printing system to reduce food loss and improve food QoL at the same time, in which we will produce long-term preservable food cartridges for 3D printers from food loss.

Bridging Nutrition and Food Science

Cheikh Ndiaye[1]

1. IUFoST (Senegal)

There are no disciplines so encompassing in human activities as Nutrition and Food Science and no factor more to human survival than food. What are the properties of food and how best can they be used to serve the needs of the body? These are the factors that characterize Nutrition and Food Science as a Science. Food Science and Nutrition is the Science behind the food we eat. From the effect food has on our behavior and wellbeing, to its new applications in food development, processing, compliance, and food safety. While Food Science focuses on manufacturing, processing and production of food, Nutrition science focuses on the maintenance of good health and wellbeing of populations. As disciplines, Nutrition and Food Science answer questions and solve problems. The questions and problems are diverse in nature and cover the spectrum of issues and are interrelated in making the world feeds itself and tomorrow (Ref. FAO's preamble in its constitution, ICN (1992) and World Food, Food Systems Summits (1996-2021), Millennium and Sustainable Development Goals and other international efforts look to Food Science and Nutrition to provide the solution. Both as may be said to include basic science of chemistry, biochemistry and microbiology just to mention a few. Microbiology of food, is less well known to the average scientist where as Food Science or more precisely the utilization of food materials and the study of the composition of food materials (the different varieties of the same Food based on genomic information) and the reaction of food to processing, cooking, packaging and storage not considered. It integrates the knowledge of the chemical composition; their physical, biological and biochemical behaviour; its interaction of food components with others (water) and their environment; pharmacology and toxicology of food materials, additives, and contaminants and the effects of manufacturing operations, processes and storage conditions. Limiting Food Science to utilization of food products alone, would be restricting its usefulness; ideally, it should serve as a support to Nutrition at its early stage. Over the past decades, the identification of vitamins and other essential nutrients and the development of appropriate Food Science and Technology, led to the fortification and thus to the modification of food to better suit and fulfill specific needs through the development and production of new nutritious foods to improve the diets of people and specific groups and to the abundance of high density, cheap calorie sources, coupled with market competition that has also facilitated overconsumption and promoted diseases of affluence such as obesity. Also, as a result, nutritional deficiencies have been drastically reduced or even eradicated. By also, carefully studying the chemical complexities of foods, their vulnerability to spoilage, their disease vectors, and varying sources of production. Food Scientists endeavor to accomplish this formidable task. To solution some nutritional deficiencies Food Science and Nutrition produced protein rich food , enriched low proteins food, guaranteed adequate sanitation and hygiene , and in addition, ensured fair trade, availability of essentials foods at all times and all seasons, increased revenue to the producer and development of food manufacturing industries to utilize local raw materials and establishment of food industries in rural areas and production centers for raw materials. The above points are extremely pertinent to show that the gap between Nutrition and Food Science can be bridged.

Role of Tradition & Food for Better Health

Pingfan Rao[1]*, Guo Jingke*

1. CIFST (China)

A couple of tests were carried out to reveal the uncertain but critical role of food's antioxidant activity in metabolism regulation. Fasting test was conducted on human subjects for 5 days, in which each subject was provided with 200 ml water daily without any food. Meanwhile, TAT-SOD, an intracellular superoxide neutralizing enzyme was topically applied to 4 acupoints around the stomach and two acupoints above the ankles of the subject with daily change. The serum glucose content and muscle glycogen content were determined twice a day. As a result, the muscle glycogen steadily decreased while the serum glucose content remained around 6 mM, indicating that utilization of glycogen could possibly regulated by superoxide content which was decreased through the topical application of TAT-SOD at acupoints. To confirm the association between the superoxide level with glucose metabolism, a fasting as carried out on mice, Mice were divided into water and TAT-SOD groups and fed with only water and 3000u TAT-SOD/ml solution, respectively, Ten mice in the water group all died and the body weight decreased from 12 g to 4 g each, while mice in TAT-SOD group survived two more days with a body weight of 8 g at death, The enormous regulating power of quantitatively insignificant TAT-SOD enzyme indicates that antioxidant activity of food is obviously an important mechanism how food directly regulates body. Delivery of the antioxidant activity either by topical application at acupoints or alimentary intake through drink all demonstrated significant impacts, Whether antioxidant activity should be the most important attribute of food in addition to nutrients and energy may take years or decades to establish, but it must have been the hidden principles behind countless traditional wisdoms and practices of utilizing food to maintain health and wellness considering the striking regulating power revealed in our simple tests. Elucidation of how antioxidant activity in traditional food, herbs, fermented food regulate body metabolism will eventually make the dream come true that food is your medicine.

Interfacing the Science of Food, Nutritionals, and Nutraceuticals for delivering Safe and Sustainable Healthy Food Products to the consumer

Vish Prakash[1]

1. IUFoST / IUNS (India)

Understanding the role of nutrition, nutraceuticals, and supplements in the context of Innovations in Food Science for a healthy diet is emerging fast. precision nutrition and a healthy lifestyle are becoming important, especially with exciting developments that have happened in the last decade where nutrition scientists and food scientists have joined hands to put in the market, products that the consumer needs for a healthy diet and healthy lifestyle. It is important to note the emergence of nutrigenomics with a deep understanding of traditional foods for better health emphasizing the concept of holistic nutrition. This is further enhanced in its approach of using the basic chemistry of Nutritionals and nutraceuticals which helps in expanding the combinatorial chemistry knowledge at the molecular level coupled with traditional wisdom and practice. It is this functional aspect that will be focused in the talk citing epidemiological evidence and webbing the science-based knowledge to provide safe and nutritious food. Such foods when enriched with needed nutrients and nutraceuticals to manage food-based nutrition and health occupy an important position in the daily diet of course need to be affordable. The scope of Nutritionals and nutraceuticals on the platform of Food Science and Technology as an integrated system is important to understand. The fundamental role of bioactive molecules and their functional attributes in the realm of functional foods cannot be undermined either. The current scientific data encourages one to look at the cross-functionality and core functionality of foods with a focus on ingredients, combinatorial chemistry, and understanding the bioavailability of the desired molecules in the context of the gut microbiome. For futuristic thinking of healthy diets and personalized nutrition, a flexible approach of understanding local problems paving way for nutritional maladies can be achieved with nutritionists working closely with food scientists and vice versa for a science-based and evidence-based knowledge networking with local solutions for global problems.

Combating Obesity in Emerging Economies: Malaysian Perspective

Mohd Ismail Noor[1]

1. Universiti Kebangsaan Malaysia (Malaysia)

Malaysia's sustained economic growth and political stability over the last five decades has brought about rapid demographic and nutrition transition which has inevitably generated marked changes in dietary habits and life styles of Malaysian. The “fat - sugar laden” local dishes and the “westernization” of global eating habits, made possible through food imports, fast foods and 24 hours food outlets has led to a rising consumption of fats and sugars coupled with, sedentary lifestyle are largely responsible for the rising epidemic of obesity and associated diseases. The epidemiology of obesity based on population estimates of BMI is very disturbing judging from the rapid increase in prevalence of overweight and obesity in both adults and children. The National Health and Morbidity Survey (NHMS) in Malaysia reported that the overall national prevalence of overweight and obesity in adults was 44.5%, 47.7% and 50.1% in 2011, 2015 and 2019, respectively. The NHMS (2019) reported 14.8% of children 5 to 17 years of age are obese, an increase from 2011 (6.1%) and 11.9% in the 2015 survey in children below 18 years old. It is also becoming more apparent that the traditional approach appears to have failed in producing the desired effect judging from the increasing trend in prevalence of obesity within the last decades. With modest weight gain, Malaysians are known to be susceptible to enhanced co-morbidities. An EIU study (2017) reported total cost of obesity estimated to be between 10% and 19% of national healthcare spending. Preventive strategies both short and long term has been developed within the national action plan that requires commitment by all stakeholders. Unless we could make policy makers, professionals, private sectors and the population at large understand the threat obesity poses and the urgency to implement possible solutions now, the natural course would be an obesity epidemic that will continue to grow beyond our control in the coming decades. This paper will highlight the prevalence and trends, issues related to the problem, efforts made to curb them and the current challenges that we faced in Malaysia.

Inflammation, Immunity and Cardiometabolic Syndrome

Vijaya Juturu[1]

1. EcoNugenics (USA)

Cardiometabolic Syndrome (CMS) remains one of the leading causes of morbidity and mortality in Western and other countries. Recent evidence shows that dysregulation of the immune system and inflammatory pathways play a pivotal role in CMS. Oxidative stress can damage practically all larger biomolecules in the cell, such as membrane lipids, proteins, and DNA. This will cause pathologically relevant oxidative stress and serious metabolic dysfunctions such as lipid peroxidation and arteriosclerosis. Immunity-related cell types and cytokines may contribute to different physiological and pathological responses in maintaining metabolic homeostasis and the healing process. Innate and adaptive immune responses mediate neuroendocrine disturbance and vascular inflammation leading to CMS. Phytonutrients known to affect immunity and infection risk, anti-inflammatory, and antioxidant capacity nutrients particularly relevant to cardiometabolic syndrome will be discussed. More research in this emerging area is warranted.

Biofortification: Future Challenges for a Newly Emerging Technology

Howarth Bouis[1]

1. HarvestPlus (Philippines)

In October 2002, the donors to the Consultative Group on International Agricultural Research (CGIAR) approved funding for the "Biofortification Challenge Program," later renamed HarvestPlus. In the early years, there was a great deal of skepticism in the nutrition and agricultural communities that biofortification would work. Twenty years later, what challenges lie ahead? Global agricultural strategies take far longer than two decades to implement. Initial crop development before the first biofortified crop releases took 8-10 years. Because of the nature of exponential growth of adoption of new crop varieties, most impact is realized on the back-end of investments. Indeed, although agricultural strategies are low cost and highly sustainable over the long-term, policymakers and donors often take a short-term perspective. HarvestPlus was the first, and remains the only, initiative to implement biofortification across several staple food crops on a global scale. From the start, biofortification focused on iron, zinc, and provitamin A—three nutrients critical to health and development, yet among those most lacking in diets globally. More than 400 high-yielding biofortified crop varieties have been released in forty countries and are in testing for release in over twenty more. The challenge is now to expand uptake in these countries to the hundreds of millions of consumers. For example, a zinc wheat variety released in Pakistan in 2019 (named Akbar-19) is poised to become the latest mega-variety, accounting for approximately 50% of wheat production in the country. In the current crop year, Akbar-19 accounts for nearly 50% of all certified wheat seed production. Its popularity derives from high yield, tolerance to heat, and resistance to constantly evolving plant viruses. For the average consumer with a daily wheat intake of 300 grams, substituting Akbar 19 one-for-one for non-biofortified wheat provides about 4 milligrams of additional zinc a day to diets—at no extra cost to consumers and no extra public investment. Although benefit-cost ratios are quite high, adding single nutrients to specific crops only scratches the surface of the full potential of biofortification. Food staples provide a high percentage of a wide range of minerals, vitamins, and other nutrients in the diets of the poor. Multiplying the food staple amount times a relatively low nutrient density, gives significant absolute levels of intake. Advanced agricultural crop development techniques offer the possibility of simultaneously adding multiple climate-smart and nutrition-smart characteristics to future food staple crops produced and consumed in low- and middle-income countries. There is now substantial evidence establishing nutritional efficacy and improvement in functional outcomes for all three nutrients in biofortified foods. In selected countries, there has been significant adoption and consumption of biofortified crops, demonstrating "proof of concept" that biofortification works. Biofortification has become a recognized strategy, among several others, that policymakers may apply to address hidden hunger. It is essential at this critical juncture of expanding impact that public and private agricultural research entities continue to develop an expanding pipeline of ever-more-dense and high-yielding biofortified crops, and for public and other agencies to expand promotion of uptake of biofortified crops.

Food and Beverage Marketing to Children: An Overview of the Landscape

Emma Boyland[1]

1. University of Liverpool (UK)

The marketing of unhealthy foods and non-alcoholic beverages (hereafter: food) has been strongly implicated in the rising levels of childhood obesity worldwide. Contemporary syntheses of research evidence show that unhealthy food marketing remains highly prevalent globally, particularly across media and settings of interest to young people (including television, digital media,

packaging, and outdoors), and predominantly promotes foods that contribute to unhealthy diets (such as fast food and sugar-sweetened beverages). This marketing has considerable persuasive power, using a range of creative strategies likely to appeal to, and resonate with, young audiences including celebrity endorsements, promotional characters, branding, and dynamic animations. There is considerable evidence that exposure to powerful food marketing messages affects the behavioural antecedents (norms, beliefs, attitudes) that underpin children's and adolescents' food behaviours. For example, positive associations have been found between young people's exposure to unhealthy food marketing and their descriptive norms about these foods. There is also robust evidence that young people's actual food behaviours are impacted by unhealthy food marketing. Specifically, this marketing is associated with increased intake, choice, preference and purchase requests in children and adolescents. However, there is a lack of research on impacts of food marketing on downstream health outcomes such as dental health and body weight. Given this evidence of impact, and with diet-related non-communicable disease risk and obesity prevention in children being public health priorities in many countries globally, best-practice recommendations have been issued by the World Health Organization (WHO) and other authoritative bodies for the restriction of unhealthy food marketing to children. Implementation of WHO recommendations has been inconsistent with a lack of comprehensive approaches, but some countries have enacted mandatory policies and some food industry groups have established self-regulatory programs that refer to encouraging more “responsible advertising”. An evaluation of these policies indicates that they can effectively reduce unhealthy food marketing exposure, power, and marketing spend, and may result in reduced purchases of unhealthy foods by, or on behalf of, children and adolescents. Few studies have explored the impact of policies on outcomes such as dietary intake or product change (e.g., reformulation). Policies including certain design elements, such as mandatory implementation and the use of a nutrient profile model, were more likely to be evaluated as effective. Children and young people are considered particularly vulnerable to food marketing messages by virtue of their cognitive and developmental immaturity that means they are less likely to recognise marketing messages or their selling and persuasive intent. Unhealthy food marketing is also said to affect numerous child rights enshrined within the UN Convention on the Rights of the Child including the right to the enjoyment of the highest attainable standard of health, the right to adequate food, and the right to privacy. Effective regulation of children's exposure to this marketing and its persuasive power is a key public health challenge to which States must rise.

WHO guideline to protect children from the harmful impact of food marketing

Katrin Engelhardt[1]

1. World Health Organization (Switzerland)

In accordance with the Organization-wide transformation in strengthening WHO's role in developing evidence-informed public health guidance, the Department of Nutrition and Food Safety (NFS) has strengthened its role and leadership in providing evidence-informed policy and programme guidance to Member States for promoting healthy diets and nutrition throughout the lifecourse, in partnership with relevant internal departments and partners, and guided by the new WHO guideline development process. To implement the strengthening of evidence-informed nutrition guidance, NFS established the WHO Nutrition Guidance Expert Advisory Group (NUGAG), its members representing all WHO Regions. To provide evidence-informed WHO guidance on effective policy measures to support Member States in developing an enabling food environment to promote healthy diets and nutrition, NFS established the ***WHO Nutrition Guidance Expert Advisory Group (NUGAG) Subgroup on Policy Actions*** in 2018. Since the Subgroup was established, it has worked on food environment policy guidelines related to school food and nutrition policies, fiscal policies to promote healthy diets, policies to protect children from the harmful impact of food marketing and nutrition labelling policies, and work on menu labelling policies is being initiated. This presentation will be on the WHO guideline on policies to protect children from the harmful impact of food marketing, which provides recommendations on measures to restrict food marketing to which children are exposed, including on policy design elements to improve the measures' effectiveness. Since the WHO Set of Recommendations on Marketing of Foods and Nonalcoholic Beverages to Children were endorsed at the Sixty-third World Health Assembly in 2010, the evidence base on the extent, nature and impact of food marketing on children has grown, with increasing recognition given to food marketing as a children's right concern. Despite numerous subsequent calls for action and the growing evidence on the harmful impact of food marketing on children, little progress has been made to protect all children. In response to Member State requests, and to strengthen and streamline support for Member States in developing and implementing new, or strengthening existing, policies to protect children from the harmful impact of food marketing, WHO began the process of developing this guideline. This presentation will provide information about the guideline development process and the guideline's content.

New Developments in Food and Beverage Marketing to Children: Upcoming issue – digital marketing

Kremlin Wickramasinghe[1], Olga Zhiteneva[2]

1. World Health Organization (Denmark), 2. World Health Organization (Switzerland)

Children are a vulnerable population group and need special protection from environments that harm their physical or mental health. A healthy diet and adequate nutrition is important throughout the life course, starting even before birth with the mother's nutrition of a child. Very early on in life children are exposed to various kinds of marketing including the marketing of unhealthy products which can influence their perception, preferences and choices. Marketing techniques become more personalized and technical making them even more effective and persuasive. The WHO set of recommendations point out the need to address cross boarder marketing within the region. Other concerning and rather emerging concerns are the promotion of brands rather than products. In the context of HFSS marketing, this means that nutrient profile models cannot be used anymore to objectively differentiate between products permitted and the ones that are prohibited to be marketed to children. Also new social media platforms, streaming services and games which include marketing have to be considered in new interventions.

The WHO European Office for the Prevention and Control of NCDs is working on three main workstreams to support Member States with the implementation of effective measures protecting children from harmful advertisement. Mapping of national contexts, the understanding of marketing ecosystem, main stakeholders and existing marketing related regulations is an important step to build a baseline which can lead to a successful implementation of interventions.

The monitoring of traditional and digital marketing is not only for countries with existing regulations essential to evaluate the effectiveness of the legislation but also for countries who have no legal framework in place yet to protect children from harmful marketing. The monitoring data can raise awareness, show the need for regulation and highlights the media platforms where children are exposed the most. The WHO CLICK monitoring framework was developed by the NCD office in 2018 and was piloted by Member States. The pilot studies were focusing on the monitoring of unhealthy foods and drinks (HFSS products). The framework will be used for the monitoring of tobacco, alcohol and other unhealthy products to children and is also adapted for BMS marketing for early mothers.

The WHO NCD Office developed an application which can capture all forms of marketing by taking screenshots of pre-defined apps. An artificial intelligence tool supports the evaluation of the collected data. The new tools are currently piloted and validated. Only very few countries have already implemented strong legislations restricting marketing of unhealthy products to children. It is essential to learn from their experiences through regular meetings and support other countries with the development strong legal frameworks. It is important to understand how marketing restrictions can be implemented in existing laws or how a new law can be built.

Keywords: Marketing, digital marketing, CLICK, marketing monitoring, unhealthy foods and beverages marketing

SSY7-4

New development – the Nutrient and Promotion Profile Model (NPPM) background

Holly Rippin[1]

1. World Health Organization (Denmark)

Globally, countries continue to struggle with high rates of childhood obesity. There is overwhelming evidence that the marketing of foods and beverages high in saturated fat, trans fat, free sugars or salt influences a child's food preferences. Increasing consumption of these promoted products high in saturated fat, trans fat, free sugars or salt, is associated with increased risk of overweight, obesity and diet-related noncommunicable diseases (NCD). Overweight and obesity in childhood can profoundly affect children's health, with negative consequences for physical, mental and social well-being. Childhood obesity is also a risk factor for developing NCDs later in life, many of which are preventable. Marketing of unhealthy products is linked to children's food preferences, requests, purchases and eating behaviours, and therefore to childhood obesity. The World Health Organization (WHO) has developed a guideline on policies to protect children from the harmful impact of food marketing. This provides recommendations on measures to restrict food marketing to which children are exposed, including on policy design elements to improve the measures' effectiveness. The WHO Regional Office for Europe has been spearheading work on regulating children's exposure to digital marketing. Realizing the need for monitoring across countries to gain credible data, the WHO Regional Office for Europe has developed the CLICK monitoring framework, which is comprehensive, flexible, and is being used by several Member States. From the start of a child's weaning journey, many commercial food products for infants and young children are inappropriate, exposing this vulnerable group to foods that disregard public health recommendations. Concerns with commercially produced foods for infants and young children are seldom tackled by legislation and include: i) high total sugars contents with large amounts of free sugars increasing their sweetness; ii) marketing from 4 months of age, despite WHO guidance to exclusively breastfeed to 6 months; iii) pervasive use of nutrient, health and marketing claims. WHO have also developed a Nutrient & Promotion Profile Model (NPPM) with an accompanying toolkit and online platform for restricting the marketing of inappropriate foods for infants and children aged under 3 years. The NPPM aims to support countries in identifying inappropriate foods for infants and young children, engage with stakeholders to raise awareness, and effect policy and legislative change to support optimum nutrition and reduce NCD risks in later life. The NPPM and toolkit will help build capacity in

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

countries to enable them to ensure products align with health and nutrition goals by evaluating suitability and supporting policy change. The session will present the underlying issues in addressing the marketing of food and non-alcoholic beverage products to children of all ages. It will provide an overview of the landscape and delve deeper into upcoming issues, focusing on digital marketing and the work WHO is doing in this space. It will also present the groundbreaking new NPPM, its composition and promotional requirements and demonstrate the toolkit resources and how these will help countries apply the NPPM. A live online tool demonstration will display how countries may quickly and practically assess and monitor product suitability.

New development – the Nutrient and Promotion Profile Model (NPPM) in practise

Janet Cade[1], Victoria Jenneson[1]

1. Leeds CC (UK)

The first draft Nutrient Profile Model for commercially available complementary foods for infants was developed for WHO in 2019. The aim was to drive changes to product composition, labelling and promotion practices in the WHO European Region. We trialled the model with 10 countries across Europe (involving 2634 baby food products) and obtained feedback from key informants. Following this, we refined the categories and nutrient thresholds for ease of use. The model was simplified through clarification of specific food categories. Nutrient requirements by food category were made clearer and promotion/labelling specifications applied to all categories. The final model was renamed the Nutrient and *Promotion* Profile Model (NPPM) to include the importance of appropriate marketing. The final model has 8 product categories: dry cereals/starches; dairy foods; fruit and vegetable purees/smoothies and fruit desserts; savoury meals/meal components; snacks and finger foods; ingredients; confectionery; drinks. The nutrient and ingredient requirements provide guidance on not permitted items such as free sugars/sweeteners, confectionery and flavoured drinks; limiting the fruit content in meals, dry cereals and dairy products; setting maximum levels for energy, sodium and total fat and minimum standards for protein content in meals and energy density. Promotional requirements refer to the age for product consumption (minimum age 6 months). The product name should be clear and indicate contents in descending order, not hiding sweet taste or high fruit content. The ingredients list must state the amount of added water/stock, fruit content and the amount of traditional protein source. Packaging with a spout should note this is not suitable for drinking. Statements on packaging should highlight the importance of continued breastfeeding. Pilot testing of the new model in Turkey on 224 baby foods showed that less than a third of products passed the compositional requirements and all products failed the NPPM promotional requirements. This is in part due to Turkish law allowing health related statements on packaging. Working with stakeholders, we plan to disseminate the tool among key audiences across Europe and beyond to influence policy and support legislation and market change.

This seminar will include a 'hands on' demonstration of a new website which includes a NPPM calculator to assess how baby food products perform. You will be able to try the website and calculator to assess compliance of baby foods to the standards.

Unraveling gut-microbiome-brain interactions

Mauro Costa-Mattioli[1]

1. Baylor College of Medicine (USA)

When we think of behavior and neurological disorders, we think about the brain. Traditional research on the biology of neurological disorders has focused on the brain, aiming to identify key brain regions and circuits, relevant molecular mechanisms, and/or new genetic variants associated with brain disorders. Consequently, current therapeutic approaches for neurological disorders aim to target the brain directly. However, we are the bearers not only our own genomes, but also the genomes of the microbes living with us in symbiosis. As we now appreciate, symbiotic microbes are fundamental to nearly every aspect of host function and fitness. In my lab, we serendipitously discovered that specific microbes in the gut can modulate brain function and behaviors in an amazingly powerful way. In this presentation, I will focus on our more recent work that aims to dissect the signals, structures and mechanisms that regulate gut-microbiome-brain interactions. In addition, I will discuss how a selective non-invasive, microbial-based approach is beneficial in preclinical animal models or neurological dysfunction and more recently in humans. Our findings could not only provide a new holistic dimension of how behaviors and the brain are controlled by gut microbes, but they could also lead to the development of new non-invasive microbial-based therapies for neurological disorders.

Quantitative approach identifies metabolic underpinnings associated with schizophrenia

Takeo Yoshikawa[1]

1. RIKEN Center for Brain Science (Japan)

Mental disorders are diagnosed and classified based on the behavior and verbalized internal experiences of the subject, which is a spectrum in many dimensions. Mental disorders have characteristics specific to human, and it is not easy to lay them out in terms of model animals. However, it is natural to pose that the equivalent of the biological basis of psychiatric disorders also exists in mice, which can be approached by targeting "quantitative traits". The prepulse inhibition phenotype (quantitative trait) has the advantage in that it can be measured in the same paradigm in both humans and mice, and a reduction in PPI function has been reported in schizophrenia and other psychiatric disorders. We measured PPI in four inbred strains of mice and found that C57BL/6N (B6) had the best PPI (far from schizophrenia when translated to humans) and C3H/HeN (C3H) had the worst (close to schizophrenia) PPI. Quantitative trait loci (QTL) analysis was performed to determine the genetic basis for the differences in PPI function between B6 and C3H mice. As a result, *Fabp7*, which encodes a fatty acid chaperon molecule, was identified as a responsible candidate gene. We evaluated the association between *FABP7*, *Fabp7* and schizophrenia from various aspects in mice and humans. On the other hand, biological phenotypes are influenced by environmental factors, which include elements consistent with the concept of Developmental Origin of Health and Disease (DOHaD). Proteomic analysis of strain differences in the brains of the B6 and C3H mice revealed that the Mpst, which has a role in hydrogen sulfide production, was highly expressed in C3H mice compared to B6. The cause of the enhanced hydrogen sulfide production system was not due to genomic polymorphisms, but thought to stem from epigenetic changes. The functional consequences and its relationship to schizophrenia were examined. In this session, based on the above stated findings, I will illuminate some metabolic underpinnings of schizophrenia pathogenesis and pathophysiology.

Keywords: schizophrenia, quantitative trait loci analysis, fatty acid binding protein, hydrogen sulfide, epigenetics

Mechanisms underlying memory impairments by Vitamin B1 deficiency

Satoshi Kida[1]

1. The University of Tokyo (Japan)

Vitamin B1 (thiamine) deficiency (TD) has known to induce cognitive dysfunction including deficits in memory formation known as Wernicke-Korsakoff's syndrome in human. However, mechanisms by which TD leads to deficits in learning and memory still remain unclear. In this study, to understand them, we examined effects of pyrithiamine-induced thiamine deficiency (PTD) on learning and memory in mice. PTD-treated mice showed comparable body weight and motor performance compared with control mice 3 weeks after PTD treatment. However, PTD-treated mice showed impairments in formations of social recognition, contextual fear, novel object recognition and spatial memories 3 weeks and 3 months after the PTD treatment, suggesting that the PTD-treatment led to chronic impairments in the formation of hippocampus-dependent memories. Importantly, anatomical analyses indicated that PTD-treated mice displayed significant decreases in sizes of hippocampus and spine density of hippocampal neurons. Our results indicated that PTD-treatment led to impairments in hippocampus-dependent memory and degeneration of hippocampal neurons, suggesting that PTD-treatment impairs the function of hippocampus. To understand molecular mechanisms of hippocampal degeneration by PTD, we performed RNA-seq analyses of hippocampus using next-generation sequencing. We found that PTD mice showed increases in expressions of inflammation-related genes in the hippocampus. Furthermore, PTD mice show impairments of neural activity dependent gene expression and significant decreases in mRNA expressions of transcription factor CREB in the hippocampus, suggesting that PTD showed impaired CREB signaling pathways in the hippocampus. Taken together, our findings suggest that PTD causes strong inflammation, thereby leading to hippocampal degeneration and subsequent impairments in CREB signaling pathways that play essential roles in memory formation. We finally examined effects of PTD on transgenic mice increasing the CREB activity by expressing a constitutively active CREB mutant in the forebrain (DIEDML mice, Suzuki et al 2011) and found that activation of CREB rescued impairments in hippocampal degeneration and hippocampus-dependent memory by PTD. These observations support our conclusion that PTD treatment impairs CREB signaling pathway, thereby leading to hippocampus-dependent memory impairments.

Genotype-based nutrition and dietary guidance

Martin Kohlmeier[1]*, Emmanuel Baah*[1]

1. University of North Carolina, Nutrition Research Institute (USA)

Numerous common genetic variants and other complex biological factors influence what we should eat and what we actually end up eating. As the evidence for adjustments based on genomic and -omic information for setting individual intake targets becomes clearer, the development of individualized meal plans remains challenging. We have developed effective strategies that generate detailed food combinations that meet very complex intake targets with high fidelity. The intake targets for individual users are set taking into account estimated energy requirements, body size, sex, age, genotypes and other sufficiently evidence-supported characteristics. By focusing on intake targets, an unlimited number of algorithms can adjust for multiple factors acting simultaneously on the same intake target. The next step is then to use parabolic functions weighted separately by intake target to calculate the sum of normalized deviations from the optimum for all nutrients in a potential menu. The settings ensure the selection of menus that closely meet all intake targets without allowing any major deviation of individual targets. As more evidence becomes available, these target-setting algorithms can be readily adapted. Currently implemented applications use a wide range of genetic algorithms for which there is sufficient evidence support. In addition to macronutrients und micronutrients, the algorithmic meal plan generation can also take into account individual food sensitivities, intolerances and preferences. Important examples are gluten-free options, vegan choices and low-carbohydrate combinations. The addition of carbon dioxide targets can help consumers to make climate-conscientious food choices that align with their nutritional and health needs.

DOI: 10.1159/000530786

multifactorial). In FCS, rare mutations in classical genes involved in triglyceride-rich lipoproteins have been clearly delineated around the function of the lipoprotein lipase (LPL): LPL itself, APOA5, APOC2, LMF1, and GPIHBP1. Moreover, severe hypertriglyceridemia is also found in congenital generalized lipodystrophies (for example, due to AGPAT2 mutations) characterized by extreme leanness, low or absent circulating leptin, insulin resistance and impaired eating behaviour. Additionally, it has been described that persons with loss-of-function mutations in APOC3 gene display a cardioprotective profile of low plasma triglycerides (both basal and after a fat meal test), representing a paradigmatic nutrigenetic interaction. This observation and subsequent research has led to the generation of new therapies against severe hypertriglyceridemia based on inhibiting Apo-CIII action. On the other hand, multiple gene variants have been significantly associated with plasma triglycerides through Genome Wide Association Studies (GWAS) at a population level. In contrast to GWAS carried out in other complex biomedical traits, many significant signals for plasma triglycerides are closely related to genes belonging to biochemical pathways involved in triglyceride-rich lipoprotein metabolism. In these studies, polygenic risk scores also contributes to the identification of the genomic load related to multifactorial hypertriglyceridemia. The genetic architecture of plasma triglycerides (from monogenic to multifactorial) represents a suitable trait to study nutrient-gene interactions.

Integrated omics for applying in food and nutrition sciences

Hisanori Kato[1]

1. The University of Tokyo (Japan)

The significance of combining different omics in nutrition will be discussed in today's talk.

Habitual coffee consumption reduces the risk of obesity and diabetes. To explore the mechanism, mice were fed a high-fat diet and the effect of adding coffee powder was examined. Coffee powder suppressed weight gain and fat accumulation. The results of transcriptomics, proteomics, and metabolomics showed that coffee consumption suppressed the transcription factor PPARg and its downstream factors, and activated the TCA cycle and the urea cycle. The latter suggested that ATP consumption was promoted by coffee. On the other hand, we searched for loci that correlated with the frequency of coffee consumption in the Japanese population. Genome-wide association analysis revealed a locus strongly associated with coffee intake frequency at position 12q24.

In general, proteins that are digested and absorbed well are regarded nutritionally superior. On the other hand, proteins that are not digested and absorbed well (resistant proteins) are known to have positive effects on the intestinal tract and others. We found that eggshell membrane (ESM), a resistant protein, had an ameliorative effect in both the DSS-induced and IL-10 knockout mouse models of inflammatory colitis. Metagenomics revealed that it ameliorates dysbiosis associated with colitis. Transcriptomics results showed that ESMs are effective in reducing colonic inflammation and maintaining intestinal integrity. Transcriptomics, proteomics, and metabolomics showed metabolic ameliorating effects of ESM.

These results indicate that the integration of omics can provide very useful and broad information in food and nutrition research.

Keywords: omics, functional food, GWAS, resistant protein, coffee

Epigenetics and Mediterranean diet

Omar Ramos-Lopez[2], *J. Alfredo Martinez*[1]

1. IUNS (Spain), 2. UABC (Mexico)

The Mediterranean diet (Med-Diet) is one of the most investigated and well-known healthy dietary patterns worldwide, which generally consist of daily intakes of fruit and vegetables, whole grains, legumes, nuts, fish, white meats, and olive oil, although it may also include moderate consumption of fermented dairy products, and red/white wine during the main course. The Med-Diet has been associated with a lower risk of develop cardiovascular disease, obesity, diabetes, cognitive decline, breast and colorectal cancers, depression, erectile dysfunction and asthma. Moreover, it has been shown that this dietary pattern may also reduce markers of inflammation/oxidative stress and metabolic syndrome features. Interestingly, scientific evidence suggests that the beneficial effects of the Med-Diet on health may be putatively mediated in part by epigenetic mechanisms, which may regulate gene expression without concomitant variations in DNA nucleotide sequence, providing a connection among genetics, diseases, and the environment. Actually, DNA methylation is one of the most studied epigenetic processes, which occurs by the addition of a methyl group in the carbon 5' position of a cytosine. Of note, nutrients and specific dietary components of the diet are able to modify gene expression at the transcriptional level through changes in DNA methylation. In this context, an ancillary study within the PREDIMED-Navarra study revealed that adherence to Med-Diet was associated with the methylation status of genes related to inflammation and immunocompetence (*EEF2*, *COL18A1*, *IL4I1*, *LEPR*, *PLAGL1*, *IFRD1*, *MAPKAPK2*, *PPARGC1B*), with a potential regulatory impact. In addition, specific components of Med-Diet, particularly nuts and extra-virgin olive oil (EVOO), were able to induce methylation changes in several genes in peripheral white blood cells, including those related to intermediate metabolism, diabetes, inflammation and signal transduction (i.e., *CPT1B* and *GNAS*). Also, cg01081346 was associated with PUFAs intake, showing a role for specific fatty acids on epigenetic modulation. Furthermore, lower methylation of the *CAMKK2* gene (involved in the regulation of critical metabolic processes such as adiposity and glucose homeostasis) was associated with inadequate folate intake and higher HOMA-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

IR index in subjects with obesity. Summing up, these findings shows that the Med-Diet may induce changes in the epigenome through methylation mechanisms, which occurred in genes mainly related to inflammation, but with other potential roles on adipogenesis, metabolism, angiogenesis and diabetes. The analysis of dietary and nutritional biomarkers and the progress in the epigenetics field is contributing not only to define new nutrient roles in health and disease, but also could facilitate the design and implementation of precision nutrition strategies targeting the epigenome. Besides, this knowledge has led to the search for epigenetic biomarkers to predict the risk of developing chronic diseases and personalizing their prevention and treatment with a precision nutrition target.

Retinoic Acid and Its Nuclear Receptors in Health and Disease

William Blane[1], Igor O Shmarakov[1], Rossana M Calderon[1], Marcin Golczak[2], Maria Marhuenda Munoz[1]

1. Columbia University (USA), 2. Case Western Reserve University (USA)

We are interested in understanding linkages between vitamin A metabolism and actions and chronic disease development, specifically metabolic disease and acute lung disease. Our research has used knockout and transgenic mouse models to study vitamin A actions in facilitating and regulating insulin secretion. Early studies explored the role of all-*trans*-retinoic acid [ATRA] in glucose stimulated insulin secretion, using a transgenic mouse that expressed specifically in pancreatic β-cells a dominant-negative retinoic acid receptor-α [RARdn] transgene that ablated most retinoic acid receptor [RAR] and ATRA signaling in these cells. These studies established that ATRA-RAR signaling is required for maintaining normal glucose-stimulated insulin secretion and for maintaining β-cell mass within the endocrine pancreas. Recently, our focus has shifted to ATRA-RAR actions in enteroendocrine cells [EECs] present within the small intestine. We have focused specifically on the incretin-secreting K- and L-cells, which respectively secrete glucose-dependent insulinotropic polypeptide [GIP] and glucagon-like peptide-1 [GLP-1]. GIP and GLP-1 are hormones secreted in response to nutrient arrival in the gut and they signal β-cells to secrete insulin. We studied mice that lack retinol-binding protein 2 [RBP2], which show elevated GIP secretion in response to an oral fat challenge. RBP2 plays a role in channeling substrate retinol towards ATRA formation. These investigations identified a role for ATRA-RAR in facilitating GIP release from K-cells. Our findings establish further that ATRA-RAR signaling is needed to assure normal differentiation of K-cells within intestinal crypts and along the crypt-villus axis. We are presently continuing our investigations of retinoid actions in EEC biology aiming to identify the processes through which ATRA-RAR signaling affects GIP release into blood in response to nutrient signals.

Recently, we initiated investigations in mice into the importance of ATRA-RAR signaling in the response of the lung to experimentally-induced acute respiratory distress [ARD]. We have focused on identifying ATRA-RAR actions in cells residing in the alveolar niche; lung lipofibroblasts [LFs], in alveolar epithelial type 2 cells [AEC2s] and in vascular endothelial cells [ECs] The current understanding of vitamin A biology in these cells is that hepatic vitamin A stores are mobilized as retinol bound to retinol-binding protein 4 (RBP4) and delivered through the circulation to lung cells where they are taken up and used for ATRA synthesis and ATRA-RAR-mediated transcriptional regulation. Our data indicate that this is incorrect and that local vitamin A stores present within each of these 3 distinct cell types of the alveolar niche are critically needed for maintaining the health of the alveoli. Single-cell RNA sequencing data establish that retinoid stores are found in LFs, in AEC2s and in ECs, and that each of these lung cell types expresses key genes needed for retinoid uptake, accumulation, and intercellular transfer. These cellular stores buffer the lung against the adverse consequences of ARD. Mice that genetically lack the ability to store vitamin A locally are more vulnerable to developing more severe ARD and death due to the loss of alveolar barrier integrity and impaired surfactant production, clearance of inflammatory stimuli, and alveolar regeneration.

Vitamin K, GGCX, and SXR

Satoshi Inoue[1]

1. Tokyo Metropolitan Institute of Gerontology (Japan)

Vitamin K is a fat-soluble vitamin which was originally discovered as an essential factor for blood coagulation. It functions for protein modulation as a co-factor for g-glutamyl carboxylase (GGCX), of which substrates include blood coagulation factors, bone matrix proteins and several other proteins. Alternatively, we previously demonstrated that vitamin K could regulate transcription by activating steroid and xenobiotic receptor (SXR). Interestingly, several studies revealed vitamin K is associated with some aging-related diseases including osteoporosis, osteoarthritis, sarcopenia, dementia, depression and frailty. Here we will discuss the roles of vitamin K, GGCX and SXR in human and animal models with genetic, biological and epidemiological studies.

SY(T1)3-3

Elucidation of molecular mechanism of vitamin D actions using genetically modified rats

Toshiyuki Sakaki[1]

1. Toyama Prefectural University (Japan)

The active form of vitamin D_3, 1α,25-dihydroxyvitamin D_3 (1,25D3), exerts various physiological actions involved in calcemic, osteogenic, anti-cancer, and immune responses. Recent studies have suggested other effects of vitamin D and/or the vitamin D receptor (VDR), including VDR-independent effects of 1,25D3, VDR-dependent or -independent effects of 25-hydroxyvitamin D_3 (25D3), and ligand-independent effects of the VDR. We have generated a novel *in vivo* system including genetically deficient or modified rats in the *Cyp27b1* or *Vdr* gene using genome editing method [1]. Human type II rickets model rats with a mutant *Vdr* (R270L), which recognizes 1,25D3 with an affinity equivalent to that of $25(OH)D_3$, were also generated. *Cyp27b1*-knockout (KO), *Vdr*-KO, *Vdr* (R270L) rats showed symptoms of rickets including growth retardation and abnormal bone formation. Among these model animals, *Cyp27b1*-KO rats had notably low levels of calcium in the blood and the most severe growth retardation, while *Vdr*-KO rats showed abnormal skin formation and alopecia [1]. Recently, we have generated another human type II rickets model rats with a mutant *Vdr* (H301Q), which shows much lower affinity for both 25D3 and 1,25D3 than the wild-type *Vdr*. In addition, we generated a double variant *Vdr* (R270L/H301Q) which has almost no ability to bind 25D3 and 1,25D3. The differences between wild type (WT) and *Vdr* (R270L) rats could be a result of VDR-dependent effects of 1,25D3. The differences between *Vdr* (R270L) and *Cyp27b1*-KO rats could be derived from VDR-independent effects of $1,25(OH)_2D_3$. Comparison of the *Vdr* (R270L/H301Q) and *Vdr*-KO rats could reveal ligand-independent effects of VDR. Based on the result that *Vdr* (R270L/H301Q) rats did not show alopecia, ligand-independent effects of VDR appear to play essential roles in hair cycle. These results strongly suggest that our novel *in vivo* system is useful for elucidating the molecular mechanism of vitamin D actions. [1] Nishikawa *et al.*, **Sci Rep 10**, 5677 (2020)

SY(T1)3-4

Targeting the nuclear receptor PPARalpha to treat metabolic disease

Jae Man Lee[1]

1. Kyungpook National University School of Medicine (Korea)

The peroxisome proliferator-activated receptor a (PPARa) is a ligand-dependent transcription factor that belongs to the nuclear receptor superfamily. PPARa is activated by various kinds of lipid species including fatty acids and phosphatidylcholine (C16:0-18:1), as well as by a class of chemicals known as peroxisome proliferators. In a clinical setting, PPARa is also the molecular target of the fibrate derivatives for hyperlipidemia patients. Studies in rodents and humans have shown that PPARa as a master transcription factor governs hepatic lipid metabolism during starvation, and exerts anti-inflammatory functions as well. Here I will present our recent work identifying a novel PPARa target gene encoding a secretory peptide hormone from the liver, which controls systemic energy balance. Our work is revealing a new endocrine signaling axis from the liver to the brain, with implications for therapeutics.

Diet timing and chronic disease – epidemiological evidence of chrono-nutrition

Gerda K Pot[1,2]

1. King's College London (UK), 2. Nutrition & Healthcare Alliance (Netherlands)

It is becoming increasingly evident that it does not only matter ***what*** we eat, but also ***when***. The research on biorhythms, nutrition and health is called chrono-nutrition. This is particularly relevant as our daily patterns are becoming less regular in our 24h economy, e.g. with more people working in shifts. The timing of eating, or temporal eating patterns, are a possible modifiable risk factor for cardio-metabolic diseases, including type 2 diabetes. Many metabolic processes in our body follow a circadian pattern. Disruption of these circadian patterns or misalignment between the timing of eating and endogenous circadian systems could have adverse health effects, including impaired cardio-metabolic health. Chrono-nutrition involves studying the impact of nutrition on circadian patterns including different aspects of time: frequency, regularity and clock time. This talk will present data on recent findings and insights on epidemiological evidence of meal timing on cardio-metabolic health.

The human circadian system: links to meal timing and type 2 diabetes

Jonathan David Johnston[1]

1. University of Surrey (UK)

The relationship between circadian biology and metabolism has been elegantly described in animal and cellular models. However, the translational benefit of this work relies on the findings of human studies. This research involves highly controlled laboratory protocols in addition to interventions within free-living people.

The presentation will describe how many aspects of human metabolism change over the day in healthy volunteers, together with the effect of obesity and type 2 diabetes on these rhythms. The role of the endogenous circadian system in daily metabolic rhythms will then be identified. Finally, the presentation will explore the 2-way interaction between the human circadian system and meal timing. Both published and currently unpublished data will be included.

Keywords: Circadian, chrononutrition, TRF, TRE, diabetes

Time-Restricted Eating for the Prevention and Treatment of Cardiometabolic Disease

Emily N.C. Manoogian[1]

1. Salk Institute for Biological Studies (USA)

Circadian rhythms optimize nutrient homeostasis by orchestrating daily rhythms in catabolic and anabolic metabolism to the appropriate time of the 24 h day. Chronic circadian rhythm disruption predisposes individuals to cardiometabolic diseases including Type-2 diabetes, obesity, and hyperlipidemia. Conversely, maintaining a daily rhythm of feeding and fasting sustains a robust circadian rhythm in metabolism. In animal models, time-restricted feeding (TRF) has been used as a successful intervention for the prevention and treatment of cardiometabolic diseases even on a high-fat and/or high-sugar diet. Benefits of TRF were also seen in mice with a genetically disrupted circadian clock. Clinical trials in humans have also shown widespread health benefits of time-restricted eating (TRE) including improved glucose regulation, decreased blood pressure, and decreased atherogenic lipids. This talk will discuss the current understanding of how TRE impacts cardiometabolic health and where the field is going.

Food-log app-based chrono-nutritional survey and intervention reveal effective information on weight loss and sleep

Yu Tahara[1,2]*, Masaki Takahashi*[3]*, Shigenobu Shibata*[2]

1. Hiroshima University (Japan), 2. Waseda University (Japan), 3. Tokyo Institute of Technology (Japan)

Prevention of obesity and type 2 diabetes is an essential research issue worldwide. Chrono-nutrition-based optimal weight-loss strategies have not been well-studied. This study explored the weight-loss parameters from six months of dietary data from 10,000 individuals (20–69-year-old men and women) recorded in a diet-tracking app. The results showed that carbohydrate intake contribution was significant along with age, sex, and app use duration. Particularly, carbohydrate intake correlated with weight loss in the order, dinner, lunch, and breakfast. Therefore, we conducted four 1-month interventions based on the chrono-nutritional evidence for the app users; 12-h time-restricted eating (TRE), increasing breakfast and decreasing dinner, decreasing carbohydrate content at dinner, and frequently logging the food intake and body weight. The participants of the intervention group showed improved sleep patterns, well-being, and daytime physical fitness than those in the control group. In addition, the subjective achievement for each intervention was correlated with weight loss. Cluster and multiple regression analyses revealed that decreasing carbohydrate content at dinner positively correlated with weight change. Thus, the most effective weight loss strategy is to reduce the carbohydrate content at dinner. In addition to the above topic, we would like to share our chrono-nutritional research, including investigation of the functional nutrients and the personalized chrono-nutrition.

SY(T1)5-1

Adaptive changes in nutrient-induced GLP-1 secretion in diet-induced obese model rats

Tohru Hira[1]

1. Hokkaido University (Japan)

Glucagon-like peptide-1 (GLP-1) is a gut hormone produced in enteroendocrine L-cells. Secretion of GLP-1 is acutely stimulated by luminal nutrients, which results in enhanced insulin secretion from the pancreatic beta-cells and various postprandial responses. GLP-1 is produced mainly (not limitedly) in the distal small intestine and the large intestine. For postprandial GLP-1 response, small intestinal GLP-1-producing cells rather than colonic ones are more likely responsible. Some of molecular mechanisms underlying respective nutrient-induced GLP-1 secretion have been elucidated. Although GLP-1 receptor agonists are recently used in the treatment of type 2 diabetes, changes in GLP-1 production/secretion under obese/diabetic conditions are not well characterized both in human and animal research [1,2]. We investigated whether nutrient-induced GLP-1 secretion is increased or diminished in diet-induced obese model rats. Rats were fed a high-fat and high-sucrose (HFS) diet for 8 weeks or 6 months, which resulted in higher body weight gain, and postprandial glycemia than rats fed a normal diet. During the experimental period, meal tolerance tests (MTTs) were performed every 2-4 weeks, and glycemic, insulin, and GLP-1 responses were monitored. In the MTTs, rats were orally given a standard diet or a liquid meal to compare postprandial responses to identical meals. Compared to rats fed a normal diet, rats fed the HFS diet had higher glycemic, insulin and GLP-1 responses in MTTs [3]. However, intestinal GLP-1 concentration and proglucagon mRNA expression levels did not differ between treatments. In rats treated with continuous administration of a GLP-1 receptor antagonist, the HFS diet further increased postprandial glycemia compared to rats fed the HFS diet without GLP-1 receptor antagonist treatment [4]. In genetically diabetic Goto-Kakizaki rats, feeding the HFS diet for 6 months did not enhance postprandial GLP-1 secretion compared to the GK rats fed a normal diet, while glycemic responses were higher than normal rats fed the HFS diet [5]. These results suggest that enhancement of the postprandial GLP-1 response during obesity development has a role in maintaining a normal postprandial glycemic response. Because GLP-1 productions were not increased in the small intestine, we speculate that the nutrient-sensing functions of GLP-1-producing cells are modified by continuous feeding of an obesogenic diet.

Further investigations are needed to clarify the adaptive changes in GLP-1-producing enteroendocrine cells under dietary, obese, and diabetic conditions.

The enteroendocrine system in human health and in gastrointestinal disease

John McLaughlin[1]

1. University of Manchester (UK)

The gastrointestinal (GI) tract contains a diffuse set of gut hormones secreting cells, the enteroendocrine system. Despite enteroendocrine cells comprising only ~1% of epithelial cells, collectively they form the largest endocrine system in the human body. There are at least 12 subtypes described, secreting multiple hormones which are mainly peptides. Partly because of its inaccessibility and diffuse nature the full roles and integrated functions of the enteroendocrine system are very incompletely understood. It is well established that they play key roles in the digestion and absorption of ingested food through their effect on intestinal secretions (eg gall bladder contraction via cholecystokinin (CCK) and pancreatic secretion via CCK and secretin), and effects on gut motility eg delayed transit via polypeptide YY and glucagon-like peptide-1).

A more recent focus has been on their potential role as satiety hormones. However, it is debatable how much of a real-world role they play in normal food intake regulation, and the impact of normal postprandial endogenous gut peptides on appetite-related behaviours in humans in is uncertain. It seems likely that hedonic drives to eat, reward mechanisms and neurocognitive factors may have more of an impact and over-ride these signals. In GI disease however (and following bariatric surgery), there is growing evidence that supraphysiological levels of gut hormones have a major impact on appetite regulation and may drive other symptoms. Perhaps this is an appropriate part of an intrinsic response to injury and inflammation.

Further research is now necessary to better understand the mechanisms involved in appetite regulation and dysregulation and to recognize the potential offered by targeting the enteroendocrine system, both in GI disease and in obesity. This talk will review our current understanding, presenting experimental evidence from both human and model studies.

Cellular and molecular mechanisms in the enteroendocrine system

Frank Reimann[1]

1. University of Cambridge (UK)

The gut harbours enteroendocrine cells scattered throughout its epithelium that secrete a plethora of predominantly peptide hormones. These modulate local intestinal physiology, such as peristalsis and nutrient absorption, as well as acting further afield, for instance affecting pancreatic insulin secretion and hunger. Our research is focussed on understanding the basic physiology of the enteroendocrine system and its involvement in the control of metabolism and food intake. Altered gut peptide secretion is thought to underlie the beneficial outcomes of bariatric bypass surgery, including strongly elevated postprandial glucagon-like peptide-1 (GLP-1) and peptideYY (PYY) plasma concentrations. Our laboratory has pioneered the use of fluorescent markers expressed under the control of specific prohormone promoters to label enteroendocrine cells, thus making them available for single cell investigations. Single cell RNAseq identifies different clusters of enteroendocrine cells broadly in line with different hormone signatures in cells derived from both transgenic mice (NeuroD1-Cre labelling) and human intestinal epithelial organoids (ChGA-Venus labelling). Many of these clusters express transporters and receptors enabling responses to specific macro-nutrients. For example, GLP-1 expressing cells use sodium-coupled transporter dependent depolarization to respond to glucose produced from carbohydrate and the G-protein coupled receptor GPR119 to respond to mono-acyl-glycerides produced from fat digestion. We use live cell imaging and whole cell electrophysiology to investigate downstream stimulus secretion coupling in enteroendocrine cells. Once released, many gut hormones engage with specific G-protein coupled receptors, and transgenic mice with Cre-recombinase expression under the control of promotors for these receptors have helped to identify target cells within the gut and the central nervous system. We aim that our research will identify new drugs for type 2 diabetes and obesity that act by targeting gut endocrine secreting cells or their target tissues, thus mimicking the gut endocrine consequences of bariatric surgery.

High-Value Nutrition - Growing New Zealand's Science to Take High-Value Foods to the World

Richard Mithen[1]*, Joanne Todd*[1]

1. University of Auckland (New Zealand)

High-Value Nutrition (HVN) is a New Zealand National Science Challenge that supports high quality translational science to enhance NZ's competitive advantage and drive innovation and value generation in New Zealand's food and beverage sector, and to provide insights to the role of foods and diets in promoting and maintaining health. HVN is positioned at the public/private research interface, involving universities, institutes and companies across NZ. Four long-term research themes have been defined: (i) infant health with a spotlight on gut microbiome around weaning; (ii) metabolic health, with a focus on early diabetes: (iii) gastro-intestinal health addressing functional gut disorders; and (iv) immune health with a focus on how diet can contribute to a robust immune system. Within these programs, research includes cohort studies linking dietary patterns with health, and short and long term human dietary intervention studies. The four individual programs are closely associated with each other, and share a common underpinning systems biology approach. Complementary to these themes, HVN leverages genuine and iconic NZ foods into higher value propositions by scientifically evaluating their health benefits. HVN is fully committed to Vision Mātauranga, the New Zealand national policy to unlock the science and innovation potential of Māori knowledge, resources and people.

A New Zealand Diet for Metabolic Health and Family Wellbeing: Participant Insights

Denise Conroy[1]*, Jenny Young*[2]

1. Plant and Food Research Ltd. (New Zealand), 2. Plant and Food Research Ltd (New Zealand)

This is an ambitious long-term multi-centre dietary intervention study that explores whether consumption of NZ F&B products based on diet principles that include a preponderance of plant-based foods (vegetables, legumes, fruits, unrefined cereals, nuts), together with lean protein from seafood, with smaller portions of lean red meat and dairy, offers

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

health benefits to people at risk of cardiometabolic disease and their families. Such plant-based diets have been shown to improve metabolic, cardiovascular, and wellbeing profiles in people at risk of cardiometabolic disease, however, this concept has not been studied in the NZ population using NZ foods and beverages. A comprehensive participant insights study was fully integrated in to the clinical trial with the aim of better understanding the cognitions, emotions, barriers and motivators for the index person participating in this trial. 40 index persons were interviewed on 3 separate occasions; at week 6, week 12, and week 24 to better understand their lived experience throughout the intervention. The interviews lasted approximately 40-60 minutes each and were undertaken via Zoom to allow for Covid 19 contingencies. 10 of the participants for the consumer insights study are Māori (indigenous persons) and were interviewed by Māori social scientists. A survey will be distributed to all 200 index participants during weeks 52-64 to gain insight into intervention experience and ongoing maintenance behaviour. There will be focus groups at week 40+ (n = 80) to explore participant experiences and their relationship to the diet followed by a survey to all participants (week 48+) to better understand their overall experiences of participation, ongoing maintenance, and with the food supplied. To date findings suggest that participants are reporting participation in this study has allowed them to 're-set' their relationship with food, to better understand portion size, to re-think when and where they are eating and to seek support when they feel it is needed. The entire family participating in this intervention has been welcomed, not just because the index person does not feel isolated but also because they feel the family's health focus has shifted.

The maintenance of metabolic health is a global challenge. In China alone almost 1 in 3 individuals are struggling with their body weight, and across Asia a staggering 300 million people have been diagnosed with type 2 diabetes, many in new urban mega cities. Previously common in the *'over-weight and over-forties'*, for many Asian consumers risk increases even whilst young and outwardly quite slim. The cause may lie in deposition of body fat within 'unsafe' ectopic stores, such as the pancreas and liver, which has been termed the TOFI profile: *'Thin on the Outside yet Fat on the Inside'*. Furthermore, during recent phenotyping of an Asian and Caucasian cohort in the TOFI_Asia study using blood biomarkers and body/organ fat storage we have shown the biomarker 'fingerprint' to differ significantly between Chinese and Caucasian individuals. However, whether this is due to different physiology, different pathology, or a different background diet remains to be determined.

The High Value Nutrition PANaMAH (Peak Nutrition for Metabolic Health) team is conducting a series of clinical intervention studies in overweight prediabetic cohorts to determine the underlying cause of this ethnic separation of the plasma metabolome. In addition, we also seek to determine the responsiveness of these biomarkers to nutritional intervention utilizing high value New Zealand food and beverages, including focus on personalized postprandial glucose response (PPGR) investigated using machine learning techniques to integrate clinical, metabolome and microbiome markers. These studies range from acute postprandial studies to a 14-day full diet controlled residential trial SYNERGY and an 8-month community weight loss study FERDINAND, using a systems nutrition approach – thus providing multi-level scientific evidence.

Knowledge gained through the PANaMAH research programme will help to better identify individuals at high risk of poor metabolic health, and also to optimize dietary strategies to prevent the development and/or progression of metabolic disease. In doing so, we will also provide the New Zealand food and beverage industry with valuable information with which to develop and market high value products targeting the metabolic health space.

Unlocking the puzzle of functional gut disorders, assessing novel biomarkers targeting gut comfort

Nicole Clemence Roy[1,4,5], Richard Gearry[1,4], Jasjot Maggo[1,4], Hwei Min Ng[1,4], Simone Bayer[1,4], Karl Fraser[2,4,5], Janine Cooney[3,4], Diana Cabrera[2,4], Wayne Young[2,4,5]

1. University of Otago (New Zealand), 2. AgResearch (New Zealand), 3. Plant and Food Research (New Zealand), 4. High-Value Nutrition National Science Challenge (New Zealand), 5. Riddet Institute Centre of Research Excellence (New Zealand)

Background: Gut health is central to wellbeing, and deviation from the physiological norm is becoming increasingly common among consumers. Functional gut disorders (FGDs) cause pain discomfort and debilitate a person's quality of life. However, despite a high prevalence rate worldwide, the cause of FGDs remains relatively unknown. Alterations in the microbiome, host-

microbial metabolism, immune function, sensitivity, and motility in the gut occur in FGDs. Between 60-89% of individuals with an FGD believe that diet exacerbates symptoms. Therefore, most individuals seek to modify their dietary intake or consume foods to help alleviate symptoms. For example, several studies have shown that consuming green kiwifruit or gold kiwifruit improved gut health by regulating laxation in people with constipation. However, the mechanisms by which kiwifruit improves gut relief and digestion remain ill-defined.

Methods: Two studies were carried out to generate mechanistic insights by which kiwifruit improves gut relief and digestion in participants with constipation. In both studies, patient-reported outcomes of gut symptoms and biological markers were assessed on all participants at baseline and four weeks of intervention. The first study aimed to identify potential mechanisms impacted by consuming gold kiwifruit in a single-blinded, positive controlled, randomised, cross-over study in home settings. Two gold kiwifruit or psyllium (fibre-content matched) was consumed daily for four weeks by participants with or without constipation. The microbiome composition and functional potential were analysed by shotgun metagenomic sequencing of faecal DNA. In addition, metabolomics analysis of plasma and faecal samples was performed using mass spectrometry to monitor polar and non-polar plasma metabolites. The second study aimed to generate comprehensive data on the changes in the gut physiology and associated host-microbiome interactions to the habitual sustained consumption of two green kiwifruit per day or maltodextrin for four weeks in participants with constipation. In addition to the metagenome and metabolome analyses, transit and gas profiles along the gut and colonic volume were measured.

Results: In the first study, the interventions had different effects on plasma and faecal metabolites in all participants, regardless of their health status. Neurotransmitter pathway mapping revealed that the relative plasma concentrations of tryptophan and tyrosine, neurotransmitter precursors, in constipated participants consuming kiwifruit were lower than downstream metabolites in their respective pathways. In contrast, the constipated participants consuming psyllium accumulated tryptophan and tyrosine in plasma, while the concentrations of downstream metabolites were lower in their respective pathways. This finding highlights potential mood benefits over and above those related to increased laxation in constipated participants consuming kiwifruit. In addition, the interventions had differential effects on the taxonomic composition (*Eggerthella* and *Bacteroides genera*) and predictive function (carbohydrate metabolism, metabolism of cofactors and vitamins, and transporters) of the faecal microbiome in all participants, regardless of their health status. **Conclusion:** The findings from these studies will provide insights into molecules of the host-microbial interactions and physiological changes associated with the positive impacts of consuming kiwifruit for gut relief and digestion.

Exploring the immunometabolic response to nutrition

David O'Sullivan[1], Jeffry S Tang[1], Sophie Faulkner[1], Yanyan Li[1], Olivier Gasser[1]

1. Malaghan Institute for Medical Research (New Zealand)

Although nutrition impacts immune function, the underlying mechanisms of action remain poorly defined. Over the past decade, the functional range of immune cells, including T cells and dendritic cells, has been consistently linked to distinct shifts in cellular metabolism, thus firmly anchoring the novel paradigm and field of research of 'immunometabolism'. As diet likely influences immunometabolism, but remains virtually unstudied in that context, the Immune Health Programme of the high-value nutrition (HVN) national science challenge is dedicating significant resources to determine the inter-relationship between diet and immunometabolism and how dietary interventions may be used to reprogram cellular metabolism of peripheral immune cells. We will introduce the general principles of immunometabolism, describe metabolic flow cytometry, a newly developed methodology which enables the exploration of immunometabolism at the single cell level in peripheral blood mononuclear cells (PBMC), and highlight key observations made to date with PBMC after ingestion of individual dietary constituents or completion of more complex nutritional interventions.

Feeding through seeding: nourishing the infant microbiome that supports immune health

Clare Rosemary Wall[1], Nicole Roy[2], Olivier Gasser[3], Jane Mullaney[4], Amy Lovell[1]

1. University of Auckland (New Zealand), 2. University of Otago (New Zealand), 3. Malaghan Institute (New Zealand), 4. AgResearch (New Zealand)

Background and objectives: The early stages of gut microbiome development are marked by unique temporal microbe uptake, colonization, and selection, all of which have variable functional characteristics throughout time. This carefully managed microbial sequence begins at birth and continues until the microbiome acquires an adult-like makeup and function around 3 years of age. Early life nutrition has been shown to be the most important modulator of the microbiome with

breastmilk seeding and modulating the microbiome with beneficial bacteria. The introduction of solid foods which are largely influenced by physiological development, culture and tradition has a significant impact on the change and development of the gut microbial diversity. Our programme aims to investigate the establishment of immune protection-beneficial microbiomes during and after the introduction of solid food.

Methods: Through data mining we have identified bacteria with supporting evidence for beneficial modulation of the evolving infant GI and systemic immune system and identified lead candidates to feed these beneficial bacteria. A pilot study has enabled us to explore the relationship between dietary intake in infants from the commencement of solids to 12 months of age and its effect on the microbiome. The pilot study also determined the feasibility to conduct a RCT.

Results: The pilot study demonstrated that the infant diet is characterized by high inter and intra individual variation of food groups compared to nutrient composition which remains relatively stable over time. The pilot study also demonstrated it is feasible to conduct a larger RCT.

Conclusion: The RCT Seeding through Feeding: nourishing the infant microbiome to support immune health (SUN) is currently underway. This study will enable us to examine the associations, and possible causality between prebiotic feeding, growth of immune health-beneficial microbes in the infant gut, with reduced number of respiratory infections and improved vaccination responses.

Neural mechanisms of post-ingestive learning

Zachary Knight[1,2]

1. University of California, San Francisco (USA), 2. Howard Hughes Medical Institute (USA)

Animals must learn through experience which foods are nutritious and should be consumed, and which are toxic and should be avoided. This learning process is critical for survival in the wild and contributes to the motivational pull of energy dense foods in modern society. However, we have only a rudimentary understanding of the underlying cells, signals and pathways. I will describe our work developing genetic tools to monitor and manipulate GI sensory pathways in the mouse, and the application of these tools to investigate mechanisms of post-ingestive learning.

A Neural Basis Behind the Hardships of Dieting

Michael Krashes[1]

1. National Institutes of Health (USA)

Maintaining healthy body weight is increasingly difficult in our obesogenic environment. Dieting efforts are often overpowered by the internal drive to consume energy-dense foods. Although the selection of calorically rich substrates over healthier options is identifiable across species, the mechanisms behind this choice remain poorly understood. Using a passive devaluation paradigm, we found that exposure to high-fat diet (HFD) suppresses the intake of nutritionally balanced standard chow diet (SD) irrespective of age, sex, body mass accrual and functional leptin or melanocortin-4 receptor signaling. Longitudinal recordings revealed that this SD devaluation and subsequent shift toward HFD consumption is encoded at the level of hypothalamic agouti-related peptide neurons and mesolimbic dopamine signaling. Prior HFD consumption vastly diminished the capacity of SD to alleviate the negative valence associated with hunger and the rewarding properties of food discovery even after periods of HFD abstinence. These data reveal a neural basis behind the hardships of dieting.

Neuronal mechanism of state-dependent modulation of taste preference

Ken-ichiro Nakajima[1]

1. National Institute for Physiological Sciences (Japan)

The gustatory system plays a critical role in sensing appetitive and aversive taste stimuli for evaluating food quality. Although taste preference is known to change depending on various factors such as internal states, a mechanistic insight remains unclear. To answer this question, we examine the neuronal mechanisms regulating hunger-induced taste modification in mice. Starved mice exhibit an increased preference for sweetness and tolerance for aversive taste. Agouti-related peptide (AgRP)-expressing neurons in the arcuate nucleus of the hypothalamus play a pivotal role in triggering appetite. We thus evaluate the role of AgRP neurons on hunger-induced taste modification with optogenetic experiments. We found that the hunger-induced taste modification is recapitulated by selective activation of AgRP neurons projecting to the lateral hypothalamus, but not to other regions. Importantly, both appetitive and aversive tastes are modified by the lateral hypothalamus projecting AgRP neurons. We next characterized the lateral hypothalamic neurons that function as downstream neurons of AgRP neurons. Pathway specific chemogenetic experiments showed that glutamatergic neurons in the lateral hypothalamus play a key role in modulating preferences for both appetitive and aversive tastes by using distinct pathways projecting to the lateral septum or the lateral habenula, respectively. Although hunger is known to make food tastier empirically ("Hunger is the best sauce"), our results show the neural mechanism behind the hunger-induced taste modification. In last parts of my talk, the role of other factors except hunger on taste perception will be also discussed.

Anti-obesity and neuroprotective effects of tocotrienols

Koji Fukui[1]

1. Shibaura Institute of Technology (Japan)

Vitamin E is a natural lipophilic vitamin, and the most famous function is an antioxidant. Daily intake of vitamin E prevents oxidation of our body. Vitamin E is selling as a supplement in the private market everywhere, and we can get it very easy. On the other hand, aging process cannot be prevented and is a degenerative process. Aging processes are divided into two categories, one is a physiological and the other is pathological. One mechanism of the progression of pathological aging is closely related to oxidation. To prevent pathological aging, administration of vitamin E is very effective. In our previous study, treatment with vitamin E in rodent models significantly improved cognitive dysfunction such as the Morris water maze and a radial arm maze. On the other hands, obesity is a severe problem all over the world, and increases the risks of secondary diseases such as diabetes, cardiovascular event, and other severe diseases. Recently, our group found that treatment with tocotrienols significantly inhibited body weight gain in obese mice. We tried several treatment volumes and periods, and every sample showed similar effects. However, the detailed mechanisms of anti-obesity effects of tocotrienols have not yet fully understood. We think one is neuroprotective and second is antioxidant effects. For example, treatment with a hydrogen peroxide induced neuronal cell death in a time- and concentration-dependent manner. Hydrogen peroxide is one kind of reactive oxygen species and very small amount of it produce in our body. However, we found that treatment with a low concentration of hydrogen peroxide induced axonal degeneration. The effect of tocotrienol is stronger than that of tocopherols. Obesity has been shown to consume more oxygen and less during calorie restriction. Treatment with tocotrienols may affect not only neural function but also lipid metabolism and mitochondrial function. In this presentation, we will introduce our research results, focusing on tocotrienols.

Role of vitamin K in health and disease

Leon Schurgers[1]

1. Maastricht University (Netherlands)

Vitamin K is an essential bioactive compound required for the activation of vitamin K-dependent proteins, necessary to fulfil physiological functions in our body. Vitamin K can be present in various isoforms, distinguishable by two main dietary structures namely phylloquinone (K1) and menaquinones (K2). The difference in K1 and K2 is seen in the structure which causes different absorption rates, tissue distribution, and bioavailability. Although differing in structure, both act as cofactor for the enzyme gamma-glutamylcarboxylase encompassing both hepatic and extrahepatic cofactor activity. Only carboxylated, hence activated, vitamin K dependent proteins promote a health profile, like hemostasis, strong bones and elastic arteries. Furthermore, vitamin K2 in the form of MK-7 has been shown as most bioactive vitamin K compound in regulating osteoporosis, atherosclerosis, and inflammatory diseases without risk of negative side effects or overdosing. Here we highlight differences

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

between isoforms vitamin K1 and K2 by means of source, function, and extrahepatic activity both in health and disease.

Niacin metabolism and life-style related diseases

Tsutomu Fukuwatari[1]

1. The University of Shiga Prefecture (Japan)

Niacin, also called vitamin B3, refers to both nicotinamide and nicotinic acid. Niacin in the form of coenzymes NAD and NADP functions in many biological reactions such as energy metabolism, redox reactions, ADP ribosylation and sirtuins activation. Recent researches have elucidated that the decreased NAD levels with aging and nutritional status impair energy metabolism, DNA repair, gene expression and cellular stress responses through inactivation of NAD requiring enzymes including poly (ADP-ribose) polymerases (PARPs) and sirtuins, and thus is involved in obese and metabolic diseases. Several studies have shown that obesity and aging lower tissue NAD levels in mice liver, skeletal muscle and adipose tissue. Low NAD levels impair glucose tolerance and reduce insulin secretion in pancreatic β cells. NAD deficiency reduces β-oxidation and consequently causes the accumulation of triglycerides in the hepatocytes, enhances oxidative stress, impairs insulin sensitivity, triggers inflammation in the liver, and hence contributes to the pathogenesis of nonalcoholic fatty liver disease (NAFLD). Supplementation of NAD precursors improves NAD levels, and has beneficial effects for obesity, insulin sensitivity, dyslipidemia and NAFLD. Especially, nicotinamide mononucleotide (NMN) and nicotinamide riboside have superb ability to increase NAD synthesis without inducing side effects. NAD is synthesized from tryptophan by the tryptophan-NAD pathway, nicotinic acid by the Preiss-Handler pathway, and nicotinamide by the salvage pathway. The NAD levels are also regulated by nicotinamide catabolic enzyme nicotinamide *N*-methyltransferase. Patients with obesity, diabetes and NAFLD show reduced expression of nicotinamide mononucleotide phosphoribosyltransferase (Nampt), rate-limiting enzyme in the salvage pathway, in serum, liver and adipose tissue. Nonalcoholic steatohepatitis (NASH) model rats impair niacin nutritional status by reduction of Nampt expression and enhancement of nicotinamide catabolism. These findings suggest that NAD-related metabolic diseases impair niacin nutritional status, and thus niacin therapy is useful tool to improve both diseases and niacin nutritional status.

SY(T1)9-1

Overview of recent developments of protein quality methodology

Daniel Tome[1]

1. Paris-Saclay University, AgroParisTech (France)

Dietary proteins provide nitrogen and AA which are required to support the synthesis of protein, and of numerous nitrogen-containing and AA-derived compounds in the body. Protein are constituted by 20 AA including 9 indispensable AA (IAA) not quantitatively synthesized in humans and which must be supplied in adequate quantity and proportion by the diet, while the other dispensable AA can be de novo synthesized from different precursors. The quality of dietary protein sources can be assessed by measuring utilization and retention of dietary nitrogen and AA in the body, but this approach is difficult due to the complexity of the physiological and metabolic processes of protein digestion and metabolic utilisation of AA. Alternatively, the quality of dietary protein sources can be assessed by their ability to meet nitrogen and IAA requirements for growth, maintenance, and specific physiological states. The three limiting factors for protein quality, include the total protein content, the IAA content and profile of these proteins, and the metabolic availability of the dietary protein-derived AA. Accordingly, protein quality has been assessed by the widely accepted chemical scoring approach that compares the IAA pattern of a protein with reference age-specific IAA requirement patterns corrected for protein or IAA digestibility. This is performed through the two simple indexes, Protein Digestibility Corrected Amino Acid Score (PD-CAAS) and Digestible Indispensable Amino Acid Score (DIAAS). A critical aspect of the chemical scoring approach is measurement of protein and IAA digestibility to correct the chemical score. The PD-CAAS that corrects the chemical IAA score by a single faecal nitrogen digestibility value has been subject to criticism. Indeed, faecal digestibility is not always a good proxy of AA digestibility, especially for low digestible proteins, possibly due to the contribution of colonic microbes to nitrogen transactions through the fermentation of undigested protein entering the colon. In addition, there are differences in digestibility between different AAs and taking a single protein nitrogen faecal digestibility value for the different AA can lead to other or underestimate the specific digestibility of each individual AA. To overcome these concerns, the DIAAS corrects the chemical score of each individual IAA for the true specific oro-ileal digestibility of the same IAA. The question of AA metabolic availability has been discussed and several models and methods of measuring protein and AA digestibility are currently available including human, pig, rat, and in vitro models. The methods traditionally assess nitrogen and AA disappearance in the intestine by measuring oro-fecal or oro-ileal balance, and more recent methods, including the dual isotope tracer method or Indicator AA oxidation method, directly measure the systemic availability of dietary AA. These methods have been applied to assess ileal digestibility of protein and IAA from different dietary sources. Moreover, the PDCAAS is truncated to 100% and does not indicate the potential of a high-quality protein to optimise the IAA composition of food mixtures with other low-quality protein,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

while DIAAS is not truncated to indicate the potential of a high-quality protein to complement low-quality protein in mixed diets.

SY(T1)9-2

Porcine model for routine detection of protein digestibility in humans

Hans H Stein[1]

1. University of Illinois (USA)

Background and objectives: Because of the similarities of the digestive tracts in humans and pigs, routine determination of digestibility of amino acids (AA) in human foods may be accomplished using a porcine model. The objective of the present work, therefore, was to demonstrate the suitability of using a porcine model to routine determination of protein quality of human foods.

Methods: A T-shaped cannula was installed in the distal part of the small intestine of pigs (the ileum), which allowed for collection of ileal fluids from pigs fed food proteins or a protein-free diet. Collected samples were lyophilized and analyzed for AA and values for standardized (true) ileal digestibility of AA were calculated. By comparing these values to reference patters for AA requirements for different groups of humans, values for the Digestible Indispensable Amino Acid Score (DIAAS) were calculated in a number of food proteins including cereal grains, pulses, oilseed concentrates and isolates, nuts, protein hydrolysates, pork, beef, fish, and dairy products.

Results: Results demonstrated that pigs easily consume any food protein that humans consume and calculation of DIAAS in food proteins is straight forward using the porcine model. In general, greater DIAAS values were calculated for animal proteins than plant proteins, but in several cases, processing of plant proteins such as fermentation or heat treatment, increased DIAAS. It was also demonstrated that values for DIAAS obtained for individual ingredients are additive in meals consisting of more than one food protein. As an example, DIAAS in the combined meal of a breakfast cereal and milk was accurately calculated from DIAAS values obtained for breakfast cereals and milk alone.

Conclusion: By determining the standardized ileal digestibility in food proteins using the porcine model, values for DIAAS were calculated for individual food proteins. These values can subsequently be used to calculated DIAAS for mixed meals consisting of several food proteins. Use of the porcine model, therefore, is a practical tool to determine the protein value of ingredients and meals consumed by humans and this model offer opportunities to increase the accuracy of food protein evaluation.

SY(T1)9-3

New doubly labelled protein method for dietary true ileal amino acid digestibility

Anura Kurpad[1]*, Sarita Devi*[1]

1. St John's Medical College (India)

Protein digestibility is an important and key limiting factor in the availability of indispensable amino acids (IAAs) from foods. It has been refined to specifically measure IAA digestibility, which is used in an index to measure protein quality, called the Digestible Indispensable Amino Acid Score (DIAAS). Protein quality is particularly for vulnerable and poor populations, subsisting on cereal and pulse based diets, and living in challenging environments where intestinal dysfunction may exist. Since the digestion of protein occurs only in the small intestine, and the metabolic activity of colonic bacteria confounds measurements at the faecal level, the measurement of protein digestibility required measurements at the ileal level, using invasive techniques like intestinal intubation and perfusion, or the use of ileostomates, to provide a window into this process. We developed a dual-tracer method with stable isotopes to characterize the IAA digestibility of uniformly labelled ^{2}H-proteins from different food groups like cereals, millets, pulses, algal and animal source foods. These foods were compared with a standard protein with known digestibility, like either ^{13}C-sprulina protein, or a mixture of ^{13}C-labeled crystalline amino acids. In a series of human adult studies, we have measured the digestibility of rice, finger millet, mung bean, chickpea, yellow pea, spirulina, hen's egg and skeletal muscle, and milk protein. We have also measured this in young children, to evaluate optimal cereal-legume mixtures to meet the age-specific DIAAS requirement in complementary foods.

SY(T1)9-4

Digestibility of amino acids in foods of India

Kiran Bains[1]

1. Punjab Agricultural University (India)

Dietary amino acid supply may potentially limit protein metabolism; hence, it is imperative to accurately monitor the dietary supply of 'available amino acids' in relation to the dietary requirements. The availability of lysine is of interest since it is often limiting in cereal-based Indian diets. Furthermore, lysine intakes are marginal in low socio-economic group Indians. The

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

presence of poorly digested protein fractions and high levels of insoluble fibre and anti-nutritional factors in cereals and legume-based meals are responsible for poor digestibility of proteins. A further consideration is that cereals tend to be limiting in lysine while legumes have less sulphur containing amino acids. Moreover, the losses of available lysine, due to Maillard reactions that may occur during food preparation, exacerbates the problem in cereals and to some extent in legumes. The overall true ileal amino acid digestibility across amino acids for prepared cereal-legume meals ranged from 66 to 93% with a mean overall digestibility of 85%. All the cereal-based foods had lower levels of both gross reactive and true ileal digestible reactive lysine than the lysine requirement for children and adults. When gross total or reactive lysine is used as a determinant of lysine content it would be predicted that only eleven of the twenty-one foods (prepared from cereals and legumes) would be lysine adequate all age groups. Finally, when the lysine content was based on true ileal digestible reactive lysine, only five of the foods would be predicted to be lysine adequate for all age groups, two would be lysine deficient for 1-3-year-old children and fourteen food samples would be lysine deficient for all age groups. This is of concern given that for the majority of the prepared meals and ingredients examined were either marginal or did not meet the nutritional requirements for both children and adults. In the present Indian food scenario, where milk and legume consumption is gradually reduced because of sharp rise in their prices, it is assumed that large Indian population may subsist on lysine inadequate diets which may have detrimental effect on muscle protein synthesis and muscle function.

Digestibility of amino acids in foods of China

Fei Han[1], Paul Moughan, Juntao Li[2], Natascha Stroebinger[2], Shaojie Pang[1]

1. Academy of National Food and Strategic Reserves Administration (China), 2. Riddet Institute, Massey University (New Zealand), 3. State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University (China).

The aim was to study the protein quality of foods by determining the amino acid content and digestibility of foods in China. The values for the digestible indispensable amino acid score (DIAAS) in cooked cereals and pulses were determined. True ileal digestibility (TID) values of amino acids relevant to adult humans were obtained. It is difficult to determine ileal amino acid digestibility in humans directly, and for this reason, the growing pig or rat is often used to obtain such values, as a preferred animal model. Three animal experiments were conducted. Each cooked cereal, pulse or blends of cooked cereal and pulse was included in a diet as the only source of crude protein. An N-free diet was given to allow determination of gut endogenous AA losses. All animal experiments were carried out in strict accordance with the methods recommended by the Report of the FAO Expert Consultation (2013). The first determined the TID values of AA obtained from nine cooked cereal grains (brown rice, polished rice, buckwheat, oats, proso millet, foxtail millet, tartary buckwheat, adlay and whole wheat) fed to growing rats. Among the TID values obtained, whole wheat had the highest values ($p<0.05$), and polished rice, proso millet and tartary buckwheat had relatively low values. The DIAAS (for children over 3 years old / adolescents / adults) was 68 for buckwheat, 47 for tartary buckwheat, 43 for oats, 42 for brown rice, 37 for polished rice, 20 for whole wheat, 13 for adlay, 10 for foxtail millet and 7 for proso millet. The second determined the TID values of AA obtained from six cooked Chinese pulses (kidney bean, mung bean, adzuki bean, broad beans, peas and chickpeas) fed to growing pigs. It was found that the TID values for the total indispensable AA were higher ($p < 0.001$) for broad beans (87.3%) and lower ($p < 0.001$) for kidney bean (73.3%) than for the other pulses. For the older child (over 3 years), adolescent and adult, the DIAAS (%) was mung bean 94 >; pea 88 >; broad bean 87 >; small bean 78 >; kidney bean 74 >; chickpea 71. The third studied the complementary effect between cereals and pulses on protein quality. The values for the DIAAS in cooked cereals and pulses, given alone (mung bean, adzuki bean, millet and adlay), and blends of cooked cereals and pulses (mung bean + millet and adzuki bean + adlay) were determined. The mean TID values for millet were the highest (89.4%) and the adzuki bean/adlay mixture the lowest (79.5%). For the older child, adolescent, and adult, the DIAAS (%) was 93 for mung beans, 78 for adzuki beans, 22 for millet, 16 for adlay, and 66 for mung beans + millet, 51 for adzuki beans + adlay. The novel data presented on the TID of the amino acids and DIAAS values for cereals and pulses in a form as typically consumed in China enrich the global database of DIAAS values.

Nutrition surveillance in Japan for sustainable population health

Nobuo Nishi[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

The Japan National Health and Nutrition Survey has been conducted over 70 years. It examines not only dietary intake of the Japanese but also their lifestyles such as physical activity, drinking and smoking. The survey results are utilized to monitor the progress of the national health promotion plan named Health Japan 21. When the lifestyle targets in the second edition of Health Japan 21 are classified according to the levels of the socioecological model, 16 out of 22 targets in lifestyles are at intrapersonal level and 2 targets each are at inter-individual, institution and community levels. The National Health and Nutrition Survey is useful for monitoring most of the target items at intrapersonal level, but no other surveys are regularly utilized to monitor the target items at inter-individual, institutional,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

community and policy levels. Target items at all socioecological levels should be comprehensively incorporated in the national health promotion plan. Also, target items at policy level should be considered as sustainable lifestyles have increasingly become important. A system dynamics model is useful in providing stakeholders and policymakers with a comprehensive understanding of the inter-relationships and feedbacks among lifestyle-related factors at all socioecological levels. Group-model building has become increasingly common in involving stakeholders and policy makers and drawing a causal-loop diagram, one of qualitative models in system dynamics, on dynamic and complex problems. Some examples of group-model building for sustainable food system will be introduced. In 2019, the Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization (WHO) released "Sustainable healthy diets: Guiding principles". It contributes to the Sustainable Development Goals (SDGs) at country level, especially Goals 1 (No Poverty), 2 (Zero Hunger), 3 (Good Health and Well-Being), 4 (Quality Education), 5 (Gender Equality), 12 (Responsible Consumption and Production) and 13 (Climate Action). The National Institute of Health and Nutrition, Japan made a commitment entitled "Food-based dietary guideline for SDGs" for the Tokyo Nutrition for Growth Summit 2021. The institute will contribute to sustainable population health by evaluating the nutrition policies of Japan from the viewpoint of SDGs as well as by proposing a food-based dietary guideline for sustainable healthy diets by 2030.

Contribution of Asian Scientists to Global Nutrition

Jeyakumar Henry[1]

1. ASTAR, Singapore Institute of Food and Biotechnology Innovation (Singapore)

In 1888, Eijkman working in present day Jakarta, reported polyneuritis in chickens fed polished rice. Observing that the disease in chicken, resembled polyneuritis in humans caused by beriberi, Eijkman proposed that beriberi was due to the presence of toxic compounds in polished rice. However, it was his successor Dr Grijns who demonstrated that the lack of thiamine was the primary cause of polyneuritis in beriberi. This illustrates one of the earliest records of nutritional research emerging from Asia, highlighting the significant role Asia has played in the conceptualization and application nutrition science. At about the same time, Japanese scientists both from the army and navy were also pursuing research on the role of polished rice in the etiology of beriberi. This symbolizes the early contribution and role of Japanese scientists in nutrition research. At the turn of the 20th Century (1920), Professor Takahira commenced his pioneering studies on measuring the basal metabolic rate and nitrogen excretion of lean and obese Japanese volunteers and the understanding of the biology of human starvation. His pioneering work laid the foundation of our contemporary understanding of tissue partitioning during starvation. These seminal studies have been rarely referred to, compared with the widely publicized studies on starvation reported by Benedict. An international figure in nutrition science was also Prof C Gopalan who was responsible for initiating nutrition research in India. Post-independence around 1948, India faced numerous nutritional challenges and deficiencies. Gopalan's work on eradicating iron, iodine and other vitamin/mineral deficiencies led to the evolution of public health policies being adopted by numerous other countries in Asia and beyond. Gopalan also pioneered in developing one of the earliest food composition tables in Asia, which even today in its revised form, is extensively used worldwide. Given that Japan has the longest life expectancy at birth, it is instructive to examine and investigate the dietary composition of the Japanese, notably the Okinawa diet. These insights will enable us to redesign and retool diets across Asia to emulate the macronutrients compositions and phytochemical profiles of these diets. This illustrates some of the many contributions that the Japanese and Asian nutritionists continue to play in developing optimal diet for health and longevity. In my presentation I will continue to walk through the history to the present day of how nutrition scientists in Asia had and will continue to make invaluable contributions to global health.

Application of nutrition, dietetics and food science in public health interventions in Asia

Sumanto Haldar[1]

1. Singapore Institute of Food and Biotechnology Innovations (SIFBI) (Singapore)

Asia is a global epicenter for type 2 diabetes and cardiometabolic diseases. Due to the wide distribution of GDP across various nations, compounded by increasing economic prudence, there is a double burden of overnutrition, combined with nutritional deficiencies. This problem is anticipated to grow further in the next few decades. Traditionally, across Asia the concept of 'food as medicine' is nothing new. In recent years, a renaissance of food as new medicine emerged through the evolution of 'functional foods', which was first conceptualized in Japan. This has enabled us to make evidence-based claims related to the effects of various foods and food components.

In this talk, I will discuss the role that research in nutrition science, dietetics and food science played in this region through multidisciplinary contributions, which have been pivotal in improving the food systems in Asia and around the globe, to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

better public health in the 21st century. Some of the pertinent areas of research will include the use of foods and food components to improve energy regulation and balance, glucose homeostasis, lipid metabolism as well as incorporation of bioactive phytochemicals that are uniquely found in Asian foods and are also culturally appropriate. Furthermore, using state of the art food technology and processing methods to complement nutrition have further enhanced molecular function, structure and sensory profile of foods to improve metabolic health. The talk will also cover the emerging area of chrononutrition, whereby it is not only what we eat but the time when we eat it that matters and how certain dietary components can enhance circadian function and consequently improve health. The final section of the talk will demonstrate some successful examples of the integration of food science, technology, nutrition and dietetics to revolutionize the way we deliver foods with distinctive health benefits, focusing on the unique nutritional challenges facing Asia and highlight how regional cooperation will be the cornerstone to alleviate the risk of type 2 diabetes, obesity and other non-communicable diseases.

Introduction of oral health: Its global burden

Ken Osaka[1]

1. Tohoku University (Japan)

A Number of studies revealed that poor oral health leads to subsequent systemic health problems including frailty, cardiovascular disease, dementia, stroke, and death. The main mechanism seems to be a change in nutrition intake. It is reported that fewer remaining teeth were associated with less consumption of meat and vegetables. I will present the current situation of the global burden of oral health and its impact on nutrition.

Public health fight against sugar

Richard Geddie Watt[1]

1. UCL (UK)

This presentation aims to highlight the importance of reducing free sugars consumption globally through the adoption of radical public health policies. Through a public health lens, the epidemiological evidence on the high intakes of free sugars will be highlighted in the context of World Health Organization 2005 guidelines. Particular attention will however be placed on the rising consumption of free sugars in many low and middle-income countries. The impact of free sugars consumption on general and oral health will then be highlighted. An overview of commercial determinants will be outlined and the direct relevance of this to sugar reduction strategies will be stressed. The presentation will then focus on the limitations of solely adopting clinical and individual level interventions and the importance of implementing a range of complementary upstream public health measures to reduce sugars consumption at a population level.

Keywords: Sugar, public health, commercial determinants

Epidemiology of oral health on nutrition and food intake

Jun Aida[1]

1. Tokyo Medical and Dental University (Japan)

Oral health has an essential role in nutritional intake. The chewing function of oral is directly related to eating and nutrition intake. Historically, epidemiological studies have reported the association of oral health with food intake, nutrition intake, and body-mass index. In addition to these direct effects of oral health, recent studies suggest the indirect effect of oral health on nutrition and food intake. Oral health is essential for speaking and smiling. Thus, oral health affects social interactions with others. A recent epidemiology study determined that older people with poor oral health had a higher possibility of eating alone. Eating alone is considered as a social determinant of poor general health. In addition to direct mechanisms such as chewing function, this kind of indirect mechanism is also considered as an important role of oral health on nutrition and food intake. In 2021, the 74th WHO World Health Assembly approved the resolution on oral health, and it described the role of oral health on general health. The role of oral health on food and nutrition intake is considered to be one mechanism between oral and general health. In fact, epidemiological studies using mediation

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

analysis support this mechanism. This presentation will explain oral health and nutrition intake from a wider range of aspects.

Keywords: Oral health, Epidemiology, Mediation analysis, Social determinants of health, Eating alone

Clinical effort to improve ingestion and swallowing among disabled older people

Haruka Tohara[1]

1. Tokyo Medical and Dental University (Japan)

There are two characteristic efforts about dysphagia in Japan. One of them is participation of dentist to dysphagia team. Actually, number of the dentists who participate in JSDR is lot. And education about dysphagia is essential for pre graduate dental students. Dentists can make not only dentures, but also particular prosthesis, such as palatal augmentation prosthesis. This can allow us to further approach. Another characteristic effort is home visiting dysphagia rehabilitation. Such intervention has been promoted so far, a lot of medical resources are face with chronic dysphagia patients now. Then, I made dysphagia rehabilitation map (https://www.swallowing.link/) to reveal the medical resources where can correspond with dysphagia. Home visiting rehabilitation should be promoted further to keep general health of prolonged chronic patients. When it comes to our recent studies, we started with developing jaw opening exercise that is training for supra hyoid muscles. Maximum opening of the jaw was effective to strengthen supra hyoid muscles. Then, jaw opening sthenometer was developed also, that allowed us to examine strength of supra hyoid muscles. We found tongue pressure, jaw opening force, and location of hyoid bone are likely to lower in men. Furthermore, trunk muscles and neck muscles related jaw opening force significantly. So, especially men need to keep trunk and neck muscles to prevent dysphagia. We conducted the study to figure out the effect of recovery of oral intake from tube feeding on oral and intestinal bacterial flora. The result was positive. Diversity and dysbiosis was increased after oral intake. So, variety of food would be important to the body rather than only high density nutritional diet.

Umami sensing and nutrition

Shizuko Satoh-Kuriwada[1]

1. Tohoku University (Japan)

Decline of taste sense induces not only the decreased quality of life (QOL), but also related to poor nutritional status or health problems have been investigated, particularly in the elderly. Our previous study has shown that elderly people with dysgeusia had a significantly lower frequency of food intake, including meat, fish, legumes, vegetables, and so on, than those with normal taste sensation. Anorexia and poor health were significantly more common in these older people with dysgeusia. Whereas patients with taste disorder often complain about the low palatability of food, even after four basic taste sensation (sweet, salty, sour, and bitter) have improved by clinical treatment. Umami is a unique taste modality, which is the fifth basic taste quality, implicated the palatability and acceptability of foods. It is also considered to be the essence of deliciousness. The patient's complaint might be due to umami taste defect, but umami sensation was not usually measured clinically. We developed the umami sensitivity test using filter paper disc method, and reported the specific decline of umami taste sensation in the elderly patients, which complained of taste problem although four basic tastes other than umami taste were normal. These studies further demonstrated that the umami taste dysfunction also related to appetite and weight loss, resulting in poor health. We tried to find the oral cause of the taste disorder. Dry mouth is also strong causative factor to evoke the taste disorder based on our previous study that showed the rate of salivary secretion was significantly less in the elderly with gustatory impairment than those in normal subjects of the same age group. Moreover, our clinical studies indicated that the treatment for dry mouth is often effective against hypogeusia. Saliva assists and influence the detection of taste sense by allowing the diffusion of taste substances to taste receptors, chemical interaction with food substance. Further it contains various organic substances that help maintain general health, such as enzyme, tissue growth factor, secretary IgA, and so on. Since saliva-promoting medication have various side effects, it is often not available to elderly patients with hyposalivation. We investigated and demonstrated that glutamate, which produces umami taste, increased salivary secretion by the gustatory-salivary reflex. Our data suggests that umami sensing might be an effective tool for the relief of dry mouth as well as regain good health without any side effect. A deeper understanding and insight of how to regain and enhance the umami sensing may have impact on the adequate food intake and the amelioration of poor nutritional status, moreover the improvement overall health.

Low calorie sweeteners; Individual and group efficacy for weight management

Rick Mattes[1]

1. Purdue University (USA)

Sweetness is an inherently pleasant sensation and a driver of food intake. In an era when overweight and obesity are prevalent globally, many have expressed concern about the role of sweet foods and beverages in promoting positive energy balance. The US Dietary Guidelines, World Health Organization and others have recommended reducing sugar intake. One approach is to replace nutritive sweeteners with low calorie sweeteners (LCS). Numerous epidemiological studies and clinical trials have examined their efficacy at moderating energy intake and body weight. Findings have been mixed. Some have suggested that LCS are actually counter-productive because they stimulate appetite. The most commonly proposed mechanism is through disruption of carbohydrate metabolism. However, the preponderance of evidence does not indicate that LCS alters either post-prandial glycemia or appetite. Similarly, energy intake is usually lower with LCS use. Multiple meta-analyses of prospective cohort studies assessing indices of body weight (e.g., weight, BMI, waist circumference) have been undertaken. Some have revealed LCS use is associated with slightly higher BMI (but not body weight), while other analyses fail to find an association with either outcome. The strongest meta-analyses of randomized clinical trials consistently document that LCS use leads to lower BMI, fat mass, and waist circumference in children and adults. Whether LCS use is superior to water as a substitute for nutritive sweeteners is not established. Several meta-analyses have suggested LCS use is associated with higher BMI, but these analyses are generally more limited in scope and include trials of questionable methodology. One explanation for the lack of consensus about LCS use and indices of adiposity may relate to the failure to carefully define the LCS studied. It is widely assumed that all commercially-available LCS are functionally equivalent. They all provide sweetness at concentrations so low that they provide little or no energy. However, they are all unique chemicals that are differentially digested, absorbed and metabolized. Consequently, it might be hypothesized that they will have different effects on body weight. Recent work supports this view. A 12-week clinical trial contrasting the effects of daily consumption of sucrose, saccharin, aspartame, sucralose and rebaudioside A on body weight revealed saccharin led to weight gain that was similar to that observed with sucrose. In contrast, sucralose led to a reduction of body weight. Replication of this finding and identification of mechanisms is required. Taken together, the evidence indicates LCS may be a useful aid for weight management if used as a substitute for energy-yielding sweeteners.

Olfactory dysfunction is related to frailty and cognitive dysfunction in the elderly

Takaki Miwa[1]*, Shigeto Morimoto*[1]*, Osamu Iritani*[1]

1. Kanazawa Medical University (Japan)

Aim: Individuals with olfactory or gustatory impairment often have associated difficulties with food-related activities. As both functions decline in older adults, we investigated the association of these impairments with sarcopenia/frailty indexes in community-dwelling older adults.

Methods: A total of 141 participants (69 men and 72 women, mean age 73.0 years) were enrolled. Odor identification was examined using the Open Essence test. Salty and sweet tastes were assessed using a whole-mouth gustatory test. Participants underwent evaluation of the appendicular skeletal muscle mass index (ASMI) by InBody720 and grip strength, and determination of the Study of Osteoporotic Fractures frailty index.

Results: Participants with olfactory impairment (Open Essence <7), but not with gustatory impairment, showed a significantly higher prevalence of ASMI and grip strength less than the cut-off values recommended by the Asian Working Group for Sarcopenia, and Study of Osteoporotic Fractures frailty and/or pre-frailty status, compared with those without impairment. Multivariate logistic regression analysis showed a significant association of olfactory impairment with ASMI less than the cut-off value, grip strength less than the cut-off value, Asian Working Group for Sarcopenia sarcopenia and pre-frailty/frailty in the Study of Osteoporotic Fractures index in the whole population, and with ASMI less than the cut-off value and Asian Working Group for Sarcopenia sarcopenia in women, after adjustment. Three (Japanese cypress, wood and roasted garlic) and four (Japanese orange, India ink, menthol and curry) Open Essence odorants were elucidated as the “sarcopenia subset” and “frailty subset,” respectively, and showed higher ability to identify sarcopenia and frailty status, compared with the remaining five odorants.

Conclusions: These findings suggest that olfactory impairment is closely associated with sarcopenia and/or frailty in community-dwelling older adults.

Changes and Mechanisms of Chronic Psychosocial Stress and Nutritional Preference

Hong Wang[1], Nancy Ellen Rawson[1]

1. Monell Chemical Senses Center (USA)

Obesity is a risk factor for a variety of illnesses. Human studies have linked stress exposure to binge eating and obesity. However, the mechanisms that drive stress-induced overeating remain incompletely understood. The sense of taste plays important roles in food preference and intake. Moreover, taste receptors are expressed in subsets of gut epithelial cells and regulate gut nutrient sensing and metabolism. Altering the sense of taste or taste-receptor-mediated mechanisms in gut may change food preference and intake and lead to weight gain. The goal of this study is to investigate whether chronic stress impacts the peripheral taste system and taste receptor expression in gut. Here, we used a chronic social defeat stress model that had been shown to induce binge eating and weight gain. Our results showed that chronic social defeat stress markedly increased the circulating levels of corticosterone, the main stress hormone. Stress also stimulated food and water intake and led to increased weight gain over time. Chronic stress significantly decreased the mRNA levels of several taste receptors and taste signaling molecules in taste buds. Immunostaining experiments showed that stress decreased the level of KCNQ1, a pan taste cell marker and a voltage-gated potassium channel. Stress also reduced the number of taste bud cells stained positive for PLC-β2, a marker for type II taste receptor cells and a signaling protein required for sweet, umami, and bitter taste signal transduction. These results suggest that stress may interfere with taste signaling and decrease taste sensitivity. Indeed, in behavioral tests, stress decreased the sensitivity and responses to umami taste compounds. In gut, chronic stress altered the expression levels of T1R taste receptors and their downstream signaling proteins. Moreover, we found that monosodium glutamate can reduce chronic-stress-induced weight gain. Together, our results indicate that chronic social defeat stress significantly impacts the peripheral taste system and may also affect taste receptor-mediated mechanisms in gut. These effects of stress likely contribute to the altered food intake and weight gain associated with chronic stress.

Health Emergency and Disaster Risk Management (Health EDRM): WHO initiative to promote global collaboration to improve research and evidence

Ryoma Kayano[1]

1. World Health Organization Centre for Health Development (Japan)

World Health Organization (WHO) has taken initiatives to develop and support the implementation of health emergency and disaster risk management (Health EDRM) by countries and support the implementation of country strategies, the Sendai Framework, International Health Regulations (2005), the Sustainable Development Goals (2015), and Paris Agreement on Climate Change (2016) and other related regional and global frameworks. The Health EDRM Framework, published by WHO in 2019, describes all the functions that are required across multiple disciplines in health and other sectors that reduce hazards, vulnerabilities, and exposures, while ensuring effective preparedness and readiness, response, and recovery to save lives, protect health and build community and country resilience. Evidence and research play vital roles in advancing all aspects of Health EDRM including understanding community risks, informing the design and delivery of health and related services, health workforce development and monitoring and evaluation. In order to improve the scientific evidence for Health EDRM and promote global and regional collaboration among researchers and experts, WHO established the WHO Thematic Platform for Health EDRM Research Network (Health EDRM RN) in 2018. The Health EDRM RN has supported the setting of key research themes which has informed WHO Health EDRM research funding over the past 3 years, and the publication of the WHO Guidance on Research Methods for Health EDRM in 2021, which was developed through the collaboration among over 100 global experts. In the context of identifying and applying the lessons from the COVID-19 pandemic and other emergencies and disasters, the Health EDRM RN will continue to strengthen multi-disciplinary including nutritional science and multi-sectoral collaboration, Health EDRM research capacities and translating the evidence base into policy and practice. In view of the progress made by the Health EDRM RN and the shifting global situation, two major projects are underway: the 2nd phase of the WHO Health EDRM Knowledge Hub · the elaboration of research priorities for Health EDRM. The opportunity to provide wider understanding of the WHO Health EDRM policy, practice and several advanced research areas is important for disaster risk management. The WHO Health EDRM Research Network provides effective multi-disciplinary and multi-sectoral collaboration for engagement in development of policy, practice and research. An opportunity to join the Research Network is shared.

Frontiers in Disaster Nutrition for Nutritional Health Care after Natural Disaster and Pandemics

Nobuyo Tsuboyama-Kasaoka[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Large-scale natural disasters frequently result in mass evacuations. During these evacuations, nutritional health care may be crucial for sustaining the lives of evacuees. To find scientific evidence of dietary improvement methods at emergency shelters worldwide a literature search was conducted. The literature search yielded seven articles. Four major factors associated with nutritional problems after natural disasters were identified from the literature review: 1) shelter size and equipment of the emergency shelter, 2) the method of provision and content of meals in emergency shelters, 3) collaboration with professionals, and 4) cooperation between shelters.

In addition, we organized the information regarding initiatives taken to improve health and nutrition after natural disasters by governments, professional organizations, and academic research organizations in Japan. After the Great East Japan Earthquake (GEJE), various initiative aimed at health and nutrition improvement after natural disasters, such as establishment of a specialized section, initiative/strategy to stockpile disaster food, development of human resources, and the nutrition standards for disasters, were started in Japan. In this symposium, I would like to introduce various approaches in Japan for solving nutritional health problems at the time of disaster.

1. Global Disaster Nutrition Section/ National Institute of Health and Nutrition.

The mission is to reduce nutrition and health problems according to natural disasters with a slogan of "Evidence to Action". (1) Research for reducing nutritional disparity according to natural disaster, (2) Develop nutritional support system during disaster, and (3) Provide information and logistic support.

2. Disaster Food Certification. Japan Disaster Food Society started a certification system of “Japan Disaster Food” in 2015. Disaster foods are extensions of daily diets. All the foods and drinks conservable at room temperature are available as disaster food. Now, more than 132 items are already certified.

3. Disaster Dietitian.

To provide nutritional health care at actual sites within the disaster-affected areas, the Japan Dietetic Association established the Japan Dietetic Association-Disaster Assistance Team (JDA-DAT). Such systematic and large-scale dietary support after a disaster is rare, even worldwide. Nutritional health care of evacuees could be partially improved by being better prepared for disasters.

Addressing Malnutrition in Humanitarian Emergencies

Abigail Perry[1]

1. World Food Programme (Italy)

The three Cs, conflict, climate change and the impacts of COVID-19 are driving alarmingly high levels of food insecurity and malnutrition. In the last two years, the number of food insecure people increased from 135 million to 283 million and is expected to increase further. The global caseload of acute malnutrition is expected to increase by 20 percent. The World Food Programme estimates that at the start of 2022 there are 33.7 million people in Integrated Food Security Phase Classification-4 or higher and just over 10 million suffering acute malnutrition in countries facing acute crises.

With nutrition crises at an all-time high, amalgamation of the ‘three Cs' has echoed the urgent need to pursue more efficient and agile methods to reaching those most at risk in disaster settings. At a time of compounding needs worldwide, the demand for safe and sustained humanitarian access is paramount to ensuring lifesaving humanitarian assistance. The ability to access catastrophe struck communities during the height of the disaster has been one of the most recurrent challenges for humanitarian action.

Vulnerable countries and communities are already suffering from severe losses and damages to lives, livelihoods, crops, and infrastructure caused by the impacts of climate change while there are also other nations where the primary driver of acute hunger is conflict and insecurity. A clear example of climate effects can be seen in Madagascar, where multiple intense cyclones during the agricultural season have the alarming propensity to wipe out harvest, send food prices soaring and increase food insecurity. Whereas In Yemen, changing policies and regulations on fuel supply, telecommunications and transportation facilities have further restricted the ability of WFP and fellow humanitarian actors to deploy and respond.

The crux to the problem is exploring better preparedness through pinpointing how to provide timely humanitarian interventions while concurrently building resilience for populations that are suspectable to disasters. This would require a galvanized efforts from different actors in the humanitarian space.

The presentation ‘Addressing Malnutrition in Humanitarian Emergencies' will delve into the importance of identifying the needs of the most vulnerable, how early warning systems can be used as a tool to combat malnutrition in emergencies and crucial lessons that can be drawn from the World Food Programmes' operation responses in Madagascar and Yemen.

Protein modification by non-enzymatic glycation and its relevance to lifestyle-related diseases

Ryoji Nagai[1]*, Hiroko Yamaguchi*[1]*, Nana Katsuta*[1]*, Yuki Tominaga*[1]*, Sayuri Kato*[1]*, Yoshitaka Hiraoka*[1]*, Yu Sato*[1]*, Himeno Takahashi*[1]*, Shintaro Kuribayashi*[1]*, Hikari Sugawa*[1]

1. Tokai University (Japan)

Non-enzymatic glycation was first reported in the field of food chemistry as a condensation reaction between reducing sugars and amino acids. This reaction is also called "glycation" and generates the advanced glycation end-products (AGEs) in an advanced stage. This reaction progresses not only in processing foods but also in physiological conditions. Although AGEs formation was believed to progress mainly from glucose, several carbonyl compounds such as methylglyoxal, glyoxal, dehydroascorbic acid, and glycolaldehyde are also reported to play an important role in AGEs formation *in vivo*. However, the detection of AGEs in physiological samples is still difficult and many studies over- or under-estimate AGEs levels in samples, and some other studies brown pigments are mistaken for AGEs. The quantification of AGEs *in vivo* was originally performed using the fluorescent characteristics of AGEs. Subsequently, an anti-AGE antibody was developed as a more specific tool for detecting AGEs, and the involvement of AGEs in various diseases has been reported. However, it is still difficult to clarify the relationship between pathology and glycation by measuring only a single AGE structure. Therefore, monitoring for multiple AGEs in biological samples by instrumental analyses, such as liquid chromatography tandem mass spectrometry (LC-MS/MS), is widely used to assess the biological significance of AGEs. However, LC-MS/MS analysis requires multiple preparation steps before the analysis can be performed and it is difficult to run a large number of clinical samples. For this reason, we developed a device, called the AGE sensor, that detects skin fluorescence intensity. The results using this sensor indicated that the fluorescence intensity at the fingertip was increased in the presence of diabetic microvascular complications. This device allows us to estimate the subject's AGE levels in one minute and the involvement of AGEs in various pathological conditions is currently being investigated. Therefore, I would like to explain the advantages and disadvantages of this simple analysis and the precise analytical methods used for AGEs.

SY(T1)14-2

Novel prevention of disease based on metabolomic aspects on glycation

Reiko Inagi[1]

1. The University of Tokyo (Japan)

Protein homeostasis, which is orchestrated by protein synthesis, folding, modification, and degradation, is essential for cellular function. Glycation is one of the protein modifications that alter protein homeostasis. Advanced glycated proteins, including advanced glycated end-products, often contribute to the development/progression of various diseases associated with metabolic abnormality and aging. The recent studies highlight the link between glycation and metabolism-related organelle function: glycation implicates the metabolic abnormality via organelle dysfunction. In addition, advanced multi-omics analysis has revealed that proteomic and metabolomic analysis shed light on the pathophysiological impact of mitochondrial dysfunction by glycation in diabetic or age-related kidney disease (1).

Meanwhile, organelle dysfunction, such as mitochondrial or endoplasmic reticulum (ER) stress, is a causal factor for cellular dysfunction, leading to disease progression. In kidney disease, organelle stress in tubular cells aggravates tubular inflammation and tubulointerstitial fibrosis, and that in glomerular cells causes severe proteinuria. Notably, such organelle stress is closely associated with metabolic alteration, including glucotoxicity and lipotoxicity (2,3). The recent intensive research, including ours, has revealed how ER stress alters fatty acid metabolism via dysregulation of mitochondrial function, suggesting the pathogenic importance of the link between organelle stress and cellular metabolism (3,4). Interaction of an organelle with another organelle, so-called organelle crosstalk, is an updated research field to reveal new insight into metabolic homeostasis. Our recent studies point out that mitochondrial damage associated with metabolic derangement causes ER-mediated tubular inflammation via mitochondrial DNA leakage into the cytosol (5) and that the mitochondria-ER axis, as well as the mitochondria-primary cilia axis, is essential for homeostatic mitochondrial metabolism (6-8). These results demonstrate that organelle crosstalk determines cell fate from the point of view of intracellular metabolism.

This presentation will summarize the most recent evidence on glycation and organelle stress, both associated with defective organelle crosstalk and metabolic alteration in kidney disease, especially chronic kidney disease (CKD), including diabetic kidney disease related to high glycation status.

Glycation reaction and the receptor for advanced glycation end-products (RAGE): foe or friend for life?

Yasuhiko Yamamoto[1]

1. Kanazawa University (Japan)

As for sources of energy for life activities, glucose is the most crucial in all livings. Glucose is provided from foods and produced by nutrient metabolism in the body. Nonenzymatic glycation reactions occur between glucose and biological macromolecules *in vivo*. Therefore, glycation is an unavoidable background reaction in living organisms. The final products of the irreversible glycation reaction are called advanced glycation end-products (AGEs). The endogenously formed AGEs are well-known to be bioactive and detrimental to human health. In addition, exogenous AGEs derived from foods are debated to contribute to the development of aging and life-style related diseases. AGEs-induced activation of different signaling pathways is known to be mediated by a cell surface receptor, named the receptor for AGEs (RAGE). RAGE also binds other ligands such as S100 proteins, lipopolysaccharides (LPS), high mobility group box (HMGB)-1, and amyloid-β, relating to inflammation, diabetes, aging-related diseases, cancer development, and Alzheimer's disease; it is now recognized as a pattern-recognition receptor. A growing body of evidence indicates that RAGE can play an important role in pathological steps of disease development and progression, as well as in physiological processes, including tissue regeneration, host defense, apoptotic cell clearance, and nurturing the mother–infant bond. It is also known that RAGE has several isoforms. Membrane-bound full-length RAGE (mRAGE) is the signal transduction form expressed on the cell surface. Soluble

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

forms of RAGE (sRAGE) include endogenous secretory RAGE (esRAGE), a product of an alternatively spliced mRNA, and an ectodomain-shed form of mRAGE. The sRAGE functions as decoys for mRAGE and potentially protects against mRAGE-mediated cytotoxicity. Therefore, the imbalance between mRAGE and sRAGE would lead to morbidity risk and the development of pathological conditions. **These above-mentioned pathophysiological roles of glycation reaction and RAGE will be presented and discussed.**

Keywords: Glycation, advanced glycation end-products (AGEs), receptor for AGEs (RAGE)

Offspring obesity prevention in pregnancy

Elvira Larque[1]

1. University of Murcia (Spain)

Maternal lifestyle during pregnancy and early nutrition and environment of their offspring´s are considered relevant factors for childhood obesity preventative efforts. In parallel with the increase of overweight and obesity prevalence in childhood, several prenatal factors that are associated with the development of infant adiposity such as prematurity and low birth weight, gestational diabetes, excess body mass gain during gestation, infant formula feeding, etc. have also raised their incidence in the last decades. Interestingly, the rise in the incidence of these perinatal risk factors have also been more pronounced in the developing than in developed countries. We will examine and interpret the knowledge on the early determinants of childhood obesity development in order to provide relevant strategies for daily clinical work. For this purpose, we have evaluated all the identified prenatal factors potentially associated to child adiposity from conception up to the end of the second year of life. Actions to be considered are promoting healthy nutrition and healthy weight status at reproductive age and during pregnancy in order to prevent early excessive weight gain in the offspring. Gynecologists and other health care professionals as midwives should provide proper scientific individual nutritional advice to families to counteract excessive adiposity in the babies. We provide information to help setting up public health strategies to offspring obesity prevention in pregnancy.

Keywords: Pregnancy, Obesity, Prevention, Gestational weight Gain, Gestational Diabetes

SY(T1)15-2

Epigenetic mechanisms involved in childhood obesity development

Concepcion Aguilera[1]

1. Department of Biochemistry and Molecular Biology II, Institute of Nutrition and Food Technology, Center of Biomedical Research. University of Granada (Spain)

Obesity is the most prevalent nutrition-related chronic condition worldwide. In children, the combined overweight and obesity prevalence is very high in all the countries, especially in those from the Mediterranean region, such as Spain. Obesity seems to have its origin from conception. Understanding the early life mechanisms involved in its development would allow developing early prevention strategies. Epigenetics refers to changes in gene function, not resulting from the primary DNA sequence, influenced by the environment. It provides a link between the molecular regulation of the genome and the environmental signals exposed during the life of individuals (including lifestyle, social behavior, development, and nutrition). Epigenetics could provide new information for the understanding of disparities in the emergence of childhood obesity. Currently the study of obesity epigenome focuses mainly on the analysis of ADN methylation patterns. In the recent years multiple epigenome-wide association studies (EWAS) analyzed thousand of DNA methylation at CpG sites and its potential relationship with common obesity and clinical variables related to the disease and adipose tissue distribution. Multiple CpGs have been identified to be involved in insulin and glucose metabolism, adipogenesis or low grade inflammation development in obese subjects. Although most of these studies used whole blood samples, a direct causal link between DNA methylation and circulating protein levels through regulation of white blood cell gene expression could be possible. The realization of EWAS in peripheral blood of children and its relationship with obesity is of great interest both for the study of the influence of maternal obesity and for the detection of epigenetic markers in childhood in order to make an early diagnosis of development of the disease and its metabolic complications. Several studies have demonstrated the stability of epigenetic marks in the form of ADN methylations during the first years of life, as well as the influence of environmental factors during pregnancy. The objectives of this communication are: 1)

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

to understand the molecular basis of the regulation of gene expression through epigenetic modifications. 2) to describe the main results of epigenome-wide association studies in peripheral blood associated with obesity and comorbidities in both adults and children.

Immune system and microbiota in obesity

Marcos Ascension[1]

1. Institute of Food Science, Technology and Nutrition (ICTAN), Spanish National Research Council (CSIC) (Spain)

Obesity is a serious public health concern that is alarmingly growing in the population around the world. It is widely accepted that high levels of body mass index (BMI), comprising a high range between overweight and obesity, can promote a risk of developing non-communicable diseases, such as metabolic syndrome, cardiovascular and musculoskeletal disorders, type 2 diabetes, non-alcoholic fatty liver disease, and certain type of cancers, leading to high rates of mortality. Indeed, obesity and its comorbidities are characterized by a low-grade chronic inflammation status. On the other hand, according to the research in the last decade, there must be an interaction between nutrients and the gut microbiota; therefore, gut microbes might play a crucial role in the regulation of host metabolism and the function of the immune system. Thus, in the context of obesity and related metabolic diseases, the gut microbiota could be proposed as an interesting therapeutic target to avoid inflammation disorders. In addition, microbiota may contribute to significantly facilitate food digestion through enriching genes in metabolizing carbohydrates, vitamins, short-chain fatty acids and amino acids, leading to homeostasis, as well as to a balanced energy metabolism and immunological status. The colon is well-known to contain the highest density of microbes, so that easily sampled using faeces is the most widely studied gut site to evaluate microbiota composition and the risk of obesity. High fat/carbohydrate ratio diets are capable to programme gut microbiotas predominating Firmicutes (Clostridium), Prevotella and Methanobrevibacter, although deficient in beneficial genera/species such as Bacteroides, Bifidobacterium, Lactobacillus and Akkermansia. Reduced amounts of beneficial microorganisms also inhibit fasting induced adipocyte factor expression leading to dyslipidemia. Moreover, altered gut microbiota is associated with decreased expression of short-chain fatty acids that maintain intestinal epithelial barrier integrity, reduce bacterial translocation and inflammation, and an increased expression of hunger-suppressing hormones. In this sense, the synergy of high-fat diets and dysbiosis could be responsible of a recipe that epigenetically programmes the host for an increased adiposity as well as serious inflammation processes.

Mediterranean lifestyles protecting children from obesity

Luis Moreno[1]

1. University of Zaragoza (Spain)

Childhood obesity is the most prevalent nutritional disorder during childhood. It develops in individuals with a genetic predisposition substrate and the presence of factors related with nutrition, sedentary behaviours and others as short sleep duration. Identifying the risk factors associated with obesity, as well as quantifying the risk of each of them, is essential to understand a multifactorial problem such as childhood obesity. We have developed a randomized controlled multi-centre clinical trial (Meli-Pop), in a cohort of children aged 3 to 6 years at baseline and being at obesity risk. The main objective consists on assessing the efficacy of an intervention during early childhood, considering a healthy lifestyle based on the promotion of a Mediterranean dietary pattern and regular physical activity, compared with a control group, on decreasing obesity incidence 5 and 10 years after the beginning of the intervention. Children, aged 3 to 6 years, having at baseline a body mass index (BMI) <; than the equivalent to 30 kg/m^2 in adults, and the mothers having a BMI >; 30 kg/m^2 are considered for inclusion. The clinical trial has two arms and it has been performed in Primary Health centers in 3 Spanish cities: Córdoba, Santiago de Compostela and Zaragoza. The control group will receive usual care by healthcare professionals. The intervention group receive education on Mediterranean lifestyle (Mediterranean diet and physical activity promotion), combined with the provision of extra-virgin olive oil and fish, in order to be consumed at least 3 times per week. Physical activity sessions with a physical activity monitor are also offered for free to the children (3 sessions of 60 minutes of moderate-vigorous physical activity, per week). Interventions trying to prevent obesity should start as early as possible as the possibility to positively influence its progress is optimal in this period.

Postbiotics is a new era for health science

Jun Kunisawa[1,2,3,4,5,6]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 2. Osaka University (Japan), 3. The University of Tokyo (Japan), 4. Kobe University (Japan), 5. Hiroshima University (Japan), 6. Waseda University (Japan)

Research on the effects of dietary components on health has been conducted for a long time, but recently, attention has also been focused on microbiome especially commensal bacteria in the gut. Probiotics (beneficial bacteria for our health) and prebiotics (food for useful bacteria) have already been put to practical use and thus well known, but recently, "postbiotics" has been attracting attention as a new concept. Postbiotics are metabolites originated from dietary components and produced by microorganisms, and after being absorbed into the body, they affect various health conditions. The concept of postbiotics would lead to the research upgrade to consider the production of postbiotics through the crosstalk between dietary components and microorganisms. In this talk, I would like to introduce our recent findings on postbiotics, including the integration of analytical technologies such as metabolomics and metagenomics, basic research using animal models and microbial culture systems, and human research using various information and samples obtained individuals at various areas in Japan.

SY(T1)16-2

Maintenance of gut homeostasis by food and probiotics

Mi-Na Kweon[1]

1. Ulsan University, Asan Medical Center (Korea)

The mammalian gastrointestinal tract, the site of digestion and nutrient absorption, is home to a microbial ecosystem that enhances resistance to infection, inflammation, allergy, and metabolic diseases. Commensal bacteria are key participants in the digestion of food, and are responsible for the extraction and synthesis of nutrients and other metabolites that are essential for the maintenance of mammalian health. Over the past decade, the connection between various disorders and gut microbiota has become a major focus of biomedical research. Because of the complexity of the microbiota community, however, the underlying molecular mechanisms by which the gut microbiota is associated with diseases remain poorly understood. Dietary signals are known to modulate stemness and tumorigenicity of intestinal progenitors; however, the impact of a high-fat diet (HFD) on the intestinal stem cell (ISC) niche and its association with colorectal cancer remains unclear. In this talk, I summarize recent studies how HFD affects the ISC niche and its regulatory factors.

Keywords: Gut microbiota, high-fat diet, intestinal stem cell, colorectal cancer

SY(T1)16-3

The importance of nutrition considering the function of the indigenous microbiota in the gut

Shin Kurihara[1]

1. Kindai University (Japan)

The human intestinal tract contains the gut microbiota, a mixture of more than 150 bacterial species, which contains several tens of trillion bacterial cells, equivalent to the number of human cells, and weighs as much as 1 kg. Recently, the gut microbiota has been found to have a significant impact on diseases related to the energy balance of the human body, such as obesity and diabetes. This suggests that the gut microbiota plays an important role in the nutritional acquisition of the human host, and the idea that "gut microbiota is another organ" is gaining popularity. Probiotics, which are defined as live bacteria that are ingested to improve the intestinal environment, influence the gut microbiota. Also prebiotics is defined as a substrate that is selectively utilized by host microorganisms conferring a health benefit. Prebiotics are widely used as commercial ingredients to modify gut microbiota. However, certain existing prebiotics meant to facilitate the growth of beneficial bacteria in the intestine also promote the growth of other prominent bacteria. Therefore, the growth-promoting effects of β-galactosides on intestinal bacteria were analyzed. Galactosyl-β1,4-l-rhamnose (Gal-β1,4-Rha) selectively promoted the growth of Bifidobacterium. Bifidobacterium longum subsp. longum 105-A has multiple solute-binding proteins belonging to ATP-binding cassette transporters for sugars. Each strain in the library of 11 B. longum subsp. longum mutants, in which each gene of the solute-binding protein was disrupted, was cultured in a medium containing Gal-β1,4-Rha as the sole carbon source, and only the BL105A_0502 gene-disruption mutant showed delayed and reduced growth compared to the wild-type strain. BL105A_0502 homolog is highly conserved in bifidobacteria. In a Gal-β1,4-Rha-containing medium, Bifidobacterium longum subsp. infantis JCM 1222T, which possesses BLIJ_2090, a homologous protein to BL105A_0502, suppressed the growth of enteric pathogen Clostridioides difficile, whereas the BLIJ_2090 gene-disrupted mutant did not. In vivo, administration of B. infantis and Gal-β1,4-Rha alleviated C. difficile infection-related weight loss in mice. We have successfully screened Gal-β1,4-Rha

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

as a next-generation prebiotic candidate that specifically promotes the growth of beneficial bacteria without promoting the growth of prominent bacteria and pathogens. The gut microbiota, "another organ", converts various diet-derived compounds entering the colon into other compounds. These are gut bacteria-derived metabolites, which have recently been reported to have a variety of effects on the host. Colonic luminal aromatic amines have been historically considered to be derived from diet, however recent studies indicate that the gut microbiota serves as an alternative source of these amines. Herein, we show that five prominent genera of Firmicutes (Blautia, Clostridium, Enterococcus, Ruminococcus, and Tyzzerella) have the ability to abundantly produce aromatic amines through the action of aromatic amino acid decarboxylase (AADC). In vitro cultivation of human fecal samples revealed that significant positive correlation between aadc copy number of Ruminococcus gnavus and phenylethylamine production. Furthermore, using genetically engineered Enterococcus faecalis-colonized mouse model, we showed that the gut bacterial aadc stimulates the production of colonic serotonin, which is reportedly involved in osteoporosis and irritable bowel syndrome. Finally, we showed that human AADC inhibitors carbidopa and benserazide inhibit phenylethylamine production in En. faecalis.

Keywords: Prebiotics, Probiotics, Gut bacteria-derived metabolites, Phenylethylamine, Serotonin

SY(T1)17-1

Antioxidant function of *Chlorella* in our body

Teruo Miyazawa[1]

1. Tohoku University (Japan)

Accumulation of phospholipid hydroperoxide (PLOOH) as a result of oxidative stress in erythrocyte membranes is found typically in patients with senile dementia, including those with Alzheimer's disease (AD). Lutein as xanthophyll is a major antioxidant present in erythrocyte membrane, and it is confirmed that erythrocyte lutein concentration is lower in AD patients than in control subjects. Green algae *Chlorella pyrenoidosa* is rich in protein and dietary fiber and is known to be particularly high in lutein. We conducted a randomized, double-blind, placebo-controlled human trial to assess the impact for a total of 2 months *Chlorella* supplementation (8 g *Chlorella*/day/person, equivalent to 23 mg lutein/day/person). After the treatment, erythrocytes and plasma lutein concentrations increased in the *Chlorella* group but not in the placebo group, and in the *Chlorella*-supplemented group, erythrocyte PLOOH after 2 months of treatment were lower than the concentration before supplementation. The findings suggest that *Chlorella* ingestion improved erythrocyte antioxidant status and lowered the aged erythrocytes rich in oxidized lipids in our body. *Chlorella* total intake rich in lutein might contribute to maintaining the normal function of erythrocytes and prevent the development of senile dementia.

Keywords: Chlorella, Lutein, Senile dementia, Alzheimer's disease, Erythrocytes

SY(T1)17-2

Capability of Chlorella as a Protein Source

Masatoshi Kubota[1]*, Motoni Kadowaki*[1]

1. Niigata Institute of Technology (Japan)

Health issues as lifestyle diseases, *e.g.*, diabetes, cancer, stroke, and cardiovascular disease, derived from excessive food intakes and lack of exercise, are serious problems in the developed countries. However, famines have still been one of the most serious issues in the developing countries. It is required to develop novel healthy plant protein sources due to resolving this food crisis because it was reported that animal proteins were not necessarily adequate protein sources based on cholesterol homeostasis compared with plant proteins. Thus, utilization of plant proteins, soybean protein, algae protein and so on, have been studied as alternative protein sources.

Chlorella is one of the microalgae and a high protein foodstuff which the protein content is as much as 60%. Chlorella protein has a superior essential amino acids balance and is recognized as a potential novel alternative protein source. However, a rigid cell wall in chlorella constricts the utilizing beneficial components in the cell. Thus, it was required to develop an effective cell wall breaking treatment and then the treatment with DYNO-MILL was developed. After this treatment, over 90% cell wall was broken down and the digestibility in treated chlorella was improved compared with one in untreated chlorella. However, it was unclear whether the protein digestibility in the treated chlorella was superior to other food proteins. Thus, we attempted to clarify whether the protein digestibility in the treated chlorella was superior to other food proteins, soybean protein, rice protein, and gluten. From the *in vitro* digestion test using pepsin and pancreatin, the chlorella protein was almost digested after 4 hours and its digestibility was superior to one of soybean protein and rice protein. Chlorella protein with broken cell wall was digestible and accessible as an alternative protein source.

Although it is shown that chlorella with broken cell wall has a capability as a protein source from our study, it is unclear whether chlorella with broken cell wall has beneficial effects on our health. Thus, we attempted to clarify novel physiological functions of chlorella, especially beneficial effects on atopic dermatitis (AD). Three weeks old female hairless mice were employed and fed the egg white diet with or without 5% chlorella for 15 weeks. After 3 weeks, 1.2% trinitrochlorobenzene application was conducted to evoke AD symptoms. Chlorella intake significantly suppressed the decrease of moisture contents of the skins after 8 weeks. In addition, chlorella intake also significantly suppressed the formation of erythema, one of

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

the typical AD symptoms. From these results, it is suggested that chlorella had the suppressive effects on deteriorating AD symptoms. These studies show that chlorella has capability as a novel alternative protein source.

Immunological Function of Chlorella

Masako Toda[1]

1. Tohoku University (Japan)

Chlorella is a unicellular green alga growing in fresh water and has widely been used as a dietary supplement with beneficial nutritious content. Among many other potential health benefits, evidence has accumulated that chlorella possess immunological function. Antigen presenting cells such as dendritic cells and macrophages are central players in innate immunity and express pattern recognition receptors (PPRs) including Toll-like receptors (TLRs) to recognize patterns of non-self molecules. Several studies have shown that polysaccharides from chlorella binds TLR2, TLR4 and complement receptors expressed on the cell surface of antigen presenting cells and activates them. We found that extract of chlorella with high contents of polysaccharides induces activation and cytokine production of human and murine dendritic cells via TLR2 engagement. The extract of chlorella also enhanced T cell responses in a co-culture system with dendritic cells. The results suggest that chlorella-derived polysaccharides could stimulate both innate and adaptive immunity. Chlorella extract also reportedly simulates activation of natural killer cells, a principal player in anti-tumor and anti-virus immunity. Studies using murine models have suggested anti-tumor, anti-pathogen, and anti-allergy effects of chlorella. In several clinical experiments on healthy subjects, supplements of chlorella increased the levels of mucosal immunoglobulin A (IgA) in body fluids including saliva and breast milk. Interestingly, extract of chlorella enhances proliferation of human-origin probiotic *lactobacilli*, suggesting that chlorella could be prebiotic to promote the growth of beneficial microbes and contribute to gut-associated mucosal immunity. In this symposium, such immunological functions and potential application of chlorella for better health are introduced.

Immunological Function of Chlorella The water extracts from the microalgae (*Chlorella pyrenoidosa*) can against dengue virus type II (DENV2) infection

Chang-Jer Wu[1]*, Yi-Lin Chan*[2]

1. National Taiwan Ocean University (Taiwan), 2. Chinese Culture University (Taiwan)

In this century, the health of human will be challenged by the newly emerged infectious disease, such as AIDS, Avian flu, Dengue and COVID-19. Dengue virus (DENV) is a positive, single-stranded RNA virus with glycoprotein envelope, which caused three outbreaks in Taiwan. DENV infection has been shown an important epidemic disease in Taiwan. Mechanisms of how DENV causes clinical symptoms are not fully understood. Now, there is still no vaccine or antiviral drug in DENV infection, although *in vitro* studies revealed the sulfated polysaccharide from the algae had anti-dengue viral activity. *In vitro* studies, we find that the *chlorella pyrenoidosa* water extracts (CPE) can inhibit viral replication of DENV2 and effectively increase the plaque reduction rate of DENV2. The anti-DENV mechanism studies of CPE have been attributed to a blockade of the virus adsorption and then make the virus unable to enter cells. In the DENV2 infected mice model, these suckling mice appear the typical dengue syndrome, plasma leakage and gastrointestinal hemorrhagic, at the 6th day of post-infection and die at the 11th day of post-infection. The CPE can attenuate hematocrit, thrombocytopenia and gastrointestinal bleeding, and improves survival rate in neonatal mice after dengue virus infection.

Through all these efforts, the CPE may be used as a health food supplement of anti-DENV and immuno-modulatory activity agents.

The nutritional significance of dietary choline -Introduction-

Yutaka Miura[1]

1. Tokyo University of Agriculture and Technology (Japan)

Choline is one of Vitamin-related nutrients belonging to the Vitamin B group. Its chemical entity is trimethyl-ethanolamine. Several choline-related compounds, such as phosphor-choline, glycerophosphocholine, phosphatidylcholine and sphingomyelin are contained in foods along with free choline. These dietary choline-related compounds seem to be differently digested, absorbed and metabolized in our body, but the details are not clarified yet. As choline is used for the substrate of acetylcholine synthesis, an important neurotransmitter, biological membrane phospholipids and involved in one-carbon metabolism pathway, suggesting its physiological significance, the recommended daily intake of choline is determined in many countries except in Japan. Choline deficiency is reported to induce the liver steatosis and liver damage. The actual choline intake in normal adults seems to be less than the RDI and the precise intake of dietary choline is now under re-evaluation in several countries and these assessments suggest that the intake of choline is not sufficient as expected. In this symposium, the nutritional and physiological significance of dietary choline is discussed. After introduction of this symposium, the present situation of choline intake in Japan will be introduced following the report of large-scale assessment of the choline intake in USA. These lectures will support the discussion of nutritional aspect of choline and final lecture will be focused on the determination of choline in biological samples and the physiological behavior of choline which help our discussion in the chemical and biological aspects of choline.

Keywords: choline, nutritional assessment, phosphatidylcholine, sphingomyelin

SY(T2)1-2

Current situation of dietary choline in Japan

Takeshi Ohkubo[1]

1. Sendai Shirayuri Women's College (Japan)

Choline is a trimethylaminoethanol with quaternary ammonium ions and is present as a hydrophilic base in such lipids (hydrophobic substances) as phosphatidylcholine and sphingomyelin. Choline is known to have a wide range of biological effects on brain function, liver function, the perinatal period, etc. In particular, Humans can produce a small amount of choline via de novo synthesis, but it is rarely synthesized in organs other than the liver, and the source of choline is mainly derived from dietary sources.

In the United States (Food and Drug Administration), for the adequate intake (AI) of choline, the AI for adults was set at 550 mg/day for men and 425 mg/day for women, based on the results on hepatic function impairment obtained from a choline-deficient diet experiment by Zeisel et al (FASEB J., 5, 2093-2098, 1991). On the other hand, the adverse effects of excessive choline intake include cholinergic side effects (e.g., sweating, diarrhea), fishy odor, and hypotension. For this reason, the upper limit (UL) for adults is set at 3.5 g/day. Incidentally, the AI was set in 2016 in recognition of the benefits of choline at the European Food Safety Authority. In the Eu, AI in adults is set at 400 mg/day and 480 mg/day for pregnant women and 520 mg/day for nursing mothers. In Japan, on the other hand, adequate intake of choline has not been prescribed because it is not yet fully recognized as a nutrient. There is no mention of choline compounds in both the Dietary Reference Intakes for Japanese (2020 edition) and the Standard Tables of Food Composition in Japan (2020 edition).

Therefore, we conducted a weighing survey on 19 female students (aged 20 to 21 years) and 17 male students (aged 19 to 21 years) at University A and University B respectively, by measuring and recording the weight of food consumed in each of their meals over a 3-day period. Considering seasonal variations, the survey was conducted on three consecutive weekdays in April, July, and October 2016, and January 2017. The choline intake was calculated by applying data broken down to a list of choline contents in food materials made publicly available through the United States Department of Agriculture. However, due to differences in the dietary habits of Americans and Japanese, the choline content could be calculated from only about 70% of food ingredients (unpublished data). We estimated the choline intakes under these circumstances. Even after considering these various factors, we believe the value is far from the standard value in the United States. The Japanese consume low amounts of dairy products, and their consumption of livestock products is also quite low compared to other countries. Furthermore, rice with its low choline content is their staple food. This suggests that it may be difficult for Japanese people to consume sufficient amounts of choline compounds in their diet.

Precision Nutrition: Lessons from studies on the nutrient choline

Steven Zeisel[1]

1. University of North Carolina at Chapel Hill (USA)

The field of precision nutrition is changing how nutrition science is translated into more precise applications for improving the diets of people. Individuals differ in their requirements for and responses to nutrients in the diet. Many inputs contribute to metabolic heterogeneity (including variations in genetics, epigenetics, microbiome, lifestyle, diet intake, and environmental exposure). This presentation will focus on genetic variation and metabolic heterogeneity. Genetic testing can stratify people on the basis of single nucleotide polymorphisms that result in metabolic inefficiencies and then we can use this stratification to better estimate the different subgroups' dietary requirements, thereby enabling better dietary recommendations and interventions. People who have higher dietary requirements for choline can be identified using analyses of patterns of single nucleotide polymorphisms. When these people are fed a diet very low in choline, they develop health probes that include fatty liver and/or loss of muscle tissue. Women with certain patterns of single nucleotide polymorphisms need to eat diets higher in choline and folate to have optimal pregnancy outcomes.

Mechanisms and implications for phospholipid fatty acid homeostasis

Junken Aoki[1]

1. The University of Tokyo (Japan)

Phospholipids, the main component of the biological membrane, contain various types of polar heads and fatty acids. Recent advances in mass spectrometry technology have revealed that phospholipids are composed of thousands of different molecular species with varying head groups and fatty acids. Elucidating these diverse phospholipid species' function and biological significance is not only one of the critical issues in lipid biology. Still, it is also important from a nutritional point of view. Choline and fatty acids are essential for living organisms, and vertebrates, including humans, take in choline and fatty acids from the outside world as nutrition. On the other hand, the type and composition (number of carbons and double bonds) of fatty acids differ between organisms. Therefore, organisms that consume different species as part of their diet will take in fatty acids specific to the species they consume. Excessive sugar and saturated fatty acid intake lead to diabetic conditions. We have found that excessive saturated fatty acid administration, such as palmitic acid (PA), to cells induces an endoplasmic reticulum stress response. It has also recently been found that specific receptor-like membrane proteins hydrolyze PA in PA-containing phospholipids and replace PA with unsaturated fatty acids, thereby contributing to the unsaturation of the membrane and thus preventing diabetic pathology. In this presentation, we will introduce you to our laboratory's lipidomics technology and a novel mechanism for maintaining the homeostasis of fatty acid species in membrane phospholipids.

Assessment of reward system among individuals with eating disorders

Masanori Isobe[1]

1. Kyoto University Hospital (Japan)

Anorexia nervosa and bulimia nervosa share the same core symptoms such as the desire to thinness and the fear of obesity despite very different physical conditions. The etiology and the mechanisms that contribute to the onset and maintenance of these disorders are still unclear, and biology-based treatments have not yet been established. It has been suggested that abnormalities in the reward system of brain, which can explain their clinical characteristics, may be involved in the onset and maintenance of symptoms in both diseases. In other words, the restriction of food intake in AN and binge eating in BN may be recognized as rewards in the brain and lead to the maintenance of behavior, from the possible perspective of "behavioral addiction". Against this background, the brain reward system has become one of the main targets of research to elucidate the pathogenesis of eating disorders. In this presentation, I will review the topics regarding brain reward system as the current model for the onset and maintenance of eating disorder, particularly focused on AN. Recently, psycho-biological findings have been accumulating that impairment of the reward system is involved in the persistence of AN symptoms. Findings of structural brain imaging suggest that structural changes in brain regions involved in the reward system may contribute to the pathogenesis of AN. Similarly, functional MRI studies have shown that the brain activity of reward system circuits in the brain of AN patients is distinctive in response to stimulus presentations that may be rewarding to them, such as food stimuli, body image related stimuli, and stimuli related to food intake restriction and overactivity. Furthermore, it is known that patients with AN, as

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

well as those with mood and anxiety disorders, do not respond adequately to many events that are conventionally perceived as reward, such as food and social interaction. On the other hand, they respond excessively to AN-related behaviors, such as restricting food intake and excessive exercise. These characteristics of responses to rewarding stimuli are likely to contribute to the persistence of AN symptoms. The effect of increased responsiveness to punishing stimuli as well as decreased responsiveness to rewarding stimuli are also pointed out. AN patients show rewarding responses to weight loss behaviors and thinness-related stimuli, but strong aversions to weight gain, social situations, and financial loss. Such responses are easily influenced by context, and clarifying what information and stimuli AN patients perceive as rewards or punishments will provide not only crucial insights into the mechanisms of symptom maintenance but also the important knowledge for more effective practical support. I will discuss the potential of the reward system in the brain as a target for condition assessment and treatment of AN.

Assessment of nutritional status and psychopathology in the treatment of eating disorders with different duration of illness

Shu Takakura[1], Chihiro Morita[1], Noriyuki Miyata[1], Tomokazu Hata[1], Nobuyuki Sudo[2]

1. Department of Psychosomatic Medicine, Kyushu University Hospital (Japan), 2. Department of Psychosomatic Medicine, Graduate School of Medical Sciences, Kyushu University (Japan)

Eating disorders (EDs) can become psychologically and physically severe.

Recently, we reported that the physical and psychological characteristics of patients with anorexia nervosa (AN) differed depending on the duration of illness. With regard to physical aspects, although there was no significant difference in body mass index (BMI), it was observed that the total protein, albumin, and potassium levels were significantly lower in patients with a longer duration of illness (>5 years) than in those with a shorter duration of illness (<5 years). The levels of total protein and albumin tend not to decrease in patients with a short illness duration despite a low BMI. Therefore, serum albumin levels may be unsuitable for nutritional assessment, especially in young patients with AN, suggesting the importance of assessing albumin levels in addition to other nutritional biomarkers such as pre-albumin.

Weight recovery is extremely important for the treatment of AN. Clinically, it is not uncommon for clinicians to observe poor weight regain in the early stages of nutritional recovery. In recent years, many studies have reported that the gut microbiota plays an important role in the regulation of weight regain. In a comparison of gut microbiota between 25 patients with AN and age-matched healthy women, the amounts of total bacteria were significantly lower in the AN group than those of the control group. In addition, in a comparison of germ-free mice reconstituted with microbiota from restricting-type AN (AN-R) patients (gAN mice) and age-matched healthy control individuals (gHC mice), gAN mice had poor weight gain and showed higher levels of anxiety than gHC mice. These results suggest that "disbiosis" in some of the pathological conditions such as decreased nutritional efficiency and the onset of psychiatric symptoms is an important finding to be considered in the treatment of AN.
With regard to psychological aspects, the psychopathology of eating disorders in our study was more severe in AN patients with a longer duration of illness (>5 years). Therefore, it is important to develop a strong therapeutic intervention according to disease duration.

In conclusion, appropriate biopsychosocial interventions based on the assessment of physical and psychological aspects according to the duration of EDs are important.

Keywords: Eating disorders, Anorexia nervosa, duration of illness, weight regain, disbiosis

SY(T2)2-3

Assessment of stage of change and intervention strategies

Hisashi Yamada[1]

1. Hyogo College of Medicine (Japan)

One of the difficulties in the treatment of eating disorders is the high level of resistance to treatment and high percentages of treatment dropout. One of the causes of treatment dropout on the part of patient is the problem of motivation. When introducing treatment, it is necessary to evaluate the patient's motivation for treatment and to consider how to motivate the patient for treatment. There are stages of attempting to change one's behavior in order to engage in treatment, and these are described in the Transtheoretical Model of the Stage of Change as a series of stages in which people make typical progress in thinking about, initiating, and continuing new behaviors as theorized by Prochaska and Diclement. The stages of change are structured as a cyclical model consisting of five stages: pre-contemplation, contemplation, preparation, action, and maintenance. Prochaska et al. showed that there is a relationship between the stages of change and the patient's self-change behavior, dropout, and treatment efficacy in addictive behaviors, and it has also been shown to be useful in patients with eating disorders. Depending on which cycle the patient is in, the therapist needs to vary the way to motivate the patient to change her eating behavior. Motivation for change has evolved from the field of substance use disorders (e.g., alcohol, illegal drugs, smoking). Motivation is considered to be multifaceted, dynamic, modifiable, and influenced by social reactions and clinician attitudes and techniques. Miller and colleagues summarized the techniques as Motivational Interviewing, which

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

has been shown to be useful in the field of alcohol and substance use disorders and has since been applied in the field of eating disorders. The 2017 NICE guideline in the UK lists Maudsly Anorexia Nervosa Treatment for Adults (MANTRA) as one of the recommended treatments for adult anorexia nervosa. The five stages of change and Motivational Interviewing are important techniques incorporated in MANTRA. As for interventions tailored to the stage of change, explanation of disease and psychological education are important in the pre-contemplation stage because of the lack of disease awareness. In the contemplation and preparation stages, techniques from Motivational Interviewing are used, and especially in the preparation stage, the patient is asked to think about the future self. In the action phase, specific behavioral goals and praise for efforts are necessary, and in the maintenance stage, efforts to prevent relapse should be made. I would like to discuss these details on the presentation day.

Assessment and treatment of refeeding phases in eating disorders

Kazuhiro Yoshiuchi[1]

1. The University of Tokyo (Japan)

Refeeding syndrome (RFS) is a life-threatening complication of nutritional replenishment in underweight patients with eating disorders (EDs). Refeeding in a malnourished state is thought to serially induce hyperglycemia, hyperinsulinemia, and fluid and electrolyte shifts. It can also lead to refeeding hypophosphatemia (RH). Because phosphate is an essential component of adenosine triphosphate, RH can cause potentially fatal complications. Therefore, RH has been widely used as a criterion of RFS in patients with anorexia nervosa (AN). Risk factors for RH in patients with AN include lower prealbumin levels, lower body mass indexes (BMIs), higher hemoglobin levels, older ages, and higher blood urea nitrogen levels. Based on expert opinion, the National Institute for Health and Clinical Excellence (NICE) guidelines state that individuals with a BMI <16 kg/m2 are at a risk for RFS; however, the exact BMI cut-off point is not known. In addition, lower calorie refeeding as a preventive strategy for RH has been previously investigated. However, there were opposing reports regarding the effectiveness of this preventive measure. It could be too conservative from the viewpoints of poor weight gain and prolonged hospital stay in inpatients with AN. Some experts reported that low-carbohydrate diet administration to inpatients with AN might prevent the occurrence of RH according to their clinical impressions. However, the exact association between carbohydrate content in diet and the occurrence of RH in patients with AN remains unrecognized. Therefore, the aims of the present study was to identify the optimal BMI cut-off point for RH in patients with EDs and to retrospectively examine the association between the ratio of carbohydrate to total energy consumption and the occurrence of RH in inpatients with AN through data extracted from their medical records. Methods: The medical charts of Japanese inpatients with EDs at the Department of Psychosomatic Medicine of the University of Tokyo Hospital between April 1, 2012 and February 29, 2020 were retrospectively reviewed. The optimal BMI cut-off point for RH was determined via receiver operating characteristic (ROC) analysis. ROC analysis was also performed to determine the cut-off point of the percentage of carbohydrate content in the diet for the occurrence of RH. Logistic regression analysis was subsequently performed to assess the association between RH and the BMI cut-off point after adjusting for the propensity score, which was based on known risk factors for RH. Multivariate logistic regression analysis was also performed with occurrence of RH as the dependent variable and the carbohydrate content of more than the identified cut-off point as the independent variable adjusting for the risk factors for RH. Logistic regression analysis was subsequently performed to assess the association between RH and the BMI cut-off point after adjusting for the propensity score, which was based on known risk factors for RH. Results: The optimal BMI cut-off point was identified as 12.6 kg/m2. A BMI lower than the cut-off point significantly correlated with the occurrence of RH after adjusting for the propensity score. The percentage of carbohydrate content that is higher than the cut-off point obtained from the ROC analysis was significantly associated with the occurrence of RH, even after adjusting for variables associated with RH in univariate logistic regression analysis (age and body mass index) as well as the average daily calorie intake. Discussion: The optimal BMI cut-off point for the occurrence of RH was 12.6 kg/m2 in patients with EDs. We also identified that diets with higher carbohydrate contents were associated with RH in inpatients with AN, even after adjusting for known risk factors. The findings of the present study may facilitate clinical decision making and early identification of patients who require prophylactic treatment for RH, and also may promote the development of dietary preventive strategies against RH in inpatients with AN.

Developing a Food Compass system in Japan

Shuhei Nomura[1]

1. Keio University (Japan)

The Dietary Reference Intakes for Japanese—a unique national nutrient-based dietary guideline in Japan—recommends target amounts of nutrient intakes as the tentative dietary goals (TDG) for Japanese people to reduce the risk of lifestyle-related chronic diseases. Previous research implied that TDG adherence based on the seven nutrients studied has a limited beneficial impact on lifestyle-related chronic outcomes. This finding supports recent nutrition science understanding that the level of each nutrient, independent of the source of the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

nutrients, may not necessarily indicate a healthy diet. Foods are more than just a collection of nutrients they contain. A new indicator, dubbed the "Food Compass" by a research team at Tufts University, is a novel nutrient profiling system that assesses the healthiness of foods, using a wider range of food characteristics, attributes, and uniform scoring principles. The Food Compass determines the healthiness of a diet and enables people to choose and consume a healthy diet on an individual level. This presentation will discuss the challenges of developing a Japanese version of the Food Compass and the various Japanese data issues associated with it.

Food Compass: development and predictive validation of a nutrient profiling system using expanded characteristics for assessing the healthfulness of foods

Meghan O'Hearn[1], Joshua Erndt-Marino[2], Suzannah Gerber[1], Brianna N Lauren[1], Christina Economos[1], John B Wong[3], Jeffrey B Blumberg[1], Dariush Mozaffarian[1,3]

1. Friedman School of Nutrition Science and Policy, Tufts University (USA), 2. Bespoke Analytics, LLC (USA), 3. Tufts Medical Center, Tufts University School of Medicine (USA)

Nutrient profiling systems (NPS) aim to discriminate the healthfulness of foods for front-of-package labelling, warning labels, taxation, company ratings, sustainable investing and more. The Food Compass is a novel NPS developed to characterize healthfulness of diverse food and beverage products including mixed dishes and restaurant meals utilizing the same algorithm and scoring system for all products; and incorporating a range of novel positive and negative attributes consistent with the best available new science – a major advance from existing NPS.

The Food Compass algorithm scores 54 attributes across 9 health-relevant domains- nutrient ratios, vitamins, minerals, food ingredients, additives, processing, specific lipids, fiber and protein, and phytochemicals, summed into a final Food Compass Score (FCS) ranging from 1 (least healthy) to 100 (most healthy) for all foods and beverages. Content validity was confirmed by assessing nutrients, food ingredients and other characteristics of public health concern; face validity was confirmed by assessing the FCS for 8,032 foods and beverages reported in NHANES FNDDS 2015-16; and convergent and discriminant validity was confirmed from comparisons with the NOVA food processing classification, Health Star Rating (HSR) and Nutri-Score. Within food categories, the FCS provided important discrimination of specific foods and beverages as compared with NOVA, HSR or Nutri-Score.

In addition, predictive validity was assessed in a nationally representative cohort of 47,999 U.S. adults, by calculating a person's individual Food Compass Score (i.FCS), ranging from 1 (least healthful) to 100 (most healthful) based on the cumulative scores of the specific food and beverages they consumed against three endpoints: (a) the Healthy Eating Index (HEI) 2015, an established measure of a healthy diet; (b) prevalence of major clinical risk factors and health conditions; and (c) prospective risk of all-cause and cause-specific mortality. Nationally, the mean (SD) i.FCS was 35.5 (10.9). i.FCS correlated highly with HEI-2015 (R=0.81), with similar findings among diverse population subgroups. In cross-sectional analysis, after multivariable-adjustment, each one SD (10.9 point) increase in i.FCS was associated with more favourable BMI (-0.60 kg/m^2 [-0.70, -0.51]), systolic blood pressure (-0.69 mmHg [-0.91, -0.48]), diastolic blood pressure (-0.49 mmHg [-0.66, -0.32]), LDL-C (-2.01 mg/dl [-2.63, -1.40]), HDL-C (1.65 mg/d [1.44, 1.85]), HbA1c (-0.02% [-0.03, -0.01]), and fasting plasma glucose (-0.44 mg/dL [-0.74, -0.15])**;** as well as lower prevalence of metabolic syndrome (OR 0.85 [0.82, 0.88]), CVD (0.92 [0.88, 0.96]), cancer (0.95 [0.91, 0.99]), and lung disease (0.92 [0.88, 0.96]); and higher prevalence of optimal cardiometabolic health, (1.24 [1.16, 1.32]). In prospective analysis, i.FCS was associated with lower all-cause mortality (HR 0.93 [0.89, 0.96]) and a trend toward lower cancer death (0.90 [0.85, 1.00]). Finding were similar in subgroups by age, sex, race/ethnicity, education, and income.

On the basis of demonstrated content, convergent, discriminant and predictive validity, the Food Compass is a powerful tool to guide public health interventions and policies and private sector strategies to identify and encourage healthier foods and beverages.

SY(T2)3-3

Construction of a database of functional components in foods related to our health

Mari Maeda-Yamamoto[1]

1. National Agriculture and Food Research Organization (Japan)

The future of personalized health care requires food personalization, which in turn requires relevant information about individuals, such as health status, genes, microbiomes, preferences, and allergies. It also requires information about foods, such as nutrients, functional components, traceability, taste, expiration dates, and cooking methods. By integrating these data and performing a detailed analysis, a new, individualized, food-based system for improving people's healthy life expectancy will be established. It is necessary to establish a new health assessment system based on health surveys of healthy people to obtain relevant information on individuals. Although information on nutritional components in foods is well established worldwide, there is little systematic information on functional components. To find food components that contribute to health from observational studies, it is important to construct a database of the nutritional and functional components of each food. Functional components described here are chemical substances in foods that are clearly involved in health, such as polyphenols, carotenoids, sulfur-containing compounds, polysaccharides, and lipids. NARO published evidence of health effects of agricultural products through human intervention studies (RCTs) and systematic reviews, as well as analysis of functional ingredients involved in these effects. The published functional ingredients include approximately 80 components, with data for 180 foods ingredients (https://www.naro.go.jp/laboratory/nfri/contens/ffdb/ffdb.html) It is important to detect and improve the state of minor health complaints, which is a state of slight mental and physical disorder from a healthy state to prevent disease. To identify food components that improve minor health complaints and prevent diseases, and to design optimal diets for individuals, data on such functional components related to health must be collected for each of the foodstuffs that make up the diet. It is necessary to establish rules and standardize the selection of foods to be analyzed and the method of food component analysis, since the food ingredient value of agricultural, forestry, and fishery products vary greatly depending on the variety, production area, cultivation method, and cooking method. Currently, a study to evaluate minor health complaints and explore and analyze food ingredients that promote health is being conducted using a cross-sectional observational study of 1,000 healthy individuals (a cross-ministerial Strategic Innovation Program (SIP) project).

Keywords: Functional component data, minor health complaints

SY(T2)4-2

Understanding eating patterns: the potential of a smartphone food diary application in nutrition research

Sarah A McNaughton[1]

1. Institute for Physical Activity and Nutrition, Deakin University (Australia)

Eating patterns is increasingly recognized as an important and complementary concept for formulating dietary guidelines and interventions, however there are still significant gaps in the evidence base. Eating patterns refers to the ways in which foods are consumed together in discrete eating occasions (such as meals and snacks). The eating patterns framework encompasses three domains: (1) patterning of eating occasions (e.g., frequency and timing); (2) content (e.g. food combinations and nutrient content), and (3) context (e.g. eating with others, location of eating and activity whilst eating). Appropriate dietary assessment methodology has been a limiting factor in the development of research examining eating occasions and eating patterns at the population level. While FFQs may have low respondent burden, they do not provide data on how foods are consumed together in meal or snacks. New technology allows real-time data collection in the settings in which food is consumed. The development of electronic food diaries, combining the ability to take photographs, record verbal messages and use reminder prompts, can decrease the participant burden associated with the more detailed measures of food intake required for the investigation of eating patterns and can more easily incorporate measures of eating occasions and provide new research opportunities in this field. We developed a Smartphone food diary using Ecological Momentary Assessment principles to examine food intake at the level of eating occasion and that allowed assessment of the three eating pattern domains. The Smartphone diary allows participants to record food and beverage intake at each eating occasion by providing an image, and/or written message describing food types and the amounts of each food consumed. For each eating occasion, the diary also incorporates questions about the context of the eating occasion such as where they ate, who they ate with, what they were doing when eating (e.g., watching television). The Smartphone diary prompts users if they have not recorded any eating occasions within a 3-hour period during waking hours and at the end of each day, participants will also be prompted to enter any forgotten foods or eating occasions. Using this food diary, we have conducted research examining eating patterns in 700 young adults examining in meal skipping, snacking, temporal eating patterns and determinants of eating patterns. We have

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

also conducted further work to examine the relationships between eating patterns, physical activity, sleep, and mood combining the Smartphone food diary with other wearable devices. Evidence generated through examining eating patterns opens new opportunities and may have multiple applications. These include the development of new evidence for associations with health outcomes that can be used in interventions for the prevention and management of chronic conditions, new ways to explore nutrition science concepts relating to nutrient interactions within meals and snacks, and new applications to behavior change interventions and other strategies with translation to consumers through targeted and tailored nutrition communication messages.

SY(T2)4-3

Development of self-administered dietary questionnaires specially designed for measuring meal-specific dietary intakes and eating patterns

Kentaro Murakami[1]

1. The University of Tokyo (Japan)

Recent studies have suggested that not only the amount and type of food intake but also the circadian timing of food intake need to be considered, given that food intake, appetite, digestion and metabolism each exhibit circadian patterns. Additionally, understanding food combinations at meals could be useful for the development of public health nutrition policies and recommendations. Unfortunately, research on these topics is constrained by the fact that the primary method of dietary assessment currently employed in most cross-sectional and prospective cohort studies is food frequency questionnaire, which precludes an informed evaluation of the timing of dietary intake and meal-specific dietary intake. This kind of information can be derived from more detailed dietary assessment methods such as dietary record (DR) and 24-h dietary recall. However, when using these methods, collection of dietary data over multiple days is essential for the assessment of habitual intake at the individual level and is still not always feasible because of its expensive and burdensome nature. Taken together, the development of dedicated fit-for-purpose methodology for collecting data on meal patterns and time of day of dietary intake which is also inexpensive to administer and has low participant burden is required to efficiently advance this new research field. Here, the author presents the development of two self-administered dietary questionnaires specially designed for measuring meal-specific dietary intakes and eating patterns. The Food Combination Questionnaire (FCQ) is a 4-page, self-administered questionnaire designed for distinguishing food combinations at each meal type. The basis of the FCQ is a food combination database developed using 16-day DR from 242 Japanese adults. An analysis showed that daily dietary intakes estimated by FCQ were comparable with those estimated by a well-established diet history questionnaire. Using the FCQ, the most common food combinations consisted of rice, vegetables, and noncaloric beverages for all main meals (breakfast, lunch, and dinner) among Japanese adults, while those for snacks consisted of confectioneries and noncaloric beverages. The FCQ may be useful in capturing the complex nature of food combinations. The Meal-based Diet History Questionnaire (MDHQ) is a self-administered questionnaire designed for estimating food and nutrient intakes for each meal type separately. The MDHQ consists of three different parts: consumption frequency of generic food groups for each meal type, relative consumption frequency of sub-food groups within one of the generic food groups, and general eating behaviors. Because the development of MDHQ is based on comprehensive information on actual food consumption (16-day DR from 242 Japanese adults), this innovative tool may be promising for future chrono-nutrition research. A rigorous evaluation of validity of the MDHQ is under preparation.

Keywords: Circadian timing, food combination, meals, snacks, questionnaire

SY(T2)5-2

Overview of Harmonization of a Global Process for Setting Nutrient Reference Values

Lindsay Allen[1]

1. USDA, ARS Western Human Nutrition Research Center (USA)

Nutrient Reference Values (NRVs) for population groups are required for estimating the proportion of the population that has inadequate or excessive intakes of specific nutrients, based on a comparison of usual intakes to the Average Requirement (AR) and the tolerable Upper Nutrient Level (UL) respectively. NRVs are also used to plan diets for population groups, and to plan gaps that need to be filled by specific foods, or by food fortification or supplementation. There is now general consensus about the model and methods that should be used to set these two values, which have been well-described by the National Academy of Sciences, Engineering and Medicine (NASEM) in the USA and by the European Food Safety Authority (EFSA) in Europe, for example. Countries and regions may decide to use this model when updating their recommendations or creating ARs and ULs for the first time, or to update some of their values based on local conditions, in view of the very expensive process that is needed to review the literature on requirements. In addition to global harmonization of the process for setting NRVs, a set of proposed harmonized NRVs has been published using values from NASEM and EFSA reports plus additional values to increase the number

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of nutrients with an AR or UL where necessary. It is likely that most population groups have similar nutrient requirements after adjustments have been made for bioavailability of iron and zinc from local diets, and possibly for infections, genetics and body size. Efforts are in progress to review and quantify the adjustments needed. Other speakers in this session will address their own experiences with setting and revising NRVs and make recommendations to support a harmonized approach to both setting and modifying existing NRVs. The overall goal is to move the harmonization process forward and enable values to be set and/or modified efficiently, and global comparisons to be made about the adequacy of nutrient intakes and interventions.

Keywords: Nutrient Reference Values, Values, Average Requirement, harmonization

The Southeast Asia Model for Harmonizing the Process for Setting Nutrient Reference Values

Emorn Udomkesmalee[1]

1. Institute of Nutrition Mahidol University (Thailand)

Over the past decade, several countries in Southeast Asia individually reviewed their nutrient intake recommendations. National committee usually considered different sets of international recommendations such as those from the US-Institute of Medicine (IOM), the United Nations-FAO/WHO, the European Food Safety Authority (EFSA), together with locally available data and the application of nutrient-specific factors that suits country's context. In the case of Thailand, the revision to update the dietary reference intake spanned from 2013 to 2020. During this period, EFSA has published their scientific opinion on dietary reference values for a group of nutrients. In addition, the National Academies of Sciences, Engineering and Medicine (NASEM) launched a Consensus Study Report on Harmonization of Approaches to Nutrient Reference Values (NRVs) in 2018. The Thai Committee and Nutrients Working Groups were able to review these publications, combined with existing relevant local data prior to making their recommendations. The challenges in making decision were related to issues surrounding nutrient bioavailability as well as bioconversion factor for beta-carotene, in addition to gaps of data on up-to-date food composition table to assess nutrient intake and population micronutrient status. Recognizing the diversity of habitual diets, food systems and multiple burden of malnutrition in Southeast Asia, a regional expert panel could be set up to review the NASEM framework for harmonizing process to derive NRVs as well as the recently published harmonized values, in order to propose the suitable approach to accommodate different scenarios in the region. A connection between the regional panel and international expert group for nutrients deemed significant for the region will be helpful to guide the decision. In addition, the panel can be a platform to share data from countries, for example, on national food consumption survey, national health exam survey, food composition database, relevant evidence and local resources, as well as to identify data gaps and priority areas for future research.

A Path Forward and What's Needed for a Country to Get There

Anura Kurpad[1]

1. St John's Medical College (India)

As stated by the Committee on the Application of Global Harmonization of Methodological Approaches to Nutrient Intake, Recommendation: The need for nutritional benchmarks is critical all over the world. Different countries set their own benchmarks, using their own processes. To a large extent, in LMIC and LIC, these benchmarks are influenced greatly by central bodies like the WHO and FAO, and by the deliberations of the IOM and EFSA. However, there is an understanding that there should be a uniform framework for deriving Nutrient Reference values, and there is already much confusion about this. Many different NRVs are in vogue, both in concept and in name, and a priority should be that the NRVs should be simplified to only the Average Requirement (AR) of nutrient in a healthy group of individuals where the interindividual requirement variability is known, and the Tolerable Upper Limit (TUL) of intake, which defines a safe limit to the intake of the nutrient. Complexities exist, since not all nutrient AR and TUL are known with any certainty. The next key point is deciding on a biological and technical review framework within which these NRVs will be set. If a new value is required, from scratch, a framework is required to help in selecting the appropriate methodological approach – using homeostatic nutrient balances under different doses of nutrient intake, or using factorial inputs, including the bioavailability of the nutrient from habitual diets. The presence of environmental factors, like pollution or parasites, that may inflate nutrient losses and the requirement. This process requires detailed systematic reviews and is a process that cannot be shortened. A more pragmatic route, of either accepting, updating, or adapting existing NRVs is possible, but even here, a clear process is required, particularly if local area evidence is being added into the mix, along with precise documentation. If NRVs are not relevant locally, an expert panel should adapt values to the local context, again, with transparency and documentation. The key, moving forward, is harmonization by agreeing to the requirement framework (which NRV?), and the process by which these are set, with rigour and transparency.

Building an international partnership to support global harmonization of nutrient reference values

Anna Lartey[1], Seth Adu-Afarwuah[1]

1. University of Ghana (Ghana)

Harmonization of **methods** for deriving Nutrient Reference Values (NRV) and the **values** themselves have been a topic of discussion among nutrition scientists. There are several advantages to pursuing global Harmonized Nutrient Reverence values (H-NRV): it provides a common basis for comparisons; it brings transparency in the values developed by different scientific groups and low-income countries can save on limited resources by using the harmonized methodologies to refine their values. Yet, there are barriers to overcome, e.g., regions may be reluctant to accept global harmonized values that do not take their unique situations into consideration, terminologies around nutrient recommendations are confusing and data sharing may lack openness. However, the current global nutrition situation has made the need for H-NRV relevant and urgent: poor diet is now a leading contributor to disease and death globally, while the 2019 EAT-Lancet report shows that the world could save 11 million premature deaths if diets became healthier. Recent global events have given impetus to the harmonization of NRV. The UN Food Systems Summit 2021 resulted in the formation of several coalitions – such as the school meals coalition and the coalition for healthy diets for all. At the Tokyo Nutrition for Growth Summit 2021, a wide range of stakeholders made financial, policy and programmatic commitments to address all forms of malnutrition. While these developments are laudable, an important basis for ensuring healthy diet are an appropriate dietary reference values to provide the common basis for assessing whether populations are meeting their nutrient requirements. The following offer opportunities for building international partnerships to support global H-NRV: i) A NRV harmonization Task force under the auspices of the International Union Nutritional Sciences will provide access to over 80 Adhering Bodies to support and adopt H-NRV; ii) FAO and WHO, as leading global UN normative agencies, can play an important role by hosting an international Expert Group to guide the harmonization process. iii) Global Academies of Sciences can provide the platform for expert consultations to facilitate the harmonization process. iv) Relevant coalitions of the UN Food systems summit will need H-NRV for assessing whether diets and school meals are meeting nutrient requirement, v) The Codex Alimentarius Commission will need H-NRVs in setting its global standards, recommendation, and labeling policies, given its mandate to protect the health of consumers and ensure fair practices in the food trade.

Role of serine in brain function

Gilles Bonvento[1]

1. University Paris-Saclay/CNRS/CEA (France)

Aside from ATP production, a major function of glycolysis is to provide precursors, such as L-serine, to support macromolecular synthesis. L-serine is a metabolic hub and plays pivotal role in the brain. It is the precursor of D-serine, the principal co-agonist of synaptic N-methyl D-aspartate receptors (NMDARs) required for the induction of long-term synaptic plasticity in the hippocampus. It also contributes to the homeostasis of synapses and of mitochondrial function by providing lipids. We found that the phosphoglycerate dehydrogenase (Phgdh), the first enzyme of the L-serine pathway, is mainly expressed in astrocytes in mouse and human brain and is critically involved in both long-term synaptic plasticity and spatial memory. We then explored the role of serine in pathological conditions leading to cognitive deficits such as Alzheimer's disease (AD). This disease is also characterized by an early decrease of brain glucose metabolism in specific brain regions. These metabolic alterations correlate with disease progression and even predict histopathological diagnosis. Recent observations suggest that changes in aerobic glycolysis prevail in the early phase of AD. We found that 3xTG mice (a genetic model of AD), at early stage of the disease, exhibit decreased L-serine levels in the hippocampus where in vivo glucose metabolism is reduced but not in the frontal cortex that does not display metabolic alteration. Accordingly, acute application of D-serine or L-serine rescues long-term synaptic plasticity and chronic oral L-serine supplementation restores memory deficits in AD mice. Such chronic treatment also restores the atrophy of hippocampal astrocytes in these AD-mice. These results indicate that a metabolic deficit of L-serine synthesis by astrocytes contributes to cognitive deficits in AD.

Histidine-derived microbial metabolites in diabetes and drug responses

Ara Koh[1]

1. Pohang University of Science and Technology (POSTECH) (Korea)

Increasing evidence indicates that interactions between the gut microbiota, diet, and the host contribute to the development of number of diseases from intestinal diseases, metabolic diseases and even to neurological disorders. Many studies investigating the role of microbiota in different diseases have identified associations between host phenotypes and microbiota

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

composition. However, associations between individual bacterial genus/species and disease can be positive or negative depending on the disease or treatment context, making it difficult to determine whether particular bacteria are beneficial or detrimental. Despite this issue, the gut microbiome has been shown to be functionally similar even in samples from geographically different regions and between human and mice. In addition, accumulating data suggest that the microbiota may affect host phenotypes through the production of metabolites, which would contribute to the development or treatment of diseases. These bioactive microbial metabolites, sensitive fingerprints of microbial function, can act as inter-kingdom signaling messengers via penetration into the liver through the portal vein and into the host blood circulation and multiple tissues. Thus, investigating microbial metabolites that reflect disease-associated changes of microbial function would overcome the limitations of current microbiome research. This seminar will focus on the microbially produced metabolite imidazole propionate and how it potentially contributes to the pathogenesis of type 2 diabetes. In addition, I will also describe our recent work about investigating potential role of microbial metabolites on inter-individual variations in responses to anti-diabetic drug and metabolic surgery.

Toward social impact outcome beyond scientific glutamate research

Hisayuki Uneyama[1], Ana San Gabriel[1]

1. Ajinomoto Co., Inc. (Japan)

In 1908, Dr. Kikunae Ikeda of the University of Tokyo discovered a new taste substance, glutamic acid, in kelp soup stock and named its sensation umami. This was also the world's first report showing that an amino acid alone has a physiological function. After that, the sodium salt of glutamic acid (monosodium glutamate, MSG) was successfully commercialized as an affordable seasoning. By making meals more delicious, MSG intended to contribute to the improvement of nutrition. In this symposium, we'd like to present first the scientific process through which "one aspect of the physiological function of amino acids" gained scientific recognition. Followed by mounting evidence that validated umami as an important factor for the health of humans and planetary health, both aligned with the achievement of the UN SDGs. To clarify these issues, we conducted a review based on a comprehensive search of academic publications listed in the Web of Science database over the past 60 years (1940-2020). Around 4,000 papers have been published during this period from over 75 countries and regions. Historically, the academic research on MSG was inspired by the famous letter to the editor from the Chinese American physician Ho Man Kowk (NEJM, 1967), which suggested a link between MSG and the so called "Chinese restaurant syndrome" (CRS). Two studies published in 1969 gave legitimacy to CRS as a plausible malaise tied to MSG as a seasoning. After that, researchers from Japan and the United States took the lead on the elucidation of the umami sensation centered on the taste of glutamate and the investigation of its application in food. Since the beginning of this century, after multiple umami receptors were reported, many studies have been focusing on its digestive and appetite-regulating functions based on the post-ingestive effects of glutamate. Currently, studies are redirected into the use of umami seasonings to make diets healthier. The second half of this talk will focus on the potential that umami has for the improvement of planetary health and the health of humans increasing the healthy life expectancy and two challenges of malnutrition, poor protein intake (undernutrition) and excess salt intake (overnutrition).

Keywords: Umami taste, monosodium glutamate, glutamic acid, nutrition, salt reduction

The Tryptophan-Kynurenine pathway in the control of energy metabolism

Jorge Lira Ruas[1]

1. Karolinska Institutet (Sweden)

Physical exercise can play an important role in the prevention and treatment of a variety of diseases that range from diabetes and obesity to depression, neurodegeneration, and cancer. We have previously shown that exercised skeletal muscle can impact the kynurenine pathway of tryptophan degradation (KP) by increasing the conversion of kynurenine to kynurenic acid (KYNA) and protect from stress-induced depression. Tryptophan catabolism through the KP is well appreciated to generate a variety of bioactive metabolites with immunomodulatory, excitotoxic or neuroprotective properties. Reducing kynurenine levels protects the brain from stress-induced neuroinflammation and other changes associated with depression. This pathway is activated in mice and humans by aerobic exercise training and results in elevated circulating KYNA levels. Our findings show that elevated plasma KYNA levels affect peripheral tissues through a skeletal muscle-adipose tissue and immune system crosstalk mechanism. This results in muscle energy efficiency, increased systemic energy expenditure and reduced adiposity due to the activation of thermogenic pathways in the adipose tissue. We continue to investigate the molecular mechanisms that mediate KYNA-induced energy expenditure, in particular as a GPR35 agonist in several target cell types. We will present recent findings that highlight how KYNA/GPR35 can change immune cell recruitment into metabolic tissues, thus affecting whole body energy homeostasis.

Non-proteinogenic amino acids in sarcopenia

Yun Ching Chang[1], Sue-Joan Chang[2]

1. I-Shou University (Taiwan), 2. National Cheng Kung University (Taiwan)

Sarcopenia is a progressive and generalized skeletal muscle disorder involving the accelerated loss of muscle mass and function that is associated with physical disability, poor quality of life and death. A series studies conducted in our laboratory demonstrated that senescence-accelerated mouse prone 8 (SAMP8) mice developed symptoms of sarcopenia and insulin resistance at 40-week old. Mitochondrial quality control and autophagy flux aberrations occurred prior to the onset of sarcopenia, which was suggested as the molecular target to prevent and/or treat the sarcopenia. By using this model, we found phytochemicals, including Lychee-derived low-molecular-weight polyphenol (LLP) and EGCG, alleviated sarcopenia. Recently, non-proteinogenic amino acids (NPAAs) have been shown to regulate skeletal muscle function. Taurine is a NPAA and expressed in high concentration in several mammalian tissues and particularly in skeletal muscle. We found that taurine increased myotube length and area by suppressing atrogenes via inhibiting AKT-NFκB-mediated muscle protein degradation in late passage (aged) C2C12 myotube. Taurine also increased the mitochondrial biogenesis and fusion, decreased damaged mitochondria in late passage C2C12 myotube. Low levels of branched-chain amino acids (BCAAs) are reported to be associated with low muscle mass, poor muscle function, and low muscle strength in community-dwelling elderly. We found levels of BCAAs in muscle appeared to be decreased, but significantly increased in serum of aged mice. We also found that down regulations of BCAAs transporter (LAT1) and metabolic enzymes (BCAT2 and BCKDH) were observed in aging mice. Dysregulated BCAAs metabolism in muscle and elevated circulating BCAAs were correlated with muscle atrophy and insulin resistance via PI3K-AKT-mTOR signaling pathway. In our Lab, LLP was found to contribute to positive protein turnover and shunt circulating BCAA to skeletal muscle, leading to the improvement of BCAA metabolism by increasing metabolic enzymes in skeletal muscle of aged mice (40- wk.- old. SAMP8). In conclusion, NPAAs, such as taurine, act as signaling molecules to modulate pathways involved in the maintenance of muscle quality in sarcopenia. Polyphenols such as LLP, may improve the metabolism/utilization of NPAAs in aging muscle. NPAAs and polyphenols are suggested as nutritional treatments beyond the protein for sarcopenia.

Regulation of gene expression and cell function by taurine

Hideo Satsu[1]

1. Maebashi Institute of Technology (Japan)

Taurine (2-aminoethanesulfonic acid) is one of the major free sulfur-containing β-amino acid found at high concentrations in mammalian tissues. Taurine has been understood to play important roles in various biological processes, including anti-oxidation, membrane stabilization, detoxification, osmoregulation, and bile acid conjugation[1,2)]. We have previously examined the relationship between taurine and its intestinal absorption via taurine transporter (TAUT; SLC6A6) and the function of intestinal epithelial cells. Additionally, we have reported that TAUT activity is regulated by various factors such as extracellular taurine concentration[3)], hyperosmolarity[4,5)], inflammatory cytokines including TNF-α[6)], and lysophosphatidylcholine which is one of the inhibitory components in sesame extracts[7)]. We also found that taurine suppressed cell damage of intestinal epithelial cells by activated macrophage-like cells in an *in vitro* intestinal inflammation model[8)] and also an *in vivo* dextran sulfate sodium (DSS)-induced colitis model[9)]. This suggested that taurine has anti-inflammatory effects in the intestine. However, its regulatory mechanism by which taurine affects the intestinal immune system and suppresses the intestinal inflammatory response is unknown. In addition to this anti-inflammatory effect, several physiological functions of taurine that have been reported[1,2)] are phenomenological and the detailed regulatory mechanisms underlying taurine function, especially at the genetic and molecular levels, remain unclear. Based on this background, we examined the effect of taurine on the gene expression profile of human intestinal-like Caco-2 cells using DNA microarray and found that taurine markedly increased the mRNA expression of thioredoxin interacting protein (TXNIP)[10)]. Further, it was also revealed that taurine regulates cell functions such as adenosine monophosphate kinase (AMPK) phosphorylation *via* TXNIP induction[11)]. The effect of taurine on gene expression in hepatic- and macrophage-like cell line[12)] is also introduced in this symposium.

L-Citrulline promotes the neurovascular unit function and brain health

Kohji Fukunaga[1]

1. Tohoku University (Japan)

L-citrulline (L-Cit) is a neutral amino acid and a major precursor of L-arginine (L-Arg) in the nitric oxide (NO) cycle. We reported that oral L-Cit administration prevents the cerebrovascular injury following cerebral ischemia in 20-min bilateral common carotid artery occlusion (BCCAO) model mice. After BCCAO ischemia, mice were treated with L-Cit (50, 75, or 100 mg/kg p.o.) for 10 days once a day. L-Cit administration not only prevented the neuronal cell death but also prevented the capillary loss in the hippocampal region following brain ischemia. The cerebrovascular protective effect of L-Cit was associated with the restoration of endothelial nitric oxide synthase (eNOS) expression in the hippocampus. Indeed, the decreased L-Arg-induced NO production was restored in the hippocampus of BCCAO mice following L-Cit administration. Moreover, combined L-Cit and glutathione (GSH) administration also significantly rescued the reduced eNOS protein levels. Finally, the memory deficits following brain ischemia were improved by oral administration of L-Cit or L-Cit/GSH combination. In summary, L-Cit or L-Cit/GSH combination is the potential therapeutic agents that protect cerebrovascular injury and in turn prevent neuronal cell death. Taken together, natural L-Cit administration improves cognitive deficits by neurovascular protection following stroke and aging. The works were in part supported by KYOWA HAKKO BIO CO., LTD.

myCircadianClock – a smartphone app to monitor and optimize daily eating patterns

Satchidananda Panda[1]*, Jialu Sui*[1]*, Jason Fleischer*[2]*, Emily N.C. Manoogian*[1]

1. The Salk Institute for Biological Studies (USA), 2. University of California, San Diego (USA)

The quality and quantity of nutrition impact health. However, chrononutrition, the timing and variation of food intake in relation to the daily sleep-wake cycle are also important contributors to health. This has necessitated an urgent need to measure, analyze, and optimize eating patterns to improve health and manage disease. While written food journals, questionnaires, and 24-hour dietary recalls are acceptable methods to assess the quantity and quality of energy consumption, they are insufficient to capture the timing and day-to-day variation of energy intake. Smartphone applications are novel methods for information-dense real-time food and beverage tracking. However, the commercial nutrient apps often ignore eating patterns, and the raw real-time data is not available to researchers for monitoring and intervening in eating patterns. Our lab developed a smartphone app called myCircadianClock (mCC) and associated software to enable long-term real-time logging that captures temporal components of eating patterns, self reported sleep and aspects of physical activity. The mCC app runs on iOS and android operating systems and can be used to track multiple cohorts in parallel studies. The logging burden is decreased by using a timestamped photo and annotation of the food/beverage being logged. Capturing temporal data of consumption in free-living individuals over weeks/months has provided new insights into diverse eating patterns in the real world. This presentation will discuss the myCircadianClock app, and offer examples of ongoing and completed studies on eating patterns and the scope for optimizing eating patterns for health benefits.

SY(T2)8-2

Assessment of total energy expenditure and physical activity using activity monitors

Guy Plasqui[1]

1. Maastricht University (Netherlands)

To assess total daily energy expenditure (TDEE) under daily living conditions, the doubly labelled water (DLW) technique is considered the gold standard. This technique is accurate but also costly and requires specific lab equipment and expertise. It also provides an average measure of TDEE over a period of one to two weeks and hence no information on physical activity (PA) patterns is available. To overcome these shortcomings, activity monitors can be used to assess activity patterns and an estimate of TDEE can be made, provided the activity monitor has been previously validated in daily life using DLW. Most activity monitors contain accelerometers, that measure the acceleration of the body and hence represent body movement. By definition, body movement leads to energy expenditure (EE) and hence the two always need to be related. That has led to a vast amount of research and the development of activity monitors that also provide an estimate of EE. Validation is essential to know what the contribution of the sensor output is to the prediction of EE. Subject characteristics such as body mass, height, gender and age already explain most of the variation of TDEE, the accelerometer should then represent the physical activity component of TDEE and improve the explained variation. In addition to accelerometers, many activity monitors contain

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

additional sensors measuring other (physiological) output parameters such as heart rate, skin temperature, galvanic skin response (which may represent changes in sweat rate) or gps positioning. Although promising, so far there is no compelling evidence that these additional sensors improve the prediction of EE, so careful consideration is needed whether or not these are worth the extra cost, the extra battery power and storage capacity needed. Again, it is important to know the individual contribution of each outcome parameter to the prediction of TDEE. Another promising development is activity recognition, that goes beyond assessing total PA and activity patterns in terms of time spent in light, moderate or high intensity PA. Using activity recognition, more context can be given to daily activity by assessing for example lying, sitting, standing walking, cycling and others. Given that the relation between accelerometer output and EE is dependent on the activity performed, this development may eventually also lead to better prediction of TDEE. In conclusion, activity monitors have been proven to be extremely valuable in objectively measuring PA. In addition, when an activity monitor has been shown to be sufficiently valid, fairly accurate estimates of TDEE can be made. With that, they are valuable tools not only in PA research but also in nutritional research when energy balance is studied.

Dietary improvement using a self-monitoring device for urinary sodium-to-potassium ratio

Atsushi Hozawa[1], Mana Kogure[1]

1. Tohoku University (Japan)

Recently, the sodium (Na)/potassium (K) ratio was reported to be associated with blood pressure (BP). Furthermore, a Na/K ratio self-monitoring device using spot urine was established recently. We are performing several studies using the device. The first, we incorporate this device to community based cohort study. We asked participants to measure urinary Na/K ratio for 10 days, and around 10,000 participants measured their Na/K ratio. The temporary analyses clearly showed that multiple measurements of the urinary Na/K ratio are strongly related to home hypertension compared with single measurement. The second, we incorporate this device to health check-up in community for several years. As a cross sectional analyses, we observed positive relationship between single measurement of Na/K ratio and blood pressure measured at screening settings. We also observed districts which showed higher Na/K ratio showed higher blood pressure level. Furthermore, as a result of follow-up measurement, both blood pressure level and Na/K ratio were declined in this measured area, and the change in systolic BP and diastolic BP was positively associated with the change in urinary Na/K ratio. The association of the change in urinary Na/K ratio with hypertension and changes in systolic and diastolic BP can be explained by a change in alcohol intake, BMI, and urinary Na/K ratio. Therefore, measuring the urinary Na/K ratio in community settings is a potential population approach for counteracting hypertension. Now we asked several communities or work sites to incorporate the device to screening settings. Our finding suggests that measuring Na/K ratio may change the consciousness for salt intake and potassium intake. This change might yield better effect on blood pressure level in communities.

Prevention of Worsening Diabetes through Behavioral Changes by an IoT-based Self-Monitoring System in Japan (PRISM-J)

Ryotaro Bouchi[1]

1. National Center for Global Health and Medicine (Japan)

The use of the Internet-of-Things has improved glycemic control in individuals with diabetes in several small-scale studies with a short follow-up period. This large-scale randomized controlled trial investigates whether a smartphone-based self-management support system prevents the worsening of glycemic control in individuals with type 2 diabetes. Individuals with type 2 diabetes (age range 20–74 years; n=1,159) were recruited, enrolled, and randomly assigned to two groups: the intensive therapy group and the conventional therapy group. Participants in the intensive therapy group were supervised to use an automated Internet-of-Things system that demonstrates a summary of lifelogging data (e.g., weight, blood pressure, and daily activities) obtained from each measurement device and received feedback messages via smartphone applications to encourage them to increase their physical activity and to monitor weight and blood pressure. Participants in the conventional therapy group were allowed to use the same measurement devices as part of the routine diabetes care but without the Internet-of-Things system. The primary endpoint is the between-group difference in HbA1c levels from baseline to 52 weeks. This randomized controlled study will test the hypothesis that an Internet-of-Things-based self-monitoring system could effectively prevent the worsening of diabetes in individuals with type 2 diabetes. The expected results of the study should facilitate the development of novel strategies for both diabetes treatment and social health.

Challenges for nutritional epidemiological research in the consortium of prospective cohort studies in Asian countries

Ryoko Katagiri[1]

1. National Institute of Health and Nutrition (Japan)

Nutrition epidemiology studies have been conducted in many prospective cohorts around the world. Each cohort incorporates its dietary assessment methods into the investigations. Among dietary assessment methods, the food frequency questionnaire (FFQ), developed based on validation studies conducted by each cohort, is often used. Problems arise when attempting to integrate cohort data nutritional epidemiologically, because the food items in FFQs are selected according to the situation in each country (e.g., food items commonly eaten or the food culture) and the same food items do not always have the same nutrient composition.

The presenter has conducted two research projects in the Asian Cohort Consortium (ACC), an integrative cohort consortium involving around 40 prospective cohorts in Asia. Two pooled analyses regarding the association between reproductive factors and endometrial cancer and coffee intake and endometrial cancer were conducted. In these two projects, 12 or 13 cohort studies in Asia (Including Japan, Korea, Singapore, China, etc) were combined. In the ACC, data provided by each cohort is compiled in the data center in the ACC management team, and each researcher examines analysis methods for integration or discusses the method for integration in the working group (WG) for the exposure. In the case of endometrial cancer, most cohorts that participated in this pooled analysis included less than 100 cases and researchers could not conduct meta-analysis after the calculation of beta estimates in each cohort. It was necessary to attempt a pooled analysis (aggregated analysis) due to the small number of cases of the outcomes. For this reason, the WG examined the questionnaires of each cohort to determine whether the exposures can be integrated and created an analysis program within the WG for integration in the case of reproductive factors.

In this session, an example of integration of prospective cohort studies will be presented, comparing studies of dietary and non-dietary exposures, including some of the difficulties related to the integration of nutritional-epidemiological exposures.

SY(T2)9-2

Opportunities and challenges of international collaborative pooled analysis of dietary cohort studies

Jung Eun Lee[1]

1. Seoul National University (Korea)

International collaborative work of prospective cohort studies has been implemented for a few decades. It has provided a rich source for the world's researchers to investigate the role of dietary factors in the development of many diseases. A pooled analysis of the existing cohort studies has strengths, including increased statistical power, disclosure of unpublished work, use of the standardized approaches, significant contrast of dietary exposures, the inclusion of diverse populations, and built-up of partnerships of investigators. The advantages of pooled analyses in nutritional epidemiology are significant, and an increase in statistical power and analysis of multi-level exposures in the consortium data allow us to have better insight and knowledge of dietary factors related to chronic diseases. However, facilitating data harmonization of foods, food groups, and nutrients in the consortium data remains challenging. Combining and standardizing dietary data is far more complex than anthropometric or pharmaceutical data, given differences in food frequency questionnaires, foods assessed, dietary assessment's validity, and nutrient databases' availability across individual studies. The Asia Cohort Consortium is an international collaboration that aims to understand the etiology of common and rare diseases by combining data from multiple Asian prospective cohort studies. Opportunities and challenges of international collaborative pooled analysis of dietary cohort studies will be presented based on the experiences of the Pooling Project of Prospective Studies of Diet and Cancer and the Asia Cohort Consortium.

Methods for pooling epidemiologic studies: the Pooling Project of Prospective Studies of Diet and Cancer

Stephanie Smith-Warner[1], Molin Wang[1,2], Jeanine M. Genkinger[3], Pietro Ferrari[4], Walter C. Willett[1]

1. Harvard T.H. Chan School of Public Health (USA), 2. Harvard Medical School (USA), 3. Columbia University Irving Medical Center (USA), 4. International Agency for Research on Cancer (France)

The Pooling Project of Prospective Studies of Diet and Cancer [DCPP] is an international consortium of cohort studies that was established in 1991. To maximize the quality and comparability of the studies in the consortium, the following criteria are used for inclusion in the consortium: (a) prospective design; (b) use of a validated long-term, comprehensive dietary assessment method sufficient to calculate total energy intake; and (c) at least one publication on any diet and cancer association. For each outcome evaluated, a minimum number of cases in women and in men is also specified for a study to be included in analyses of that outcome. Additional inclusion criteria may be identified for each project. For a recent project to examine associations with alcohol use and multiple cancers, the consortium was expanded to include cohort studies that had detailed data on alcohol use but did not administer a comprehensive dietary assessment method. Currently, the consortium includes 36 cohort studies located in North America, Europe, Asia, and Australia; 32 of which meet the dietary inclusion criteria.

The consortium uses an opt in model in which cohorts indicate whether they are interested in participating in each project. Participating cohorts send their primary participant-level data (without personal identifiers) to the coordinating center which has the primary responsibility for checking and harmonizing the data from each cohort and maintaining the centralized data repository. To date, data collected at study enrollment on dietary, anthropometric, reproductive, and other lifestyle factors and medical histories, as well as cancer and mortality outcomes, have been harmonized. Authorized researchers access the data through a secure password-protected server. The data repository has been expanded over time to accommodate new projects evaluating new exposures and/or new outcomes. To date, projects have examined/are examining bladder, breast, colorectal, kidney, lung, ovarian, pancreatic, prostate, stomach, thyroid, and upper aerodigestive tract cancer, non-Hodgkin lymphoma, amyotrophic lateral sclerosis, and coronary heart disease.

We primarily use a two-stage analytic approach in which study-specific risk estimates are calculated and then pooled using random effects models. Analyses have also been conducted in which the data from the participating cohorts are combined into a single data set prior to analysis. In those analyses, the models are stratified by study. Analyzing the harmonized participant-level data in each cohort reduces potential sources of heterogeneity across the studies; allows flexibility in the modeling of the exposures; enables investigation of population subgroups and tumor subtypes; permits evaluation of whether participant- and study-level characteristics modify the exposure-disease association being evaluated; and facilitates examination of rare exposures and rare outcomes that individual studies may not have sufficient power to evaluate. As a result, comprehensive analyses of numerous exposure-disease associations can be conducted to generate key evidence on those associations.

A brief overview of EPIC: its rationale, dietary assessment methodology and key achievements

W.M.Monique Verschuren[1,2], for the EPIC Study Group

1. National Institute for Public Health and the Environment (Netherlands), 2. Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht University, Utrecht (Netherlands)

The European Prospective Investigation into Cancer and Nutrition (EPIC Study) is one of the largest prospective cohort studies in the world, with more than half a million (about 520 000) participants enrolled from 23 study centers in 10 European countries: Greece, Spain, Italy, France, Germany, Netherlands, United Kingdom, Denmark, Sweden, and Norway. The EPIC Study was designed to investigate the relationships between diet, nutritional status, lifestyle and environmental factors, and the incidence of cancer and other chronic diseases. Due to the geographical spread of the countries, from northern to southern Europe, variation in dietary intake was large, which makes it possible to study the impact of diet across a wide range of intakes. This is important, because within a country dietary habit can be relatively homogenous, which makes it difficult to study associations. For dietary assessment, information on usual diet was collected by country-specific dietary assessment questionnaires at enrollment in 1992-2000. To this end, questions were included on consumption of the foods that contributed most to dietary intake in the specific countries. Questions on both frequency of consumption, as well as on portion size were included and for a number of foods photographs of different portion sizes on a plate were added, to improve estimation of the portion size. To calibrate dietary measures, a standardized, computer-assisted 24-hour dietary recall was also conducted at each study center on stratified random samples of the participants (about 37 000 individuals). To improve comparability of nutrient databases across 10 European countries, a harmonized nutrient database was developed, containing 26 major nutrients and their related components between 550 and 1500 foods per countries (about 10 000 foods in total). A biobank has been established, storing different blood fractions at -196 degrees Celsius. EPIC represents the largest single resource available today world-wide for prospective investigations on the etiology of cancers and other disease that can integrate questionnaire data on lifestyle and

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

diet, biomarkers of diet and of endogenous metabolism and genetic polymorphisms, and so far, more than 1600 scientific articles have been published based on EPIC. In this presentation the methodology of EPIC will be discussed, as well as challenges in nutritional research and some important contributions of the EPIC Study to the scientific literature will be presented.

How different are dietary habits and eating patterns between East Asian and European countries? Findings from Japan

Kentaro Murakami[1]

1. The University of Tokyo (Japan)

Mainly because of their possible contribution to long life expectancy, much attention has focused on the characteristics of Japanese dietary habits. Here, the author describes a number of studies on dietary habits and eating patterns in Japanese, in comparison with findings from the European Prospective Investigation into Cancer and Nutrition (EPIC) study. Eating frequency has been the most widely investigated variable of eating behaviors in adults. In EPIC study, mean total eating frequency varied across countries (4.9 to 7.0 times/d), with a trend for lower eating frequency in Mediterranean countries (Greece, Spain, Italy, and France) compared with central European (Germany, the Netherlands, and UK) and Nordic (Denmark, Sweden, and Norway) countries. In contrast, mean total eating frequency in 2681 Japanese adults (4.7 times/d) was consistently lower than that observed in European countries. This appears to be mainly due to a low snack frequency in Japanese (mean 1.7 times/d) compared with snack frequency in Europe (mean 2.1 to 4.2 times/d). Further, it appears that meal skipping is rare in Japan. On the basis of 8-day dietary record data collected by 2681 Japanese adults, 86%, 91%, and 96% of adults reported consumption of breakfast, lunch, and dinner, respectively, over all eight days. Although the direct comparison is difficult due to difference in dietary assessment method, the proportion of consumers on a diet recall day ranged from 86.0 % to 99.8 % for breakfast, from 72.4 % to 100% for lunch and from 89.2 % to 100% for dinner in 10 European countries in EPIC study. The Japanese diet is also characterized by three large meals with small snacks. An analysis based on the National Health and Nutrition Survey showed that the proportion of daily energy intake consumed at breakfast, lunch, dinner, and snacks was, on average, 23%, 30%, 40%, and 8%, respectively, in Japan. In contrast, in 10 countries in EPIC study, the proportion of daily energy intake consumed at breakfast, lunch, dinner, and snacks ranged from 9% to 9% to 20% (median 16%), from 16% to 45% (median 26%), from 24% to 40% (median 32%), and from 10% to 35% (26%), respectively. However, studies have consistently shown that Japanese diets are high in dietary glycemic index (GI) compared with Western countries. According to an analysis based on the National Health and Nutrition Survey, mean dietary GI was 65.9 for men and 63.9 for women (GI of glucose = 100). In contrast, in EPIC study, overall mean GI was 56.8 for men and 55.3 for women. This is highly likely due to differences in the major food contributors to dietary GI. In Western diets, these are based on a variety of foods, including bread, pasta, potatoes, sweetened beverages, sugar, fruit, and breakfast cereals. In contrast, the major contributor in Japanese diets is white rice, a major staple food with a high GI (i.e., 76). These large differences in dietary habits warrant thorough investigation on the association between dietary factors and chronic diseases within a specific population.

Keywords: EPIC, Europe, Japan, diet, epidemiology

Further Collaborators: Dr. Kentaro Murakami is an Assistant Professor in the Department of Social and Preventive Epidemiology, School of Public Health, University of Tokyo. He is a nutritional epidemiologist whose research interests include validation of dietary assessment methods, assessment of dietary patterns, eating behaviors, and dietary quality, and identification of determinants of healthy and unhealthy eating behaviors.

After graduating from Hokkaido University (Faculty of Education), Dr. Murakami received his M.S. and Ph.D. degrees in Food Science and Nutritional Science from the University of Shizuoka, Japan. After post-doctoral training at the University of Ulster in Northern Ireland, he moved to Tokyo in 2016. He has published over 150 research papers and serves on the editorial board of several scientific journals, including as a Deputy Editor of the British Journal of Nutrition.

What we can learn from EPIC: a vision for East-Asia collaboration from the European experience

Heiner Boeing[1]

1. Federation of European Nutrition Societies (Germany)

EPIC used the most advanced assessment tool at that time, a validated self-administered food frequency questionnaire (FFQ) for optical scanning tailored to the local population. This strategy had the advantage that local FFQs were available at the beginning of the recruitment but the disadvantage that not all of the FFQs covered the agreed nutrients and food groups well, as shown in the validation studies. Thus, it was concluded that this diversity of the local country-specific FFQs might limit EPIC-wide diet-health analyses due to differences in assessment quality. Subsequently, a calibration tool was introduced in a small subgroup (N=36,000) comprising of one 24h-recall per subject. Unfortunately, the decision to obtain one 24h-recall per subject limited the calibration approach to the local mean reflected by

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

the reference mean but did not allow to reconstruct the variation within the local population. The so-called linear calibration approach calculated the variation within the center population measurable by the local FFQ. Nevertheless, in many of the publications about diet-health relationships calibrated and uncalibrated results were shown. In my memory, this publication strategy often resulted into confusion for the readers. In the subsequent time periods, statistical groups including EPIC developed models that identified the error structure of the main assessment instrument (FFQ) in a study compared to the reference instrument (food records and 24h-recalls) and recovery biomarkers, collected in small subgroups. Hardly, the parameters obtained in such models were used to correct the initially found diet-health relationships based on the FFQ. A clear learning experience from EPIC could be seen in the fact that all the assessment instruments and their analytical strategies should be agreed in advance and that they should be available from the beginning of a collaboration. Any ex-post standardization at later stages requires optimal conditions which will often not exist. It should be aim that the assessment instruments show high external and internal quantitative validity. The most recent insights into proper dietary assessment favour a combination of short-term (24-h-recalls) and long-term assessment instruments (FFQs) coupled with a modelling strategy of the individual diet. The 24h-recall is now available as self-administered program (p.e. ASA24 for the US amd MyFood for Europe) that show high external validity compared to survey data. Such programs allow to collect a number of 24h-recalls per subject across seasons without a high load for the organizers of the study. In addition, common FFQs across different eating cultures using the same food coding as the 24h-recall will limit differences due to different FFQ instruments. Hybrid solutions are also possible as developed for the German Health study. The ability of the 24h-recall to record time and meal context of food consumption offers the possibility to include timing of food consumption into the risk analyses leading to a more extended understanding of eating. Our group could among others already show that timing of food intake matters in terms of metabolic effects.

Potential barriers and opportunities for the development of cross-country nutritional epidemiologic research in East Asia: Experience in Singapore

Shan Xuan Lim[1], Mary Foong Fong Chong[1,2]

1. National University of Singapore (Singapore), 2. Agency for Science, Technology and Research (Singapore)

Cross-country nutritional epidemiological research brings about multiple benefits, from encouraging multi-level analyses that explore local, national and global influences on diet to offering the opportunity for conceptual and methodological development through the exchange of ideas and experiences between diverse research teams. Moreover, the population context of individual characteristics has shown to be a stronger determinant of disease at population level than individual level risk factors. However, the increased logistical complexity and costs involved, the methodological and analytical challenges and trade-offs are important issues to consider before embarking on cross-country comparative work. In particular, comparisons across heterogenous populations such as multi-ethnic populations have their own set of challenges. Based on data and my experience from a few cross-country research studies in the area of maternal and child nutrition, these considerations and lessons learnt will be shared and illustrated.

WHO project: Use and interpretation of haemoglobin concentrations for assessing anaemia status in individuals and populations

Maria Nieves Garcia-Casal[1]

1. World Health Organization (Switzerland)

Controlling the global burden of anaemia is an important public health priority: the 2025 Global Nutrition Targets pursue a 50% reduction in the prevalence of anaemia in women of reproductive age, while the 2030 Sustainable Development Goals 2 and 3 describe alleviation of anaemia. Trends in the prevalence of anaemia for the years 2000 to 2019 indicate a slower decline in anaemia prevalence since 2010, as compared to the period 2000 to 2010, with 30% (571 million) of women 15-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

49 years of age and 37% (32 million) of pregnant women estimated to be affected by anaemia globally in 2019. The World Health Organization has initiated a project to review global guidelines on haemoglobin cutoffs to define anaemia. Appropriate guidelines for measurement of haemoglobin and definition of anaemia are crucial for both clinical and public health medicine but require consideration of the range of complexities across different populations. Decisions to implement and monitor programmes that integrate nutrition specific and nutrition-sensitive interventions are predicated on the prevalence of anaemia as well as monitoring differences across groups in terms of accessibility, availability, acceptability and the quality of the interventions. Based on priority questions and research needs posed by experts after a public call and in review of the priorities outlined in the 2030 Sustainable Development Goals, the WHO Department of Nutrition and Food Safety convened a technical meeting on the use and interpretation of haemoglobin concentrations for assessing anaemia status in individuals and populations. The outcomes of this meeting served as the foundation for developing a scoping document for producing the key questions to be addressed in the revised guidelines. The first guideline development group meeting was held in November 2019 where the final key questions were agreed. One of the key questions related to the review of evidence on the need for adjustments in haemoglobin concentrations to account for differences in settings and populations. Several technical meetings have been developed to cover various aspects highlighted during the guideline development meeting, including the variations in haemoglobin concentrations during the lifecycle as well as the need for adjustments by elevation above sea level of the place of residence/work, smoking, genetic background, indoor cooking, outdoor pollution and malaria endemicity. Other critical aspects for discussion included the role of infection, inflammation and genetic ancestry as potential determinants for adjustments of haemoglobin concentrations to define anaemia, especially at population level, and also considerations about blood sampling and analytical methods used for haemoglobin determinations. The main focus of discussions on all those technical meetings was identifying the need and magnitude of adjustments required to account for the effect of all the above-mentioned determinants in different settings and populations with explicit consideration of age and sex. All the findings and conclusions from technical meetings will be presented to the guideline development group for reviewing, discussing, and preparing recommendations for the new guideline on the revised cutoffs to define anaemia in individuals and populations.

SY(T2)11-2

Variability in haemoglobin concentration by blood source and analytical devices

Maria Elena D Jefferds[1]

1. US Centers for Disease Control and Prevention (USA)

Background: The accurate and reliable measurement of haemoglobin (Hb) concentrations to identify anaemia in individuals and populations is a global priority. The cyanmethemoglobin method to analyze venous blood is the standard to assess Hb concentrations, however, various blood sources and analytical devices are used in both uncontrolled field settings and controlled clinical settings that may result in systematic or random bias. Single drop capillary blood is often the preferred blood source and most feasible in low resource settings, for screening blood donors or for entry into public health programs, and in large population-based surveys. Non-invasive and invasive point of care devices are often the preferred analytical devices for those settings and purposes. Automated hematology analyzers are typically used in clinical laboratory settings. This presentation will describe select evidence reviewed at WHO technical consultations and WHO Guideline Development Group meetings on the methods to assess Hb concentration for identifying anaemia in individuals and populations with a focus on variation and error by blood source (capillary vs venous) and invasive analytical devices (HemoCue models vs automated hematology analyzers).

Methods: WHO commissioned papers including systematic reviews and case studies to summarize technical areas and identify evidence gaps to provide stakeholders with state-of-the-art information, research needs and guidance on assessment of Hb concentrations in individuals and populations. The Hb assessment papers summarized the range of methodologies used to measure Hb concentrations in i) clinical laboratories, and ii) field studies, the principles of each assay, the benefits and limitations of each method, those currently considered best practice for use in clinical and field studies, and quality control aspects of laboratory and field measurements. In addition, after the call for authors closed and a journal supplement of the commissioned articles was published, newly published manuscripts and relevant manuscripts under preparation were also shared with meeting participants or their conclusions summarized and presented at the WHO meetings.

Results: Literature shows that single drop capillary blood compared to venous blood results in systematic bias in Hb measurement that may introduce small variation, but it was agreed during the meetings that correction is not feasible. For various reasons, such as human error or individual variation, single drop capillary blood compared to venous blood may also result in poor precision that causes random error and wide variation, and it was concluded this cannot be corrected. For example, in a 2016 Demographic and Health Survey (DHS) in Malawi that collected single drop capillary blood to assess anaemia, as is typically done in the main DHS survey, but also included a national micronutrient survey component that assessed anaemia using venous blood, there was a difference in anaemia prevalence of 31% in children and 9% in non-pregnant

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

women. Comparing HemoCue models to automated hematology analyzers found HemoCue models generally performed adequately, and any variation could be addressed with quality assurance activities. Training is required for high quality blood extraction and use of analyzers.

Conclusions: Venous blood is the preferred blood source, when possible, and training is critical for high quality Hb assessment.

SY(T2)11-3

Hemoglobin corrections for elevation and smoking

Andrea J Sharma[1], Florence A Kanu[1], Laura Pompano[1], Yaw Addo[1,2], Zuguo Mei[1], Parminder S Suchdev[1,2]

1. US Centers for Disease Control and Prevention (USA), 2. Emory University (USA)

Background: Interpretation of hemoglobin (Hb) to identify anemia requires correcting for elevation and smoking, hypoxia-inducing factors that raise Hb concentration. Current WHO recommendations to correct Hb were derived from data collected before 1985, from low-income preschool-aged children in the United States and indigenous men in Peru for elevation, and from white women-of-reproductive-age in the United States for smoking. Given age of the data and limited representativeness of these data, we reexamined associations between Hb and elevation or smoking using population-based data collected after year 2000. This presentation provides an overview and summary of analyses examining infants (INF; < 6 months), preschool-aged children (PSC; 6-59 months), school-aged children (SAC; 5-14 years), men and non-pregnant women-of-reproductive-age (M, WRA; 15-49 years), and older men and women (OM, OW; 50-80 years).

Methods: Analyses pooled data from population-based surveys or health center data that included data on hemoglobin and elevation and/or smoking from the following countries (years): Afghanistan (2014), Azerbaijan (2013), Bolivia (2013-2015), Colombia (2010), Ecuador (2012), Georgia (2009), Guatemala (2013, 2015-2019), Laos (2006), Malawi (2016), Mexico (2006, 2012), Nepal (2016), Papua New Guinea (2005), Peru (2015-2019), United Kingdom (2008-2014), and United States (2003-2006, 2015-2018). While not all countries contributed data to each population group, in total there were 3,450,834 and 27,911 observations examining elevation and smoking, respectively. Elevation data ranged from -28 to 5,012 meters (m). Smoking was examined as smoker/nonsmoker and by cigarette quantity per day. Generalized linear models were used to assess Hb associations with elevation and/or smoking by population group. Where data was available, robustness of associations was examined controlling for known causes of anemia [inflammation-corrected iron (ID) and vitamin A deficiency (VAD)] or restricting to healthier populations [no ID and no VAD]. Models were used to propose corrections to Hb for elevation and smoking and compared to WHO recommendations.

Results: Models confirm Hb is positively associated with both elevation and smoking and associations were robust to model specification. Elevation corrections were similar (differences <5 g/L at any elevation) across population groups (INF, PSC, SAC, WRA) at elevations <3500 m. Data were sparse above 3000 m but corrections began to diverge by region (e.g., Nepal vs Ecuador, Bolivia, Peru). Only WRA had both elevation and smoking data; these models confirm elevation and smoking corrections are additive. Data among heavy smokers (>20 cigarettes/day) were sparse. Corrections for any smoking and by quantity differed between men and women by ≦3 g/L. Proposed corrections using contemporary, multinational data suggest current recommendations under-correct Hb for light smokers (<10 cigarettes/day) and for residence at lower elevations (500-2000 m) and over-correct Hb at higher elevations (>3000 m).

Conclusions: Hb corrections for elevation and smoking likely need updating. It is possible that one set of corrections for elevation can be applied to all age groups living <2500m where 95% of the world population reside. However, epigenetic adaptions to elevation exist for populations residing at higher elevations; elevation corrections for these populations may need to differ by region. Findings will inform global guidelines on anemia assessment.

Additional factors influencing haemoglobin thresholds to define anaemia

Lisa M Rogers[1], Sant-Rayn Pasricha[2], Maria Nieves Garcia-Casal[1]

1. World Heath Organization (Switzerland), 2. The Walter and Eliza Hall Institute of Medical Research (Australia)

Accurate characterization of anaemia is critical to understand the burden and epidemiology of this problem, for planning public health interventions, and for the care of patients across the life course. As part of the World Health Organization's (WHO) work on reviewing global recommendations for defining anaemia and its significance as a public health problem, three technical consultations were held to discuss priority topics. These topics included the variations in haemoglobin concentrations during the lifecycle; the role of elevation above sea level, smoking,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

infections, inflammation and genetic ancestry as determinants for adjusting haemoglobin cut-offs to define anaemia; and methods for the assessment of haemoglobin concentrations.

Previous presentations in this session will have covered a summary of the discussions on corrections in haemoglobin concentrations to account for elevation above sea level and smoking, as well as the variability in haemoglobin concentration by blood source and analytical devices. This presentation will summarize discussions on the role of infections, inflammation and genetic ancestry as possible determinants for adjusting haemoglobin concentrations, in addition to variations in haemoglobin concentrations throughout the lifecycle.

Outcomes of these technical consultations are being used to inform updated WHO guidance on the use and interpretation of haemoglobin concentrations for assessing anaemia status in individuals and populations.

Iron metabolism and physiologically based approaches to identify serum ferritin thresholds to define iron deficiency

Gary M Brittenham[1], O Yaw Addo[2], Maria Elena Jefferds[2], Andrea J Sharma[2], Rafael C Flores-Ayala[2], Zuguo Mei[2]

1. Columbia University (USA), 2. US Centers for Disease Control and Prevention (USA)

Our overall objective is to develop a physiologically based method to determine serum ferritin thresholds for iron deficiency. Accurate determination of iron status is vital for diagnosis, for clinical and epidemiological screening, and for assessment of pharmaceutical treatments and public health interventions for iron deficiency. Thresholds recommended in current guidelines vary considerably and are derived from statistical analyses of the distribution of serum ferritin in samples from various sources or from small studies of patients who have undergone bone marrow examination, phlebotomy, or iron treatment. We have proposed a new method for identifying serum ferritin thresholds that uses independent physiological indicators of iron deficiency, including circulating hemoglobin, serum transferrin receptor (sTfR), and erythrocyte zinc protoporphyrin (eZnPP, also known as ePP). As body iron stores decline, serum ferritin decreases. With the onset of iron deficiency without anemia, iron requirements for red cell production and tissue needs cannot be provided from stores. A multitude of homeostatic mechanisms then act to reduce the iron used for red blood cell production to conserve the supply of iron to tissue. As iron deficits worsen, the circulating hemoglobin concentration falls. Erythroid and tissue cells increase the production of cellular transferrin receptor to procure more iron. sTfR is an extracellular fragment of cellular transferrin receptor that is shed into plasma. Approximately 80% originates in the erythroid marrow. The sTfR concentration is a measure of the total body mass of cellular transferrin receptor. In the absence of erythroid hyperplasia, the sTfR concentration is a sensitive, specific, and quantitative indicator of the earliest stage of iron deficiency. In the developing red blood cell, iron deficiency decreases the iron available for insertion into protoporphyrin IX, the final step in the synthesis of hemoglobin. Divalent zinc is then incorporated instead, producing eZnPP, which persists for the life of the red blood cell as an indicator of iron deficiency. Consequently, the serum ferritin concentration at which the circulating hemoglobin concentration begins to fall and the sTfR and eZnPP concentrations begin to rise provides a physiological basis for identifying the onset of iron deficiency without anemia. As iron deficits become more severe, iron deficiency anemia develops when the circulating hemoglobin concentration falls beneath the population standard used to distinguish anemic from non-anemic states. To validate physiologically based serum ferritin thresholds for iron deficiency, harmonization of results from international studies is required and will need to take account of variation in methods, instrumentation, and other factors. The serum ferritin thresholds for iron deficiency that are determined using the physiological approach detect the onset of iron deficiency and are well above the thresholds in most current guidelines, which identify a more advanced stage of iron deficiency. Earlier recognition of the need for iron could help prevent iron deficiency from remaining untreated and help avoid progression to more severe iron deficiency and anemia. With higher serum ferritin thresholds, future prospective clinical trials would be needed to determine optimal management through dietary changes, iron fortification or supplementation, or some combination of corrective interventions.

Comparison of physiologically based ferritin thresholds for iron deficiency in healthy young children with current World Health Organization (WHO) guidelines

Zuguo Mei[1], O Yaw Addo[1], Maria E Jefferds[1], Andrea J Sharma[1], Rafael C Flores-Ayala[1], Christine M Pfeiffer[1], Gary M Brittenham[2]

1. Centers for Disease Control and Prevention (USA), 2. Columbia University (USA)

We compare physiologically based serum ferritin (SF) thresholds for iron deficiency in healthy young children with current World Health Organization guidelines (WHO, 2020). After comprehensive review, the WHO determined that insufficient data were available to revise the SF threshold of <12 µg /L for

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

apparently healthy children <5 years of age, which is based on expert opinion dating from 1993 (https://www.who.int/vmnis/indicators/serum_ferritin.pdf). Despite the availability of international reference materials, the standardization of immunoassays for SF is complicated by the heterogeneity of antibodies used and the absence of physicochemical reference methods. To ensure comparability with the assays available at the time of the formulation of the expert opinion, we analyze data from the Third National Health and Nutrition Examination Survey (NHANES III, 1988-1994). NHANES III used the BioRad assay for SF while our previous study using the physiologically based method analyzed data from NHANES 2003-2010 and 2015-2018 using the Roche Hitachi 912 clinical analyzer (Lancet Haematol 2021;8:e572–582). The more recent NHANES study examined the relationship of SF with two independent indicators of iron deficient erythropoiesis, hemoglobin (Hb) and soluble transferrin receptor concentration and identified a SF threshold of about 20 µg /L in children 12-59 months. With the earlier NHANES III data, we examined the relationship of SF with two independent indicators of iron deficient erythropoiesis, Hb and erythrocyte zinc protoporphyrin (eZnPP). Overall, 2616 children aged 12-59 months were included after excluding anyone with infection (n=55, white blood cell counts >10.0 x 10^9/L) or at risk of iron overload (n=13, SF >150 µg /L) to define healthy individuals. We examined the distributions of median Hb and median eZnPP with SF and used restricted cubic spline (RCS) regression models to determine SF thresholds for iron deficient erythropoiesis. At lower SF, median Hb decreased as median eZnPP increased, with each varying in a curvilinear manner. Using RCS plateau points to determine the onset of iron-deficient erythropoiesis, the SF thresholds identified by Hb and eZnPP did not differ significantly and were 21.2 (95% CI: 18.5, 26.5) and 18.7 (17.9, 19.7) µg /L for children 12-59 months, respectively, much higher than the current WHO threshold of <12 µg /L. Because this study relied on data from the BioRad assay, this difference in SF thresholds for iron deficiency found using the physiologically based approach and WHO guidelines derived from expert opinion is not the result of differences in assays, as it could have been in our NHANES 2003-2010 and 2015-2018 study. Instead, we suggest that the physiologically based approach identifies the onset of iron deficient erythropoiesis while the WHO expert opinion values characterize a more advanced stage of established iron deficient erythropoiesis. Use of a higher SF threshold would increase the proportion of children < 5 years of age who are identified as iron deficient. Recognizing a need for iron in more children could help prevent the adverse effects of iron deficiency from remaining untreated and prevent progression to more severe iron deficiency and anemia.

Comparison of physiologically based ferritin thresholds for iron deficiency in healthy non-pregnant women aged 15-49 y with current World Health Organization (WHO) guidelines

Yaw Addo[1], Zuguo Mei[1], Maria Elena Jefferds[1], Andrea J Sharma[1], Rafael Flores-Ayala[1], Christine M Pfeiffer[1], Gary M Brittenham[2]

1. US Centers for Disease Control and Prevention (USA), 2. Columbia University (USA)

We compare physiologically based ferritin thresholds for iron deficiency in healthy non-pregnant women aged 15-49 y with current World Health Organization guidelines (WHO, 2020). After comprehensive review, the WHO determined insufficient data were available to revise the serum ferritin (SF) threshold of <15 µg /L for non-pregnant women which is based on expert opinion dating from 1993 (https://www.who.int/vmnis/indicators/serum_ferritin.pdf). Despite the availability of international reference materials, the standardization of immunoassays for SF is complicated by the heterogeneity of antibodies used and the absence of physicochemical reference methods. To ensure comparability with the assays available at the time of the formulation of the expert opinion, we analyze data from the Third National Health and Nutrition Examination Survey (NHANES III, 1988-1994). NHANES III used the BioRad assay for SF. In our previous NHANES analyses with data from 2003-2010 and 2015-2018, SF was assessed using the Roche Hitachi 912 clinical analyzer and the onset of iron-deficient erythropoiesis as identified by SF thresholds via hemoglobin (Hb) and soluble transferrin receptor were 25.1 and 24.0 µg /L, respectively (Lancet Haematol 2021;8: e572–582). Using NHANES III data, we examined the relationship of SF with two independent indicators of iron deficient erythropoiesis, Hb and erythrocyte zinc protoporphyrin (eZnPP). Data from 4639 apparently healthy non-pregnant women aged 15-49 y were analyzed after excluding infection (n=621, white blood cell counts <10.0 x 10^9/L), inflammation (n=17, C-reactive protein >5.0 mg/L), possible liver disease (n=35, defined by abnormal elevation of alanine amino transferase >70 U/L or aspartate amino transferase >70 U/L), and at risk of iron overload (n=312, SF >150 µg /L). Restricted cubic spline (RCS) regressions were used to determine SF thresholds for iron-deficient erythropoiesis via two separate curve models (Hb-SF and eZnPP-SF). SF concentrations increased with Hb and decreased with eZnPP in a curvilinear manner with defined inflection plateau. These plateau points were used to calculate the onset of iron-deficient erythropoiesis. The SF thresholds identified by Hb [24.8 µg /L (95% CI 23.4, 26.9)] and eZnPP [22.5 µg /L (95% CI 21.7, 23.3)] were similar (p-difference= 0.0163); both higher than the WHO threshold of <15 µg /L. Because this study relied on data from the BioRad assay, the difference in serum ferritin thresholds for iron deficiency found using the physiologically based approach and WHO guideline is not the result of differences in assays, as it could have been in our previous study. Instead, we suggest that the physiologically based approach identifies the onset of iron deficient erythropoiesis while the WHO expert

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

opinion value characterize a more advanced stage of established iron deficient erythropoiesis. The close correspondence of SF thresholds identified by two independently measured indicators further supports the evidence that iron deficiency without anemia begins well before the WHO guideline of SF <15 µg /L. Use of a higher SF threshold would increase the proportion of non-pregnant women of reproductive ages 15-49 years who are identified as iron deficient. Recognizing a need for iron among non-pregnant women could help prevent adverse effects of iron deficiency from remaining untreated and prevent the potential progression to severe iron deficiency and anemia, particularly before pregnancy.

Threshold ferritin and hepcidin concentrations indicating early iron deficiency in healthy infants and young women based on upregulation of iron absorption

Michael B Zimmermann[1], Nicole Stoffel[1], Hanna von Siebenthal[1], Diego Moretti[1], Valeria Galetti[1]

1. ETH Zurich (Switzerland)

Background: Plasma ferritin is a widely used indicator to detect iron deficiency, but the threshold ferritin that defines iron deficiency in women and infants remain uncertain. Our aim was to define the ferritin concentration at which the body begins to upregulate iron absorption from the diet; this could provide a functionally-defined threshold of incipient iron deficiency. We hypothesized this threshold ferritin concentration would correspond to the threshold hepcidin concentration at which iron absorption begins to increase.

Methods: We performed a pooled analysis of: 1) our stable iron isotope studies (n=1058) conducted from 2006 to 2019 in healthy, non-inflamed women (age 18-50 years; mean±SD ferritin 33.7±27.1 mg/L); and 2) our stable iron isotope studies in Kenyan and Thai infants (n=269, age 2.9 to 15.1 months); 66.8% were iron deficient and 50.4% were anemic. In all studies, we measured iron absorption from labeled test meals providing physiological amounts of iron. To fit relationships between iron absorption, ferritin and hepcidin, we used generalized additive mixed modelling (GAMM), and to identify thresholds, we estimated the first derivatives of the fitted trend to assess inflection points in these relationships.

Findings: In women, hepcidin increased linearly with increasing ferritin over the entire range of ferritin values. Iron absorption began to increase below a threshold hepcidin value of 3.09 (95%CI: 2.80, 3.38) nmol/l, above which iron absorption remained stable. Iron absorption began to increase below a threshold ferritin value of 51.1 (95%CI: 49.1, 53.1) µg /l, above which iron absorption remained stable. The latter two findings were internally consistent in that, in the relationship between hepcidin and ferritin, a hepcidin of ~3 nmol/l corresponded to a ferritin of ~51 µg /l. In infants, the fitted trend of PF versus FIA showed a significant negative slope until a PF of 46.3 (95% CI: 42.1, 50.5) µg /L, which corresponded to a FIA decrease from 26.5 to 8.3%; above this PF value, FIA remained stable. The fitted trend of hepcidin versus FIA showed a significant negative slope until a hepcidin of 3.15 (95% CI: 2.67, 3.63) nmol/L, above which FIA remained stable.

Interpretation : Based on physiological upregulation of iron absorption, threshold values indicating incipient iron deficiency are: 1) in young women, a ferritin of <50 µg /L, and a hepcidin of <3 nmol/l; 2) in infants, a ferritin of <46 µg /L and a hepcidin <3 nmol/L.

Reflections on new evidence to inform serum ferritin thresholds for assessing iron status

Lisa M Rogers[1], Maria Nieves Garcia-Casal[1]

1. World Heath Organization (Switzerland)

Accurate determination of iron status is crucial for diagnostic and screening purposes in the clinical setting and to guide public health interventions at the population level. The World Health Organization (WHO) undertook an evaluation of the evidence on the use of ferritin concentrations to assess iron status in individuals and populations and published updated guidance in 2020. Serum ferritin concentrations were confirmed to be a good marker of iron stores and a valuable indicator for the diagnosis of iron deficiency in otherwise apparently healthy individuals. Although the evidence at that time was insufficient to justify a change in published cut-off values for defining iron deficiency and risk of iron overload, it was recommended that ferritin values be assessed along with a marker of inflammation, and that ferritin values in those individuals with infection or inflammation be adjusted using one of several proposed methods.

Members of the WHO guideline development group and an expert resource group identified important areas of research that may lead to improved future guidance. WHO continues to follow research developments on iron deficiency, particularly on biomarkers for its detection.

Eating together throughout the lifecourse in the United States

Barbara A Lohse[1]

1. Rochester Institute of Technology (USA)

As you know, the United States of America is heterogeneous in demographics, philosophies, lifestyle and consequently in eating behaviors and attitudes. Thus, dietary intake ranging from vegan to organic-only to subsisting on fast foods and snacking is not surprising. However, a feature common across the dietary spectrum is the absence of *eating competence*. Eating competence (ecSatter), as devised by Ellyn Satter, is an "intra-individual approach to eating and food-related behaviors that entrains positive bio-psychosocial outcomes including maintaining energy homeostasis." Eating competent persons practice nutritional judo: They give themselves permission to eat what they want in amounts they find satisfying rather than going by dietary rules. At the same time, they exercise the positive discipline of providing themselves with regular meals and snacks. Satter suggests that this *nutritional judo* promotes movement toward a healthy lifecourse. Numerous research studies have demonstrated compelling reasons to incorporate eating competence-based counseling in educational and clinical practice. Competent eaters have been shown to have a lower body mass index, better sleep quality, more physical activity, less emotional and uncontrolled eating, lower cardiovascular risk, do better with respect to feeding their children, and to have a higher dietary quality including greater intake of fruits and vegetables. These findings are surprising given that ecSatter doesn't promote specific foods or portions or focus on weight. Instead, ecSatter addresses four pillars: Positive eating attitudes and behaviors, food acceptance skills to support increasing food variety, internal regulation of food intake, and contextual skills that enable regular and reliable meals and snacks. This session will detail each of these pillars and present research supporting their role in lifecourse and health. Finally, the development and application of a tool to measure ecSatter will be described with tool access information.

Nurturing health, embracing conviviality: Sharing meals along the lifespan in the Mediterranean region

Suzanne Maria Piscopo[1]

1. University of Malta (Malta)

Since its inception on the UNESCO Representative List of the Intangible Cultural Heritage of Humanity in 2010, the Mediterranean Diet (MeD) has gained recognition as an eating pattern to be emulated and promoted, not only for its health value, but also for its sustainability and socio-cultural value. The preventive and therapeutic benefits of consuming a MeD for a host of health problems and conditions, ranging from cardiovascular disease, to cancer, diabetes, metabolic syndrome, obesity, neurodegenerative diseases and frailty, amongst others, have continued to be proven ever since Professor Ancel Keys globally publicized the positive link between the MeD and cardiovascular health in the 1960s and 1970s. However, proponents of the lifestyle concept of the MeD, which started to be emphasized over recent decades and which stems from the Greek meaning of the word 'diaita' (way of life), are now highlighting even more strongly conviviality - or pleasure around meal sharing - as an integral component of the MeD, providing additional benefits for wellbeing throughout the lifecycle.

Indeed, the national dietary guidelines of a number of different countries have referred to the importance of meal sharing, indicating that there is evidence to justify such a recommendation. More specifically, in graphical food guides based on the MeD eating pattern developed in the past two decades, the requisite characteristic of conviviality involving shared food consumption and sometimes also food preparation is always portrayed. Yet whilst several studies have shown that eating with others, particularly family, is associated with healthier dietary outcomes across the lifespan, the prevalence of meal sharing and the relationship between this traditional cultural practice and physical, mental and social wellbeing for different population groups in the Mediterranean region is still an emerging area of research. Nonetheless, although research is somewhat scarce on frequency of family meals at different lifestages in Mediterranean countries, some studies have shown that sharing breakfast or family meals is a predictor for higher adherence to MeD consumption among children and adolescents in particular. Other studies have shown that high adherence to the MeD was associated with better Health-Related Quality of Life (HRQOL) and more subjective happiness among adolescents, and that, similarly, the number of meals per day consumed with the family was significantly positively associated with HRQOL as perceived by this younger generation. Of interest is one study that revealed a halo effect on non-intervention family members of an individual following a weightloss diet intervention based on the MeD. These family members also improved their diet and one of the influential factors was meal sharing.

Clearly more research is required to uncover the holistic health and wellbeing benefits for different population groups in the Mediterranean region (and beyond) of regularly experiencing conviviality as part of a MeD eating pattern and lifestyle. Sharing and enjoying meals with family and friends is a fundamental

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

characteristic of the MeD which deserves preserving, strengthening and facilitating through different educational and environmental policies, strategies and interventions.

SY(T3)1-3

The importance of eating together for a healthy life throughout the lifecourse in Japan

Kumi Eto[1]

1. Kagawa Nutrition University (Japan)

Eating meals together has benefits for both children and adults in Japan. Consequently, this overview presents the recent national trends of eating together among children and adults in Japan. Additionally, the trends observed in studies concerning associations of "eating together" with behavior, health, and well-being among Japanese populations will be discussed from quantitative and qualitative viewpoints.

Results from a recent national-wide survey in Japan revealed a higher proportion of children eat meals alone at breakfast than at dinner, which also increases with school grades. Likewise, the frequency of eating together with the family among adults was higher at dinner than at breakfast and higher among females than males, particularly in young and middle-aged adults.

A systematic review was conducted in 2018 on the benefits of eating together among the Japanese population. Articles published between 2001 and 2018 were accessed using domestic and international databases (Igaku Chuo Zasshi, CiNii, J-stage, PubMed, Scopus, and Eric). After screening titles, abstracts, and full texts, a total of 62 articles matching the criteria were included in the review. Most articles were cross-sectional studies. Target populations included preschool children (n = 8), school-aged children through to university students (n = 34), and adults and the elderly (n = 20). Although the definition of "eating together" differed in the study, the most used indicator was "frequency of eating together," with whom eating meals together being "family," and the targeted meals were "breakfast and dinner." Having either "eating together" occasions or few "eating alone" chances were associated with better quality of life (QOL), subjective health, food intake, balanced diet, dietary behavior, and life rhythm across the lifecourse. The study results were shared via a brochure titled "What are the benefits of Shokuiku (food and nutrition education)?" published by the Ministry of Agriculture, Forestry, and Fisheries.

As mentioned, many studies focus on the frequency or quantity of eating together. However, some studies focused not only on the frequency but also the quality of mealtime when people are eating together. One example is a study on voluntary mealtime communication (VMC), or whether children talk by themselves at the dining table while eating meals with family. Students in the fifth and eighth grades who had family dinner ≧4 times per wee substantial VMC had more positive dietary attitudes, dietary behaviors, and quality of life (QOL) than those with less frequent family dinners or without engaging in VMC. Another study reported that the existence and compliance with rules prohibiting smartphone use at mealtimes were associated with the enjoyment of family meals among high school students. Additionally, enjoyable eating experiences in childhood were positively associated with a balanced diet, eating vegetable dishes, and subjective diet-related QOL scores in adulthood.

Studies on eating meals together among the Japanese suggested that eating together is important across the lifecourse, and both frequency and quality of mealtime should be considered when exploring better eating together occasions. More research, especially targeting adults and the elderly or focusing on meals with non-family members, is expected.

Overview of maternal nutrition and evidence for key interventions

Parul Christian[1]

1. Johns Hopkins Bloomberg School of Public Health (USA)

Maternal undernutrition and micronutrient deficiencies continue to be highly prevalent in many low- and middle-income countries. These conditions give rise of adverse pregnancy outcomes of low birth weight (LBW), and its two underlying causes of small-for-gestational age (SGA) and preterm birth (PTB). Annually, 20 m newborns are born with low birth weight, which increases their risk of mortality and poor postnatal growth and development. Maternal morbidity and mortality are also linked to nutritional causes including low intakes of calcium and iron that can result in increasing the risk of preeclampsia and anemia, respectively. Gestational weight gain during pregnancy is not systematically assessed but modeled estimates indicate a high burden of inadequate increase in South Asia and sub-Saharan Africa. The recent WHO antenatal care guidelines include several evidence-based interventions for nutritional support during pregnancy that need to be delivered as part of antenatal care. Counseling for healthy eating and physical activity to prevent excessive weight gain as well increased energy intake to promote increased weight gain in undernourished context is important for every pregnant woman. Universal daily iron-folic acid (IFA) with iron dosage between 30-60 mg is recommended to prevent maternal anemia, although there is low-certainty evidence for its impact on LBW. The risk reduction for maternal anemia is high at 0.30 (95%CI: 0.19-0.46), suggesting that a high proportion of anemia during pregnancy is due to iron deficiency. There is moderate-certainty evidence that balanced energy and protein supplementation (BEP) reduces SGA and stillbirths and increases birth weight by 41 g, although in stratified analysis, in undernourished populations the increase was about 100 g. BEP supplementation is recommended for use in undernourished populations. Ongoing trials of fortified, ready-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

to-use BEP supplements designed using the specifications created by an expert group consensus process (https://gatesopenresearch.org/documents/3-1498) will provide evidence for the effects of combined macro and micro-nutrients on birth outcomes. Multiple micronutrient supplements (MMS), also containing IFA and shown to be superior relative to IFA alone for reducing low birth weight, are recommended in the context of rigorous research, including implementation research. Lastly high-dose calcium (1.5-2g) is recommended for reducing the risk of preeclampsia in low intake settings. There is moderate-quality evidence showing a 64% risk reduction in preeclampsia. Ongoing non-inferiority trials will demonstrate if low-dose calcium at 500 mg will have a similar impact. In summary, nutrition guidelines for pregnancy exist, but implementation lags and "nutrition-quality" in ANC needs urgent attention. Ongoing implementation research, especially in the use of MMS and BEP in pregnancy including testing of targeting strategies will enhance our understanding of program delivery at scale.

Periconceptional multiple micronutrient supplementation reduces risk of early pregnancy loss in rural Bangladesh: The JiVitA-5 Trial

Keith P. West, Jr.[1], Hasmot Ali[1,2], Kelsey Alland[1,2], Saijuddin Shaikh[1,2], Lee S-F Wu[1], Rezwanul Haque[2], Brian Dyer[1], Klaus Kraemer[1,3], Alain B. Labrique[1,2], Kerry J. Schulze[1,2]

1. Johns Hopkins Bloomberg School of Public Health (USA), 2. The JiVitA Project (Bangladesh), 3. Sight and Life Foundation (Switzerland)

Background and Objectives: Micronutrient deficiencies are prevalent among pregnant women in low-middle income countries. Antenatal multiple micronutrient supplementation (MMS) can reduce adverse pregnancy outcomes, is recommended by WHO and on its Essential Medicines List. However, unknown is whether periconceptional MMS can prevent miscarriage and further improve materno-fetal health.

Methods: The JiVitA-5 trial was a double-masked, cluster-randomized, placebo-controlled trial conducted in 566 communities to assess the efficacy of MMS (15 nutrients at ~1 RDA) starting before a last menstrual period (LMP) through 1st trimester, in reducing miscarriage <24 weeks in rural Bangladesh. The trial enrolled 7,967 consenting newlyweds, of whom 4,269 became pregnant: 2,044 and 2,225 in placebo and MMS groups, respectively, similarly distributed among those detected by a (a) history of amenorrhea confirmed by urine test during pre-COVID-19 era monthly home visits (67%) and (b) history of amenorrhea and self-report of pregnancy by mobile phone interviews during the COVID-19 era (33%), after March 2020. In both randomized groups, 80% of participants began daily coded supplementation prior to their LMP, comprising the intent-to-treat group. By end of the 1st trimester, all women were switched to an open-labelled MMS through 3-months postpartum as an efficacious health intervention (West et al JAMA 2014).

Results: At baseline participants were comparable by allocation, with 86% <20 years of age. Among women who started supplementation before their LMP, the miscarriage rate (<24 weeks' gestation) was 11.53% and 8.9% in the placebo and MMS groups, yielding a relative risk (RR, design effect-adjusted 95% CI) of 0.77 (0.63-0.95, p=0.013). The RR (95% CI) of any pregnancy loss <24 weeks was 0.76 (0.64-0.91, p=0.0024). Among mothers starting coded supplementation on/after week of LMP, the RR of miscarriage was 1.10 (0.74-1.63, p=0.65), and any pregnancy loss <24 weeks was 0.96 (0.70-1.32, p=0.81). There was no apparent effect on risk of stillbirth (RR=0.89; 0.63-1.25) or preterm birth (<37 weeks, RR=0.89; 0.75-1.05).

Conclusions: Multiple micronutrient supplementation, from preconception through 1st trimester, reduced miscarriage by 23% among primigravid mothers in rural Bangladesh. Nutrients of interest include vitamins E and D, both widely deficient in rural South Asia and associated with risk of miscarriage.

The scale and scope of implementing maternal nutrition interventions

Martin N. Mwangi[1,2], Marti van Liere[1], Saskia Osendarp[1]

1. The Micronutrient Forum (France), 2. University of Malawi (Malawi)

This synopsis assesses the current scale and scope of maternal nutrition interventions (MNIs) to prevent or treat maternal morbidity and mortality. MNIs include micronutrient supplementation, weight-gain monitoring, dietary counseling and are efficacious in improving maternal health and birth outcomes. Globally more than 240 million women of reproductive age in low- and middle-income countries are underweight, 610 million are overweight, 571 million are anemic, and 450 million are stunted, a sign of chronic undernutrition. Deficiency rates of crucial micronutrients (such as iron, folate, vitamins B12 and D, iodine, and zinc) are high irrespective of whether women are underweight, normal weight, or overweight: 63% of women are vitamin D-deficient, 41% are zinc-

deficient, and 40% are iodine-deficient. Women require adequate access to nutritious, safe, affordable, and sustainable diets across the life course, especially during adolescence, preconception, pregnancy, and breastfeeding periods.

The Lancet's 2021 Series papers on maternal and child undernutrition progress noted that multiple micronutrient supplements (MMS) coverage is too variable and inequitable to deliver impact and thus recommended to national governments to 1) immediately scale up and routinely measure the coverage for MMS during pregnancy, and 2) prioritize efforts to acquire the implementation-related evidence required in settings with a high prevalence of maternal undernutrition and low dietary intakes of calcium and balanced energy protein supplements. Notably, despite over 20 years of evidence for the positive impact of MMS on maternal nutritional status and birth outcomes, progress on implementation has been very slow. In 2021, implementation research related to MMS integration into antenatal care services was ongoing in less than 20 countries, targeting less than two million pregnant women. Despite the recent inclusion of MMS in the WHO Model Essential Medicine List, no country has scaled up MMS distribution to the national level.

Keeping track of the scale and scope of implementing MNIs will accelerate progress toward the Sustainable Development Goals and the nutrition targets set by the World Health Assembly across countries. The maternal nutrition and maternal health communities must take collective action to accelerate the implementation of evidence-based, cost-effective MNIs. This will impact the health and well-being of the women and deliver substantial human capital gains for their babies.

Antenatal multiple micronutrient supplementation; implementation lessons

Vilma Qahoush Tyler[1], Nita Dalmiya[1]

1. UNICEF (USA)

Meeting the nutritional needs of pregnant and lactating women in low and middle income countries, LMICs, remains a challenge due to the high cost, low availability, and poor access to nutrient rich diets. Multiple micronutrient supplements, MMS, containing 15 vitamins and minerals, fills this gap and has been demonstrated to be a safe, affordable, and effective intervention when it comes to improving maternal and child nutrition and health outcomes. As a growing number of countries are interested in introducing MMS to strengthen nutrition programs as part of implementation research, understanding the barriers and facilitators to implementation and uptake are paramount for successful initiation and scale up. The Improving Maternal and Pregnancy Outcomes through Vital Nutrition and Growth, IMPROVING, is a multi country project funded by the Bill and Melinda Gates Foundation. It aims to advocate for and introduce the provision of MMS for use among pregnant women in four priority countries with high burdens of maternal and child undernutrition: Burkina Faso, Bangladesh, Madagascar, and Tanzania, through existing government delivery systems. In addition, the project aims to strengthen global support systems on MMS supply chains and programmatic delivery approaches which will help guarantee the availability of MMS supplies in the four countries. The project is applying an implementation research approach to guide programming and scaling up based on lessons learned, with a special emphasis on addressing barriers to uptake and utilization of maternal nutrition services and MMS. The proposed presentation will focus on highlighting key features of IMPROVING and the implementation research approach focused on testing strategies and using routine health and nutrition data to assess how implementation is going and feed it back into system, thereby creating feedback loops in each country. In doing so, it will share evidence on the strategies and approaches being used to increase access to and utilization of MMS among pregnant women; as well as how evidence and knowledge is being tracked, consolidated, and analyzed. This result being to not only support scale up efforts in the four countries, but also other countries that become interested in introducing MMS and support a global normative transition to MMS.

Antenatal micronutrient supplementation in humanitarian settings

Philip T James[1], Natasha Lelijveld[1], Stephanie Wrottesley[1], Brenda Akwanyi[1], Eilise Brennan[1], Emily Mates[1]

1. Emergency Nutrition Network (UK)

In this short presentation we will first briefly set the scene by describing the aspects of nutrition for women and adolescent girls that are being addressed in humanitarian programmes, and specifically where multiple micronutrient supplementation (MMS) fits in. We will then use a case study to offer a snapshot of one country's specific experience across the spectrum of humanitarian programming for women, with relevant MMS programming for women's nutrition. We will summarize the views and experiences of multiple stakeholders working within that country. Firstly, we will explore how effective humanitarian programming has been, particularly the MMS programmes, as well as any barriers to access and uptake. Alongside the programmatic considerations, we will describe which policies and guidance documentation were used to guide humanitarian interventions, including MMS programming in that context, and whether stakeholders felt there were any policy gaps to fill. As part of this we will explore the extent to which it was clear when decision-makers should switch from development to

humanitarian programming or vice versa, especially if different policies exist for each context. For example, this could be the case for countries where iron-folic acid supplementation is used in developmental settings, yet MMS is used in humanitarian settings. We will consider stakeholders' perceptions on what the gaps in evidence are that may be hindering progress in nutrition programming for women and girls in humanitarian contexts. We will ask how well nutrition for women and adolescent girls, focusing on MMS, is being integrated into other health policies and/or programmes in humanitarian settings. Finally, we will summarize the lessons learnt from the case study for the wider nutrition and health communities, and what the related key priorities for progressing the nutrition agenda for women and adolescent girls in humanitarian contexts are.

Impact of scaling up prenatal nutrition interventions on human capital outcomes in low- and middle-income countries: a modelling analysis

Nandita Perumal[1], Mia M. Blakstad[1], Günther Fink[2,3], Mark Lambiris[2,3], Lilia Bliznashka[1], Goodarz Danaei[1], Christopher R. Sudfeld[1]

1. T.H. Chan School of Public Health, Harvard University (USA), 2. Swiss Tropical and Public Health Institute (Switzerland), 3. University of Basel (Switzerland)

Background: Prenatal nutrition interventions can improve birth outcomes, which in turn are associated with better education and human capital potential later in life.

Objective: To estimate the impact of scaling up iron-folic acid (IFA), calcium, multiple micronutrient (MMS), and balanced energy protein (BEP) supplementation for pregnant women, on human capital outcomes in low- and middle-income countries (LMICs).

Methods: We used mathematical modelling with proportional reductions in adverse birth outcomes to estimate the potential gains in school years and lifetime income due to scaling-up each prenatal nutrition interventions separately. Estimates of intervention effects on birth outcomes were derived from meta-analyses of randomized trials. Estimates of the associations between birth outcomes and schooling and lifetime income were derived from *de novo* meta-analyses of observational studies.

Results: Across 132 LMICs, scaling up prenatal nutrition interventions to 90% coverage was estimated to increase school years and lifetime income per birth cohort by: 5.02 million years (95% uncertainty interval: 1.07, 11.0) and $18.1 billion (3.88, 39.1) for MMS; 4.08 million years (0.12, 9.68) and $18.9 billion (0.59, 44.6) for calcium; 2.28 million years (-0.44, 6.26) and $8.26 billion (-1.60, 22.4) for IFA; and 5.25 million years (-0.49, 1.70) and $1.34 billion (-1.10, 3.10) for BEP supplementation. South Asia and sub-Saharan Africa tended to have the largest estimated regional gains in school years for scaling up each intervention due to the large population size and high burden of poor birth outcomes. Income benefits for each intervention were estimated to be the largest in Latin America, where returns to education and incomes are higher relative to other regions.

Conclusion: Increasing coverage of prenatal nutrition interventions in LMICs may lead to substantial gains in schooling and lifetime income. Decision makers should consider the potential long-term human capital returns of investments in maternal nutrition.

Protein quality and optimal intakes to prevent sarcopenia risk

Satoshi Fujita[1]

1. Ritsumeikan University (Japan)

Skeletal muscle is necessary for force production in the activity of daily living, but it is also critical for the regulation of carbohydrate and fat metabolism. Sarcopenia not only increases the risk of falls but also induces insulin resistance and metabolic syndrome, which subsequently exacerbate the physical independence of older individuals.

Acute protein intake increases muscle protein synthesis which is essential for maintaining muscle protein anabolism and muscle mass. On the contrary, lack of protein intake, especially at breakfast, has been shown to increase the risk of skeletal muscle loss regardless of the age group. Essential amino acids, especially leucine, have been shown to stimulate mTORC1 pathway which subsequently regulates muscle protein synthesis. Therefore, protein quality (i.e. leucine content) is a factor that strongly influences post-prandial protein anabolism.

Resistance exercise is another intervention that can stimulate muscle protein synthesis and prevent and/or delay sarcopenia, while inactivity accelerates muscle loss. The anabolic effect of resistance exercise can last up to 48hrs post-exercise, and protein intake post-exercise can further augment exercise-induced muscle protein anabolism. Furthermore, lack of protein at breakfast negatively affects muscle hypertrophy; conversely, adding protein to breakfast and consuming sufficient amounts can enhance the effect of muscle hypertrophy.

We will review recent studies regarding the role of protein quality and optimal intake to prevent sarcopenia risk.

Keywords: Sarcopenia, protein intake, skeletal muscle, leucine, resistance exercise

SY(T3)3-2

Dietary protein: a key to active and healthy aging?

Marjolein Visser[1]

1. Vrije Universiteit Amsterdam (Netherlands)

In this presentation, firstly, the different existing recommendations for protein intake in older adults will be reviewed, and the results of a systematic literature review of nutritional intervention studies to support the recently developed Dutch recommendation, which is similar to the recommendation from the European Food and Safety Authority. The actual intake of protein by older adults will be reviewed in light of these recommendations. Furthermore, risk groups for a lower protein intake will be highlighted based on cohort data and data from national dietary surveys. In developing nutritional advice on protein intake for older adults, information on older adults' knowledge about dietary protein is crucial. The results of an international survey on this topic conducted among 1,825 older adults will be presented. Secondly, the relationship between protein intake and physical functioning based on two recent studies will be presented. Results from a meta-analysis using pooled prospective data from almost 6000 older adults participating in four prospective cohort studies around the world will be shown. The association of protein intake with change in self-reported mobility limitations over time, as well as with change in objectively assessed walking speed over time will be described. Moreover, the effect of dietary advice to increase protein intake on 6-month change in physical functioning will be presented, using the results of the PROMISS trial, a randomized controlled trial among 276 older adults. Lastly, information will be provided on how to advice older adults to effectively increase their protein intake.

SY(T3)3-3

Dietary pattern approach to stop frailty

Wen-Harn Pan[1]

1. Academia Sinica (Taiwan)

Frailty has been associated with insufficient protein intake and it has been documented that protein supplementation can significantly reverse the condition of frailty or sarcopenia. The effect may be strengthened if it is combined with physical activity intervention. Since frailty is associated with multiple nutrient insufficiency and unbalanced food group distribution, we anticipate that more can be done to manage and to prevent frailty. Foods are not consumed alone rather in patterns. Nutrients and beneficial non-nutrient food substances very often exert effects in concert. Protective dietary patterns include Mediterranean diet, DASH diet, prudent diet, and healthy Taiwanese eating approach; risky patterns include western diet and ultra-processed food patterns, etc. It points to the benefit of plant-based dietary pattern, i.e. mainly plant foods and drinks with beans and moderate amount of dairy and earth friendly sea foods as protein sources. Interventions using dietary pattern approach are limited. Promising but moderate effects have been observed in some randomized controlled trials including our Taiwanese studies. The cost-effective group activity interventions are just handful. More should be trialed out for versatile implementation needs.

Preventive dietary factors for frailty, sarcopenia, and dementia; Results from NILS-LSA cohort study

Rei Otsuka[1]

1. National Center for Geriatrics and Gerontology (Japan)

In aged societies, the number of older people with physical frailty, sarcopenia and dementia is increasing. Nutrition is one of the key factors to prevent these age-related impairments. The National Institute for Longevity Sciences - Longitudinal Study of Aging (NILS-LSA), a comprehensive longitudinal epidemiological study of aging, started in 1997 at the National Center for Geriatrics and Gerontology (NCGG) in Aichi Prefecture, Japan. Participants in this study were 2,300 residents aged 40-79 years who were age- and sex-stratified random samples selected from the area around the NCGG. Participants were examined at the NCGG examination center every 2 years from 1997 to 2012 and were followed-up from 2012 to 2022.

Nutrition and food intakes were calculated based on 3-day dietary records with photographs. Physical frailty was assessed using the modified criteria of the Cardiovascular Health Study, which included weight loss, weakness, exhaustion, slow walking speed, and low physical activity. Muscle mass was assessed using dual-energy X-ray absorptiometry, and low muscle mass was defined as skeletal muscle mass index <7.0 for men and <5.4 kg/m^2 for women. Cognitive function was assessed by the Mini-Mental State Examination for participants ≧60 years old.

This presentation will show the key nutritional findings from the NILS-LSA. Prospective analyses of the NILS-LSA cohort showed that higher meat and dairy consumption to ensure sufficient protein and fat intake (to achieve higher energy intake levels) may be an appropriate option to help prevent the development of physical frailty. And high levels of daily protein intake and protein intake at lunch may help prevent skeletal muscle mass declines. In addition, compared to less varied diets,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

moderately to highly varied diets containing fish, soybeans, and dairy products prevented cognitive decline.

These findings suggest that a daily diet that includes a variety of foods with sufficient protein and fat might be effective for preventing physical frailty, sarcopenia, and dementia in the Japanese community.

Counseling is Complex: Approaches and Tools to Improve Infant and Young Child Feeding Counseling Quality

Lesley Oot[1], Jeniece Alvey[3], Elaine Gray[3], Lindy Fenalson[3], Grainne Moloney[4], Kristen Cashin[2], Catherine Kirk[2], Altrena Mukuria[2]

1. JSI Research & Training Institute, Inc (USA), 2. Save the Children (USA), 3. USAID (USA), 4. UNICEF (USA)

Background and Objective: The World Health Organization (WHO) and the United Nations Children's Fund (UNICEF) define nutrition counseling as “a way of working with people so that you understand their feelings and help them to develop confidence and decide what to do.” Providing quality counseling is an effective means to achieve optimal infant and young child feeding (IYCF) practices, identified by WHO as a key approach to improve breastfeeding rates globally. However, long-standing barriers (e.g. overburdened workforces, insufficient counselor capacity, poor remuneration, inadequate supervision and support, and lack of prioritization/funding) continue to affect the provision of quality counseling, highlighting the complexity of effective implementation. These challenges underscore the need for more practical information, guidance, and tools to support effective IYCF counseling. The purpose of this session is to facilitate discussion and sharing of resources on how to improve the quality of IYCF counseling.

Methods: This informative, interactive session will utilize presentations, storytelling, and facilitated discussion. We begin by sharing counseling experiences and presentations from the U.S. Agency for International Development (USAID) and UNICEF highlighting approaches to strengthening counseling, including key considerations, barriers, and opportunities. Participants break into groups to discuss areas to improve IYCF counseling: 1) capacity strengthening (e.g. training, mentorship); 2) support to counselor performance (e.g. tools, job aids, supervision); 3) support to caregiver enabling environment (e.g. resources for family engagement, caregiving evidence measures). Handouts provide additional examples of tools and resources from USAID Advancing Nutrition, the Agency's flagship multi-sectoral nutrition project, UNICEF, and others. The session concludes by highlighting areas of discussion, applications to current work, and next steps.

Results: This session aims to improve understanding of the challenges that impede effective counseling implementation, and identify key approaches, tools, and resources that can address barriers to quality IYCF counseling.

Conclusions: Despite the importance of counseling in supporting optimal IYCF practices, long-standing barriers limit the provision of quality IYCF counseling to the detriment of families, communities, and countries. Focused discussion on how to address key barriers to effective counseling is critical to improving IYCF practices and ultimately nutrition outcomes.

Preconception diet for healthy pregnancy outcomes

Naoko Arata[1]

1. National Center for Child Health and Development (Japan)

Improving nutritional status during the "first 1000 days of life" is important because the fetal to early postnatal environment has a strong impact on lifelong health (https://thousanddays.org/). On the other hand, preconception health care is important because even if women intervene in nutrition and lifestyle after becoming pregnant, their effects on pregnancy outcomes are limited. For example, undernutrition in pre-pregnancy women causes premature birth and low birth weight infants and is associated with future metabolic syndrome, and overweight and obesity in pre-pregnancy women are large for gestational age infants, gestational diabetes, and preeclampsia. The Lancet magazine highlighted the need for preconception interventions in nutrition, while discussing the difficulty of interventions in care recipients (Lancet, 391 (10132), 2018). In the United States, since 2006, the PCHHC Initiative, which consists of related organizations, has been increasing interest in the health of the younger generation while involving companies (Upsala Journal of Medical Sciences, 2016.DOI: 10.1080 / 03009734.2016.1204395). In Japan, the increase in the proportion of underweight (BMI <18.5) among young women during the period from the 1980s to the quarter century from 15% to over 20% and the decrease in the average birth weight of children born are regarded as problems. On the other hand, the proportion of overweight / obesity (BMI > = 25) in young women is on the rise (about 10%). According to data from the Japan Environment and Children's Study (JECS), which enrolled approximately 100,000 pregnant women in 15 locations nationwide over the three years from 2010, the regional difference in the proportion of overweight / obese pregnant women is as large as 7.3% (Journal of Epidemiology 2018; 28:99). Furthermore, there are some areas where the ratio of overweight / obesity pregnant women is higher than that of underweight pregnant women, and not only the increase in

underweight but also the overweight / obesity of young women is a big problem. The low intake of appropriate folic acid supplements for women of reproductive age (8.3%) (Congenit Anom. 2019; 59: 110) is also one of problems. In Japan, double burden of nutrition has become a problem within individuals, households and populations, and urgent measures are required considering the short-term and long-term effects on children.

Keywords: Nutrition, preconception care, double burden of nutrition

Maternal & child health service delivery in Sri Lanka

Kapila Jayaratne[1]

1. Ministry of Health (Sri Lanka)

Sri Lanka is a low and middle income country, with a population of 22 million, located in the Indian subcontinent. The country boasts of impressive maternal and child health (MCH) indices on par with high income countries. In the year 2020, there were 301,706 live births and a maternal mortality ratio of 30.2 (per 100,000 live births) was reported. The country's neonatal mortality, infant mortality and under 5 mortality rates were 6.0, 8.5 and 10.1 (per 1000 live births) respectively (2015). The secret behind the success is the strong maternal & child health service delivery system operative throughout the country.

The public health sector dominates in the MCH service delivery and is structured into two parallel systems with community health services and curative care delivered through a variety of hospitals. Started in the year 1926, the MCH programme has been evolved over many decades. The service delivery is based on the life course approach starting from the registration of newborns by field healthcare workers at home. Domiciliary and institution based care is provided for infants, preschool children, school children, adolescents, pre-pregnant women and pregnant women. All the service recipients are registered and followed up at household level by a hierarchy of healthcare providers at strategic points with a parallelly running health information system. Currently, it has reached almost all families in the country forming a well organized health care network with 354 divisional areas.

The country's MCH service delivery model is inbuilt with nutritional action points starting from birth, exclusive breastfeeding, Infant and young child feeding (IYCF) program for under 2 years, community-based growth monitoring, provision of supplementary food, institutional management of severe wasting, school medical inspections, adolescent healthcare, prepregnant care package and maternal nutrition monitoring and interventions.

The outcomes are satisfactory; low birth rate (16.1%), Exclusive breastfeeding under 6 months (82%), Children ever breastfed of all children <5 years (99.4%), Children under five: Underweight (weight- for- age <-2SD) (20.5%), Wasting (weight for height <-2SD)(15.1%) and Chronic malnutrition (height for age <-2SD) (17.3%), at 12 weeks of gestation maternal BMI < 18.5 (16%), BMI > 25 (29.9%) and Hb % below 11g/dl (18.4%), 7.6 % and 5.6% of school children in grades 1 and 4 are stunted respectively.

Sri Lanka executes a well organized MCH program addressing nutritional demands of the service recipients.

WHO global recommendations for improving health through maternal nutrition

Lisa M Rogers[1]

1. World Heath Organization (Switzerland)

Good maternal nutrition supports the protection and promotion of health through improved well-being of women, especially during the preconception, pregnancy and postpartum periods. This provides beneficial effects starting at the earliest stages of the life course, during fetal development and early life – having both short- and longer-term effects.

This presentation will highlight existing WHO global recommendations on maternal nutrition, underlining opportunities for action on maternal health. Actions related to women prior to pregnancy, as well during the antenatal, intrapartum and postpartum periods, will be presented in which countries may wish to choose to adapt while developing their own maternal health policies and programmes. These actions are targeted to women for her benefit and the benefit of the child. By contributing to the well-being of women, we can support mothers who are healthy, happy and better able to nurture their child, while reaching Sustainable Development Goal 3 (Ensure healthy lives and promote well-being for all at all ages) and its associated targets on reducing global preventable maternal and newborn mortality.

Revised dietary guidelines for pregnant and lactating women in Japan

Hidemi Takimoto[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Numerous previous studies suggest that impaired fetal growth poses the infant to increased risk of non-communicable disease, such as obesity, cardiovascular disease, and type 2 diabetes. In Japan, approximately 10 % of newborn infants are born low birthweight. The unique characteristic of these low birthweight infants is, that around 60% of them are term born, according to the 2020 Vital Statistics data. Furthermore, the relatively high proportion (nearly one in five) of underweight young women in Japan, who may have the increased risk of malnutrition, may be one of the underlying factors for impaired fetal growth among Japanese infants. Therefore, improving the nutritional status of pregnant and lactating mothers is a priority for promoting the health of future generations. However, results from nutritional intervention studies on pregnant and lactating mothers aimed at improving pregnancy outcomes or infant growth are non-consistent. One reason may be that pre-pregnancy nutritional status of the women is more influential than short term dietary improvements. Prior to the revision of the "Dietary guidelines for pregnant and lactating women" in 2021, we conducted systematic reviews regarding nutrition and diet among East Asian women in a 2019 research project, to provide evidence for this revision. We share our experience in the revision process of the "Dietary guidelines".

Infant nutrition for growth and future health

Berthold Koletzko[1]

1. LMU University Hospitals (Germany)

Early nutrition and lifestyle factors acting during sensitive pre- and postnatal time windows of developmental plasticity have long-lasting programming effects on later health, performance and disease risks. Early growth trajectories modulate later risks of obesity, adiposity, and associated non-communicable diseases (NCDs). Improved early nutrition offers major preventive opportunities. Rapid weight gain in the first two years of life is associated with increased later obesity. Breastfeeding is associated with reduced later obesity, compared to infant formula feeding. We explored the hypothesis that the lower protein content of human milk, as compared to conventional formula, results in lesser infant weight gain and body fat deposition (*The Early Protein Hypothesis*) (1) in a large double blind randomized clinical trial (2-4) with conventional bottle milk, or isoenergetic intervention formula with reduced protein content more similar to contents in human milk. The reduced protein supply normalized body weight and Body-Mass-Index (BMI) at age 2 yrs, compared to breastfed children. The beneficial effect on BMI persisted until school age. At 6 yrs, the adjusted relative obesity risk of children previously fed high protein formula was 2.60fold higher than with a reduced infant protein intake (3). Follow up at 11 yrs showed persistent effects. Lower protein supply reduced IGF-1 and insulin secretion which predicted weight gain (5). Dietary effects on the IGF-1 axis outweighed by far the effects of genetics and gender (6). High protein supply appeared to suppress fatty acid beta-oxidation (7), which may explain increased body fat deposition and adiposity at ages 2 and 6 yrs (4). Metabolomic and amino acid data suggest that also protein quality provided in infancy is important for modulating growth, providing further opportunities for early prevention. We tested a formula with a modified amino acid composition better matching infant amino acid requirements, first in an animal study to evaluate safety (8, 9) followed by a randomized trial in infants (10-12).

Early nutrition and later outcomes in preterm infants

M Jeeva Sankar[1]

1. All India Institute of Medical Sciences (India)

Many studies have shown a positive association between nutritional intake during the neonatal intensive care unit (NICU) stay and the long-term neurodevelopmental outcomes at 18 months of corrected age (CA) and beyond in preterm infants. The association is, however, confounded by several factors, including maternal nutrition and socioeconomic status, obstetric

conditions like gestational diabetes and hypertension, fetal genetic potential, and, importantly, neonatal morbidities such as bronchopulmonary dysplasia and preterm brain injury. These factors are likely to play a more critical role in delineating the association between early nutrition and long-term outcomes in preterm infants from low- and middle-income countries (LMIC) with suboptimal antenatal and neonatal care practices and high prevalence of intrauterine growth restriction. For example, the growth trajectory from birth to term corrected age in preterm infants in LMIC settings is quite different from those born in high-income countries. In a study involving about 400 preterm neonates born before 34 weeks of gestation, we found a considerable drop in weight-for-age z-scores from around -0.8 z-score at birth to -2.8 z-score at term corrected age despite receiving adequate parenteral and enteral nutrition at a level-3 NICU in India. Despite some catch-up during infancy, the median z-score was -1.6 at 12 months of CA. In another study of 195 very preterm or very low birth weight infants, we observed no association between the average energy and protein intake during the NICU stay and the weight-for-age z-scores at 18 months' CA. Though there was a weak positive correlation between the weight-for-age z-scores at term corrected age and the motor and mental developmental quotients (MoDQ and MeDQ) at 18 months' CA, the multivariable regression did not demonstrate any association between the two variables after adjusting for gender and gestation. The effect of nutritional intake before discharge from the NICU on the risk of metabolic syndromes in later life is largely unknown in preterm infants from LMICs. The paucity of information underscores the need for large observational studies with well-defined protocols and methodologies to examine the association between early nutrition and long-term growth and development and the risk of adult-onset diseases after accounting for all relevant confounding factors in preterm infants from both high-income and low and middle-income countries.

Keywords: Newborn, prematurity, nutrition, development

SY(T3)6-3

Dietary exposures among infants in the United States

Regan L Bailey[1,2]

1. Texas A&M University (USA), 2. Institute for Advancing Health through Agriculture (USA)

Establishing optimal dietary patterns in early childhood is critical not only to support optimal growth and development, but also to promote life-long health. Using nationally-representative survey data in the US, the dietary patterns and feeding behaviors of older infants (i.e., 6 to <12 months), when complementary foods and beverages [CFB] are recommended to be introduced, are summarized. Breastfeeding initiation is high (84%), but the prevalence of exclusive breastfeeding at 6 months (26%) is below the Healthy People 2030 goal (42%). Most U.S. infants consume CFB prior to 6 months (51%). Indeed, about one-third (32%) of infants are provided CFB prior to 4 months, which is higher among formula-fed (42%) when compared with mixed-fed (32%), or exclusively breast-fed infants (19%). Formula- and mixed-fed [FMF] infants are more likely to receive cow's milk (36% vs. 24%) and fruit juice (45% vs. 20%) at <12 months than human-milk-fed [HMF] infants, respectively. The primary mode of feeding is associated with the timing of introduction and types of CFB reported. FMF are more likely to consume grains (91% vs. 81%), proteins (51% vs. 35%), fruits (86% vs. 75%), dairy (46% vs 40%), fats (62% vs. 49%), and added sugars (64% vs 55%) than their HMF counterparts. HMF infants consume more fruit from non-baby food sources, more grains from snacks and sweets, and less total protein foods than FMF infants. HMF infants obtain more oils from vegetables and less from snacks/sweets, mixed dishes, and baby foods than FMF infants. HMF infants receive more energy from fruits, vegetables, milk and dairy, and grains and less energy from mixed dishes than FMF infants. These dietary patterns result in differences in amounts of total energy (845 vs. 631 kcal), protein (22 vs. 12 g), and sodium (508 vs 305mg) from all sources, and more energy (345 vs. 204 kcal), protein (11 vs. 6 g), and sodium (344 vs 201 mg) from CFB alone. HMF have a higher prevalence of risk of inadequate intakes of iron (77% vs. 7%), zinc (54% vs. <3%), and protein (27% vs. <3%) than FMF infants. Taken together, these data suggest that the primary mode of feeding plays a critical role in the timing, amounts, and energy and nutrient intakes from CFB. CFB are needed to provide more than half of the infant's requirements for vitamins B6, D, E, thiamin, and niacin, iron, zinc, magnesium, phosphorus, manganese, and fluoride, but this varies by the amounts and combinations of human milk and infant formula. Given the estimated calorie requirements during this life stage, it can be quite challenging to meet these nutrient requirements without careful consideration of choices for CFB. Given, the large differences in energy intakes relative to recommendations, tailored advice for providing CFBs is needed by mode of feeding to reduce the risk of pediatric overweight and obesity and to support infants' nutrient adequacy.

SY(T3)6-4

Promoting Healthy Food Preferences from Early Life - Flavor Perception and Preference Development

Catherine A. Forestell[1]

1. College of William & Mary (USA)

To understand the development of children's flavor preferences, it is important to consider the interplay of nature and nurture. Children are biologically predisposed to prefer sweet-tasting foods and beverages and to avoid bitter-tasting foods such as green leafy vegetables. In addition, food neophobia, or the avoidance of new foods, increases during early childhood and by the end of the second year, food refusals become common. In today's obesogenic environment these

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

biological predispositions place children at risk for a variety of serious health consequences, such as type 2 diabetes, cardiovascular disease, and heightened risk of obesity. Although early preference for sweet taste and avoidance of bitter taste are inborn, an important feature of the olfactory and gustatory systems is that they are inherently plastic, especially during infancy and childhood. Throughout development parents play an important role in setting the stage for healthy food acceptance patterns. Before birth, the gustatory and olfactory systems are well developed, allowing the fetus to detect the continually changing flavor profile of amniotic fluid, which reflects the mother's diet. These sensory experiences continue after birth if the mother chooses to breastfeed. Through this process of familiarization, women who maintain a healthy diet throughout pregnancy and lactation expose infants to the flavors of these healthful foods and prepare their infants to like them after birth. This process continues once infants begin to eat complementary foods. Repeated exposure to a variety of healthful foods further promotes preferences for these foods and also encourages acceptance of novel foods. By modeling healthy eating behaviors and by creating supportive feeding environments, parents can shape their children's flavor preferences. Although this developmental process may seem relatively simple, it is important to remember that these practices are influenced by demographic and societal characteristics. By considering the context in which children and families live, more effective evidence-based strategies can be developed to empower a broader population of parents and caregivers to encourage healthy eating in young children's everyday environments.

Introducing multiple micronutrient supplementation (MMS) for improved maternal nutrition in low- and middle-income countries

Kristen Hurley[1,2], Ruchika Chugh Sachdeva[3], Parul Christian[1], Martin Mwangi[4], Toslim Uddin Khan[5], Trisari Anggondowati[6], Aissata Ba[7]

1. Johns Hopkins Bloomberg School of Public Health (USA), 2. Vitamin Angel Alliance (USA), 3. Bill and Melinda Gates Foundation (India), 4. Healthy Mothers Healthy Babies Consortium (USA), 5. Social Marketing Company (SMC) (Bangladesh), 6. Universitas Indonesia (Indonesia), 7. jhpiego (Mali)

The United Nations International Multiple Micronutrient Antenatal Preparation of Multiple Micronutrient Supplements (UNIMMAP MMS) is a nutritional supplement for pregnant women. It contains 15 essential vitamins and minerals (including iron and folic acid) for pregnant women; and is supported by more than 20 years of research showing that it safely and effectively improves maternal health and pregnancy outcomes above and beyond that of Iron and Folic Acid (IFA). This evidence informed the 2020 update to the WHO antenatal care recommendations for UNIMMAP MMS. The new guidelines now recommend the use of MMS containing iron and folic acid in the context of rigorous research (context-specific recommendation – research). At a program level, UNIMMAP MMS are recommended to be introduced into antenatal care services, informed by implementation research (IR) including an evaluation of acceptability, feasibility, sustainability, equity, and cost-effectiveness of switching from IFA to MMS.

More recently, in October 2021, WHO included MMS in the Model List of Essential Medicines (EML) based on the strong evidence that it is a safe and effective intervention and is available now for inclusion in antenatal care programs. Inclusion of UNIMMAP MMS on WHO's EML and its implications for inclusion on national EMLs is a significant step forward for procurement, supply, implementation research efforts, and ultimately for wider accessibility and use of UNIMMAP MMS.

As a result, the number of countries exploring UNIMMAP MMS introduction is increasing, and new findings and lessons learned have emerged. These experiences emphasize the importance of exploring UNIMMAP MMS introduction using an implementation science approach. Presenters will share the latest results from national level UNIMMAP MMS implementation science activities, including from Bangladesh, Indonesia, and Mali. Each country case study will share lessons learned related to building an enabling environment (via landscaping and advocacy efforts) for UNIMMAP MMS, formative research results, and/or the co-design and testing of different implementation strategies. After the presentations, presenters will answer questions from the audience.

Aligning Newborn and Nutrition Priorities to Save Infant Lives

Kiersten Israel-Ballard[1]

1. PATH (USA)

PATH is a global health NGO, with globally recognized expertise across the nutrition spectrum. A key area of our focus is in the gap that currently exists in nutrition and lactation related to small and sick newborns. This remains a massive challenge, largely due to the disparate fields of nutrition and newborn care – often not interlinking at a programmatic, implementation, policy and funding level. As a result, optimal systems to ensure these infants receive human milk or that their mothers receive specialized lactation support are often lacking – especially in LMIC settings. PATH is a global leader in this space, advocating across the fields to bring together a shared vision of including newborn nutrition as a key component in the care of the small and sick newborn. ICN2022 presents a unique and powerful platform to further advocate for this linkage. In this special session, we will focus on the topic 'Aligning Newborn and Nutrition Priorities to Save Infant Lives' including a round table discussion with newborn and nutrition technical/policy leads and

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

importantly the country perspective with representatives from key Ministries of Health. Topics for discussion will include the specific gaps in the current field, the potential for alignment of newborn and nutrition indicators and implementation guidance for a shared story, and the needed package of support materials that are required to facilitate this linkage at the systems level.

Fish and Chronic Disease Prevention

Angel Gil[1]

1. University of Granada (Spain)

Background: Chronic non-communicable diseases (NCDs) represent one of the major health and development challenges of the 21st century and are the leading cause of death worldwide (GBD, 2020). Forty-one million deaths per year are due to NCDs, accounting for 71% of deaths worldwide. Most NCD deaths are potentially preventable; they last a long time and generally progress slowly (WHO, 2014). The type of fat in the diet can influence, directly or indirectly, some of the mediators of the inflammatory response involved in the development of NCDs (Gil et al. 2012). Fishery products are the main source of n-3 (also known as omega-3) long-chain polyunsaturated fatty acids (LC-PUFA) in the diet (FAO/WHO, 2010). The nutritional importance of n-3 LC-PUFA and in particular eicosapentaenoic acid (EPA, 20:5 n-3) and docosahexaenoic acid (DHA, 22:6 n-3), derives from their metabolic implications in different physiological and pathological mechanisms. LC-PUFA n-3 are present in membranes and influence their structure and functions. They are key nutrients for growth and maturation during pregnancy and early life. In addition, they are precursors of many anti-inflammatory mediators, i.e. eicosanoids and docosanoids, and also modulate the expression of key genes.

Objectives: The present study aimed to review the nutritional importance of n-3 LC-PUFA and in particular EPA and DHA in the prevention of NCDs and provide data of fatty acid profiles from fish consumed in Spain and how they contribute to international dietary recommendations.

Methods: Review of current literature on the effects of n-3 LC-PUFA on the prevention of NCDs using data search in public databases such as PubMed, EMBASE, Scopus, Web of Science, and the Cochrane Library Collaboration, and analysis by GLC of fatty acid profiles on Spanish fish and mollusks.

Results: n-3 LC-PUFA contribute to the prevention and treatment of NCDs of inflammatory origin, such as cardiovascular disease, cancer, lung disease, and inflammatory bowel disease (Gil et al. 2012). In addition, n-3 LC-PUFA reduces plasma triacylglycerols and lower blood pressure, as well as regulates thrombogenesis. Our results obtained in fish of Spanish origin confirm the high levels of variation in the fatty acid content of the different species of fish products that provide a substantial amount of LC-PUFA n-3, mainly DHA (Gil et a al. 2015; Mesa et al. 2021). Due to this variation, the consumption of 2 to 3 servings per week of a variety of fish products may help to meet the recommended daily intake of LC-PUFA n-3 in adults, including pregnant and lactating women, and also contribute to the prevention of NCDs of inflammatory origin.

Conclusions: Adequate consumption of n-3 LC-PUFA seems to contribute to the prevention of NCDs.

Diet Quality and Health in the Japanese Population

Kayo Kurotani[1]

1. Showa Women's University (Japan)

Japan is one of the highest countries with average life expectancy and healthy life expectancy. There are some reasons for longevity in Japan, such as socioeconomic factors, the medical system, and diet. Japanese cuisine, called Washoku in Japanese, was recognized by UNESCO as an intangible cultural heritage in 2013. Fish is necessary for Japanese cuisine. The Ministry of Health, Labour and Welfare and the Ministry of Agriculture, Forestry and Fisheries jointly developed the "Japanese Food Guide Spinning Top" as a practical and easy way to improve eating habits for all the people. The recommended amounts of dishes (grain dishes, vegetable dishes, fish and meat dishes, milk, and fruit) were drawn in descending order of intake in the Spinning Top. To clarify the effect of diet on longevity, we examined the association between adherence to the Food Guide and mortality in population-based surveys all over Japan in Japan Public Health Center-based prospective study (JPHC study). We found that individuals with closer adherence to the Japanese Food Guide (those with higher diet quality) had a lower risk of mortality, especially mortality from cardiovascular diseases, and cerebrovascular diseases (Kurotani et al. 2016). Similar associations were obtained among Japanese women in a prospective cohort study (Oba et al. 2009). In a longitudinal study, men with higher adherence to the Japanese Food Guide Spinning Top were more likely to have a higher skeletal mass index (SMI) than the Japanese elderly (Huang et al. 2021). A cross-sectional study showed an inverse dose-response relationship between diet quality and prevalence of both physical and comprehensive frailty in older adults (Watanabe et al. 2022). Additionally, a cross-sectional study of young Japanese women showed that higher adherence to the Japanese Food Guide Spinning Top was associated with lower waist circumference and LDL-cholesterol concentrations (Nishimura et al. 2015). This evidence suggests the benefits of the Japanese Food Guide Spinning Top, which was characterized by favorable dietary intakes of foods and nutrients as well as lower energy density. Balanced consumption of foods adhering to the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Japanese Food Guide can contribute to health, especially by encouraging the intake of vegetable dishes and fruits that are often insufficient.

Atlantic Diet: Fish, Health and sustainability

Rosaura Leis[1]

1. University of Santiago de Compostela/Atlantic Diet Foundation (Spain)

Atlantic Diet is the diet of the countries bathed by the Atlantic Ocean, being its maximum representatives Galicia, Autonomous Community of Northwest of Spain and North of Portugal. It is characterized by the consumption of seasonal, local, fresh and minimally processed foods, with a culinary preparation in which steaming and boiling predominate over frying and where enjoyment and social relations around the table take center stage. The consumption of fish and shellfish in Atlantic Diet is high. These foods provide proteins of high biological value, vitamins and minerals, and omega-3 fatty acids. Multiple studies link this higher consumption in the earliest years with beneficial effects for the development of the brain and retina and throughout life with better cardiovascular and metabolic health. The expectation and quality of life in Galicia is higher, related to the Atlantic lifestyles. However, we are witnessing an increase in prevalence of obesity and comorbidities, especially in children and adolescents, associated with loss of adherence to our traditional eating patterns. This fact could cause them to live less and with worse quality than their grandparents. Intervention, centered on the child, the family and the school and involving the whole of society, is necessary. We must increase adherence to our culinary traditions from the earliest years. GALIAT study, a recent randomized clinical trial, carried out in families with Atlantic Diet, from primary care health center and involving the municipality and entire community, has observed after 6 months of intervention, a decrease in BMI and a lipid status and healthier inflammatory In addition, recent studies show that Atlantic diet is among the most sustainable, with a low carbon and water footprint. Fish and sea products have a water footprint of 0 and their carbon footprint is also low, because we consume products from our coasts. Therefore, the traditional Atlantic Diet is healthy for individual and environment. We must establish strategies to promote Atlantic lifestyles and consumption of its characteristic foods such as fish and shellfish from childhood to elderly.

Work-related and work-environmental factors that influence diet: a Japanese perspective.

Mieko Nakamura[1]

1. Hamamatsu University School of Medicine (Japan)

Workers' diets are associated with various factors, including work-related and work-environmental factors, in addition to personal lifestyle and preferences. The most evident work-related factor affecting diet was shift work, including late-night shift. Shift workers are at a high risk of obesity, cardiovascular disease, and type 2 diabetes. However, the quantity and quality of dietary intake among shift workers are still controversial. We previously reported that shift workers were more likely to be overweight, consume high total energy and low dietary fiber, vitamin B_2, folic acid, vitamin C, potassium, calcium, magnesium, and iron than daytime workers in Japan's manufacturing companies (Nakamura, et al. J Occup Health, 2018). In addition, irregular dinner timing among daytime and shift workers was also associated with a low intake of some nutrients in this study. Moreover, long working hours and commuting time also affect workers' diets, including breakfast skipping and late dinner time. Regarding work-environmental factors, menus and the prices offered in workplace cafeterias also affected the dietary intake of workers. A recent topic of behavioral and environmental factors in the workplace cafeteria is coronavirus disease 2019 (COVID-19) related regulation. During the COVID-19 pandemic, infection control regulations, including short lunchtime and avoiding crowded spaces in the workplace cafeterias, affected workers' dietary intake. We reported fewer cafeteria visits and reduced intake of vegetables per cafeteria visit under COVID-19 related infection control regulations in a Japanese manufacturing factory (Nakamura, et al. Nutrients, 2021). Although it is essential to take preventive countermeasures against COVID-19 in eating and drinking places, prolonged regulations could worsen employee nutrient intake and health status. In addition, providing nutritious menus and their nutritional information could positively impact dietary intake and employee health (Shirai, et al, Food & Function, 2022). Various barriers need to be removed to enable workers to eat a healthy diet under their working conditions and dietary environment in the workplace.

The effect of educational background music on reducing salt intake at a university canteen

Ribeka Takachi[1], Sachiko Maruya[1]

1. Nara Women's University Graduate School of Humanities and Sciences (Japan)

Objective: It is necessary to establish population approach for healthy low-risk people compared to conventionally tailored interventions for high-risk people, considering young people's lifestyle. Particularly, in countries, such as Japan, Korea, and China, where the primary sources of salt are soups and discretionary seasonings added to homemade foods or cooked foods already at the table (i.e., soy sauce and *miso*), public approaches raising the individual's awareness on reducing salt intake may be effective. For instance, a song that encourages salt intake reduction consisting of interesting sound and lyrics was developed as an educational tool by the government of Nara Prefecture(1). Use of educational songs as background music (BGM) is potentially becoming a common and versatile approach in food purchasing and/or eating environments to nudge consumers toward healthier choices. Thus, we examined the effect of a dietary educational song as BGM on individual salt related behavioral modification at a university canteen. This was conducted by comparing the control and intervention periods (2).

Design: The study design is a small-scale community trial that compared the control and the intervention periods. Subjects were unspecified consumers at a university canteen Interventions. We displayed visual materials at a university canteen for 5 weeks (control period) and then broadcasted BGM for another 5 weeks (intervention period). Measures of outcome were the consumption amount of discretionary seasonings, the consumption amount of soup in noodles, the consumption number of soup bowls, and the consumption number of noodles among the consumers. The changes in the four outcome indices during both periods were compared by Mann–Whitney U test.

Results: Reductions in the consumption number of soup bowls and noodles were higher in the intervention period than those in the control period with statistical significance (median values: −7.5 and 5.4 per 100 rice consumers, p = 0.01; ratios to rice consumers, −0.02 and 0.10, p = 0.02, respectively).

Conclusion: Using a dietary education song on salt intake as BGM may be effective in influencing individuals toward healthier menu choices rather than seasoning behavior at a university's canteen. However, these results based on representative values for unspecified users of the canteen over a short intervention period should be interpreted with caution.

A school-based education programme to reduce salt intake in children and their families (School-EduSalt): Results from a cluster randomised controlled trial

Yangfeng Wu[1]

1. Peking University Clinical Research Institute (China)

Objective: To determine effect and cost-effectiveness of an school-based health education programme in lowering salt intake and blood pressure (BP) and social network influencers of the intervention effect in children and their families.

Methods: A health education programme targeting on school students with the aim to reduce salt intake in their families was developed. The effect and cost-effectiveness of the intervention was tested with a cluster randomised controlled trial in 28 primary schools in urban Changzhi, northern China (Trial registration: ClinicalTrials.gov NCT01821144). Participants included 279 children in Grade 5 of primary schools and 553 adult family members. Children in the intervention group received the intervention with 3 interactive lectures and 5 themed activities built in the official curriculum of one school term (≈3.5 months). Children in the control group received no intervention. The change in salt intake (measured by 24h urinary sodium) from baseline was used as the primary outcome. Secondary outcomes included the change in systolic BP and the salt reduction behaviour (SRB) score obtained via questionnaire. The SRB score was validated by the changes in 24-hour urine sodium in a random sample of 135 children.

Results: The mean baseline salt intake in children was 7.3±0.3 g/d and in adults 11.3±0.4 g/d. After intervention, salt intake decreased in the intervention group but increased in control group. The net difference of the change in salt intake between intervention and control was -0.9 g/d (95% CI: -2.6 to -1.3, P<0.0001) in children and -2.9 g/d (-3.7 to -2.2, P<0.0001) in adults. The net difference in change in systolic BP was -0.8 (-3.0 to 1.5, P=0.510) in children and -2.3 (-4.5 to -0.04, P=0.046) in adults. The intervention cost Int$19.04 per family and yielded an ICER of Int$2.74 (90% CI: 1.17–12.30) per mmHg reduction of SBP in all participants (combining children and adult participants together) compared with control group. If scaled up nationwide for 10 years and assumed deterioration in treatment effect of 50% over this period, it would reach 165 million families and estimated to avert 42,720 acute myocardial infarction deaths and 107,512 stroke deaths in China. This would represent a gain of 635,816 QALYs over 10-year time frame, translating into Int$1,358 per QALY gained. Further analysis indicated that children from families with more family members not supporting salt reduction had significantly lower SRB scores (p<0.0001). Children from a class with a smaller size and from a class with more friendship connections, as well as children having more friends within the class all showed higher SRB scores (all p<0.05). Children whose school teachers attended the intervention programme more frequently also had higher SRB scores (p=0.043).

Conclusions: The School EduSalt intervention is effective and cost-effective in lowering salt intake in families of primary school

students, which translated into significant reduction in blood pressure in adults, offering a novel approach for community prevention and control of hypertension and related disease. Family members, teachers and peers all have significant influence on the students' salt reduction behaviours.

Integrated Complementary Feeding of Eggs as a Strategy to Improve Developmental Outcomes in Children at Risk of Malnutrition: The Saqmolo' Project

Gabriela Montenegro-Bethancourt[1,2], Peter Rohloff[1,7], Elizabeth Yakes-Jimenez[3,2], Taylor C. Wallace[4,5], George McCabe[6], Gabriela Proaño[2], Alison Steiber[2]

1. Maya Health Alliance | Wuqu'Kawoq (Guatemala), 2. Academy of Nutrition and Dietetics (USA), 3. University of New Mexico Health Sciences Center (USA), 4. Think Healthy Group, Inc (USA), 5. Department of Nutrition and Food Studies, George Mason University, Washington, DC (USA), 6. Department of Statistics, Purdue University, West Lafayette, IN (USA), 7. Brigham and Women's Hospital Boston, MA (USA)

Integrated nutrition interventions that address malnutrition during the complementary feeding period can help promote achievement of the U.N. Sustainable Development Goals. Inadequate micronutrient intake is associated with poor child development. Clinical interventions have suggested daily complementary feeding of chicken eggs can promote more optimal growth in Ecuadorian but not Malawian children. Effects on long-term child development also remain unclear and likely differ amongst various populations. About half of children under the age of 24-months are chronically malnourished in Guatemala. 80% of the indigenous Mayan population are food insecure and lack access to nutritious food, medical services, and education. The Saqmolo' (i.e “egg” in the Mayan language Kaqchiquel) Project is a large randomized-controlled, comparative effectiveness trial that aims to evaluate the impact of adding a single egg per day to the local standard care on child development, growth and diet quality in 1,200 rural Maya infants residing in central Guatemala (6-9 months at baseline). We will present preliminary findings (baseline) from participant children enrolled in the on-going Saqmolo' project: (i) demographic characteristics, (ii) distribution of the overall and domain specific Z-scores from the Caregiver Reported Child Development Instruments (CREDI), (iii) diet quality indicators, and (iv) anthropometric Z-scores. The team will share our experience in overcoming common challenges with implementation processes, during the COVID-19 pandemic, potential effect modifiers, and other barriers that offer perspective in assisting future development of successful nutrition intervention programs. An overview of The Saqmolo' Project Microbiome Sub-study will offer attendees a novel insight into emerging area of malnutrition research. Trial registration: NCT04316221

The Potential of Comparative Effectiveness Trials During the Complementary Feeding Period to Enhance Child Development and Lifelong Cognition in Food Insecure Regions

Taylor C. Wallace[1,2], Peter Rohloff[3,4], Elizabeth Yakes Jimenez[5,6], Gabriela Proano[6], Gabriela Montenegro Bethancourt[3,6], George P. McCabe[7], Alison Steiber[6]

1. Think Healthy Group (USA), 2. Department of Nutrition and Food Studies, George Mason University (USA), 3. Wuqu' Kawoq / Maya Health Alliance (Guatemala), 4. Brigham and Women's Hospital (USA), 5. University of New Mexico Health Sciences Center (USA), 6. Academy of Nutrition and Dietetics (USA), 7. Purdue University (USA)

Optimizing dietary diversity and nutrition during the complementary feeding period (6- to 24-months) is critical for a child's long-term development; however, the most efficient means of achieving these goals are relatively unknown. Increasing evidence demonstrates that early childhood, within the first 1000-days post-conception, is a sensitive period of development where children cultivate foundational skills necessary to learn, interact and thrive in society. Poor growth and development are also correlated with an increased risk of infection, lifelong cognitive impairment, and fewer economic opportunities. Around the age of 6-months, an infant's need for energy and nutrients starts to exceed what is provided by breast milk, and complementary foods are necessary to help meet those needs. Although all nutrients are necessary for brain growth, authoritative groups like the American Academy of Pediatrics (AAP) consider the following nutrients as critical to support neurodevelopment during the first 1000 days: protein, zinc, iron, choline, folate, iodine, vitamins A, D, B_6, and B_{12}, and long-chain polyunsaturated fatty acids. An absence in one or more of these nutrients may result in lifelong deficits in brain function, despite subsequent repletion efforts. Prioritizing multicomponent integrated complementary feeding solutions that are economically, socially, environmentally, and nutritionally sustainable are key for the fulfilling the recent United Nations' Sustainable Development goals, which call for reducing stunting and wasting in children <5 years by 40%. Plant and animal agriculture have complementary and symbiotic roles in healthy and sustainable food systems. Animal-sourced foods are of particular interest in complementary feeding interventions to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

reduce stunting and other inadequate growth measures in early childhood, as protein quality remains a major concern in many parts of the world. Comparative effectiveness research compares two or more care options to determine which works best, for whom, and in what circumstances. It provides scientific evidence that applies to real world situations, enabling governments, policymakers and non-profits to make more informed decisions. Despite multiple factors playing a role in a child's growth and development most research to date has focused on a single intervention domain (e.g., micronutrients) versus the comparative effectiveness across multiple domains (e.g., micronutrients, food supplements, deworming medications, maternal education, and water, sanitation, and hygiene [WASH] solutions) that can be used to optimize child development.

Using Community Engagement and Implementation Research Strategies to Address Food Insecurity in Indigenous Guatemalan Communities

Gabriela V Proano[1], Peter Rohloff[2,3], Elizabeth Yakes Jimenez[1,4], Taylor C Wallace[5,6], Gabriela Montenegro Bethancourt[1,2], George P. McCabe[7], Alison Steiber[1]

1. Academy of Nutrition and Dietetics (USA), 2. Wuqu' Kawoq/Maya Health Alliance (Guatemala), 3. Brigham and Women's Hospital (USA), 4. University of New Mexico Health Sciences Center (USA), 5. Think Healthy Group, Inc. (USA), 6. George Mason University (USA), 7. Purdue University (USA)

Guatemala is an upper-middle income country with high prevalence of malnutrition, food insecurity and low investments in health care. Access to quality health services is further limited for vulnerable populations, i.e., rural indigenous Maya children, putting them at risk for poor health outcomes including chronic malnutrition and stunting. Therefore, programs are needed to improve nutrition-related outcomes, such as food security, development, growth, and dietary diversity. Equitable community engagement is a means of working collaboratively with governmental, private, and local community organizations and families to design and provide effective nutrition programs and services. Program implementers must think strategically and practically about how to engage communities in program planning and implementation to ensure interventions are contextually appropriate and sustainable. Wuqu' Kawoq/Maya Health Alliance (MHA) is a nonprofit health organization that offers culturally and linguistically appropriate healthcare services to rural indigenous Maya populations in Guatemala. MHA has developed an integrated local standard for nutrition care, which includes growth monitoring, deworming medication, point-of use-fortification with micronutrient powders, and complementary and responsive feeding education provided to caregivers by community health workers in their preferred language. MHA, in collaboration with the Academy of Nutrition and Dietetics, has implemented two comparative-effectiveness research projects in rural Guatemala that compare the nutrition standard of care alone to the nutrition standard of care plus other interventions: home gardens or daily eggs for infants age 6-9 months *(The Saqmolo' Study)*. In this presentation, we will discuss how both projects engaged community members and empowered families, including the formative work that was done to provide individualized and culturally acceptable interventions. Additionally, implementation and effectiveness outcomes for the home garden intervention will be discussed. The home garden intervention provided seeds and seedlings, garden construction materials, and education and support from an agronomist to families of 70 children with stunting in rural Guatemala. This study was conducted from January 2019 to July 2020 and after a 6 month intervention, compared to the standard of care alone, the garden group had better length-for-age z-score (change difference [CD] 0.22 SD, 95% CI 0.05-0.38, P= 0.009), crop species count (CD 2.97 crops, 95% CI 1.79-4.16, P<0.001), and nutritional dietary diversity (CD 0.04 points, 95% CI 0.01-0.07,P =0.006). Additionally, implementation outcomes were evaluated using the RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance) framework. This demonstrated the garden intervention had good reach, improved access to diverse foods, increased cultivation of crops by 5 species (95% confidence interval [CI], 4–6), and led to adoption of agricultural best practices. Potential barriers and considerations for sustainability include seed sourcing, access to water, and improving crop consumption. This session will offer unique insights for developing future effective and sustainable nutrition intervention programs among vulnerable populations in Guatemala and Central America.

SY(T3)12-1

The role of lutein in early life

Elizabeth J. Johnson[1]

1. Tufts University (USA)

Lutein is a non-provitamin A dietary carotenoid found in dark green leafy vegetables, corn, eggs, and avocados. Among the carotenoids, lutein and its isomer, zeaxanthin, are the only 2 that cross the blood–retina barrier to form macular pigment in the retina. Lutein also preferentially accumulates in the human brain across multiple life stages. The purpose of this presentation is to summarize the latest science on lutein's role in the eye and the brain in early life. A variety of scientific evidence supports a role for lutein status (diet, tissue levels) in vision and cognition. Lutein is not an essential nutrient and currently there are no recommendations for intakes of lutein in infants and children in this regard. However, supplementation with lutein can increase lutein in breast milk and plasma of lactating mothers taking the supplement as well as corresponding plasma lutein concentrations in their infants. Furthermore, formulas supplemented with lutein enrich this bioactive in tissues, including retina and brain, compared with infants consuming lower amounts. Therefore, higher intakes may be warranted to optimize ocular and brain development and recommendations for breastfeeding mothers may be necessary to ensure adequate lutein content in breast milk. If future intervention studies with children confirm the initial cross-sectional observations, then they may also motivate the need to improve diet in early life. Lutein intake in American adults is low (~1–2 mg/d) but it tends to be even lower in early adolescence (~300–500 μg/d) (42). As with many aspects of diet, such deficits in childhood can start a cascade that simply amplifies with age. Interventions with children likely yield lifetime benefits. Although the precise mechanisms by which lutein may be influencing neural health across the lifespan remain to be investigated, efforts may be warranted to establish recommended intakes for this dietary bioactive given the sum of the evidence to dates.

Relations between carbohydrate-responsive epigenetics and DOHaD

Kazuki Mochizuki[1]*, Hariya Natsuyo*[2]*, Ishiyama Shiori*[1]*, Hiroaki Itoh*[3]

1. University of Yamanashi (Japan), 2. Yamanashi Gakuin University (Japan), 3. Hamamatsu University School of Medicine (Japan)

Many epidemiological studies suggest the environmental stresses including less of dietary nutrients during the developmental periods develop metabolic diseases in later life (DOHaD theory). One of the mechanism underlying the development of metabolic diseases in adult stages by environmental stresses is considered to be expressional changes of carbohydrate-responsive metabolic- and immune response-genes, because expression of those genes alter during development of metabolic diseases in adult stages. Recent studies demonstrated that expression of genes including carbohydrate responsive genes is regulated by epigenetic memories (histone modifications and DNA methylation) as well as by transcriptional factors. We have demonstrated that carbohydrate intake in adult stages enhances expression of metabolic- and immune response-genes, several histone modifications, which are concerned with transactivation including histone acetylation, and the histone acetylation reader bromodomain-containing protein 4 (BRD4) binding, around those genes in metabolic and immune response organs including liver, adipose and leukocytes. The transactivation related histone modifications and/or BRD4 binding, rather than transcriptional factor bindings, around the carbohydrate-responsible genes are strongly-positively associated with expression of those genes in adult stage. Furthermore, we have demonstrated that malnutrition including energy-restriction during pregnancy induces impaired glucose tolerance and/or hepatic steatosis, and enhanced expression of carbohydrate-responsive genes, and transactivation related histone modifications including histone acetylation around some of these genes, in the offspring. These results indicate that environmental stresses including less of dietary nutrients during the pregnancy develop metabolic diseases in the offspring, and one of the mechanism underlying to develop metabolic diseases in the offspring would be alteration of histone modifications around carbohydrate-responsive genes.

One-carbon metabolism during pregnancy and the fetal period

Kumiko Shoji[1], Yoshinori Kubo[1], Hideoki Fukuoka[3], Terue kawabata[1], Chisato Mori[4], Kenichi Sakurai[4], Masazumi Nishikawa[5], Kyoichi Oshida[2], Yuichiro Yamashiro[6]

1. Kagawa Nutrition University (Japan), 2. Taiko Pharmaceutical Co., Ltd. (Japan), 3. Fukushima Medical University (Japan), 4. Chiba University (Japan), 5. Miyagi University (Japan), 6. Juntendo University (Japan)

One-carbon metabolism (OCM) is involved in the methionine and folate cycles, in which one-carbon units (methyl groups) are transferred during the synthesis and methylation of DNA, and during the metabolism of some amino acids. Folate is an essential nutrient for fetal development, and more than 70 countries require the fortification of staple grains with folic acid (FA) to reduce the incidence of neural tube defects. However, Japan currently does not have such a policy. An increasing number of countries with mandatory FA fortification are reporting unmetabolized FA in serum samples from their respective populations. The risk of unmetabolized FA remains unquantified, and thus the analysis of individual unknown OCM metabolites instead of "total" folate is increasing. Our research group successfully evaluated 18 intermediate metabolites involving OCM using liquid chromatography-tandem mass spectrometry (LC-MS/MS): 5-methyltetrahydrofolate (5-MTHF), homocysteine, homocysteic acid, methionine, S-adenocylmethionine (SAM), S-adenocylhomocysteine (SAH), cystathionine, cysteine, taurine, serine, glycine, choline, betaine, dimethylglycine (DMG), pyridoxamine, pyridoxine, riboflavin and unmetabolized FA. By analyzing the OCM metabolites of maternal and cord blood, we are aiming to elucidate the role of OCM during pregnancy and the fetal period.

Our study was based on the Chiba study of Mother and Child Health (C-MACH), conducted at the Center for Preventive Medical Science, Chiba University, and the Research Institute for Science and Engineering, Waseda University. Blood samples were collected during four sampling periods: maternal blood during the first and third trimester and, at delivery, and umbilical vein blood at birth.

We found that throughout pregnancy, 5-MTHF, which is a biologically active form of folate, decreased towards delivery, but was significantly higher in cord blood than in maternal serum. In contrast, FA did not change in concentration during pregnancy and in cord blood. These findings suggest that FA might be transported to the fetus in a maternal blood-dependent manner, whereas 5-MTHF might be actively transported from the mother to the fetus against gradients of concentration in the placenta. Changes in the levels of 5-MTHF were accompanied by a decrease in betaine, while a slight increase in DMG towards delivery, possibly suggesting that betaine compensates for the shortage of methyl groups from 5-MTHF to metabolize homocysteine.

Genetic polymorphisms of OCM are considered maternal risk factors for some birth defects. The most widely investigated single nucleotide polymorphism is that of methylenetetrahydrofolate reductase (MTHFR) C677T. 5-MTHF of the *MTHFR* TT genotype (minor allele homozygotes) decreased more than the *MTHFR* CC genotype (major allele homozygotes). In contrast, homocysteine increased towards delivery, and the *MTHFR* TT genotype remained higher throughout the pregnancy compared to the CT and CC genotypes.

Our current analysis did not show notable findings with methionine, SAM or SAH, which are key compounds for DNA methylation. Methionine is an amino acid, and its level might be controlled by amino acid metabolism in addition to OCM. Although the influence of OCM in epigenetics remains unclear, our recent intervention trial of long-term FA supplementation by women of childbearing age may reveal the effect of FA intake on OCM and DNA methylation.

Providing all infants with the best start to life is a universal but challenging goal for the global community. Historically, the size and shape of infants, quantified by anthropometry and commencing with birthweight, has been the common yardstick for physical growth and development. Anthropometry has long been considered a proxy for nutritional status during infancy when, under ideal circumstances, changes in size and shape are most rapid. Developed from data collected in the Multicentre Growth Reference Study (MGRS), World Health Organisation (WHO) child growth standards for healthy infants and children have been widely accepted and progressively adopted. In contrast, and somewhat surprisingly, much less is understood about the 'quality' of growth as reflected by body composition during infancy. Recent advances in body composition assessment have contributed to a progressive increase in our knowledge and understanding of growth and development. Using stable isotope approaches, most commonly the deuterium dilution technique, the criterion measure of total body water (TBW), we can quantify lean and fat tissue using a two-compartment model. However, until now, global reference charts for the body composition of healthy infants have been lacking. Here we detail some of the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

historical challenges associated with the assessment of body composition across the first two years of life, and sets the scene for the presentations in the Symposium, including reference charts, generated from a recent multicentre body composition initiative.

University of Tasmania (Australia)

Background: A healthy start to life is a universal, but challenging, aspiration for global health. Given the critical importance of the infant developmental period for establishing trajectories, our aim was to investigate longitudinal growth and body composition in six countries.

Methods: This longitudinal study followed infants from birth to 24 months-of-age in lower-middle (India, Pakistan and Sri Lanka), upper-middle (Brazil and South Africa) and high-income (Australia) countries. A total of 1152 mother-infant dyads (48.7% female infants) were recruited; 444 infants were enrolled into the sub-study using air-displacement plethysmography (ADP; total of 1781 data points) to determine body composition at birth, 1, 2, 3, 4 and 6-months of age, and 708 infants into the sub-study using the deuterium dilution technique (DD; total of 3598 data points) at 3, 6, 9, 12, 18 and 24-months of age. Mother-infant dyads were approached and screened at all sites and newborns with no health, environmental or economic constraints on growth were purposively recruited. For all infants, we measured length, weight, mid-upper arm circumference (MUAC), triceps and subscapular skinfolds, fat-free mass, and derived fat mass.

Results: The average for the pooled sample for length, weight and weight-for-length-for-age, as well as MUAC and skinfold thickness z-scores, were, as expected, approximately at the median of the WHO child growth standards given our recruitment criteria. By 24-months of age, in the pooled sample, stunting prevalence peaked at 10.3% for males and 7.8% for females with South Africa having the greater prevalence (19.7% and 14.3% for boys and girls respectively) and Brazil (2% and 3% for boys and girls, respectively). In the pooled sample, adjusting for length by deriving a Fat Mass Index (FMI; fat mass/length2) for both boys and girls, FMI increased from birth to 3-months and then remained similar across infancy. However, by 24-months, girls had greater fat mass for size (10%) than boys. For all time points, South African infants had greater FMI than Brazil, Pakistan, Sri-Lanka, with Sri-Lanka having the lowest fat mass for size.

Conclusion: In a multi-country infant population sample with optimum maternal and environmental factors, a low prevalence of undernutrition, and similar growth patterns, fat mass adjusted for length is heterogeneous across the countries. This variance may indicate that independent of growth-restricting factors, infant fat mass gain is influenced by ethnic and dietary-pattern differences, such that in some settings may contribute to early childhood obesity.

SY(T3)13-3

Body composition reference charts for infants aged birth to 24 months

Shane Norris[1], Ina Santos[3], Shabina Ariff[4], Andrew Hill[7], Rebecca Kuriyan[6], Pujitha Wickramasinghe[5], Lukhanyo Nyati[1], Nishani Lucas[5], Caroline Costa[3], Alexia Murphy-Alford[2]

1. University of the Witwatersrand (South Africa), 2. International Atomic Energy Agency (Austria), 3. Federal University of Pelotas (Brazil), 4. The Aga Khan University (Pakistan), 5. University of Colombo (Sri Lanka), 6. St John's Research Institute (India), 7. University of Tasmania (Australia)

Background: Body composition assessment in the first 2 years of life provides important clinical and research insights for child nutrition and health. The application and interpretation of body composition data in infants and young children has been challenged by reference data only being available from a few high-income heterogenous samples that have not been selected to represent “optimal” growth.

Objective: To develop body composition reference charts from 0-6 months based on air displacement plethysmography (ADP) and 3-24 months based on total body water (TBW) by deuterium dilution (DD).

Method: Body composition was assessed by ADP in infants aged 0-6 months from Australia, India and South Africa. TBW using deuterium dilution was assessed for infants aged 3 to 24 months from Brazil, Pakistan, South Africa and Sri Lanka.

Reference charts and centiles were constructed for body composition using the lambda-mu-sigma method (LMS).

Results: Sex-specific reference charts were produced for fat mass (FM), fat-free mass (FFM), fat mass index (FMI), fat-free mass index (FFMI), and percent fat mass (%FM) for 0-6 months (n=468 infants; 1,899 observations) and 3-24 months (n=925 infants; 3690 observations). When compared to other available references, there were observable differences, but similar patterns in FM and FFM accretion.

Conclusion: These reference charts will strengthen the interpretation and understanding of body composition in infants across the first 24 months of life.

SY(T3)13-4

Determinants of infant growth and body composition from birth to 24 months: What are the driving factors?

Ina Santos[1], Caroline Costa[1], Andrew Hills[2], Shabina Ariff[3], Pujitha Wickramasinghe[4], Shane Norris[5], Alexia Murphy-Alford[6], Lukhanyo Nyati[5], Nishani Lucas[4], Rebecca Kuriyan[7]

1. Universidade Federal de Pelotas (Brazil), 2. University of Tasmania (Australia), 3. Aga Khan University (Pakistan), 4. University of Colombo (Sri Lanka), 5. University of the Witwatersrand (South Africa), 6. International Atomic Energy Agency (Austria), 7. St. John's Research Institute (India)

Background: The first 1000 days, from conception to 2 years of age, represent a critical window for growth and development that is central for the concept of developmental origin of chronic non-communicable diseases in the future. Growth assessment during this period has been mainly based on anthropometry. However, infants with equal weight and length may vary substantially on quality of growth. There is a need to better capture the quality of growth at early life through the assessment of body composition and to understand its driving factors.

Objective: To investigate the determinants of infant growth and body composition from birth to 24 months of age.

Method: This was a multicenter, prospective, observational study, with data from two cohorts: the 0-6-month cohort (Australia, India and South Africa) and the 3-24-month cohort (Brazil, Pakistan, South Africa, and Sri Lanka), which enrolled 468 and 925 newborns, respectively. Anthropometry measurements followed the World Health Organization Multicentre Growth Reference Study protocol. At the 0-6-month cohort, body composition was assessed by air-displacement plethysmography within 2-3 days of birth, 2 weeks, 1, 2, 3, 4, and 6 months. At the 3-24-month cohort, body composition was assessed by the Deuterium Dilution method at 3, 6, 9, 12, 18, and 24 months. For both cohorts, weight-for-age (WAZ), length-for-age (LAZ) and weight-for-length (WLZ) z-scores, fat mass (FM), fat free mass (FFM), FM index (FMI), and FFM index (FFMI) were calculated. Independent variables comprised the Gini index of the country, maternal and child characteristics at birth, and breastfeeding pattern at 3 months. For the 3-24-month cohort, information on breastfeeding and minimum dietary diversity at the 12-month was also included. Crude and adjusted beta coefficients (with 95%CI) were calculated by multilevel modelling using mixed effect models.

Results: At 6 and 24 months a total of 231 and 490 children, respectively, from the 0-6-month cohort and the 3-24-month cohort were analyzed. At 6 months, boys were on average 450 grams heavier and had 460 grams more of FFM than girls; at 24 months, boys had on average 380 grams more in FFM than girls, while all other nutrition indices were similar between sexes. Birth weight was the strongest and most consistent positive predictor of anthropometric and body composition indices at 6 (WAZ, FFM) and 24 months (WAZ, LAZ, WLZ, FFM, and FFMI), irrespective of sex. In girls birth weight was also positively related to LAZ and FFMI at 6 months, and to FM at 24 months. On the other hand, exclusive breastfeeding at 3 months and continued breastfeeding at 12 months were the strongest and most consistent negative predictors of body composition indices, respectively at 6 and 24 months, independently of sex. At 6 months, exclusively breastfed boys and girls at 3 months had lower FFMI, and at 24 months those breastfed at 12 months presented lower FM, FFM and FFMI (FMI was lower in boys only).

Conclusion: Birth weight and breastfeeding are independent predictors of body composition in early life, irrespective of sex.

Body composition of infants at 6 months of age using the 3-compartment model

Rebecca Kuriyan[1], Andrew P Hills[2], Alexia Murphy-Alford[3], Ramya Padmanabha[1], Anura V Kurpad[4], Lukhanyo Nyati[5], Nuala M Byrne[2], Shane Norris[5]

1. St John's Research Institute (India), 2. University of Tasmania (Australia), 3. International Atomic Energy Agency (Austria), 4. Department of Physiology, St John's Medical College, St John's National Academy of Health Sciences (India), 5. University of the Witwatersrand (South Africa)

Background: Early life body composition plays an important role in programming later life health outcomes. The commonly used 2-compartment (2C) model assumes that the composition of fat-free mass (FFM) remains constant, which may not be accurate in infants during periods of rapid growth and maturation. The 3-compartment (3C) model based on measurements of hydrometry, and densitometry overcomes some of the uncertainties concerning the hydration of FFM. There is paucity of data with regard to the hydration and density of FFM in infants from different countries/ethnicities.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Objective: The objectives of the present study were (1) to determine the body composition of infants at 6 months of age from 3 countries (Australia, India and South Africa) using the 3C model, (2) to compare the estimates of body composition obtained from Air Displacement Plethysmography (ADP) and Deuterium Dilution (DD), (3) to compare the biological variation in the density and hydration of FFM between the three countries.

Method: Anthropometry and body composition were measured at 6 months of age in 176 healthy infants (46 from Australia; 86 from India and 44 from South Africa) using ADP (PEA POD, Software version 3.5.0, 201, COSMED, USA) and DD using standard protocols, from which 3C model estimates were calculated. Details on maternal characteristics and feeding history of the infants were recorded using questionnaires. Bland Altman and correlation analyses were carried out to compare the estimates of ADP with DD. The density and hydration of FFM were determined and compared between the infants of the different countries using one way ANOVA.

Results: The mean body weight and length of the infants was 7.2 ± 0.8 kg and 65.5 ± 2.5 cm. Girls comprised 52% of the group. The pooled estimates of % fat mass (FM) was 27.2 ± 5.0%, while % FFM was 72.8 ± 5.0% from the 3C model; infants from South Africa had significantly higher % FM in comparison to Australia and India. The mean difference (bias) between estimates of % FM obtained from ADP and DD was -0.66%, [95% CI; -8.9-7.6%] and correlation was r = 0.83 (p<0.01). The hydration factor of FFM in infants was 0.796 ± 0.015, 0.796 ± 0.023, and 0.785 ± 0.020 in Australia, India and South Africa, respectively; Australian infants had significantly higher hydration in comparison to South Africa (p<0.05), while the density of FFM in South African infants (1.071 ± 0.008 g/mL) was significantly higher when compared to Australian (1.067 ± 0.006 g/mL) and Indian infants (1.067 ± 0.009 g/mL).

Conclusion: The % FM estimates from 3C model suggests that South African infants may have higher % FM. The estimates of % FM from ADP and DD correlated well and had a relatively low bias. Biological variability seems to exist in the hydration and density of FFM in the infants from the three countries. Our findings suggest the need to revisit assumed constant values for infants, particularly regarding FFM composition, which would have important implications for the different 2C methods that are widely used in infant research.

Anthropometric indicators of body composition from birth to 24 months

Pujitha Wickramasinghe[1], Shabina Ariff[2], Caroline Costa[3], Rebecca Kuriyan[4], Jithin Sam Varghese[5], Shane Norris[6], Lukhanyo Nyati[6], Ina Santos[3], Andrew Hills on behalf of the IAEA Body Composition Infant Reference Study Group[7]

1. University of Colombo (Sri Lanka), 2. The Aga Khan University (Pakistan), 3. Federal University of Pelotas (Brazil), 4. St John's Research Institute (India), 5. Rollins School of Public Health, Emory University (USA), 6. University of the Withwatersrand (South Africa), 7. University of Tasmania (Australia)

Background: Early life body composition plays an important role in programming later life health outcomes. The commonly used 2-compartment (2C) model assumes that the composition of fat-free mass (FFM) remains constant, which may not be accurate in infants during periods of rapid growth and maturation. The 3-compartment (3C) model based on measurements of hydrometry, and densitometry overcomes some of the uncertainties concerning the hydration of FFM. There is paucity of data with regard to the hydration and density of FFM in infants from different countries/ethnicities. Assessment of growth during the rapid growth period has gained importance with the increase in incidence of childhood obesity as well as understanding the impact of early growth on health throughout life. However, most of the currently available body composition methods are not suitable for field or clinical practice. This multicenter study attempts to develop an anthropometry-based technique to estimate body composition of 3–24-month-old infants.

Method: A multicenter longitudinal body composition study involving infants from Brazil, Pakistan, South Africa, and Sri Lanka was carried out with the assessment of body composition using the two-compartment model. Fat free mass (FFM) was assessed using deuterium dilution (DD) technique and fat mass (FM) was derived by subtracting FFM from body weight. Anthropometric measurements were taken at 3, 6, 12, 18, and 24 months. The study sample consisted of 1896(942 girls) training observations which were used to develop the model, 941(441 girls) validation observations for internal validation of the model and 349(185 girls) test observations for external validation. The test group consisting of 3–6-month-old infants from South Africa, Australia, and India where data were collected independent to the longitudinal study group. Distribution of all variables were assessed using scatterplots and Pearson correlations. A linear mixed model on the training data separately for girls and boys was used to develop equations to predict FM and FFM. Models were tested on validation data and the quality of predictions were assessed using: (a) error metrics (root mean squared error-RMSE), root mean squared percentage error (RMSPE), mean absolute error (MAE), mean absolute percentage error (MAPE) values, and (b) the number of true values outside the prediction interval.

Results: Length and weight adjusted for covariates were positively associated with FM and FFM in both sexes. Skinfolds were positively associated with FM. A linear mixed model was

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

fitted on training data separately for girls and boys to develop the prediction equations for FM (kg) and FFM (kg). The model was adjusted for length (cm), weight-for-height (kg/cm), triceps and subscapular skinfold thicknesses (cm), and Asian ethnicity. Head circumference and arm circumference did not affect the model outcome. Equations were developed to predict FM and FFM for each sex for three age categories (3-9 mo; 10-18mo; 19-24mo). RMSE was higher for FM and FFM among older children in both males and females. RMSE was also similar between validation and test data. Majority of observations were within the prediction intervals. RMSPE and MAPE were higher for validation data while predicting FM in males and females, compared to test data, but both were higher in test data for predicting FFM. RMSPE was very high for prediction of FM but was quite low (approximately 10%) for predicting FFM. MAE was about 500g for assessment of both FM and FFM in all three groups, but the MAPE was low (under 10%) for assessment of FFM in all three groups.

Conclusion: Anthropometry based prediction equations to assess FFM provides acceptable results in this multi-ethnic cohort of children for field use.

Using implementation research to improve programs targeting adolescents– experiences from Indonesia and Bangladesh

Wendy Gonzalez [1], Cut Novianti Rachmi [2], Inka Barnett [3], Pedro Prieto Martin [3], Eny Kurnia Sari [4], Aang Sutrisna [4]

1.The Global Alliance for Improved Nutrition (Switzerland), *2.* Reconstra Utama Integra (Indonesia), *3.* Institute of Development Studies (UK), *4.* The Global Alliance for Improved Nutrition (Indonesia)

Adolescents are increasingly becoming important 'agents of change' who actively reshape their social environments and even spearhead global movements for change. Programmes that aim to improve adolescents' diet quality should actively involve them and leverage their agency to become drivers of change towards improved diets. The aim of this session is to present and discuss the learning from implementation research conducted to assess two initiatives designed to engage adolescents in making better food choices - the *Bhalo Khabo Bhalo Thakbo* ("Eat Well, Live Well" in Bengali) and *Saya Pemberani* ("I'm Courageous" in Indonesian) campaigns in Bangladesh and Indonesia, respectively.

The Bhalo Khabo Bhalo Thakbo campaign was implemented nationwide by the Global Alliance for Improved Nutrition (GAIN) and partners between 2019 and 2021. The campaign combined social media (including promotional videos by celebrities and influencers), in-person components (such as school events), use of traditional media (radio show), for promoting improved food choices, including a pledge by adolescents to change their food habits. A research consortium led by the Institute of Development Studies (UK) conducted an external evaluation of the campaign. The evaluation adopted a theory-based mixed methods approach using contribution analysis. The evaluation included an observational quantitative design (with a baseline and endline survey and with ex post assignment of treatment status based on the observed level of intensity of exposure to the campaign), in-depth interviews, stakeholder interviews and an online survey.

Using the social entrepreneurship approach, Saya Pemberani aimed to engage young people living in urban areas in articulating solutions to contextual problems that preclude healthy diets. Teaming up with Ashoka, a non-profit organisation that fosters social entrepreneurship, GAIN designed and implemented the programme between April 2019 and June 2020 in the city of Surabaya and the Jember district in East Java, Indonesia. An independent process evaluation was conducted by Reconstra between March and December 2020. The study aimed to assess Saya Pemberani's reach (to what extent the programme reached its intended audience), fidelity (to what extent the programme components were implemented as intended) and the participants' satisfaction (how the participants characterised their engagement with Saya Pemberani). Results from both countries revealed the importance of building flexible and adaptable programs that respond to the dynamic nature and changing realities and context of adolescents, using multiple platforms to reach adolescents, engaging other influential actors in adolescents' life such as parents, teachers, and peers, and recognizing the particular characteristics and needs of the different adolescent subgroups (younger vs older adolescents, rural vs urban, etc.).

Both campaigns failed to engage adolescents of lower socioeconomic status, which highlights the need for purposively designing more inclusive programs. In Bangladesh, the campaign sparked interest for improving their consumption of nutritious foods; however, as compared to non-intervention groups, adolescents exposed to the campaign did not show a significant change in willingness to purchase more nutritious foods. Qualitative findings suggest that the COVID-19 pandemic heightened adolescents' interest in healthy eating, which might help explain the campaign's lack of impact on purchase and consumption of more nutritious foods. In conclusion, implementation research identified key elements that should be considered for designing, implementing, and evaluating adolescent programs.

Building adolescent self-efficacy, health and resilience: lessons from Nepal and Bangladesh

Jennifer Notkin Nielsen[1], Femila Saopkota[3], Jyoti Karki[4], Sujata Singh[3], Karuna Shakya[3], Meraz Rahman[2], Treena Bishop[2], Meredith De Graffenried[1], Ame Stormer[1], Mackenzie Green[1]

1. Helen Keller International (USA), 2. Helen Keller International (Bangladesh), 3. Helen Keller International (Nepal), 4. CARE (Nepal)

Adolescents ages 10-19 make up about one-quarter of the population of Nepal and of Chittagong Hill Tracts (CHT) of Bangladesh. Girls in both settings are less likely to attend secondary school, more likely to marry and begin childbearing, and have suboptimal dietary diversity. In Nepal 27% of girls marry before age 19, while in CHT 54% of women aged 20-24 were married before age 18. As a consequence, young girls face narrowing access to information and life choices.

To inform design of programs to counteract these trends, formative research was conducted with n=840 girls ages 10-19 via a survey panel in Nepal and with n=52 girls and n=52 boys ages 12-17 in CHT via focus group discussions exploring aspirations and their determinants. Despite their challenging circumstances, in both settings adolescents' educational and occupational aspirations are high. In Nepal 58.6% wish to study beyond grade 12 and 75% to pursue occupations requiring professional or higher formal education. Adolescents from all ethnicities in CHT wish to complete their education and be financially self-sufficient. They also aspire to be a good person, mother, member of society and respected. In Nepal girls on average wish to defer marriage until age 22 and childbearing to age 24, while in CHT they perceive early marriage to be linked to poverty and poor physical and mental health. Among Nepali youth, higher aspirations are positively associated with higher self-efficacy scores, especially among younger adolescents (ages 10-14), caste and wealth, and in CHT aspirations are more limited where parents do not support their children's education and career goals.

Building on these findings, the USAID-funded Suaahara II project in Nepal targeted younger, in-school adolescents with an integrated package of materials for use by teachers and resource students covering nutrition and health, hand and menstrual hygiene, delaying marriage, continuing education, and building student self-confidence, self-efficacy, and leadership skills. They content was pre-tested and adjusted with feedback. Resource students set a goal of sharing themes with at least 5 peers, either in school, through specially designed *sathi* (friend) resource corners, or after school. Concepts were further reinforced through integration in the popular national radio program "Chatting with my best friend". In Bangladesh, the USAID-funded Sapling project developed a suite of strategies to build confidence and leadership skills in youth and strengthen community cohesion. Community-based girls empowerment groups aimed to build problem-solving and critical thinking skills, self-esteem and confidence, health and life skills and reproductive health and nutrition knowledge. Young boys and girls were trained to become "little doctors" or health and hygiene champions in their schools and communities. Older adolescents were trained in natural resource management techniques to become "forest management brigades" or in first aid, search and rescue and disaster risk management to become "Red Crescent youth". Altogether about 22,600 young people participated in these opportunities, building self-confidence and contributing to their communities. More outcomes forthcoming.

Enabling improvements in adolescent nutrition through youth inclusive and gender responsive programs at scale

Lucy Murage[2], Shibani Sharma[1], Anjali Bhardwaj[3], Marion Roche[1], Mandana Arabi[1]

1. Nutrition International (Canada), 2. Nutrition International, Africa Regional Office (Kenya), 3. Nutrition International, Asia Regional Office (India)

Background & Objectives: Through the Right Start initiative from 2015-2019, Nutrition International supported national governments were supported to initiate Adolescent Nutrition programs in six countries across Africa and Asia and the existing program was strengthened in 5 Indian states, with the goals of reducing anaemia for adolescent girls through WIFAS and nutrition education. From 2020 there is an additional focus of increasing adolescents' understanding of their own growth, development, and nutritional needs.

Methods: National governments were supported in developing, updating, and adapting guidelines for adolescent nutrition. Demonstration projects enabled testing of optimal delivery platforms for in and out-of-school girls that could be expanded to additional geographies, then scaled up. Key aspects of each program were formative research for behaviour change interventions; training of teachers and health providers; nutrition curriculum development and revision; strengthening WIFAS supply and logistics; establishing monitoring and reporting systems across sectors; advocacy and policy review; and fostering multisectoral collaboration. Youth were engaged in formative research; creating Behaviour change strategies; youth nutrition and health clubs; delivering and reporting on WIFAS consumption; and in identifying gendered barriers to equitable participation.

Results: A total of 195k intermediaries were trained on adolescent nutrition and anaemia across multiple sectors, including teachers, frontline health workers, managers, and key policy makers and programmers. Government programs were established and reached an additional 10 million adolescent girls with WIFAS and 6.6 million adolescent girls and boys with nutrition education. An estimated 1.2 million cases of anaemia were averted. Out of school adolescent girls were among the most vulnerable and delivery of nutrition interventions to those out of school was more resource intensive during the Right Start

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

project (2015-2019). With COVID-19 related closures from 2020-2022 school-based delivery was limited and programmers were challenged to adapt.

Conclusions: Adolescent nutrition gained priority in global and national agendas and multi-sectoral programs. School-based anaemia reduction programs demonstrated the potential to improve well being for adolescents. Vulnerable adolescent girls face gender inequities and will benefit from increased youth responsiveness of health and education systems. Youth participation is key to strengthening these systems and adolescent nutrition programs to be more resilient and equitable.

Conflict of Interest Disclosure: We have no conflicts of interest to declare.

Approaches to reach and engage adolescents and adolescent mothers in Africa and Asia

Natalie Roschnik[1], Eriana Asri[2], Firda Dewi[3], Dee Jupp[4], Phindile Lupafya[5], Brenda Phiri[5], Danielle Stein[6], Julia Weatherson[7]

1. Save the Children (UK), 2. Nutrition International (Indonesia), 3. Save the Children (Indonesia), 4. Empatika (UK), 5. Save the Children (Malawi), 6. Empatika (South Africa), 7. Save the Children (Cambodia)

Background and objectives: Reaching and engaging adolescents (girls and boys) before and when they conceive a child and become parents is key to breaking the inter-generational cycle of malnutrition. The needs, challenges and aspirations adolescents face vary widely by context and so must the approaches and solutions to address them. Save the Children is currently implementing nutrition programmes in 40 countries globally reaching nearly 12 million children (including adolescents). This presentation will discuss the very different issues adolescents face in each context and the range of approaches used to reach and actively engage adolescent girls, boys, schools, family and community members in addressing these issues.

Methods: The presentation will draw on 1) formative research findings, including from Immersion Research, Reality Check Approach (RCA) and People-Centred Design studies conducted in Indonesia and Malawi; 2) Programme examples from 2-3 countries in Asia and Africa on approaches used to reach and engage adolescents to improve their own health and nutrition, delay pregnancy (where early pregnancy is common), and receive appropriate care and support when they become pregnant, mothers and fathers themselves.

Results: In rural Malawi, adolescent marriage and pregnancy is common and viewed as normal after leaving primary school; poverty, food insecurity, poor diets (staple-maize based with little vegetable or animal-based foods); low access to nutrition services (iron supplements) and frequent disease (malaria, diarrhoea) are some of the main drivers of undernutrition and anaemia amongst adolescent girls. In Indonesia (NTT and West Java), while adolescent marriage and pregnancy are less common, poverty and food insecurity less acute, adolescent diets are still primarily rice based, supplemented by fried, sweetened, and packaged foods, with low nutrient content, coupled with low adherence to school iron supplementation programmes. In both countries, a people centred design process was used to identify small doable actions which adolescents can do and promote themselves through school, youth groups or adolescent mother groups. These adolescent-led "solutions" will be presented alongside other examples from community and school-based programmes.

Conclusion: The challenges, needs and aspirations of adolescents, girls and boys, before and after they become parents vary widely by and within each context. They cannot be treated as one homogenous "beneficiary" group but instead need to be engaged and become the main actors in finding their own solutions to problems they recognise as important. This presentation draws on Save the Children and its partners (Empatika, Nutrition International and others) experience in Asia and Africa, engaging adolescents to improve their own and their children's health, nutrition and in doing so, help break the intergenerational cycle of malnutrition.

Overview: Specific nutritional status and involvement in health problems in older people

Masafumi Kuzuya[1, 2]

1. Meitetsu Hospital (Japan), 2. Nagoya University (Japan)

Body composition changes with age. In general, older people have less muscle mass and more fat, especially visceral fat mass, than middle-aged adults. Age-related changes in muscle mass cause sarcopenia and frailty, which are the themes of this symposium. In addition, the height decreases with aging, and the body mass index (BMI) increases even if they maintain their middle-aged weight. In addition, the weight itself often gradually decreases in older old.

Good nutritional status is crucial for maintaining growth and health in all stages of life. However, the relationship between nutritional status and health and the effect on various health-related outcomes differ, depending on the life stage. Many adverse outcomes in older adults, directly linked to different nutritional status, are not present in middle-aged adults, and their ideal nutritional status may differ. In fact, it is possible that

the optimal nutritional status for poor health outcomes such as mortality and physical dysfunction related to healthy life expectancy in the older adults is different from that in middle-aged adults.

Presence of metabolic syndrome is already established as a risk factor associated with all-cause and cardiovascular deaths in middle-aged adults, but the impact of metabolic syndrome on the life prognosis in the older adults is clearly reduced compared to middle-aged adults. The adverse health effects of obesity in middle age are also mitigated in the older people, especially in the older old. In fact, regardless of race, the hazard ratios of all-cause mortality for overweight and obesity were lower in older ages than in younger ages.

However, on the contrary, the problems of weight loss and undernutrition are highlighted in the older people. Weight loss and undernutrition cause physical frailty and sarcopenia, and pose a risk of various new illnesses, physical dysfunction, and death in older people. It should be noted that the main nutritional targets of middle-aged adults and the older old thus face the opposite problems (overnutrition and undernutrition). Therefore, it is extremely important for nutritional guidance by medical personnel to take into consideration the age of the subject.

Home-based exercise and nutrition interventions for frailty

Chih-Cheng Hsu[1]

1. Center for Geriatrics and Welfare Research, National Health Research Institutes (Taiwan)

Frailty is a geriatric syndrome characterized by declined physiological reserves and resistance to stressor events that can increase the risks of adverse health outcomes, such as functional disability, hospitalization, and death. Therefore, the prevention and management of frailty is of great importance for both clinicians and elders. The objective of this study was to develop individualized home-based exercise and nutrition interventions for improvement of frailty in the elderly. In this talk, I would like to report to you a study with a four-arm, single-blind, randomized controlled trial, which was conducted at the Miaoli General Hospital in Taiwan. Participants were randomly assigned into one of four study groups for 3-month intervention and 3-month self-maintenance period: control; exercise; nutrition; combination (exercise plus nutrition) group. The frailty phenotypes were quantified by frailty score, which was the primary outcome in this study. A total of 1,160 elderly were invited to participate this study, from whom there were 319 eligible subjects who coincided with the selection criteria. At 6 months, compared to the control group, the exercise (points: -0.23; 95% confidence interval [CI]: -0.41, -0.05; $p < 0.05$), nutrition (points: -0.28; 95% CI: -0.46, -0.11; $p < 0.01$), and combination (points: -0.34; 95% CI: -0.52, -0.16; $p < 0.001$) groups revealed significant improvement in frailty score change from baseline. Significant improvements also observed in handgrip strength, 10 m gait speed, back scratch, sit and reach, and lower extremity strength in the exercise, nutrition or combination groups, improvement of short form-12 mental component summary score in the nutrition group. The results revealed that individualized home-based exercise and nutrition interventions can help to improve frailty score and physical performances for the elderly with pre-frailty or frailty. In addition, the combination intervention has synergistic effects.

SY(T4)1-3

Combined exercise and nutritional intervention for sarcopenia and frailty

Hiroyuki Sasai[1]*, Hunkyung Kim*[1]

1. Tokyo Metropolitan Institute of Gerontology (Japan)

Frailty is a state of increased vulnerability to various stressors and increased risk of adverse health outcomes, such as loss of independence and death. Frailty is not an irreversible aging process but a reversible state with appropriate interventions (The Japan Geriatrics Society, 2014). Although the prevalence of frailty varies by definition, a systematic review of studies on the Japanese population reported it to be 7.4% (Kojima et al., *J Epidemiol*, 2017). A recent national survey reported a prevalence of 8.7% (Murayama et al., *Arch Gerontol Geriatr*, 2020). Based on Fried's physical phenotype model (Fried et al., *J Gerontol A Biol Sci Med Sci*, 2001), a representative conceptual model of frailty, physical frailty characterizes slowness (slow walking speed), weakness (low strength), weight loss, exhaustion, and low physical activity. Sarcopenia, which shares some diagnostic criteria with the physical phenotype models described above, refers to the age-related loss of muscle mass and muscle strength and function (Chen et al., *J Am Med Dir Assoc*, 2020). In October 2016, sarcopenia was coded as per the International Classification of Diseases, 10th edition and officially recognized as a disease. As frailty and sarcopenia are overlapping concepts, their underlying treatment strategies are similar. The Asia-Pacific Clinical Practice Guideline for the Management of Frailty (Dent et al., *J Am Med Dir Assoc*, 2017) and The ICFSR International Clinical Practice Guidelines for the Identification and Management (Dent et al., *J Nutr Health Aging*, 2019) gave a "strong recommendation" for a multicomponent exercise program (including resistance-based training) as the first-choice option for improving frailty. In addition, an increase in energy and protein intake is conditionally recommended, especially for older adults with weight loss or malnutrition. Furthermore, a conditional recommendation is also given for a combined exercise and nutritional intervention. A systematic review also

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

reported that combined resistance exercise and nutrition are particularly effective in treating sarcopenia (Yoshimura et al., *J Am Med Dir Assoc*, 2017). Which nutritional supplementation strategies effectively improve frailty and sarcopenia? Over the past 10 years, the authors' research group has conducted exercise and nutritional intervention studies in older adults with frailty and sarcopenia. In particular, we have investigated the effects of resistance exercise combined with essential amino acids (Kim et al., *J Am Geriatr Soc*, 2012), tea catechins (Kim et al., *Geriatr Gerontol Int*, 2013), milk-fat globule membrane (Kim et al., *Plos One*, 2015), and β-hydroxy-β-methyl-butyrate (Osuka et al., *Am J Clin Nutr*, 2021) using randomized controlled trials. Thus, our talk provides an overview of these studies and discussions for future directions.

Keywords: Resistance training, Milk fat globule membrane, β-hydroxy-β-methylbutyrate, Essential amino acids, Tea catechins

Nutritional strategy for sarcopenic dysphagia

Keisuke Maeda[1]

1. National Center for Geriatrics and Gerontology (Japan)

Sarcopenia, a decrease in skeletal-muscle mass and function, is an important disease with regard to geriatric nutrition. Interest in sarcopenic dysphagia, which is defined as swallowing difficulty caused by decreased muscle mass and function in eating-related muscles, is growing. In 2019, four Japanese academic societies published a position paper that focused on the concept, definition, and diagnosis of sarcopenic dysphagia. The proposed diagnostic criteria for sarcopenic dysphagia include the presence of generalized sarcopenia, low tongue strength, and dysphagia with no obvious cause such as stroke or neurodegenerative disease. The prevalence of sarcopenic dysphagia has been reported to range from 13% to 42% in hospitalized elderly patients and 32% in hospitalized patients undergoing dysphagia rehabilitation. The known risk factors for the development of sarcopenic dysphagia include poor physical function, malnutrition, and severe sarcopenia. Physical and nutritional interventions are expected to improve the strength of the muscles of deglutition. We recently reported that physical and nutritional interventions improved tongue strength in older adults in a rehabilitation hospital. Tongue strength increased with higher energy and protein intake and during regular physical and occupational therapy without swallowing training. These results suggest that the treatment of dysphagia in sarcopenia requires physical intervention with nutritional supplementation, in addition to swallowing training. Another study in a rehabilitation hospital found that aggressive nutritional therapy contributed to improved swallowing function in patients with sarcopenic dysphagia. The group with a mean energy intake ≧30 kcal/kg/day had significantly higher rates of achieving clinically important differences in swallowing function and activities of daily living at discharge. Proactive nutritional care for sarcopenic dysphagia appears to be crucial, in addition to traditional swallowing training.

Effect of Carbohydrate-restricted Diets and Intermittent Fasting on Type 2 Diabetes Management

Kee-Ho Song[1]

1. Konkuk University Medical Center (Korea)

Carbohydrate-restricted diets and intermittent fasting (IF) have been rapidly gaining interest among the general population and patients with cardiometabolic disease, such as overweight or obesity, diabetes. However, there are limited expert recommendations for these dietary regimens. This study aimed to evaluate the level of scientific evidence on the benefits and harms of carbohydrate-restricted diets and IF to make responsible recommendations. A meta-analysis and systematic literature review of 66 articles on 50 randomized controlled clinical trials (RCTs) of carbohydrate-restricted diets and ten articles on eight RCTs of IF was performed. Based on the analysis, the following recommendations are suggested. In adults with type 2 diabetes, a moderately-low carbohydrate or low carbohydrate diet can be considered as a dietary regimen for improving glycemic control and reducing body weight. In contrast, a very-low carbohydrate diet and IF are not recommended in patients with diabetes.

Dietary guidelines and management status of Korean Diabetes

Hae-Jeung Lee[1]

1. Gachon University (Korea)

In East Asia, the number of adults with diabetes had the largest absolute rise, 106 million in 2014 compared to 1980, based on the NCD Risk Factor Collaboration 2016 report. Since dietary intervention plays a pivotal role in maintaining good glycemic control for diabetes, dietary guidelines reflecting ethnic

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

traits have been developed and recommended. In South Korea, the prevalence of diabetes increased moderately from 2007 to 2017. Nutrition therapy plays a key role in the management of diabetes. I will briefly introduce dietary guidelines of Koreans and medical nutrition therapy (MNT) by the Korean Diabetes Association. I will present the differences in health behaviors and nutrient intake status among aware and unaware Korean adults with diabetes using Korea National Health and Nutrition Examination Survey data. I will also discuss the adherence to MNT guidelines based on diabetes awareness among Korean adults and nutrition education and treatment in the diabetes-aware group. This national level data analysis provides useful insights into Korea's approach to diabetes management.

Keywords: Korean diabetes, medical nutrition therapy, nutrient intake, adherence to dietary guideline, awareness

SY(T4)2-3

Nutrition therapy for diabetes in Japan

Michiaki Fukui[1]

1. Kyoto Prefectural University of Medicine (Japan)

Optimal dietary therapy for diabetic patients is to implement diet therapy that has an appropriate amount of energy, is well-balanced in nutrition, and implements regular diets to suppress the onset or progression of complications. In Diabetes Clinical Practice Guidelines 2019, it was decided that the appropriate amount of energy should be determined by setting a target weight and multiplying it by an energy factor based on the physical activity level and pathology. On the other hand, the number of obesity cases is increasing, and postprandial hyperglycemia and blood sugar spikes increase the risk of vascular and organ damage, so dietary habits are also important. Ingestion of dietary fiber mainly derived from grains leads to the prevention of diabetes, and it is thought that there are many merits in ingesting water-soluble dietary fiber in particular. Eating in the morning has many benefits, such as suppressing obesity, improving blood sugar levels, and increasing muscle. The "Food Exchange Table for Diabetic Diet" ("Food Exchange Table") is a diet bible created from the perspective of what a diabetic diet is and what kind of foods should be taken. If you make a meal plan according to the "Food Exchange Table" and choose ingredients that contain different nutrients in just the right amount, you will be able to take in the amount of energy and nutrients that are suitable for treatment. It has been reported that the elderly have a low muscle synthesis rate and diabetes leads to a decrease in muscle mass, so it is important for elderly diabetic patients to take in sufficient protein. To prevent frailty and sarcopenia in the elderly, adequate protein intake is necessary unless severe renal impairment is present. To maintain muscle mass in the elderly, it is recommended to consume at least 1.0 g/kg body weight/day of protein. It is important to actively ingest leucine-rich white meat. It has also been reported that if the protein distribution is even at three meals (30 g breakfast, 30 g lunch, and 30 g dinner), the muscle protein synthesis reaction will be higher for 24 hours than if the protein intake is skew (10 g breakfast, 15 g lunch, and 65 g dinner). Dietary fiber, especially water-soluble dietary fiber and miso, may not only improve postprandial hyperglycemia but also increase muscle mass through the production of intestinal metabolites. A feature of Japanese food is that it is based on rice (carbohydrate), which is the "staple food", plus "main dishes" such as seafood and soybean products, and "side dishes" such as seaweed, root vegetables, mushrooms and beans. We believe that it is important to practice an appropriate diet for the prevention and treatment of diseases. Moreover, in order to enable long-term continuation, it is necessary to consider not only safety but also Japanese food culture and patient preferences.

Nutrition Therapy for Diabetes:

Clinical Guidelines, Clinical Trials and Clinical Practice

William S Yancy[1]

1. Duke University (USA)

Nutrition therapy can have a profound effect on diabetes outcomes, improving glycemic control, blood lipid levels, weight, and quality of life, and reducing hypoglycemic events and medications. A low-carbohydrate nutritional approach that reduces intake of starch and sugar has been used successfully to improve all of these outcomes. In this presentation, the composition and underlying physiology behind low-carbohydrate diets will be described. The effects of low-carbohydrate nutrition on diabetes outcomes in clinical trials will be explained and examples from clinical experience will be illustrated. Finally, findings from and how a low-carbohydrate eating plan fits in the context of the American Diabetes Association's consensus report on nutrition therapy will be reported.

The many faces of food allergy

Gary WK Wong[1]

1. Chinese University of Hong Kong (Hong Kong)

Food allergy is a common disorder affecting up to 5% of the population and it is usually more common in children. The manifestations vary widely from a simple itch of the skin or around the mouth to potentially fatal anaphylatic reaction affecting the cardiovascular and respiratory systems. Many factors may affect the manifestations of food allergies. These include the type of food allergens, the preparation of the food allergens, the dosages, the route of entry into the body, the age of the patients, and other cofactors such as exercise, use of drugs, or menstruation. The most common manifestations of food allergy include itchy skin rash, tingling and itching of the mouth or around the mouth, swelling of the face, lips, or the throat resulting in swallowing problems, difficulty of breathing, nausea, vomiting, diarrhoea, itchy and watery eyes. The most severe form is called anaphylaxis which is usually associated with breathing troubles, fainting and sudden collapse. The timing of developing these symptoms may vary. However, IgE medicated food allergy usually results in manifestation within 2 hours of ingestion of the allergen. Non IgE mediated food allergy is less common but can also be very severe especially in young infants. Exercise- induced food allergy is a very special form that the subject will develop symptoms only if ingestion is followed by exercise. Therefore, a careful history is needed to tease out what could be the potential culprit causing the symptoms. Testing such as measurements of IgE or skin test must be interpreted in light of the history. Otherwise, excessive and unnecessary dietary restrictions will result in more harm to the subjects especially in children.

SY(T4)3-2

Food allergy management in Japan

Motohiro Ebisawa[1]

1. National Hospital Organization Sagamihara National Hospital (Japan)

Food allergies in Japan are generally classified into four clinical types: (1) neonatal and infantile gastrointestinal allergy, (2) infantile atopic dermatitis associated with food allergy, (3) immediate-type of food allergy (urticaria, anaphylaxis, etc.), and (4) special forms of immediate-type of food allergy such as food dependent exercise-induced anaphylaxis (FDEIA) and oral allergy syndrome (OAS). Most common food allergy is the immediate-type of food allergy that is seen from childhood to adulthood. Infantile atopic dermatitis associated with food allergy type is especially important as the onset of most food allergies occurs during infancy. Most frequent causative foods during infancy were hen's egg, cow's milk, and wheat. Recently, tree nuts allergies, especially walnut and cashew are increasing trend in Japan. FDEIA are mostly seen in school age children to adolescence, most common causative foods are wheat, shrimp and fruits. OAS is almost identical to pollen-food allergy syndrome (PFAS), and cross reactivity between pollen and fruits such as PR-10 family and profilin is the cause of PFAS. Detailed history taking on food allergy and dietary life by both doctors and registered dietitians are the most important diagnostic procedures. Diagnosis accuracy using antigen-specific IgE is recently improved by the application of probability curves and component-resolved diagnosis (CRD). CRDs for hen's egg (ovomucoid), peanut (Ara h 2), walnut (Jug r 1), and cashew (Ana o 3) are approved by the nationwide insurance and widely used as a routine diagnostic procedure. Oral food challenge (OFC) using a stepwise approach (low dose, medium dose and full dose) is recommended to avoid complete elimination of causative foods in our guidelines. Although avoidance is the gold standard of management of food allergy in the rest of the world, recommendation of partial intake proved by OFC is quite unique approach. Systematic reviews of domestic reports on OFC for hen's egg and cow's milk were performed and to prove the efficacy and adverse events. After stepwise OFC dietary advice and guidance by registered dietitians are also recommended. Although oral immunotherapy (OIT) has not been approved as a routine treatment by nationwide insurance, OITs against hen's egg, cow's milk, wheat and peanut are widely performed in Japan as research procedure. Prevention of food allergy is currently the focus of interest, and many changes were made based on recent evidence. Finally, team practice including allergy specialists and registered dietitians play a very important role for the management of food allergy.

SY(T4)3-3

Nutritional guidance in food allergy

Noriko Hayashi[1, 2]

1. Jumonji University (Japan), 2. Sagamihara Hospital (Japan)

Patients with food allergies have to eliminate specific foods from their diet, which imposes a heavy burden on their eating habits, such as narrowing their range of food choices. Therefore, it is necessary for a dietitian to support the dietary habits of such patients through nutritional guidance, so that their quality of life stemming from their dietary habits can be improved as much as possible. Nutritional guidance includes the following major points: First, patients with food allergies must eliminate the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

minimum kind and amount of food from their diet. In other words, it is important for patients to accurately understand what they can and cannot eat. It is necessary for them to learn the characteristics of the food allergen, which foods must be eliminated, and how to read food labels. For example, in the case of hen's egg allergy, the patient should know about the characteristics of hen's egg allergens, the types of processed foods that need to be eliminated and those that can be eaten, and how these allergens are labeled as a raw material in processed foods. Second, patients must learn how to ensure their own safety. They must know how to avoid the accidental ingestion of food allergens under different situations, such as when selecting, cooking, and eating food. Third, the nutritional status of the patient should be assessed. Patients should also be aware of the nutrients that will tend to be deficient after causative foods have been eliminated from their diet and understand that a balanced diet is important for maintaining good nutrition. There are other points that patients should be aware of depending on their life stage. Patients can reduce their anxiety about their diet and that of their children by receiving related advice during pregnancy and lactation, on the progression of baby food, on correspondence at nursery centers and school lunches, and on precautions to take when eating out and when expanding their diet after oral food challenges. Patients face difficulties and anxiety in various aspects of their diet. It is very important for dietitians to work with doctors to support patients and their families through nutritional guidance so that they can lead a safe and comfortable life.

Keywords: food allergy, dietitian, quality of Life

Looking back on the progress in nutritional management for liver disease

Akinobu Kato[1]

1. Morioka Municipal Hospital (Japan)

The liver is the center of nutrition metabolism, and it is known that various nutritional metabolic disorders occur in liver disease. Here we present an overview of the transition of nutritional interventions for patients with liver cirrhosis and non-alcoholic steatohepatitis. Nutritional therapy for liver disease in Japan consisted of a low-protein and carbohydrate-dominant diet before the 1940's, but since then it has changed to a high-protein high energy diet. However, due to the westernization of the Japanese diet, the number of obese people has gradually increased, and a balanced diet has been the basic dietary therapy since the 1970's. Patients with liver cirrhosis have abnormalities not only of carbohydrate, lipid, protein, and amino acid metabolism, but also vitamin and trace element metabolism, and it has become clear that imbalance of plasma free amino acids is involved in decreased utilization efficiency of early morning fasting carbohydrates and in protein/amino acid metabolism abnormalities, and hypoproteinemia, hyperammonemia, negative nitrogen balance, etc., are also observed. As nutritional intervention methods, eating before bedtime as a measure against abnormal energy metabolism and oral branched-chain amino acid preparations for treatment of abnormal protein and amino acid metabolism have been used. Since fatty liver and NASH are frequently associated with lifestyle-related diseases such as obesity, glucose tolerance abnormality, hyperlipidemia, and high blood pressure, it is basic to carry out a diet therapy consistent with these disease states, and it is recommended that patients receive regular nutrition education and avoid sudden weight loss due to diet. Clinical practice guidelines for liver cirrhosis and fatty liver/NASH were published in the 2000's, and standard evidence-based nutritional interventions have become more common.

SY(T4)4-2

Recent progress of nutritional management for liver cirrhosis

Takumi Kawaguchi[1]

1. Kurume University School of Medicine (Japan)

Evidence-based Clinical Practice Guidelines for Liver Cirrhosis have been updated in 2021 by The Japanese Society of Gastroenterology/Japan Society of Hepatology. In the guidelines, the flowchart for the nutritional therapy was revised based on the accumulated evidence. In this session, I summarize the updated points for nutritional therapy.

The initial step of nutritional therapy is assessment. Nutritional status is evaluated by the following three criteria: 1) serum albumin level < 3.5 g/dL, 2) Child-Pugh class B/C, 3) sarcopenia. Patients who fulfill any of the above three criteria are considered as having malnutrition. In particular, sarcopenia is recently known as an independent prognostic factor and should be paid attention to. For cirrhotic patients with malnutrition, the 1st-line nutritional therapy is divided meal/late evening snacks (LES). LES is originally developed for the improvement of nocturnal starvation. Nocturnal starvation is frequently seen in cirrhotic patients while asleep and is associated with disease progression. One of the pathogenesis for nocturnal starvation is a decrease in hepatic glycogen, which results in an energy shortage while asleep. Whereas, LES acts as an energy source and helps to maintain blood glucose concentration while asleep, leading to the improvement of nocturnal starvation. In addition, LES exerts beneficial effects on hepatic biochemical parameters including albumin, ammonia, and prothrombin time. LES is also reported to suppress the development of ascites and hepatic encephalopathy.

In case of worsening nutritional status after treatment with LES, the 2nd-line nutritional therapy is oral branched-chain amino acids (BCAA) agents. There are two types of oral BCAA agents in Japan such as BCAA granules and BCAA-enriched supplementation. BCAA granules consist of L-isoleucine, L-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

leucine, and L-valine, and are approved for hypoalbuminemia in decompensated cirrhotic patients with sufficient energy intake. BCAA-enriched supplementation consists of BCAA, other amino acids, lipids, carbohydrates, minerals, and vitamins. BCAA-enriched supplementation is approved for malnutrition in patients with chronic liver failure accompanying hepatic encephalopathy. Moreover, several clinical studies have demonstrated that BCAA inhibits the development of hepatocellular carcinoma and prolongs the overall survival of cirrhotic patients. Although the precise mechanisms are under investigation, BCAA is not a simple nutrient and is considered a pharmacological nutrient for patients with liver cirrhosis.

Carnitine and zinc are nutrients associated with various metabolisms including ammonia detoxification. In patients with cirrhosis, carnitine and zinc deficiencies are highly prevalent. Therefore, supplementation of these nutrients is recommended for cirrhotic patients with hepatic encephalopathy and deficiency of carnitine and zinc. In addition, supplementation of these nutrients is thought to be beneficial for sarcopenia in cirrhotic patients.

In conclusion, an assessment of not only liver function but also sarcopenia is crucial for the nutritional management of cirrhotic patients. For cirrhotic patients with liver failure/sarcopenia, LES should be considered as a 1st-line nutritional therapy. Then, BCAA agent should be considered as a 2nd-line therapy. In addition, carnitine and zinc deficiencies are highly prevalent in patients with liver cirrhosis. Supplementation of these nutrients contributes to further improvement of the nutritional status of cirrhotic patients.

Impact of treatment of diabetes in patients with no-alcoholic fatty liver disease

Tomomi Koiso[1], Takaomi Sagawa[1], Yuichi Ikarashi[1], Makiko Taniai[1], Etsuko Hahimoto[1], Katsutoshi Tokushige[1]

1. Tokyo Women's Medical University (Japan)

Aims: Specific treatment for non-alcoholic fatty liver disease (NAFLD) was poorly developed. The patients with diabetes mellitus are frequently complicated with NAFLD. However, the impact of diabetes treatment and genetic background in NAFLD are unclear. In this study, we investigated the clinical course for treatment of an oral hypoglycemic agent (OHA) for one year. Methods: The 544 patients (275 men; 50.6%) enrolled in the study had biopsy-confirmed NAFLD and a median age of 53 (range: 10-84) years. There were 272 patients without diabetes, and 64, 141 and 67 with type 2 diabetes not treated with an OHA, with an OHA and insulin, respectively. 1) Changes in biochemical parameters and body weight over 1 year were determined in patients treated with incretin agents (n = 91), a sodium glucose cotransporter 2 inhibitor (SGLT-2) (n = 19), or both (n = 33). The voltage-gated potassium channel KQT-like subfamily member 1 (KCNQ1) gene was identified as a risk allele for diabetes and assessed the association of the treatment response. 2) The serum level of glucose was measured in 48 cases by continuous glucose monitoring (CGM). Results: 1) Among patients with NAFLD, half had type 2 diabetes and the incidence was high in those with advanced fibrosis. The serum level of transaminase, and hemoglobin^{A1C} was reduced after 1 year of OHA treatment without significant difference regardless of the type of OHA. Platelet counts did not change significantly. The reduction in body weight was higher after SGLT2 treatment ($p = 0.05$) and in the KCNQ1 CC subjects ($p < 0.05$). 2) The serum level of glucose was reduced at night time in patients with mild fibrosis (F0-2, n= 8) in 25 cases and advanced fibrosis (F3-4, n= 4) in 23 cases without significant difference. Conclusions: SGLT2 was effectively treated in NAFLD patients with type 2 diabetes. The patient's genetic background affected the treatment response in patients with NAFLD. The serum level of glucose in night time was reduced even in mild fibrosis cases, we should be aware the hypoglycemia.

SY (T4)4-4

Nutritional management for liver cirrhosis in Thailand

Teerha Piratvisuth[1]

1. NKC Institute of Gastroenterology and Hepatology (Thailand)

Protein calorie malnutrition (PCM) is a common and important problem in patients with cirrhosis and is associated with functional severity of liver disease. Malnutrition in cirrhosis can be undernutrition or excess in nutrition (patients with NAFLD). The recommended calorie for undernutrition is 35-40 kcal/kg/day and 25 kcal/kg/day for those with nutrition excess. The proportion of nutrient in cirrhosis is 50-55% and 30-35% for carbohydrate and fat, respectively. Protein requirement is 1.2-1.5 g/kg/d and 1.5-2.0 g/kg/d for compensated and decompensated cirrhosis, respectively. Branch Chain Amino Acid (BCAA) is commonly recommended in Thai patients with cirrhosis who could not tolerate recommended amount of protein supplement due to aggravating hepatic encephalopathy. Due to economic-constrain in Thailand, vegetable protein is added as a snack in late morning and afternoon and keep BCAA as a late supper at around 8.00 pm. Nutrition intervention should be divided to 3-4 meals and 5-6 meals for compensated and decompensated cirrhosis, respectively. Fasting over 6 hours should be avoided in cirrhosis, particularly in those with more advanced liver disease. Micronutrient deficiency is also common

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

in patients with cirrhosis, particularly, alcoholic cirrhosis. Micronutrition should be evaluated and supplemented accordingly. Due to insulin resistance, overt hyperglycemia can occure up to 15-37% in patients after nutritional management, FBS and postprandial BS should therefore be assessed and adding insulin in those who develop overt hyperglycemia.

Optimal nutritional management is one of the key factors to not only improve patients' survival but also quality of life.

Dietary fats and cardiovascular disease – Dispelling the myths

Julie Anne Lovegrove[1]

1. University of Reading (UK)

Cardiovascular diseases (CVD) are the greatest cause of death globally. High intakes of dietary saturated fatty acids (SFA) have been linked to an increased risk of cardiovascular events, primarily through their association with raised serum low density lipoprotein (LDL) cholesterol, and their reduction has formed the backbone of dietary guidelines to prevent CVD for decades. However, there is some confusion over what should replace SFA in our diets. Evidence indicates that replacement of SFA with carbohydrates, particularly refined sources, has minimal benefit to CVD mortality. Whereas replacement with unsaturated fats, particularly cis polyunsaturated fatty acids, has beneficial effects and is a recommendation in current guidelines. However not all SFA are equal and foods rich in SFA have differential associations with CVD risk. The associations of dietary sources of dietary fats, including dairy, meat and plants will be presented. The evidence for the associations of dairy and CVD will be discussed and potential mechanistic links between saturated fats, dairy foods and CVD risk factors will be explored.

Keywords: Dietary fats, Saturated fats, Cardiovascular diseases, Dairy, LDL-cholesterol

Cardiovascular benefits of whole grain consumption: evidence explained and mechanisms explored

Frank Thies[1]

1. University of Aberdeen (UK)

There is increasing evidence that high consumption of whole-grain food is associated with low risk of chronic disease such as cardiovascular disease and type 2 diabetes. The bulk of the evidence for the benefits of wholegrain comes mainly from observational studies, but evidence of benefit in intervention studies is increasing. Most of the biologically active compounds found in a grain are located in the germ and bran compartments, and include B vitamins and minerals, amino acids, essential fatty acids and vitamin E. The bran also contains a range of insoluble and soluble fibres, and numerous phytochemicals, (phytates, phenolics, phytosterols), some presenting potential anti-inflammatory properties. The composition differs between types of wholegrain, which could determine different physiological responses with regard to markers for cardiovascular risk. Research has particularly focused on b-glucan-rich cereals such as oats and barley for their potential effect on serum cholesterol concentration and postprandial glycaemia. However, other beneficial physiological effects have been suggested such as blood pressure lowering and inflammatory markers' reduction, improvement of vascular function and increasing satiety. The mechanisms involved remain to be fully elucidated but phenolic compounds, predominantly covalently bound to the fibre, can be released and metabolised by the colonic bacteria into bioavailable bioactive compounds which could exert antioxidant and anti-inflammatory activities in the gut and in other tissues. Changes in the gut microbiota composition and functionality, initiated by increased wholegrain consumption could also lead to functional and metabolic changes resulting in favourably modulating some cardiovascular risk markers. The presentation will critically review the evidence to date regarding the cardiovascular benefits of increased wholegrain consumption and provide an overview of the potential mechanisms involved.

Fibre interventions for colorectal neoplasia prevention: a re-evaluation of design and interpretation considerations.

Bernard Corfe[1]

1. University of Newcastle (UK)

Diet advice to cancer survivors, especially in colorectal cancers, is generally to follow guidance aiumied at the primary prevention of the disease (fibres, lower protein, salt, meat). However, the underlying data to support the efficacy of this approach is sparse. To date intervention studies with dietary fibre to prevention cancer recurrence (including both pre-cancerous and cancerous lesions) is sparse. This lecture will review the guidance, assess the assumptions and available trial evidence. It will then review factors affecting cancer recurrence to explore why trials have generally not been effective (at prevention of recurrence).

Nutritional management in elderly CKD patients in Japan

Eiichiro Kanda[1]

1. Kawasaki Medical School (Japan)

The number of chronic kidney disease (CKD) patients is increasing globally because kidney function is affected by aging and lifestyle habits. Malnutrition, muscle weakness, and a decline in activities of daily living (ADL) are often observed in elderly CKD patients and dialysis patients and are related to their CKD prognosis and life prognoses. Chronic inflammation and atherosclerotic disease are associated with malnutrition. Because malnutrition and its related factors affect patients' prognoses, it is necessary to identify and treat patients with malnutrition at an early stage. The state in which the stored protein and energy sources are reduced in CKD is called protein energy wasting (PEW). PEW is diagnosed on the basis of biochemical test findings such as hypoalbuminemia, unhealthy physique, and decreased muscle mass and dietary intake. For evaluating PEW, a complex nutritional index taking into account the pathophysiology specific to CKD patients is useful. Not only nutritional therapy but also exercise therapy is necessary to stop the vicious cycle associated with PEW and the decline in ADL.

SY(T4)6-3

Nutrition Management for Patients with Chronic Kidney Disease

Bui Van Pham[1, 2]

1. Pham Ngoc Thach University of Medicine (Viet Nam), 2. Nguyen Tri Phuong University Hospital (Viet Nam)

Loss of appetite and anorexia are among the earliest and most common symptoms in patients with chronic kidney disease (CKD). The CKD-related malnutrition prevalence is 28%-48% in CKD stage 1- 4 (glomerular filtration rate (GFR) ≧ 90 - 15mL/minute/1.73m^2), and up to 75% in end-stage kidney disease (ESKD) (GFR < 15mL/minute/1.73m^2) (1). Nutrition management in CKD patients is very delicate and complicated, and must be adapted to every single individual, race, culture, age, palatability, kidney disease (KD) and comorbidities. Sodium, potassium, phosphorus, and calcium should be taken into account in their daily diets. The excessive sodium intake would worsen hypertension, and heart failure, and hence must be ≦ 2000 mg/day. The hyperkalemia (> 5.4 mmol/L) can cause fatal consequences (arrhythmia, ventricular fibrillation, respiratory muscle paralysis…); the Kidney Disease Improving Global Outcomes (K-DIGO) 2020 (2) suggests: in CKD 1-4 adults, the increased fruit and vegetable intake may decrease body weight, blood pressure, and net acid production though they contain a lot of potassium. The phosphorus and calcium intake should be adjusted to maintain their levels in the normal range. If their serum levels elevate, they can deposit in the tissues (like heart, vessels, coronary artery), and cause life-threatening complications. Also, a fluid restriction may be required (especially in ESRD or dialysis) as excessive fluid intake can lead to volume overload, and cause hypertension, congestive heart failure, and even acute respiratory failure (1). Regarding the protein intake for non-diabetic CKD 3 – 5 adults (2), under close clinical supervision, a protein restriction regime would reduce the risk for ESKD or death and improve quality of life: – 0.55 – 0.60 g dietary protein/kg (weight)/day, or – 0.28 – 0.43 g dietary protein/kg (weight)/day with additional keto acid/amino acid analogs to meet protein requirements (0.55 – 0.60 g/kg (weight)/day) – 1.0 –1.2 g protein /kg (weight)/ day to maintain a stable nutritional status for patients on dialysis (maintenance hemodialysis/peritoneal dialysis). For Diabetic and CKD patients not on dialysis, KDIGO 2020 GUIDELINE FOR DIABETES MANAGEMENT IN CKD (3) suggests maintaining a protein intake of 0.8 g protein/kg (weight)/d, and they should consume an individualized diet high in vegetables, fruits, whole grains, fiber, legumes, plant-based proteins, unsaturated fats, and nuts; and lower in processed meats, refined carbohydrates, and sweetened beverages. However, the protein restriction may not be proposed to all patients with CKD, since it is not adapted to patients with high comorbidities, malnutrition (predictor of bad outcomes when patients go on dialysis) or poor life expectancy and since patients may not want to limit their protein intake(4) Additionally, for metabolically stable adults with CKD 1– 5D or post-transplantation, the energy intake of 25 – 35 kcal/kg (weight)/ day based on age, sex, level of physical activity, body composition, weight status goals, CKD stage, and concurrent illness or presence of inflammation would help to maintain

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

normal nutritional status (2). Lastly, for CKD 3-5D or post-transplantation adults with inadequate dietary intake, it is reasonable to consider multivitamin supplementation including all the water-soluble vitamins, and essential trace elements to prevent or treat micronutrient deficiencies (1).

SY(T4)6-4

Nutritional evaluation in patients undergoing dialysis

Katsuhito Mori[1], Yoshihiko Kanno[2]

1. Osaka Metropolitan University (Japan), 2. Tokyo Medical University (Japan)

Patients with ESKD, especially those receiving dialysis, often show characteristic loss of muscle and fat mass, termed protein energy wasting (PEW). PEW is associated with poor prognosis. At the same time, life extension has led to unexpected geriatric syndromes such as frailty and sarcopenia. Maintenance of nutritional condition has a key role in defending against PEW, frailty, and sarcopenia in elderly patients undergoing dialysis. To counteract these disorders, appropriate nutritional evaluation is indispensable. Although a composite nutritional assessment including malnutrition inflammation score is preferable, it is not easy to perform the nutritional assessment in clinical settings in Japan. Another problem may be the cut-off value of each component in PEW. For example, direct adaptation of original PEW criteria for Asian patients is difficult, considering the relatively low level of serum albumin (mean level: 3.6 g/dL) in Japanese patients undergoing dialysis. Therefore, nutritional risk index for Japanese hemodialysis patients (NRI-JH) has been proposed according to the concept of PEW. NRI-JH is calculated based on serum albumin, serum total cholesterol, BMI, and serum creatinine, with considerations for age and sex. Patients were divided into low-, medium, and high-risk groups. Inclusion of creatinine in this index may reflect an aspect of sarcopenia as a surrogate marker of muscle mass. A considerable overlap of PEW, sarcopenia, and frailty is expected, though little information is available because of the lack of clear each diagnosis. As compared to a diagnosis of frailty, the criteria for sarcopenia presented by the Asian Working Group on Sarcopenia are clear (AWGS 2019). Recently, it has been reported the direct relationship between nutritional status assessed by NRI-JH and sarcopenia evaluated by the AWGS 2019 criteria in 315 Japanese patients undergoing hemodialysis. The prevalence of sarcopenia was 44.1%. The prevalence of medium-/high-risk patients was 31.1%, of whom 64.3% were diagnosed with sarcopenia, suggesting a profound association of nutritional disorder with sarcopenia. Since NRI-JH has been developed based on one-year mortality, it was not clear whether it can predict long-term mortality. A recent study showed a significant relationship between NRI-JH and long-term all-cause mortality in 3046 Japanese patients undergoing hemodialysis. In addition, NRI-JH predicted CVD mortality and infection-related mortality in that study. A novel NRI-JH is an objective tool based on practical measurements and repeated use of this index may be useful for evaluation of need for nutritional intervention. An appropriate nutritional status can result in maintaining physical activity that can protect PEW, sarcopenia, and frailty in elderly patients undergoing dialysis.

SY(T4)7-1

Reciprocal interplay of ZIP4 and ZNT1 in zinc absorption

Taiho Kambe[1]

1. Kyoto University (Japan)

Cellular zinc homeostasis is maintained by the cooperative functions of two zinc transporter family proteins, Zrt-/Irt-like protein (ZIP) and Zn transporter (ZNT), as well as by the cytosolic zinc-binding protein metallothionein (MT). The zinc homeostatic proteins ZNT1 and MT function in dampening increases in cytosolic zinc concentrations. Conversely, the expression of ZNT1 and MT is expected to be suppressed during decreases in cytosolic zinc concentrations. Thus, ZNT1/MT homeostatic responses are considered to be essential for maintaining cellular zinc homeostasis because cellular zinc concentrations are readily altered by changes in the expression of several Zrt-/Irt-like proteins (ZIPs) under both physiological and pathological conditions. However, this notion remains to be tested experimentally. Here, we investigated the aforementioned homeostatic process by analyzing ZNT1 and MT protein expression in response to ZIP expression. Overexpression of cell-surface-localized ZIPs, such as ZIP4 and ZIP5, increased the cellular zinc content, which caused an increase in the expression of cell-surface ZNT1 and cytosolic MT in the absence of zinc supplementation in the culture medium. By contrast, elimination of the overexpressed ZIP4 and ZIP5 resulted in decreased expression of ZNT1 but not MT, which suggests that differential regulation of ZNT1 and MT expression at the protein level underlies the homeostatic responses necessary for zinc metabolism under certain conditions. Moreover, increased expression of apically localized ZIP4 facilitated basolateral ZNT1 expression in polarized cells, which indicates that such a coordinated expression mechanism is crucial for vectorial transcellular transport. The ZIP-driven ZNT1 expression mechanism reported here to function in polarized cells is expected to be operative in zinc absorption in enterocytes, with ZIP4 and ZNT1 being involved in the process. Our results provide novel insights into the physiological maintenance of cellular zinc homeostasis in response to alterations in cytosolic zinc concentrations caused by changes in the expression of ZIPs.

Clinical and societal implication of vitamin insufficiency.

Kiyoshi Tanaka[1]

1. Kobe Gakuin University (Japan)

Non-communicable diseases (NCDs) are serious health problems in developed countries. For their prevention, life-style modification can play important roles, and the significance of vitamins in the health promotion must be considered from such viewpoint.

Vitamin deficiency causes classical deficiency diseases. Examples with the responsible vitamins in the parentheses include beriberi (vitamin B1), pellagra (niacin), scurvy (vitamin C), rickets and osteomalacia (vitamin D), and coagulation abnormality (vitamin K). These severe deficiency diseases are generally considered to be mostly overcome in developed countries, and the significance of vitamins in health promotion is often overlooked. Recently, however, vitamin insufficiency has been receiving increasing concern. Vitamin insufficiency, which is milder than deficiency, does not cause such diseases, but is associated with the increased risk of NCDs. Patients with vitamin deficiency have typical phenotypic changes, and can be individually diagnosed. In contrast, although vitamin insufficiency is related to the increased disease risk, it is not accompanied by the phenotypic abnormalities in each subject. Therefore, it cannot be diagnosed individually, and tends to receive little attention.

Much more amount of vitamin is needed for the prevention of insufficiency than that of deficiency. “How much vitamins do we need for health promotion” is greatly influenced by the indices based on which we define the required vitamin amount; deficiency or insufficiency. Considering the social background that NCDs are the leading cause of morbidity and mortality in developed countries, vitamin requirement must be defined based on the disease risk.

Recently, breakthrough drugs with robust evidence for true endpoint have been developed for various diseases. For example, in the case of osteoporosis, bisphosphonates, which are potent inhibitor of bone resorption, improve the surrogate endpoint such as the bone mineral density, and markedly decrease the incidence of fragility fracture. Nutritional therapy is not so potent as the treatment effects of novel breakthrough drugs, which, however, does not preclude the importance of nutritional therapy.

Intervention by drugs to subjects with high risk for fracture is cost-effective. However, because of the limited number of subjects in the high-risk group, absolute number of fractures prevented is limited. In contrast, those in the low to intermediate risk comprise most of the population, and the absolute number of fractures occurrence are large, despite the lower risk in each subject. Drug intervention for low to intermediate-risk subjects is unsuitable considering the cost and the concern for the adverse events. A previous systematic review has reported that oral nutritional supplements use in the community produce an overall cost advantage or near neutral balance, often in association with clinically relevant outcomes, suggesting cost effectiveness. Then, prevention through lifestyle modification such as nutrition and exercise should be considered. Thus, vitamin insufficiency is a significant risk for various diseases, and its correction can be of great clinical and societal significance.

Inadequate nutrient intakes in Filipino schoolchildren and adolescents are common among those from rural areas and poor families

Imelda Angeles-Agdeppa[1]*, Liya Denney, Marvin Toledo*[1]*, Virgilyn Anne Obligar, Emma Jacquier*[2]*, Alicia Carriquiry*[3]*, Mario Capanzana*

1. Food and Nutrition Research Institute (Philippines), 2. Switzerland Nestlé Research Centre, Lausanne (Switzerland), 3. Iowa State University (USA)

Background: Nutrient needs tend to be directly proportional with growth rates, making adequate nutrition an essential component of childhood and adolescence growth and development. This study evaluated usual energy and nutrient intakes of schoolchildren and adolescents in the Philippines.

Methods: Food and beverage intakes were evaluated using 24-h dietary recalls from a nationally representative sample of schoolchildren aged 6–9 and 10–12 years (n = 3,594 and n = 2,971, respectively) and adolescents aged 13–18 years (n = 5,447). The distributions of usual energy, nutrient intakes, and the prevalence of inadequate intakes – which is defined as the percent of children with intakes less than estimated average requirements or acceptable macronutrient distribution ranges – were estimated using the Personal Computer Software for Intake Distribution Estimation (PC-SIDE) program.

Results: The results showed that macro- and micronutrient intake had a high prevalence of inadequacy, wherein the prevalence of inadequacies was as follows: 12-47% for protein, 38-52% for total fat (as percentage of energy), 92-94% for calcium, 75-90% for iron, 68-96% for vitamin C, 61-93% for folate, 58-81% for vitamin A, 58-91% for Riboflavin, 27-75% for Thiamine, and 18-91% for Phosphorus, such inadequacies also results to a mean energy intake of 19-35% lower than the age group's estimated energy requirement.

Conclusions: In general, adolescents and schoolchildren, especially those from poor families and rural areas, have a high prevalence of inadequacy when it comes to key nutrients for growth. This study demonstrated that nutrient intakes of Filipino schoolchildren and adolescents were highly inadequate, more so among the poor and/or those living in rural areas.

Dietary management of phosphorus in CKD patients

Yutaka Taketani[1], Masashi Masuda[1], Hirokazu Ohminami[1]

1. Tokushima University (Japan)

Hyperphosphatemia is a common complication in advanced chronic kidney disease (CKD), especially end-stage kidney disease. Since the kidney plays a critical role in the maintenance of phosphorus balance, dietary management of phosphorus is the first-line treatment of hyperphosphatemia. Dietary phosphorus intake shows strongly positive association with dietary protein intake. Thus, low protein diet, which is a common dietary treatment in CKD patients, is useful for treatment of hyperphosphatemia. Phosphorus to protein ratio is also considered in dietary management for CKD patients with hyperphosphatemia. Phosphorus to protein ratio is different in foods. Consumption of foods with high phosphorus to protein ratio is significantly associated with mortality in end-stage CKD patients. Plant foods and animal foods are sometimes attractive issues. In general, animal foods have higher phosphorus availability than plant foods. A crossover intervention study demonstrated that vegetarian diet consumption lowered serum phosphorus levels compared to meat diet in CKD patients. Another important issue is food additives. Phosphorus-containing food additives are widely used in various food processing, thus processed foods have higher bioavailability of phosphorus rather than natural foods. We recently proposed “phosphatemic index” that is a novel index can reflect the phosphorus bioavailability. Phosphatemic index is based on postprandial increase in serum phosphorus level following the ingestion of various foods as similar as glycemic index. Phosphatemic index can evaluate more accurately the effect of phosphorus containing foods on serum phosphorus levels compared with phosphorus to protein ratio, plant/animal food ratio. Dietary phosphorus restriction can also affect metabolism of other nutrients including minerals and vitamins. I will discuss dietary management of phosphorus in CKD patients from metabolic points of view.

Conflict of Interest Disclosure: The authors declare that they have no conflict of interest.

Novel approaches to oral iron supplementation

Diego Moreti[1, 2], Nicole Stoffel[3]

1. Swiss Distance University of Applied Sciences (Switzerland), 2. University of Applied Sciences of South Switzerland (Switzerland), 3. ETH Zurich (Switzerland)

Background and objectives: Oral iron supplementation is the first line of treatment for iron deficiency and iron deficiency anaemia. Treatment schedules usually entail the daily provision of a total of 100-200 mg elemental Fe in single or in divided doses. Our objective was to review recent advances and evidence in the field of oral iron supplementation. Methods: non systematic review. Results: Iron absorption from supplements is generally low, 5-25 percent when administered in fasting state, and 0.5-13 percent when consumed with meals. Recent studies suggest that oral iron doses less or equal to 60 mg elicit an acute iron-induced rise in hepcidin, which reduces iron absorption of a subsequent dose at 24 h, but not at 48 h. Alternate day dosing provides higher fractional iron absorption than daily dosing and may, by providing an overall lower Fe dose, lower gastrointestinal side effects. Dividing high iron doses into multiple lower doses spread over the day does not provide benefits regarding the total amount of iron absorbed and should not be recommended. Recent guidelines suggest that daily morning doses of 50-100 mg iron on alternate days may be a viable treatment option for oral iron supplementation in iron deficient patients with or without mild anaemia. Conclusions: To be widely adopted, these findings need further confirmation in different patient groups, in long-term double blind, randomized controlled trials.

The Emerging Role of Vitamin D Deficiency in Anemia

Tim J Green[1, 2], Karen P Best[1, 2], Merryn J Netting[1, 2]

1. South Australian Health and Medical Research Institute (Australia), 2. University of Adelaide (Australia)

Background and objectives: Vitamin D deficiency and anemia are common and often coexist in populations suggesting that vitamin D may be involved in the etiology of anemia.

Our objectives were to examine: 1) the mechanistic evidence linking vitamin D to anemia, 2) the human observational evidence linking vitamin D status to anemia, and 3) and the effect of vitamin D supplementation on anemia.

Methods: We conducted a comprehensive review of the current evidence linking vitamin D to anemia.

Result: Vitamin D appears to increase the amount of iron available for red blood cell synthesis by reducing hepatic hepcidin synthesis. This hormone binds to ferroportin and blocks cellular iron export.

An association between serum 25-hydroxyvitamin D (25OHD), a biomarker of vitamin D status, and hemoglobin concentration has been reported in several studies. The association is weak and is modified by sex, ethnicity, and background rates of inflammation and anemia. Moreover, the association between 25OHD and hemoglobin is not continuous with a threshold effect at approximately 50 nmol/L, above which higher 25OHD is no longer associated with hemoglobin.

Randomized control trials do not support vitamin D supplementation to reduce anemia. Still, studies so far have been small and conducted in heterogeneous populations, including participants without anemia or inflammation.

Keywords: Vitamin D, Anemia, Inflammation, Hepcidin, Iron

Conclusion: Larger, high-quality trials are needed, ideally in participants with a high baseline burden of inflammation and anemia and low 25OHD, to determine the role of vitamin D in anemia.

Cognitive and behavioural consequences of iron deficiency in children and women of reproductive age

Laura E Murray-Kolb[1], Amrita Arcot[2]

1. Purdue University (USA), 2. Penn State (USA)

Background and objectives: Iron deficiency is a biological risk factor for the failure of >250 million children in reaching their full developmental potential as adults, resulting in significant reductions in economic productivity and perpetuating the vicious cycle of poverty and malnutrition. Here, we review evidence from randomized controlled trials (RCT), published in the past decade, examining the cognitive and behavioral consequences of iron deficiency.

Methods: A review of the literature over the past 10 years was conducted to identify RCTs involving iron intervention with cognitive and/or behavioral assessments in children and women of reproductive age (WRA).

Results: Ten studies assessed the effects of iron treatment on cognitive outcomes in children. Three reported no significant differences between the intervention and the control group after treatment, five reported improvements in cognition favorable to the iron treatment group, and two reported worse cognitive outcomes for children who had been treated with higher vs. lower iron formula. Of the studies that reported no significant differences or worse cognitive outcomes for the treated group, all but one provided the supplementation during infancy; while, for those reporting improvements after treatment, the intervention occurred during the preschool or school age years. Additionally, studies not conducted in Western countries but where Western norms were used to calculate the cognitive scores, were less likely to report a significant difference between groups vs studies that used raw scores. Seven recent studies assessed the effects of iron treatment on behavioral outcomes in children and five reported a lower prevalence of behavior problems or more positive affect in children who received iron; one found no difference in behavioral scores after intervention; and one reported higher ADHD symptoms in those who received iron. In WRA, three recent RCTs examined the effects of iron on cognition (memory, attention, perception); one reported no differences at endline while the other two reported greater cognitive improvements in those treated with iron. Interestingly, the iron status of the women in the studies reporting significant improvements after treatment were significantly lower at baseline, when compared to that of women in the study where no group differences were found after treatment. Three RCTs in WRA also examined behavioral outcomes and fatigue. One reported no differences between groups after supplementation while two reported significant improvements (in fatigue or depressive symptoms) after treatment.

Conclusion: An association between iron deficiency (with and without anemia) and cognition/behavior exists for children and WRA with implications for optimal achievement. Outcome tests chosen as well as the manner in which the test scores are computed need to receive more attention. Well-designed RCTs are needed to better understand the effects of timing, duration,

and severity of the deficiency as well as the optimal treatment timing, duration and dose.

Safety of interventions to reduce nutritional anaemia

Andrew M Prentice[1], Carla Cerami[1], Martin N. Mwangi[2], Hans Verhoef [3]

1. MRC Unit The Gambia at London School of Hygiene & Tropical Medicine (Gambia), 2. University of Malawi, Training and Research Unit of Excellence (TRUE) (Malawi), 3. Wageningen University (Netherlands)

Iron deficiency is estimated to cause more ill health and disability worldwide than any other nutrient deficiency. This underpins a public health drive to combat iron deficiency by interventions on multiple fronts. Many interventions such as increasing dietary diversity, introducing biofortified crops, or improving sanitation and hygiene have no safety concerns, but can have limited efficacy. Direct supplementation with iron in the form of tablets, syrups or point-of-use micronutrient powders have greater efficacy but have been associated with a range of adverse outcomes, especially in the settings of poverty and poor hygiene where they are most needed. These adverse outcomes result from a battle for iron between humans and micro-organisms in which iron can enhance the virulence of numerous human pathogens. This chapter provides a high-level review of the existing evidence that iron interventions increase the likelihood of serious infections by bacteria, protozoa, viruses or fungi, and whether they cause adverse perturbations of the gut microflora. We conclude that the evidence for possible harm is real, but that there are ways to ameliorate the risks, and that the benefits of iron interventions will generally outweigh any risks.

Epidemiological evidence of Japanese diet

Yasutake Tomata[1]

1. Kanagawa University of Human Services (Japan)

Japanese diet has been noted as one of the factors contributing to population characteristics that Japan had the longest average life expectancy in the world since the latter half of the 20th century, a lower ischemic heart disease mortality rate and obesity prevalence compared to Western countries. However, as with “westernization of diets”, adherence to Japanese dietary patterns in the Japanese population appears to be declining even after 2000. Since 2000, several epidemiological studies from U.S. and Japan have reported characters of Japanese diet relating to health outcomes such as cardiovascular disease. Based on previous epidemiological findings of Japanese diet, we defined Japanese Diet Index score based on 9 food items; 7 adhering components (“rice”, “miso soup”, “fish and shellfish”, “green and yellow vegetables”, “seaweed”, “pickles”, “green tea”), 2 non-adhering components (“beef and pork”, “coffee”). Observational epidemiological studies revealed that higher score of Japanese Diet Index is associated with better health and nutrition outcomes; higher nutrient density, lower risk of total mortality, lower risk of cardiovascular disease mortality, lower risk of incident functional disability, and lower risk of incident dementia, longer survival, and longer disability-free survival. However, these findings of observational studies do not directly demonstrate the effectiveness of interventions to change the diet to a Japanese diet. Nowadays, several evidence from intervention studies can also be referred. One randomized controlled trial showed the efficacy that the Japanese diet reduced body fat mass, LDL cholesterol level (major risk factors of ischemic heart disease), hemoglobin A1c level (measure of blood glucose), and C-reactive protein level (inflammatory marker) in overweight adults. Another randomized controlled trial also showed the effectiveness that dietary education of the Japanese diet improved LDL cholesterol level in dyslipidemia patients. Taken together, these findings hold promise that Japanese diet eventually contributes to reduce mortality and prolong healthy life expectancy, although this expectation has not been verified by intervention studies.

Interaction of diet and gut microbiome in Asians and its effect on their health

Jiro Nakayama[1], Riko Mishima[1], Akari Shinoda[1], Endang Sutriswati Rahayu[2], Massalin Nakphaichit[3], Shirchin Demberel[4], Lesilie Michelle Dalmacio[5], Yuan-Kun Lee[6]

1. Kyushu University (Japan), 2. Universitas Gadjah Mada (Indonesia), 3. Kasetsart University (Thailand), 4. Mongolian University of Life Sciences (Mongolia), 5. University of the Philippines Manila (Philippines), 6. National University of Singapore (Singapore)

Forty trillions of bacterial cells consisting of more than a hundred species of microbes inhabit digestive tract of human being. This microbial community called “gut microbiota” utilizes unabsorbed nutrients from consumed diets in the colon and affects host health through fermentative production of a variety of metabolites. Therefore, gut microbiota can be considered hidden organ and attracts much interest in medical and food sciences. Notably, we have attracted interest in gut microbiota of Asian people with plenty of dietary cultures and established international consortium called “Asian Microbiome Project (AMP)” to collect and share the information about the link among diets, gut microbiome, and health in each population. Thus far, we have conducted four phases study. In Phase I, we investigated gut microbiome of school-age children of five countries as a pilot study. In Phase II, we built up basal database of gut microbiota of Asian people covering from newborns to elderlies. In Phase III, we looked into the interaction of foods and gut microbiota in more depth in certain areas, namely Leyte Island in Philippines and Bangkok and Buriram in Thailand. In Phase IV, we focused on the association of gut microbiome with lifestyle diseases, particularly obesity and type 2 diabetes. As a result, we have gained insights in the following six points. (1) There are two types of gut microbiome in Asians. (2) The gut microbiome mirrors dietary habits in each country. (3) Among Asians, Japanese have unique gut microbiome structure such as prominently high abundance of Bifidobacterium. (4) In developing area, structure and function of gut microbiome are being changed under the modernization of diets. Notably, loss of classical type of dietary habit mainly consisting of crops and vegetables decreases fermentative production of short chain fatty acids which have indispensable role to maintain host metabolic and energy homeostasis. (5) In Japanese study, we found that high consumption of fat and alcohol induces dysbiosis. (6) Asian traditional foods contain ingredients having capabilities of conditioning of gut microbiome. Taken together, although Asian microbiome reflects goodness of Asian traditional foods, the fact that the introduction of modern diets have started remodeling Asian gut microbiome warrants retrospective studies to close up benefits of Asian traditional foods.

Characterizing the diets consumed by Japanese based on various dietary variables: Are Japanese diets really healthy?

Kentaro Murakami[1]

1. The University of Tokyo (Japan)

Japan is not only one of the world's top countries in terms of longevity, but is also considered to have eating habits that differ greatly from those of Western countries. For this reason, there is a great deal of interest from around the world in the food and eating habits of the Japanese people. However, there are surprisingly few studies that have scientifically and quantitatively measured, evaluated, and compared Japanese eating habits with those of Western people, and how healthy their food and eating habits are, without common sense and preconceptions. Here, the author shows several recent studies that examined the characteristics of the Japanese diet. There is a trend analysis in dietary patterns based on the Japanese National Health and Nutrition Survey 2003-2015. Using repeated, independent cross-sectional designs, dietary intake was assessed by using a 1-d weighed dietary record in 88527 Japanese adults. Using principal component analysis based on the daily consumption of 31 food groups, three dietary patterns were identified: “plant food and fish”, “bread and dairy”, and “animal food and oil” patterns. In the whole sample, the “plant food and fish” pattern score decreased while the “bread and dairy” and “animal food and oil” pattern scores increased. These results suggest continuous Westernization of the Japanese diet. In another analysis based on the Japanese National Health and Nutrition Survey dataset and the US National Health and Nutrition Examination Survey dataset, the quality of overall diet was compared between Japanese and Americans. The overall diet quality was assessed by using Healthy Eating Index-2015 (HEI-2015) and Nutrient-Rich Food Index 9.3 (NRF9.3). The mean total scores of HEI-2015 and NRF9.3 were similar between Japanese and American adults, respectively). However, component scores between the two populations were considerably different. For HEI-2015, Japanese had higher scores for whole fruits, total vegetables, green and beans, total protein foods, seafood and plant proteins, fatty acids, added sugars, and saturated fats, but lower scores for total fruits, whole grains, dairy, refined grains, and sodium. For NRF9.3, the intakes of vitamin C, vitamin D, potassium, added sugars, and saturated fats were more favorable in Japanese, while those of dietary fiber, vitamin A, calcium, iron, magnesium, and sodium were less favorable. Taken together, it appears that although it is widely perceived that the diet consumed by the Japanese population is healthy, recent evidence suggests that the overall diet quality in Japanese adults is far from optimal and that there are different nutritional concerns between Japan and Western countries.

Conflict of Interest Disclosure: Dr. Kentaro Murakami is an Assistant Professor in the Department of Social and Preventive Epidemiology, School of Public Health, University of Tokyo. He is a nutritional epidemiologist whose research interests include validation of dietary assessment methods, assessment of dietary patterns, eating behaviors, and dietary quality, and identification of determinants of healthy and unhealthy eating behaviors.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

After graduating from Hokkaido University (Faculty of Education), Dr. Murakami received his M.S. and Ph.D. degrees in Food Science and Nutritional Science from the University of Shizuoka, Japan. After post-doctoral training at the University of Ulster in Northern Ireland, he moved to Tokyo in 2016. He has published over 150 research papers and serves on the editorial board of several scientific journals, including as a Deputy Editor of the British Journal of Nutrition.

Cognitive health benefits by bioactive compounds in traditional Japanese foods

Shigeru Katayama[1]

1. Shinshu University (Japan)

Some evidence suggests that characteristic Japanese foods and/or a particular Japanese diet can prevent lifestyle-related diseases. A typical Japanese diet consists of rice, which is the staple food, and fish or soybeans, which is the common protein sources. The protein sources from fish and soybeans are generally effective in the prevention of lifestyle-related disease. With the increase in the aging population worldwide, cognitive impairment has emerged as a significant problem affecting elderly people. There has been increasing interest in food-derived bioactive compounds with potential neuroprotective and brain health benefits, including the prevention of cognitive impairment and dementia. Because initial cognition decline is believed to result from dysfunctional synaptic plasticity, the induction of neuroprotective proteins (including neurotrophic factors, protein chaperones, and antioxidant enzymes) by dietary bioactive compounds appear to contribute towards the prevention of age-related cognition decline. Some bioactive food components have been demonstrated to potentially prevent the age-related cognitive decline in different animal models.

Senescence-accelerated mouse (SAM) strains were established as a model of accelerated aging, and SAM prone 8 (SAMP8) spontaneously exhibits age-related behavioral disorders, including shortened life span and cognitive impairment. Our studies using SAMP8 mice have indicated that prolonged intake of a diet supplemented with soybean peptide and soymilk residue (okara) suppressed age-related cognitive decline compared to that in the controls. In both groups, significant upregulation of brain-derived neurotrophic factor (BDNF) expression via activation of CREB transcription was observed in the brain. Similar results were obtained when fermented soybean (natto) was orally administered to SAMP8 mice. Another study examined the effects of rice, wheat, and buckwheat flour intake on cognitive decline in SAMP8 mice. The mice administered with buckwheat flour showed improved cognitive function compared to those administered with rice and wheat flours. Oral administration of laboratory-isolated buckwheat starch also improved cognitive function as well as BDNF upregulation in SAMP8 mice, suggesting the importance of starch in buckwheat. Furthermore, the buckwheat flour resulted in a significant change in the gut microbiota. This presentation will focus on the beneficial brain health effects of these bioactive compounds in the SAMP8 mouse model and their underlying mechanisms.

Child poverty, dietary intake and health in Japan

Aya Abe[1]

1. Tokyo Metropolitan University (Japan)

Even before the COVID-19 epidemic struck Japan in 2020, Japan's child poverty rate was 13.5% using the OECD definition of 50% of median equivalized household income as the poverty threshold. Child poverty is a social issue that plagues Japan just as in other developed countries. However, studies investigating the association between poor nutritious intake and economic poverty using data on Japanese children are fairly new and have just begun to be reported in recent years. The economic strain affects nutrition intake of children in a myriad of pathways including financial constraints in purchasing food, time constraints and physical and psychological well-being of parents, time constraints of children themselves due to part-time jobs and household chores, and lack of information and skill in preparing nutritious meals. Yet, there has not been much studies investigating what are mediating factors which connect the economic strain and children's dietary well-being. In this presentation, an overview of recent studies which have looked into the mediating factors that affect the dietary well-being of children from poor households in Japan. Then based on these new evidences, it will review Japan's policies to combat child poverty and discuss its adequacy. It then explores policy options for improving the dietary well-being of poor children in Japan.

Triple Burden of Malnutrition among settled populations and Syrian and Palestinian refugees in Jordan

Masako Horino[1, 2], Rawhieh Barham[3], Akihiro Seita[2], Keith P West[1]

1. Center for Human Nutrition and Sight & Life Global Nutrition

Research Institute, Johns Hopkins Bloomberg School of Public Health (USA), 2. United Nations Relief and Works Agency for Palestine Refugees in the Near East (Jordan), 3. Jordanian Ministry of Health (Jordan)

Background and objectives: Micronutrient deficiencies, stunting, undernutrition and overweight-to-obesity represent public health concerns in Jordan. A "triple burden," characterized by these coexisting aspects of malnutrition, may especially affect health of refugees dealing with economic, civil and food insecurities[1], likely exacerbated by the COVID-19 pandemic. This review landscapes nutritional burdens across the mix of settled (permanent) and refugee populations of Jordan that may help guide national nutrition policies and in other Middle Eastern countries hosting refugee communities.

Methods: We assimilated evidence from a 2019 National Micronutrient Survey[2], a 2021 UN Relief and Works Agency (UNWRA) survey of Palestinian refugee pregnant women[3] and available clinic-based and published reports[4-8] of dietary inadequacy, food insecurity (by Arab Family Food Security Score[9]), serum micronutrient and blood Hb levels below conventional cut-offs, and indicators of overweight (2<BMI-for-age z-score<3 for adolescents, 25≦BMI<30 for adults) and obesity (BMI-for-age z-score>3 for adolescents, BMI≧30 for adults). Nutrition-specific programs and policies addressing these concerns were reviewed.

Results: In 2019, preschool prevalence of iron (ferritin <12μg/L), zinc (<57 μg/dL and 65 μg/dL for morning and afternoon non-fasting) and vitamins A (<0.7 μg mol/L) and D (<12 ng/ml) deficiencies were 26%, 12%, 8% and 28% among settled residents, and 36%, 13%, 9% and 10% among encamped Syrian refugees[2]; school-aged rates of iron, zinc and vitamins A, B^{12} (<150 pmol/L) and D deficiencies were 31%, 4%, 7%, and 44% among settled Jordanians and 35%, 9%, 7%, 2% and 16% among encamped Syrian refugees[2]; and, non-pregnant women rates of iron, vitamins A, B^{12}, and D deficiencies were 66%, 3%, 19% and 64%, and 68, 3%, 12% and 56%, among settled Jordanians and encamped Syrian refugees, respectively[2]. Anemia was higher among school-aged (11%) and non-pregnant women (36%) in encamped Syrian refugees than settled Jordanians (6% and 24%)[2]. Among clinic-attending Palestinian refugees in 2020, anemia affected 40% of infants, and 24% and 44% of pregnant women in the 1st and 2nd-to-3rd trimesters[4]. Among settled Jordanians and Syrian refugees, stunting affected 7% and 14% of preschoolers while overweight-to-obese rates were 12%-to-16% and 16%-to-6% of school-aged children and 29%-to-30% and 29%-to-40% of non-pregnant women, respectively[2]. Among Palestinian refugees, 23%-to-52% of women were overweight-to-obese, while among households of pregnant women, 35% were moderately (score: 3-5) and 20% severely (score: 6-7) food insecure[3]. Antenatal multiple micronutrient supplementation, guided by implementation research, is planned to start in Palestinian camps in 2022-23 and nationally thereafter[5, 6]. Policy initiatives exist to improve dietary quality, encourage physical activity, regulate unhealthy food marketing, and strengthen nutritional labeling[7]. National vitamin A supplementation program is offered to preschoolers[7]. Ongoing wheat flour fortification with iron, folic acid, zinc, vitamins A, D and several B-vitamins is being evaluated for coverage and effectiveness[7, 8].

Conclusions: Triple burden of malnutrition, across Jordanian populations, is being addressed with increased coordination and evaluation.

Keywords: triple burden of malnutrition, micronutrient deficiency, anemia, food insecurity

Food support and nutrition management programs for reducing health disparity in Korean children

Yoonna Lee[1]

1. Shingu College (Korea)

South Korea is one of the fastest aging and lowest fertility rate societies, which increased the necessity of developing various programs and policies to ensure sustainability of Korean society. The increasing needs include not only the policies to increase fertility rate, but also the programs and policies to improve the nutritional status of Koreans, especially of infants and young children. NutriPlus program was developed by Ministry of Health and welfare and Korea Health Industry Development Institute, benchmarking the WIC program of U.S. NutriPlus program is a nutrition support program for pregnant & breastfeeding women, infants and young children. Since 2001 Korean National Health and Nutrition Examination Survey data showed that young children of low socio-economic class are vulnerable to malnutrition, the eligibility criteria included household income, age, pregnancy/breastfeeding status, and nutrition risk factors such as anemia, stunting, underweight, and inadequate food & nutrient intake. The program was designed to provide nutrition education and food packages to improve health and nutritional status of the participants. The results of 3-year pilot study from 2005 to 2007 and the nationwide program data since 2008 revealed that the program has been effective in reducing nutritional risk factors of the participants. Although NutriPlus program has been implemented successfully to support nutritionally vulnerable individuals and households, there have also been growing demands for policies to ensure a healthy & safe foodservice in child-care facilities. Under the Article 21 of the 'Special Act on the Safety Control of Children's Dietary Life', the Center for Children's Foodservice Management (CCFSM) has been established by the Ministry of Food and Drug Safety to improve the quality of foodservice in child-care facilities. As of July 2022, CCFSM is run in 234 cities and towns, providing service for foodservice hygiene control, nutritious menu & recipes, and nutrition education for children, cooks, directors, teachers, and parents and to build healthy eating

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

habits and systematic foodservice management. NutriPlus program and CCFSM have been evaluated as good policy models for reducing health disparity and improving nutritional status of children. However, since the health risk factors of children are changing, continuous research is needed to improve the programs and policies.

Problem nutrients in the diet of under-five children in stunting priority areas in Indonesia with different food security conditions

Umi Fahmida[1], Indriya Laras Pramesthi[1], Sari Kusuma[1], Arienta Rahmania Putri Sudibya[1], Rahmawati Rahmawati[1], Dini Suciyanti[1], Gusnedi Gusnedi[1, 2], Aly Diana[1, 3]

1. SEAMEO RECFON Universitas Indonesia, Jakarta (Indonesia), 2. Department of Nutrition, Health Polytechnic of Padang, Padang (Indonesia), 3. Department of Public Health, Faculty of Medicine, Universitas Padjadjaran, Bandung (Indonesia)

Background and objectives: Given the diversity of dietary patterns and district food security in Indonesia, it is important to identify problem nutrients (PNs) and local-specific food-based recommendations (FBRs) to strengthen infant and young child feeding programs for stunting reduction. This study aims to identify PNs in the diet of under-five children in selected 37 stunting priority districts in Indonesia and assess whether the number of PNs was associated with district food security status.

Methods: Linear programming analysis (LP) using Optifood was used to analyze dietary data collected using a single 24-hour dietary recall in the Food Consumption Survey 2016 conducted by the Ministry of Health, Indonesia. PN was defined as a nutrient that did not meet 100% Recommended Nutrient Intake (RNI) based on Indonesian-RNI in the 2-best-diets scenario. PNs were further classified based on %RNI in the best-case scenario as either absolute (<100%RNI) or partial (≧100%RNI). District food security status was classified based on Food Security Vulnerability Atlas (FSVA) 2018 as either food insecure (score 1-3) or food secure (score 4-6). Districts were categorized as having high numbers of PNs if there were a total of six or more PNs in the four age groups.

Results: The top-3 PNs by age group were: iron, folate, vitamin B12 (6-11mo); folate, calcium, zinc (12-23mo); folate, calcium, vitamin C (24-35mo); and calcium, folate, vitamin C (36-59mo). There were no significant differences in the number of PNs based on district food security status. Out of the 37 districts, only six districts (16%) were categorized as food insecure. Based on combined categories, 15 districts (41%) were food secure and had low PNs, 16 (43%) were food secure but had high PNs, 2 (5%) were food insecure with low PNs, and 4 (11%) were food insecure with high PNs. PNs were mostly absolute problem nutrients, suggesting that the food baskets of the children were lacking nutrient-dense foods despite the food availability in the area.

Conclusions: PNs varied by age group but there was no significant association between district food security status and the number of PNs. Our findings suggest the importance of promoting local-specific FBRs compatible with PNs in different age groups and using the FBRs as a reference for local food production of nutrient-dense foods, both in food insecure and food secure areas.

Keywords: food-based recommendations, food security, linear programming, problem nutrients, under-five children

SY(T5)3-1

The International Breakfast Research Initiative: Development of nutrient recommendations for breakfast for Europe and North America

Michael J Gibney[1]

1. University College Dublin (Ireland)

Background and objectives: Breakfast is regarded as an important meal and one that is subject to nutritional guidelines to assist governmental institutions, such as schools, to set targets to optimise nutrient intakes at breakfast. To date, no systematic global analysis of actual eating habits at breakfast has been completed that would guide policy makers in devising nutritional standards for breakfast. The present project set out to obtain and interpret such data. The project also explored the cultural variation in the meaning of breakfast in different regions of Asia

Methods: To date, 18 countries have participated in the International Breakfast Research Initiative ((IBRI) covering North and South America, Europe, and Asia. Each centre used their national food consumption database to examine nutrient intakes at breakfast among those at the highest tertile of the nutrient rich food index for overall daily nutrient intake. The proposed ideal nutrient standards for breakfast were based on 20% of the Codex Alimentarius reference nutrient intake for nutritional labelling. In the case of total fat, saturated fat, sodium and added sugars, WHO guidelines were used.

Results: In general, breakfast was found to provide around 20% of total daily energy intake but that figure did not apply to micronutrients where breakfast was rich in many B-vitamins but provided less than 20% of the daily intake of several micronutrients and fibre. Where nutrient intakes at breakfast were below the target levels, a series of principle to set new goals was established. Linear programming software was developed to improve food choice for an optimal nutrient intake at breakfast among those with the lowest overall daily nutrient intake.

Conclusions: The IBRI project has identified methods to optimise nutrient intake at breakfast. These can be applied at national level and, in some instances where the cultural norms of breakfast are similar (e.g. USA and Canada), such findings could be applied at the regional level.

Proposed nutrient recommendations for breakfast in Latin America

Regina Fisberg [4], Agatha Nogueira Previdelli[2], Iona Zalcman Zimberg[3], Jacqueline Lopez Pereira[4], Irina Kovalskys[1], Georgina Gomez[5], Lilia Cortez Sanabria[6], Marta Yepez Garcia[7], Marianella Herrera Cuenca[8], Mauro Fisberg[3]

1. Pontificia Universidad Católica Argentina (Argentine), 2. Universidade São Judas Tadeu (Brazil), 3. Universidade Federal de São Paulo (Brazil), 4. Faculdade de Saúde Púbica. Universidade de São Paulo (Brazil), 5. Universidad de Costa Rica. (Costa Rica), 6. Pontificia Universidad Javeriana. (Colombia), 7. Universidad San Francisco de Quito. (Ecuador), 8. Universidad Central de Venezuela (CENDES-UCV)/Fundación Bengoa. (Venezuela)

Introduction: Several studies have reported a wide variation in the contribution of breakfast to nutrients intake and diet quality in various parts of the world, however data on the Latin American composition of breakfast are scarce.

Objectives: To provide updated data on the breakfast nutritional composition and its contribution to daily intakes among the Latin American population. Also to evaluate the nutritional composition of breakfast in the LA population and propose recommendations for a balanced breakfast.

Methods: 8,714 subjects from 15-65 years old were evaluated in the ELANS study, a multicenter cross-sectional survey conducted in eight Latin American countries (Argentina, Brazil, Chile, Colombia, Costa Rica, Ecuador, Peru, and Venezuela). Dietary data were obtained by two 24-hour dietary recalls. The total intakes and proportion of daily energy and nutrients from breakfast were calculated. Comparison of food and nutrient intake of breakfast across NRF9.3 tertiles were analyzed using the Kruskal-Wallis rank sum test.

Results: On average, ELANS sample consumed 444kcal at breakfast, which accounted for 23% of the total daily EI (ranging 16–27%). The contribution of breakfast to mean daily intakes ranged from >30% of total added sugar, riboflavin and calcium; 20-30% of total protein, carbohydrates, fat, saturated fat, fiber, sodium, vitamins A, D, thiamin, niacin, vitamin B12, iron, potassium, magnesium and zinc; and <20% of total vitamins B6 and C. Individuals in the upper NRF9.3 tertile had, at breakfast, higher intake of key micronutrients such as calcium and potassium and higher intakes of energy, protein, carbohydrates, polyunsaturated fatty acids, fiber, vitamins A, C, and from complex B., and lower intake of added sugar and sodium compared with other tertiles.

Conclusions: Breakfast contributed to the daily intake of B vitamins, protein, and carbohydrates but also added sugar and total and saturated fat intakes for all countries. The proposed recommendations support the nutrient density of existing highest-quality breakfast in the LA population while addressing concerns about nutrients to be encouraged or reduced.

Keywords: Breakfast, Nutrient recommendations, Latin America

Conflict of Interest Disclosure The International Breakfast Research Initiative and this workshop were funded by Cereal Partner Worldwide (Latinamerican and European Studies) and General Mills, INC. (Canadian and United States studies). All the authors have no conflicts of interest to declare. None of the entities mentioned had or have any role in the design or preparation of this workshop.

SY(T5)3-3

What will we have for breakfast? Ethno-nutritional perspective of the first meal of the day

Jean-Pierre Poulain[1], Elise Mognard[1]

1. Taylor's University (Malaysia)

Background and objectives: Breakfast, as the first meal of the day, varies considerably over time and space. Within the same culture, it changes over time, in terms of content, timing, form of socialization. It differs also regarding the position of the eater in the social hierarchy. Between cultures, it varies in the same ways but with even greater amplitudes. The experience of a breakfast buffet in an international hotel offers a concrete vision of this diversity. What differences between the Anglo-Saxon breakfast with eggs, bacon, fried potatoes, toast, tea... and the French breakfast with coffee, bread, butter, jam; between the Indian breakfast with roti chanay, dalls... masala puris, upuma, idlis and dosas... and the Chinese breakfast based on Congee (Steamed stuffed buns), Wontons, Guilin rice noodles…

Methods: The presentation will be based on a review of the food anthropological literature in order to conduct a comparative analyze. The focus will be put on the diversity of food, of patterns of intake and of importance in the food system.

Results: Adopting an anthropological perspective allows us to place breakfasts in the frame of the concrete food cultures of a social group. That means into the social representations of food and into the meal's patterns, including the organization of the food day (how many food intakes a day and what are their relative weights). We will therefore avoid ethnocentrism that for example considers as universal a food day to be composed of breakfast, lunch, dinner. Some social contexts have two meals a day and some other more than three. However, the globalization of the food market and the dissemination of the nutritional knowledge can promote the Anglo-Saxon breakfast.

Conclusion: This ethno-nutritional perspective invites public health actors to be careful with the "clandestine passenger" of their scientific discourse that could be the food cultures of the western countries. Starting the presentation with the word

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

"breakfast", the reading grill will move to idea of first meal of the day.

A study of breakfast patterns in Indonesia, Malaysia and Philippines

Imelda Angeles-Agdeppa[5], Elise Mognard[1], Yasmine Alen[1,2], Ismail Mohd Noor[3], Helda Khusun[4], Judhiastuty Februhartanty[4], Roselynne Anggraini[4], Jean-Pierre Poulain[1,2] , Maria Rosel Custodio[5], Marvin Toledo[5]

1. Taylor's University (Malaysia), 2. Toulouse University (France), 3. Universiti Kebangsaan (Malaysia), 4. Universitas Muhammadiyah Prof. Dr. Hamka (Indonesia), 5. Food and Nutrition Research Institute (Philippines)

Background and objectives: This research takes place in the frame of the **International Breakfast Research Initiative (IBRI)** which aims to develop breakfast nutrient guidelines to take in account both breakfast and daily nutrient intakes and the association between the two. As the nature of food and the organisation of this meal itself are strongly determined by cultures, nutrient recommendations for breakfast have to be translated into practical advice, whether for individuals or health professionals.

Methods: The project involved harmonised analyses from three national nutrition databases in Indonesia, (Indonesian Food Barometer), in Malaysia (Malaysian Food Barometer) and in the Philippines (National Nutrition Survey). Total daily nutrient intakes were scored using the Nutrient Rich Food Index, adapted to the policy needs of each country. The top tertile of such total daily nutrient intakes were used to examine the contribution of breakfast to nutrient intake.

Results: Nutrient intakes at breakfast in the top NRF tertile were compared to the standard value of 20% of nutrient intakes derived from breakfast. Based on these data, recommendations for the improvement of nutrient intake were developed in each country.

Conclusion: Each of the participating countries can offer more informed advice on breakfast to national policy makers and when considered together, can help elucidate guiding principles on the formulation of advice on optimal nutrient intakes at breakfast.

SY(T5)3-5

Translating nutrient recommendations for breakfast into practical advice for individuals and health professionals

Katarzyna Janiszewska[1], Matthieu Maillot[2], Ángela García González[3,1], Elisabeth Farmer[4,1]

1. The European Federation of the Associations of Dietitians (Netherlands), 2. MS Nutrition (France), 3. Universidad CEU-San Pablo (Spain), 4. Fachhochschule Gesundheitsberufe Oberösterreich (Austria)

Background and objectives: The derivation of breakfast recommendations on nutrient intake and their translation into culturally tailored food-based dietary advice can help dietitians to develop better public health nutrition strategies to optimize food choices at breakfast. The International Breakfast Research Initiative (IBRI) consortium developed evidence-based nutrient recommendations for a balanced breakfast that could be applied by a variety of end users including policymakers, healthcare professionals and consumers. The objective of this project is to develop tools to translate the IBRI nutrient recommendations for breakfast into practical advice for individuals and to support dietitians in patient education.

Methods: Two research groups based in Austria and Spain will conduct the study. As a first step, an algorithm will be developed to condense 20 nutrient targets from the IBRI Europe and North America recommendations to a single continuous score from 1-100 that could easily be incorporated into a digital tool. French food consumption data from INCA 3 survey will be used to validate the score through analyses of correlations between the proposed score and energy content and energy density of breakfast and overall diet quality. Focus groups will be organised with dietitians and people from the community to identify key features and functionalities required for a digital educational tool for breakfast. Local food consumption surveys will be reviewed to identify the most common food groups consumed at breakfast.

Results: A digital toolkit will be developed and tailored to meet the needs of dietitians to educate patients on the importance of breakfast and how to choose a balanced breakfast. A second intuitive digital tool, based on the breakfast score will aim to educate individuals who don't have access to a dietitian. A pilot study will be conducted with dietitians and people in the community to understand the user-friendliness and practicality of the tools.

Conclusion: This study will explore whether IBRI recommendations can be applied as an evidence base for practical educational tools and campaigns to educate individuals and patients on how to choose a balanced breakfast. We also aim to investigate if the toolkit can be readily adapted to different countries by importing national food composition data and applying the IBRI targets to national dietary reference values.

Creating a Sustainable Food Future

Janet Ranganathan[1]

1. The World Resources Institute (USA)

Global human population is projected to increase to around 10 billion by 2050 —about 3 billion more mouths to feed than there were in 2010. As incomes rise, people will increasingly consume more resource-intensive, animal-based foods. At the same time, we urgently need to cut greenhouse gas (GHG) emissions from agricultural production and stop conversion of remaining forests to agricultural land. To sustainably feed a population of 10 billion, requires closing three gaps:

1. A 56 percent food gap between crop calories produced in 2010 and those needed in 2050 under "business as usual" growth;

2. A 593 million-hectare land gap (an area nearly twice the size of India) between global agricultural land area in 2010 and expected agricultural expansion by 2050; and

3. An 11-gigaton GHG mitigation gap between expected agricultural emissions in 2050 and the target level needed to hold global warming below 2oC (3.6°F), the level necessary for preventing the worst climate impacts., worldwide food availability will need to increase by at least 70 percent (FAO 2009).

The presentation will begin with an overview of the three gaps. It will then outline a five-course menu to address these 3 gaps: (1) reduce growth in demand for food and other agricultural products; (2) increase food production without expanding agricultural land; (3) protect and restore natural ecosystems; (4) increase fish supply; and (5) reduce GHG emissions from agricultural production. The presentation will draw on real-world examples of how World Resources Institute and others are putting into practice the five-course menu.

Balancing nutritional adequacy and environmental sustainability: what do we learn from modeling studies?

Frans Kok[1]

1. Wageningen University (Netherlands)

Food systems are major drivers of greenhouse gas (GHG) emissions, water, land use, eutrophication (N, P), and biodiversity. Some supply chains are short, others are long, reaching across the globe. The EAT-Lancet commission provided a picture of healthy and sustainable diets for large global regions. However, the evidence base is still scarce on what this means on national and local level, as well as how this translates to consumers and their food choices. Thus, food categories need to be evaluated regarding health-environment-culture-cost trade-offs. Animal products such as meat, especially beef, and dairy have a higher environmental burden than most plant products. For estimating the impact, it is important to differentiate in the type of meat (beef, pork, chicken) and dairy (milk, cheese, yogurt). Moreover, dietary change towards more sustainable diets, should fulfil nutritional requirements, be cultural and socially acceptable, and affordable. Key nutrients that require attention in more plant-based diets (flexitarians, pescatarians, vegetarians, and vegans) and affluent western diets are calcium, iodine, vitamin B12, omega-3 fatty acids, zinc, and iron. However, diets in low and middle income countries would benefit from more (micro) nutrient and protein dense foods from animal sources. Therefore, trade-offs for inclusion of foods in healthy and sustainable diets will differ between western and non-western countries. To evaluate to what extent food categories can be part of sustainable diets, observational and scenario-based approaches, and modeling/optimization strategies have been used. Results indicate that dairy has a moderate impact on sustainability: an emerging rank order is beef, other meat (chicken, pork), (hard) cheese, milk, plant products. Daily intake of 1-2 servings of dairy may fit in sustainable and healthy diets. Yogurt and milk are of special interest, because of their nutrient richness and low fat content, but more studies are necessary to quantify their impact. Sustainable diets can be composed in different ways. Ideally, current local dietary habits and eating cultures should be the basis for change. In future analyses, we need to increase the evidence base beyond summaries of national case studies by using optimization approaches with individual data on dietary intake. Most probably, convergence guidelines which recommend a reduction and substitution rather than elimination approach may be more effective in increasing dietary transition rates for planetary health.

Family-based interventions to promote sustainable healthy diets

Jess Haines[1]

1. University of Guelph (Canada)

Objective: Identifying effective strategies to promote environmentally sustainable and healthy diets is a critical component of creating sustainable food systems. The objective of this presentation is to describe the development, implementation and evaluation of family-based interventions designed to promote sustainable healthy diets.

Methods: Formative assessment with both parents and children were conducted to identify feasible and contextually-relevant intervention strategies to increase intake of plant-based proteins and reduce household food waste. These results informed the development and pilot testing of family-based interventions focused on the promotion of sustainable healthy eating.

Results & Discussion: Findings from pilot studies among families with children aged 9-12 years suggest our intervention strategies are well accepted by families and may increase intake of plant-based protein foods and reduce level of household food waste. Key learnings and next steps regarding approaches to promote sustainable healthy diets will be discussed.

Keywords: food waste, plant-based protein, family, intervention

SY(T5)5-01

Ideal Models for Mutually reinforcing policies to create a Healthier Diets and Reduce Ultra-processed food consumption

Barry Michael Popkin[1]

1. University of North Carolina at Chapel Hill Gillings School of Global Public Health (USA)

The push to reduce nutrition-related noncommunicable diseases (NCDs) focused on policies to address our diets. The most successful efforts globally have focused on attempt to reduce ultra-processed foods and beverages (UPFs) high in added sugar, added unhealthy saturated fats, added sodium, and usually refined carbohydrates (HFSS foods). Fiscal policies, more specifically taxes, front-of-the-package food labels (FOPLs}, marketing controls, and school feeding have been the common targets.

In the Nutrition Transition's latest phase, we are seeing increasing consumption of UPFs, These are the unhealthiest proportion of our diet and linked with large increased risk of nutrition-related NCDs and mortality. While most high-income countries are already dominated by consumption of these UPFs, increasing consumption is found in low- and middle-income countries.

While many countries have instituted taxation, mainly on sugar-sweetened beverages (SSBs) mainly though several countries have successfully implemented junk food taxes. No one to date has instituted a broader tax on HFSS foods and beverages though we expect to see such taxes within the next few years.

Also, an increasing number of countries have adopted the only front-of-the-package label (FOPL) system shown to impact food purchases in a large way by reducing intake of the unhealthiest UPFs, the warning label.

It is when we see a combination of these policies created around a common nutrient profile model to identify the unhealthiest UPFs that we see the largest effect. Ideally, we would like to see a warning label on these UPFs combined with not only a strong marketing ban and school food ban for these same UPFs but also a tax on them. Then we have the full constellation of mutually reinforcing laws. And, if the tax revenue is used to promote healthier diets or public health, then their impact would be further enhanced.

Chile and Israel are the two countries which have introduced a wide range of policies. Chile's approach is ideal as all the marketing ban, FOPL warning label, and school bans use the same warning label with its strong cutoffs to identify the unhealthiest UPFs. Israel's policies are comparable, but they are not linked in the same way. We focus on Chile's law and early revaluations of impact.

We then speak of an addition regulation Israel has added, a focus on truly healthy foods that are minimally processed. This component needs to be evaluated as results of other positive logo's have not been shown to be impactful; however, this logos comes with the earlier warning label on other foods and they should work together.

We are still at a very early period in understanding which regulations work, how impactful are they, and what impacts do these make on food purchases and ultimately our diets and health. Reducing ultra-processed food consumption promises to have large impacts on NCD's but these and any changes in child obesity will take time to see. Furthermore, we must begin to develop subsidies linked with the taxes so we can reduce the prices of quality foods such as legumes, fruits, and vegetables for lower income households.

SY(T5)5-2

Identifying policy priorities for equitable and healthy food environments: a people-centred approach

Corinna Hawkes[1]

1. City, University of London (UK)

Successfully intervening to improve diets is not easy. Evidence, including from studies of people's "lived experience" of food, shows diets are shaped by people's daily realities, which in turn are shaped by underlying systems. These realities include financial insecurity resulting from inequitable economic and livelihood systems, unhealthy food environments rooted in commercially-driven food systems, gender norms influenced by social systems, and deeply-embedded "meanings" of food emerging from cultural systems. These realities combine in people's daily lives to drive populations towards foods that do little to support health or sustainability and away from foods that do.

These realities also shape the ability of policies and actions to have impact on improving diets. Yet efforts to address the problem often fail to consider the full picture of people's realities, so undermining their ability to achieve impact. Given the realities of more marginalised groups are far more challenging, this is particularly problematic for tackling inequalities.

In this context, this presentation will present a tool that enables policymakers, practitioners and researchers to consider the full picture of people's realities relevant to identifying, designing and evaluating policies, programmes and interventions to achieve healthy diets for all. It aims to increase the likelihood of equitable impact by facilitating the selection of portfolio of actions designed and tailored to context and population. Clarifying what the realities are also provides an empathetic space for policymakers and practitioners to gain a deeper understanding of the realities of the people they serve. To address these realities, the tool also indicates who is needed to provide what solutions.

Salt Reduction Strategies in Thailand

Surasak Kantachuvesiri[1]

1. Ramathibodi Hospital, Mahidol University (Thailand)

Evidence has shown that salt (sodium) intake in our population is twice as high as the optimal recommended amount. Sodium intake reduction is one of the best-buy policies recommended by WHO for the prevention of non-communicable diseases especially hypertension, cardiovascular disease, cerebrovascular accident (CVA), and *chronic kidney disease*. High sodium content in packaged food and street food is commonly found in Thailand. This project on reducing sodium intake in Thailand was carried out by the Thai low salt network which was supported by the Thai Health Promotion, Faculty of Medicine, Ramathibodi hospital, Mahidol University, Ministry of Public Health, and the Nephrology Society of Thailand with a goal of 30% reduction in sodium intake among the Thai population by 2025. This project has been successful in many aspects. Project achievements include: 1) In 2015, the 8th National Health Assembly adopted a strategic policy for reducing sodium intake. This led to the implementation of a national strategy for salt reduction by many stakeholders including the ministry of public health, the ministry of education, and public relations agencies 2) Development of a simple salt meter for measuring sodium content in a food sample. Its application enabled people to reduce salt intake and thus reduce blood pressure. 3) Creation of a sodium database of common food consumed in the Thai population and conduction of a national sodium intake survey by measuring 24-hour urinary sodium excretion which revealed the average sodium consumption in a Thai of 3,636 mg/day. 4) Food reformulation in popular dishes by nutritionists and celebrity chefs. Regarding packaged food, a voluntary target of salt reduction was set in conjunction with the Thai FDA and food industry 4 years ago. Since then, with monitoring of sodium content in food and snacks, little progress has been made in the reduction of their salt content. As a result, policies of maximum sodium limit, regulation of their advertisement, and tax measures on high sodium products are in development and undergoing discussions with the food industry. Furthermore, environmental reforms in hospitals, schools, workplaces, and communities to favor a healthy diet were carried out in many parts of Thailand. 5) Food labeling project in collaboration with the Institute of Nutrition, Mahidol University, and the food and drug administration (FDA) including monochrome GDA, and a "healthier" logo was implemented. An interpretative labeling system including traffic lights system and warning signs have also been proposed to the FDA. 6. Using mass and social media as a method of raising public awareness was successful in drawing public interest, resulting in much increased demand of low-sodium condiments, food delivery, and packaged food. These projects contribute to the success of the primary prevention of chronic diseases.

SY(T5)5-04

Creating a healthy food environment by public-private-academia collaboration in Japan

Yukari Takemi[1]

1. Kagawa Nutrition University (Japan)

Nutrition education is important to encourage people to promote healthy diet, however, education alone exerts a limited effect. It is crucial to create a healthy food environment, including food systems that supply diversified, balanced, and healthy food options.

In Japan, creating a healthy food environment has been promoted in the national health action plan named Health Japan 21 initiated in 2000.

Recently, there are movements by academic societies to support private sectors to produce and sell healthy options. The Japanese Society of Hypertension (JSH) has accredited reduced salt products since 2013. Food companies are responding to this accreditation, and approximately 270 reduced salt products with good taste, such as seasonings, numerous processed fish and meat items, pickled vegetables, noodles, and snacks, are being voluntarily developed by food industries. The total sales of these accredited products increase every year, and the market reached 45.5 billion yen in 2021. The amount of salt provided to consumers has reached 7,376 tons since 2013. There are not any mandatory reformulation schemes in Japan, but this strategy by JSH is a good practice of voluntary food reformulation to reduce salt intake.

Another example involves improving the availability of healthy options in the community. A recent certification system for “healthy meals and healthy environment” was initiated in 2018 for food retailers, restaurants, and worksite cafeterias, which continually provide well-balanced meals termed “Smart Meal”. The certification's criteria were based on dietary reference intakes and other scientific evidence. A consortium consisting of thirteen academic bodies related to nutrition and noncommunicable diseases judge and certify the retailers. At present, 547 retailers have been certified all over Japan. Local governments utilize this certification system to help local restaurants and retailers provide healthy diets. We conducted a non-randomized controlled trial to reduce salt intake in a medium sized company in Saitama prefecture using Smart meal lunch box. After 1 year intervention, significant decrease in salt intake was observed (Sakaguchi K et al. J Occup Health 2021.) Public-private-academia collaboration is critical to promote healthy food environment.

These Japanese initiatives for creating a healthy food environment will be useful information for other countries, especially for Asian countries which have similar food culture.

Critical health literacy in nutrition

Don Nutbeam[1]

1. University of Sydney (Australia)

Digital technologies have provided unprecedented access to health information, including information on food choices and nutrition. For consumers the volume of information can be overwhelming. Finding accurate, trustworthy and understandable nutrition information can be challenging for many people. This presentation highlights the importance of developing critical health literacy skills that enable consumers to distinguish between different sources of information, and to find information on food and nutrition that is understandable and useful.

Workplace Health Promotion and Health Literacy

Hiroshi Fukuda[1]

1. Juntendo University Graduate School of Medicine (Japan)

Integration of Occupational Health and Safety (OHS) and Workplace Health Promotion (WHP) aiming at employees' health and well-being attracts attention to WHO's "Healthy Workplace Framework" and NIOSH's "Total Worker Health." In Japan, the Ministry of Economy, Trade, and Industry began certifying health and productivity management brands in 2014, causing significant occupational health promotion. One of the certification criteria adopted is "improvement of health literacy,” which is expected to be an effective intervention. WHP is actively conducted in many companies under health and productivity management. However, there are few studies on the effectiveness of WHP in Japan. Therefore, we examined the impact of workplace health promotion on lifestyle and health literacy based on the practical experience of workplace health promotion by several companies and health promotion programs in the Tokyo area. We also examined the importance of dietary behavior interventions in workplace health promotion, such as company cafeterias and healthy lunch boxes. As an example of occupational health promotion, a design consultant company in Tokyo has conducted various health promotions for about 20 years. Through multiple measures such as the establishment of a health policy, field day and summer festivals, radio calisthenics with the president, healthy lunch box project, round refresh project, and health design handbook, the company has been promoting health literacy (CCHL, Ishikawa2008) and diet, exercise, and sleep indicators. The number of employees has been increasing for five consecutive years. An example of an ICT-based health promotion

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

program is the "Eat, Sleep, Walk" health literacy development project using ICT + nudge + incentive. This project was selected and subsidized by the Ministry of Health, Labour and Welfare's FY2018, and a consortium was established by 15 health insurance unions and Value HR Corporation. On the portal site accessible by PCs and smartphones, helpful content that enhanced health literacy was provided, including a daily e-mail magazine with single-frame cartoons; a daily activity record; distribution of videos on health concepts such as diet, exercise, and sleep; an online walking competition among companies; and a health cafeteria. Participant recruitment was completed in October and December 2018, and about 14,000 people participated. Evaluating lifestyle habits using a before-and-after comparison design, improvements were seen in the following areas: eating breakfast, nutritional balance, sleep duration, exercise, and several steps. In health literacy, the subscales of judgment, communication, and self-determination improved by 5–10%. This project will be continued from 2020 as "Eat, Sleep, Walk + Prevent," with the addition of content on infection prevention during the COVID-19 pandemic. Improving the health literacy of individual employees and organizations is a critical factor in workplace health promotion; we will continue to improve the program and conduct more detailed evaluations. In countries with declining birthrates and aging populations, occupational health promotion will continue to become increasingly important to ensure a healthy workforce and maintain productivity. The goal is thought to improve individual and organizational health literacy, and dietary behavior interventions may also play a role.

Health Literacy: An asset for effective nutrition education and communication for behavior change

Mary Murimi[1]

1. Texas Tech University (USA)

Background: Inadequate health literacy affects approximately 26% of the world's adult population, with a majority being the elderly, minority populations, and individuals with limited resources and or possessing less than a high school education. Health Literacy is the degree to which an individual has the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions according to the Institute of Medicine. However, studies indicate that health literacy is an independent risk factor for all-causes of mortality after adjusting for age, race, gender, income, education, health status, and other sociodemographic variables. Fortunately, convincing evidence indicate that addressing health literacy is an effective way to manage health disparities and that health literacy interventions are associated with improved clinical outcomes and health care utilization. It is therefore imperative for health care professionals to assess health literacy levels and utilize the information to develop effective interventions for the low literacy population.

The objective of this session is to discuss factors that contribute to the efficacy of health literacy interventions among adults with low literacy levels by answering the following research questions: 1) What tools are effective in assessing different domains of health literacy? 2) How do researchers and health promotion practitioners use health literacy assessment to design messages that are meeting the literacy levels of the participants? 3) What health education strategies and tools are being successful in objectively increasing knowledge, health literacy scores, and modifying behaviors?

Conclusion: Health literacy interventions among adults should utilize comprehensive baseline assessments to tailor messages to health literacy levels of the participants and employ relevant health literacy approaches such as the use of plain language and the teach back method and have a duration of at least 6 months.

Keywords: Health literacy, assessment tools, intervention approaches, intervention duration, Low literacy adults

The current situation of school meal organization and solutions to improve the quality of school meals at primary schools in Vietnam

Anh Vinh Le[1]*, Do Huy Nguyen*[2]*, Quoc Bien Ly*[1]*, Trang Nhung Nguyen*[2]*, Thu Huyen Nguyen*[1]

1. Vietnam Institute of Educational Sciences (Viet Nam), 2. National Institute of Nutrition (Viet Nam)

According to the General Education National Curriculum 2018, primary school students in Vietnam will study two sessions per day. As a consequence, the percentage of schools that provide school meals in Vietnam has increased rapidly, but there is still much concern about quality and effectiveness of school meal plan implementation. This presentation will focus on discussing the actual situation of school meals in some Vietnam primary schools. Solutions to improve the quality of school meals in Vietnam will also be discussed. This work is a part of the project carried out by a research team of the Vietnam Institute of Educational Sciences (MOET) and the Institute of Nutrition (MOH), under the support of the Ajinomoto Foundation.

Implementing Malaysia School Nutrition Promotion Programme (MySNPP) during COVID-19 pandemic

Yit-Siew Chin[3], Choon-Huey Teo[2], E-Siong Tee[1], Hwee-Teng Goh[2], Shi-Jia Koo[2], Shirley Ng[2]

1. Nutrition Society of Malaysia (Malaysia), 2. Johore Health Department (Malaysia), 3. Universiti Putra Malaysia (Malaysia)

Findings from nation-wide nutrition surveys of school-age children showed high prevalence of both over- and under-nutrition problems, with the former a much larger problem. In line with the recommendations of the National Plan of Action for Nutrition of Malaysia III (2016-2025), the Malaysia School Nutrition Promotion Programme (MySNPP) has been developed to contribute towards efforts in promoting healthy nutrition among school children. It focuses on providing nutrition knowledge as well as a supportive school canteen environment in order to bring about various beneficial effects. This presentation provides an overview of MySNPP, including its concept, main components and implementation approach. This presentation also shares experiences and learnings from its implementation in three districts in Johore, during the COVID-19 pandemic when schools were closed most of the time.

The MySNPP comprises two main components: (1) delivery of nutrition education to the children by trained teachers using the Good Nutrition Key to Healthy Children (GNKHC) educational package and (2) provision of daily healthy meal to the children by trained canteen operator during school recess. GNKHC was developed by the Southeast Asia Public Health Nutrition (SEA-PHN) Network, with simple nutrition messages adapted from the national dietary guidelines of the five partner nutrition societies in SEA. In the second component, school canteen food handlers were to be trained to prepare nutritious meals using a revised Healthy Catering Modules of the Ministry of Health and monitored by nutritionists.

With the outbreak of the COVID-19 pandemic in March 2020 in Malaysia and the prolonged duration of the disease, the original implementation plan of MySNPP had to shelved. In 2021, recognising the importance to provide nutrition education to the children during the lockdown, the GNKHC was delivered by trained nutritionists during school holiday utilising an online platform. Modifications were made to the interactive activities of the modules to suit the virtual platform. Local nutritionists from three districts in Johore implemented the 4-day online nutrition education holiday camps in seven schools, involving 34 teachers and 369 primary 3 students. Using an online form before and after attending the holiday camp, the children were found to have showed significant improvement in the knowledge, attitude and practice on nutrition ($p< 0.05$). It was also found that majority of the children, parents and teachers gave positive feedback to the programme.

The online nutrition education component of MySNPP was generally successfully implemented, with positive outcome on the children. It was challenging, but the support of school authorities, parents and children played major roles in this success. Various experiences and learning points were gained from this series of camps organised. Our team will continue to engage more schools and implement GNKHC modules during school holidays in 2022. The provision of nutritious school meals, placed on hold these past years, will be resumed once the situation permits the schools to reopen. In view of the long-term benefits of providing nutrition education to school children, along with a daily nutritious meal, we highly recommend the MySNPP to be implemented to all primary schools in the country.

Role of Foodservice Programs for Children in Korea

Jihyun Yoon[1]

1. Seoul National University (Korea)

Two major foodservice programs play a vital role in improving nutritional status and cultivating healthy dietary habits of children in Korea. One is the School Foodservice Program and the other is the Child Care Foodservice Program. School lunch service started in 1953 as the international relief work for children affected by the Korean War and institutionalized to the School Foodservice Program in 1981 by the enactment of the School Meals Act. The program was rapidly expanded in the 1990s and has been implemented in 100% of the elementary, middle, high, and special-education schools in Korea since 2012. Some schools started to serve universal free lunches to their students in 2011 and 100% of the school lunches served in Korea are free as of the school year 2022-2023. Nutrition teachers or dietitians are stationed in most schools and manage school food service. As nutrition teachers started to replace school dietitians in 2007, the educational role of the School Foodservice Program has grown. While schools were closed due to the COVID-19 Pandemic, the School Foodservice Program still played an important role in providing meal solution for children studying online by delivering foods to home or supplying coupons for lunch boxes sold in convenient stores. The quality of the Child Care Foodservice Program has dramatically increased in terms of nutrition and hygiene since 2011 as the Ministry of Food and Drug Safety started to establish Centers for Children's Foodservice Management. As of March 2022, 236 centers are under operation nationwide. Full time dietitians hired by the centers provide management and technical support for foodservice in child care centers by field visit with counseling, education, and information provision including menu and recipes. They also provide young children enrolled in the centers and their parents with food and nutrition education. Child care centers serve not only lunches but also morning and afternoon snacks, and therefore are responsible for significant proportion of nutritional intakes of young children. For the next decade, the roles of foodservice programs for children in Korea are expected

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

to be increasingly important in the food system transformation for sustainable development.

Keywords: foodservice management, school lunch, nutrition education, sustainable development

SY(T5)7-04

The Contribution of School Lunch Program to Nutrition Management for Japanese Children

Hiromi Ishida[1]

1. Kagawa Nutrition University (Japan)

The school lunch program in Japan began in 1889 with the aim of helping impoverished children and became a national project in 1932, with government subsidies, to fight poverty. The school lunch service was suspended due to food shortages during World War II, but it resumed after the war, spread nationwide, and was institutionalized in 1952. In 1954, the School Lunch Act was enacted and the framework for the current school lunch program was legally established. It has been 70 years since the school lunch program started nationwide. According to the 2018 survey, approximately 6.42 million elementary school students and 3.25 million junior high school students use the school lunch program.

School meals consist of a staple food, an accompanying dish, and milk in accordance with the School Lunch Nutritional Standards. Based on the Dietary Reference Intakes for Japanese for one-third of the daily intake, the School Lunch Nutritional Standards stipulate that approximately 40%–50% of nutrients likely to be deficient should be provided through school meals. After World War II, school lunch service effecting the improvement of the physique was confirmed. However, currently with sufficient energy intake, clear effects of the school lunch service on children's physique cannot be confirmed making the evaluation of the effects difficult.

Our research team conducted a dietary survey of fifth graders and compared the nutritional intake of children on school days and non-school days. The results demonstrated that the lunch service played an important role in their nutrient intake. Simultaneously, the survey demonstrated that a higher percentage of children are deficient in several nutrients in low-income households compared to high-income households and that protein intake, especially animal protein intake, was significantly low. For children in low-income households, the impact of school lunch service was greater, suggesting that school lunches reduce the disparity in nutrient intake.

Overseas studies show that obesity tends to be prevalent in poor children, but the disparity in physique is not prominent in Japan, which may be one of the effects of the school lunch service. In Japan, food supply is abundant, and the environment is in place where children can enjoy a rich and varied diet, however there are some problems with nutritional management. During their growth process, the range of eating experiences is narrow for Japanese children. However, the number of food and dishes that they eat for the first time in school lunch service is increasing. Increasing food options and eating a variety of dishes during the growing years leads to balanced food selection and intake behavior leading to the lifelong appropriate nutrient intake and wellbeing. School lunch services not only supply nutrients but also contribute to food and nutrition education as lively learning material.

Promoting health equity through the National School Lunch Program in the United States

Betty Tomoko Izumi[1]*, Carmen Byker Shanks*[2]*, Dayle Hayes*[3]

1. Portland State University (USA), 2. Gretchen Swanson Center for Nutrition (USA), 3. Nutrition for the Future (USA)

Schools are essential to meeting the nutritional needs of children, millions of whom rely on school meals for at least one meal each day. The National School Lunch Program is a federally assisted meal program that provides nutritionally balanced and free or low-cost lunches to children in schools in the United States (U.S.).

During the 2018-2019 school year, about 28.5 million U.S. children received school meals daily, including nearly 20 million who received a free lunch. In March, 2020, the World Health Organization declared COVID-19 a pandemic. Shortly thereafter, schools across the U.S. closed their doors, and face-to-face instruction was suspended. To facilitate continued access to school meals during school closures, new policies and practices at the federal and local levels were put in place. Waivers issued by the federal government provided school districts with flexibility in distributing school meals safely during the pandemic. These flexibilities included: serving multiple days of meals at once, allowing parents to pick up their children's meals, distributing meals in parks or other non-congregate settings, and providing meals to all children at no charge. Meal pattern flexibilities were also provided. Although these waivers — and the tireless efforts of school nutrition professionals — were critical, they did not address all of the challenges related to serving school meals during a pandemic, including staffing shortages, supply chain disruptions, and transportation barriers. As the COVID-19 pandemic retreated and schools shifted to a hybrid model and eventually back to in-person instruction, school nutrition professionals had to repeatedly pivot to comply with the ever-changing guidance about preventing and reducing the spread of COVID-19 in schools.

More than two years into the COVID-19 pandemic, how have these policies and practices affected the National School Lunch Program and the nation's most vulnerable children? This presentation will provide an overview of school meal programs

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

in the U.S. with a focus on policies, practices, innovations, and impacts before and during the COVID-19 pandemic.

Keywords: school lunch, COVID-19 pandemic, health equity

SY(T5)8-01

The concepts of Indigenous, traditional, and territorial diets and what they offer toward obtaining sustainable and healthy diets

Harriet V. Kuhnlein[1]

1. McGill University (Canada)

Sustainable and healthy diets promote all aspects of good health and well-being and have low environmental impact now and for future generations. These diets are accessible, affordable, safe, equitable and culturally meaningful. With planning and care, Indigenous diets, traditional diets, and territorial diets can all meet these criteria. Diets of Indigenous Peoples contain foods and traditions specific to their defined culture as well as commercial foods (ie. Hopi diet); traditional diets also relate to culture and include foods, recipes and traditions for use defined by individual, community, or region (ie. vegetarian diet); and territorial diets refer to diets and ways of eating in a country or geographical region (ie. the Japanese diet). This presentation aims to explore how to build strategies for diets to be sustainable and healthy within these dietary patterns. Importantly, consideration is given to cultural values, history, economy, food qualities and dietary practices, and ecological settings.

Indigenous Peoples, as defined by the United Nations Permanent Forum on Indigenous Issues (UNPFII), are recognized as having experienced sustainable and healthy diets by virtue of their continuous existence over millennia in a defined biocultural location. The collective knowledge of the more than 470 million Indigenous Peoples globally encompasses respect for the interconnection of people with nature and its resources, for the vast diversity of plants and animals as dietary resources, and for the keepers of traditional knowledge that create physical, mental, emotional, and spiritual health. Extensive and continuing research is needed to understand and document these knowledges.

Change for Indigenous diets, traditional diets and territorial diets is constant because of lifestyle change, climate change, changing access to traditional lands and resources, encroachment of others on resources, demographic changes bringing newcomers to a traditional area, and relocation to urban areas and employment. Personal change to dietary patterns results from changing taste appreciations, knowledge and availability of new foods, constraints in local harvests, and intercultural education.

The United Nations Food Systems Summit (UNFSS) of 2021 stimulated reflection on strategies for ensuring safe and nutritious access to food, creating sustainable diets and food systems, boosting nature positive solutions for healthy food for all, advancing equitable livelihoods, and building resilience to food system shocks and stresses. Led by thinking within the Food and Agriculture Organization Global-Hub on Indigenous Peoples' Food Systems (FAO Global-Hub) Indigenous, traditional, and territorial dietary practitioners can offer perspectives on how to meet the UNFSS goals. Suggestions toward creating sustainable and healthy diets include: consider and include diverse cultures and worldviews; ensure free, prior, and informed consent for land/water management to enhance biodiversity-rich practices, include women's empowerment, restore cultural languages and knowledges within intercultural diet and food system education, and provide for self-governance and inclusive contributions to policies.

Keywords: sustainable and healthy diets, Indigenous diets, traditional diets, territorial diets

Incorporating traditional and indigenous foods into food-based dietary guidelines in Africa: opportunities and challenges

Namukolo Covic[1]*, Linley Chiwona Karltun*[2]*, Anna Lartey*[3]*, Gina Kennedy*[4]*, Amos Laar*[3]

1. International Livestock Research Institute (Ethiopia), 2. Swedish University of Agricultural Sciences (Sweden), 3. University of Ghana (Ghana), 4. Global Alliance for Improved Nutrition (USA)

Background and objectives: Globally, Food Based Dietary Guidelines (FBDGs) are an important tool for promoting healthy food consumption habits. In addition, diverse food systems actors can use FBDGs to inform actions supportive to attaining healthy diets from sustainable food systems. However, in Africa, only 9 of the 55 countries currently have FBDGs, the latest being Ethiopia and Zambia that launched their guidelines in 2021 and 2022 respectively. Both Ethiopian and Zambian FBDGs aspire to promote the use of traditional and indigenous foods (TIFs) to improve not just nutrient intake but also resilience in an ever-complex climate change context. Furthermore, the Africa Common Position on the United Nations Food System Summit (UNFSS) identified TIFs as an area requiring much investment for TIFs to play their potential role in improving food consumption habits, nutrient intake, and resilience of African food systems for better food security, as the climate changes. Nevertheless, incorporation of TIFs into FBDGs presents a number of significant challenges. **The objective** was to identify the opportunities and challenges that must be addressed, so that as more African countries embark on developing FBDGs, the incorporation of TIFs can be facilitated so that the potential of TIFs in African food systems and diets can be realized.

Method: The paper uses evidence from a scoping review of literature and the existing FBDGs on the African continent, and outcomes of three independent dialogues of the UNFSS process

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

to identify and describe the opportunities and challenges that limit the incorporation of TIFs in FBDGs towards making recommendations on what needs to be done by different food systems actors.

Results: The challenges identified include limited data on food composition, loss of knowledge on TIFs among the younger components of the population and in urban settings, poor market development, a dietary transition that is leading to the undervaluing of TIFs, and lack of attention and investment from the food and agriculture sector on promoting production as part of agricultural production diversification and value chain development. There are clear opportunities for TIFs to have a positive impact on both nutrient intakes and resilience of African food systems in the changing climate.

Conclusions: There is a deficiency regarding efforts to position TIFs for use in context relevant FBDGs in Africa. For FBDGs to support and promote a shift towards healthier consumption habits and food security resilience, TIF's must be leveraged in efforts of all food systems actors. This would contribute to promoting positive transition to healthier more sustainable diets. In so doing, this would support efforts of the UNFSS 2021 that many African countries are still actively engaged in to promote positive food systems transformation that can deliver better diets and better nutrition and health outcomes.

Keywords: Food based dietary guidelines, Diet transition, Africa, Nutrition, Resilience

Engaging Indigenous Peoples in Food Based Dietary Guidelines in Canada: Opportunities and challenges

Treena Delormie[1,2]

1. McGill University (Canada), 2. Center for Indigenous Peoples' Nutrition & Environment (CINE) (Canada)

Background: This presentation discusses the engagement of Indigenous Peoples in the development of food based dietary guidelines (FBDG) in Canada. Dietary guidelines form the basis of policies and programs to promote healthy eating across the country, and hold particular relevance for Indigenous populations. In Canada, Indigenous populations shoulder nutrition and health inequities resulting from colonial policies that have, and continue, to shape the distinct social determinants of their health status. Policies and programs developed to improve Indigenous Peoples' nutrition will be most impactful when they respect their realities.

Case examples: The last two revisions of Canada's dietary guidelines attended to Indigenous Peoples' expressed needs, each time using a different approach. The 2007 revision process included a needs assessment, stakeholder consultation, and end-user focus groups. An advisory group was created to guide the tailoring of the visual communication tool called 'Canada's Food Guide' which translates dietary guidelines into practical food choice advice for consumers. This process reflected an important policy response in considering the food choices, values and traditions of First Nations, Inuit and Métis, the three constitutionally recognised Indigenous groups. The 2019 revision did not produce a tailored version of the signature communication for First Nations, Inuit and Métis. Those leading the revision noted the absence stating the 2007 tailored version still provided valid guidance. Significant in 2019 were the revised dietary guidelines developed specifically for policy makers and health professionals who implement them. The revision was informed by a consultation process with consumers, and invited Indigenous organisations, and experts to comment on drafts of the document. In the spirit of Canada's reconciliation process with Indigenous Peoples, issues included: a) recognising that health inequities vary among Indigenous groups ; b) citing evidence for the significant nutritional contributions of Indigenous diets; c) identifying challenges in accessing land and water to access traditional food systems; d) describing high rates of food insecurity and lack of access to safe drinking water and; e) considering the social, cultural, and historical context of food skills and food literacy. The recognised role colonial polices play in creating many of these issues is absent, but their recognition will be significant for future policy making to be truly transformative.

Discussion: In a global context, Canada's efforts to address Indigenous Peoples' needs for dietary guidelines stands out. However, Indigenous Peoples' meaningful engagement in these policy processes that impact their food and nutrition has been limited. Without their collaboration on dietary guidelines policy, healthy eating narratives in Canada will undervalue Indigenous knowledges, diversity of food systems and economies, and their contribution to sustainable diets for health. Canada recognises the need for distinctions-based dietary guidelines for Indigenous Peoples. Indigenous communities are generating and translating their own creative dietary guidelines resources and recommendations placing value on Indigenous knowledge and cultural responsibilities that ensure the continuity of sacred and sustainable food systems. This presentation will share some of these examples and outline opportunities for policy development to engage meaningfully with Indigenous peoples.

Keywords: Indigenous Peoples, nutrition, dietary guidelines, policy, decolonisation

An investigation of the sustainability of National FBDGs and challenges of incorporating traditional foods into FBDGs in Iran

Nasrin Omidvar[1], Seid-Reza Sobhani[2], Hassan Eini-Zinab[1], Sare Edalati[1], Gina Kennedy[3]

1. Shahid Beheshti Medical Univesity (Iran), 2. Mashhad University of Medical Sciences (Iran), 3. Global Alliance for Improved Nutrition (GAIN) (USA)

Background and Objectives: In order to move food consumption toward sustainability, inclusion of elements of sustainability into national food based dietary guidelines (FBDGs) is a priority. We assessed the sustainability dimensions of two modeled diets based on the official national FBDGs introduced in 2006 and 2015 and compared it with the Iranians' usual diet. In addition, we evaluated sustainability of some of the Iranin traditional foods to promote their incorporation into the national FBDGs to emphasize the local food resources and culinary habits.

Methods: Usual dietary intakes of Iranians were estimated using national household Income and Expenditure Survey data. Diet sustainability dimensions, including environmental footprints (water, carbon and land footprints), cost and nutrient rich food (NRF) index were calculated for the usual diet and compared with those of the old and new Iranian FBDGs, the Mediterranean diet pyramid and different vegetarian diet pyramids. Using linear and goal programming, optimal food models were calculated with the aim of minimizing environmental footprints, and cost and maximizing NRF, simultaneously, for each FBDG, while maintaining restrictions recommended by the FBDG, energy preferences, energy intake, macronutrient composition and micronutrient content. Percent change of substituting the usual consumption with dietary models were then compared.

Results: Replacing the usual dietary intake of Iranians with the optimal diet based on the 2016 Iranian FBDG can be associated with 20.9% reductions for water footprint, 22.48% for carbon footprint, 20.39% for land footprint, 31.83% for cost, as well as 7.64% increase in NRF index. The optimal model based on the new FBDGs was 10% more sustainable compared with the previous version. Changing the usual consumption of Iranians to the optimal model based on the Mediterranean Pyramid result in the highest NRF index, while water, carbon, and land footprints and cost were lower compared to other models.

Conclusion: Next generation of food-based dietary guidelines is expected to be more in line with a sustainable diet. Considering the dimensions of a sustainable diet is recommended in designing the next national FBDG. In addition, since traditional Iranian dietary pattern is basically a semi-vegetarian and plant-based diet, translating the guidelines to possible traditional Iranian foods can help through the process.

Keywords: Indigenous Peoples, nutrition, dietary guidelines, policy, decolonisation

Further Collaborators: This abstract is presented for the Symposium: The advantages and challenges of incorporating traditional foods in food-based dietary guidelines (FBDG) for more sustainable and inclusive population guidance

SY(T5)9-01

Connecting the dots: Sport nutrition knowledge, education and eating behaviors in youth athletes.

Melinda M Manore[1]

1. Oregon State University (USA)

Adolescent athletes begin their sport at a young age, yet their knowledge of food and food choices that enhance growth, health and sport performance is limited. As they age, their independence to make food choices increases, yet few receive evidence-based sport nutrition guidance. The diet and physical activity (PA) behaviors learned in these early years can continue into adulthood, thus, impacting long-term health, weight and sport performance. Not all youth athletes will transition into higher level sports, thus, without positive reinforcement to make good food choices and maintain PA, the risk of chronic disease and overweight/obesity increases as adolescents' transition out of their sport and into adulthood. Capturing adolescents while they are still active and engaged in youth sports may be a 'window of opportunity' to cultivate skills that support life-long health and obesity prevention. These skills will also serve them if they transition into collegiate or elite sports. This session will review the results, challenges and lessons learned from a 2-y sport nutrition/PA intervention in ethnically diverse youth athletes (14-18y; ~55% female; ~41% Latino; ~41% low-income), participating in high school soccer. The changes in nutrition knowledge, diet and PA behaviors, food preferences, and supplement use over this intervention will be presented. The state of youth sport research will be reviewed and challenging issues discussed. How can you translate the interest youth have in sport into better eating behaviors for health, growth, and sport performance? How can we help youth adopt healthy diet and PA behaviors they can use for a lifetime? How can we prevent unhealthy dieting, body image, and weight tissues from occurring in young athletes? We will also share our publicly available youth sport nutrition curriculum. If we want youth athletes to make good diet and PA decisions, we must teach them about sport nutrition, and encourage healthy eating behaviors and life-long PA skills.

Keywords: adolescent athletes, ethnic diversity, physical activity, soccer, sport nutrition

SY(T5)9-02

Malaysian perspective: Sports supplement and doping awareness

Wen Jin Chai[1]

1. National Sports Institute of Malaysia (Malaysia)

Sports supplement is a common sports nutrition strategy that used by athletes for varies reasons. It could be used as intervention for nutrient deficiency / insufficiency, convenient alternative to complement dietary intake according nutrient requirement for sports and ergogenic aid to enhance sports performance. However, the usage of sports supplement could potentially carry risk of anti-doping rules violation (ADRV) among athletes according to World Anti-Doping Code published by World Anti-Doping Agency (WADA). Undeclared banned substance in ingredient list and contamination of banned substance in supplement products are among the cause of unintentional doping among athletes. Questionnaire survey in the area of knowledge, attitude, practice and relation to risk of doping were conducted among Malaysian athletes, both at elite national athletes and young state athletes. Both studies indicated education on appropriate use of sports supplement is important among athletes and it should be provided by qualified nutritionist and dietitian. In order to improve the education level on sports supplement and doping awareness among athletes in Malaysia, plans were initiated and implemented through different strategies. Sports Nutrition Centre under National Sports Institute of Malaysia (ISN) is the main reference point for the national athletes. However, the reach out to state and grassroot level required the empowerment of coaches, through the national coaching course curriculum that include sports nutrition and anti-doping topics. Even nutritionist and dietitian under public health setting should equip with knowledge in this area, going in line with the increasing market of sports supplement products. Sports supplement guideline development project is already underway, which will serve as main reference document in sports nutrition. In summary, the usage of sports supplement can be beneficial to athletes for health and/or sports performance, however appropriateness in usage and doping safety concern are areas that need further improvement among the athletes in Malaysia through strategies at different levels and approaches.

Prevention and early detection of energy deficiency in free-living athletes

Motoko Taguchi[1]

1. Waseda University (Japan)

Athletes have high energy expenditure from daily training. Thus, adequate energy intake equal to the expended energy is essential for optimal health and athletic performance. In athletes, chronic energy deficiency contributes to numerous health issues, including metabolic, reproductive, endocrine, hematological, bone, and gastrointestinal problems. Energy availability (EA) is used as an indicator of energy deficiency. EA is defined as the amount of dietary energy remaining for other body functions after the energy consumed by training is covered. Low EA is the key etiological factor that triggers the unfavorable health and performance consequences in both female and male athletes. EA is calculated as dietary energy intake (EI) minus exercise energy expenditure (EEE), normalized to fat-free mass (FFM). However, there are no clear guidelines for field calculations of EA; accurate assessment of each component of EA (EI, EEE, and FFM) is challenging in the sports field. Since EI is often underestimated, and access to precision measuring equipment of EEE and FFM is difficult, further research is needed to apply EA to free-living athletes. In our latest study of EA, we used a doubly labeled water (DLW) method surrogate for EI and dual-energy x-ray absorptiometry (DXA) for body composition assessment. The results showed that measured resting energy expenditure (REE), REE ratio (measured REE to predicted REE ratio), and triiodothyronine levels could enable early detection of energy deficit. This data will be presented at this symposium. It is crucial to accumulate evidence for the physiological effects of low EA by facilitating studies using accurate quantitative methods; however, DLW and DXA are not field methods. Therefore, other more convenient markers need to be found for nutritional support of athletes in the sports fields. Monitoring REE is one of the simple ways. If REE measurement is not possible, applying estimated energy requirement (EER) using REE prediction equations based on FFM is recommended. Overall, the assessment of EA is not a helpful field tool to detect energy deficiency in free-living athletes. Instead, keeping the energy intake close to the EER goal and bringing the energy balance closer to zero will help to prevent energy deficiency in athletes.

Food provision and dietary support at major competition events: The connection between research and practice

Fiona E Pelly[1]

1. University of the Sunshine Coast (Australia)

High performance athletes regularly travel and compete at major competition events. Many of these events involve residing in an athletes' village where meals are provided. However, evidence shows that athletes do not always eat suitable food while competing at these events due to inadequate knowledge on the best menu choices or not prioritising performance when choosing what to eat. There may also be environmental barriers to providing suitable food options due to budgets, location or limited experience of caterers. COVID-19 has created additional new challenges for those working in this environment. This symposium will demonstrate how research can be integrated with sports nutrition practice in this unique setting to provide evidence for future change.

Historically, sports dietitians have not consistently been included in the organisation and delivery of food provision and nutrition support at major competition events. Yet, research conducted by those that have attended provides the evidence that teams from different countries have varied degrees of performance nutrition understanding due to limited access to experts with appropriate skills and training in their home environment and therefore rely on suitable food and services provided on site. Those that seek advice from dietitians working at major events have been shown to have dietary intakes that are less than adequate for their general health and sports performance.

Research over the past 20 years demonstrates the positive impact that sports nutrition expertise can have on the food environment at major events through a variety of means including education sessions held with coaches and teams, advice on making weight or recovery, dietary plans for training and competition, and physique assessment. Another identified challenge is the increased demand in therapeutic dietary needs, particularly food allergies or intolerances. Data collected at these events shows around 13% of athletes report following a dietary regimen related to a specific food allergy or intolerance. There is also a wide range of clinical conditions where diet is central to management (e.g. diabetes, coeliac or cardiovascular disease, inflammatory or irritable bowel syndrome) and there is increased demand for personal food preferences such as vegan or vegetarian diets, and natural/organic food. Sports dietitians can play an integral role in planning for food allergy management. Further impact on the food environment can be provided through input into nutrition labelling, staff training, quality assurance checks of menu items and advice on sustainable practices.

Recently, we examined stakeholders' perspectives of integration of nutrition in catering to better understand the barriers and enablers to improving the food provision at major events. The evidence suggests that the integration of sports nutrition expertise into the planning and operational stage of these events has better outcomes in terms of appropriate food for athletes' needs. The food environment at major events has the potential to influence food intake and educate on the importance of nutrition for both health and performance.

Pathways for Including Social Inquiry Into Nutrition Research: The CeSSIAM Guatemala Experience

Rosario Garcia Meza[1]

1. The Center for Studies of Sensory Impairment, Aging and Metabolism (Guatemala)

Anthropologists working in Guatemala have long documented violence and human rights violations in the country, shedding light on social inequities among local populations that give rise to health disparities and undernutrition. As a response, important research centers such as INCAP, social science Institutes, and universities led applied anthropology studies to help health and nutrition interventions to work better.

In that context the Center of Studies for Sensory Impairment, Aging and Metabolism (CeSSIAM) was founded with the aim to create new biomedical knowledge and to train young scientists. CeSSIAM biomedical research agenda attracted international doctoral and masters' students who conducted anthropological research. Their studies brought a renewed awareness and led to a more comprehensive social science inquiry pathway.

As a result, the Center has included social research in several mixed-methods biomedical studies. CeSSIAM researchers and exchange students have used ethnographic approached to study, e.g.: health and nutrition worldviews during critical life cycle periods such as pregnancy, lactation, and infancy; food environments; and nutritional transitions. Findings have shed light on different worldviews of nutrition, shaping nutrition and health interventions for the local context, and helping to inform the implementation of Guatemala health and nutrition policy locally. For example, in a zinc-treatment program [in highland Guatemala], local perspectives of illness informed intervention design and evaluation. Adaptations in treatment delivery formats and the use of local concepts of diarrhea by MOH personnel increased treatment adherence.

The interdisciplinary of CeSSIAM's science has not, however, occurred without challenges. Mixed methods studies, in their focus on specific ideas-practices, may not be designed to address social complexities and heterogeneities of context. Capacity building in ethnographic methods takes a significant amount of time, especially for students from biomedical traditions. Additionally, audiences with quantitative backgrounds may not completely understand qualitative findings.

This talk reflects upon the benefits and challenges of integrating social inquiry into nutrition science research. It also shows how designing research to be flexible and to embrace tensions between different disciplinary paradigms can enrich both nutrition-health and anthropology studies.

Translating research on breastfeeding between anthropology and nutrition

Eileen Rivera[1]

1. The Center for Studies of Sensory Impairment, Aging and Metabolism (Guatemala)

Research on breastfeeding suggests that social and cultural factors affect milk volume, milk composition, and maternal reproductive status (Hausman, 2003), but little is known about how, exactly, culture shapes what and how breastfeeding women eat. This talk describes a study that examined how cultural aspects influence the breastfeeding behaviors of lactating women in the Eastern town of Livingston, Guatemala, a multi-ethnic community where three major cultural groups converge (Garífuna, Maya Q'eqchí, and Ladino). A group of adult women from the three major cultural groups with breastfeeding experience were interviewed to collect information on their dietary intake patterns. Questions focused on: 1) Who guided their breastfeeding practice? (eg.: midwives, family members, or other health professionals). 2) Personal beliefs and perspectives on breastfeeding. 3) Economic deliberations related to dietary intake, including the availability and affordability of foods. We found that lactating behavior of breastfeeding women were mostly influenced by grandmothers, midwives, and health professionals. Recommended lactating practices vary between ethnic groups, based on generations of accumulated knowledge and life experiences. However there is one common denominator: all women use breastfeeding to prevent diseases and infections, for themselves and their children. Working with midwives, who acted as cultural translators, our research team found that all ethnic groups avoided seafood, highly spiced foods, and dairy, believing them to be unhealthy. In contrast, they all ranked simply cooked vegetables as the most consumed food during pregnancy and lactation. Combining nutrition and anthropology to analyze and interpret information ensures a comprehensive study. This comparison among three ethnic groups of lactating women in Livingston, Guatemala, is the first study of its kind. It not only provides valuable confirmation about the importance of cultural beliefs in dictating feeding practices. It also highlights the need for anthropologists and nutrition scientists to work with local communities when carrying out research on food and eating habits.

Maya and Scientific Cultures of Nutrition in Guatemala

Miguel cuj[1]

1. Vanderbilt University (USA)

How people classify and describe food affects what and how they eat. This study uses anthropological methods to examine how K'iche' Maya food concepts influence how K'iche' people interact with Guatemala's nutritional food guidelines. In Guatemala, K'iche' Mayan is the largest Indigenous group with about a million speakers. I collected data by employing ethnographic and pragmatic linguistic research methods including dietary records, in-depth interviews, and participatory observation as they prepared food and ate during meal times to contrast with Guatemalan nutrition guidelines. In Guatemala, health policy institutions design and disseminate national food guidelines in Indigenous communities. My research shows how these food guidelines, which are shaped by biomedical cultures, overlooked the religious, cultural, and social values that K'iche' Maya people attributed to food and eating. Using textual analysis and participant observation with K'iche' families as they prepared and ate food, I contrast Maya food classifications with biomedical food classifications. I draw attention to embedded, but often unrecognized, cultural values of standardization and individual responsibility in Guatemala's food guidelines. K'iche' concepts of food have different food domains with regards to the Guatemalan nutrition Guidelines. In multilinguistic and multiethnic contexts, nutrition policy would be improved by attending to the cultural values within nutrition science. Additionally, to strengthen food and nutrition policy, Indigenous knowledge of food must be respected and integrated into biomedical food guidelines.

Keywords: K'iche', Maya, Guatemala, Women, Anthropology of Food and Nutrition

Anthropology and Nutritional Trial Design in the 21st Century

Gabriela Montenegro-Bethancourt[2],*Meghan Farley Webb*[1, 2]

1. Albion College (USA), 2. Wuqu' Kawoq (Guatemala)

Guatemala has one of the highest stunting rates in the world. Despite diverse nutritional landscapes, nationally, the under five stunting rate is 49.8 percent. This rate is as high as 75 percent in the rural Maya population. Guatemala's Indigenous Maya communities simultaneously represent the country's cultural richness and ongoing racism and inequality in almost all aspects related to socio-economic well being. These characteristics have

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

made Guatemala a key site for investigations by both (medical) anthropologists and nutritionists. It has also made Guatemala home to numerous non-governmental organizations (NGOs), many of which provide nutritional programming. Too often such programming uses either anthropological or nutritional insights, reifying the arbitrary divide between the “hard” and "soft" sciences. Using examples from their work with the medical NGO Wuqu' Kawoq|Maya Health Alliance, the authors explore the iterative process of nutritional trial design that is both scientifically rigorous and culturally responsible. Examples discussed include multicomponent interventions and community engagement in two specific projects: household gardens and a protein supplementation. Authors will also examine the ethical responsibilities of conducting nutritional trials among marginalized populations.

The important role of umami taste in oral and overall health

Takashi Sasano[1]

1. Tohoku University (Japan)

Enjoying tastes should be a life pleasure. However, aging is sometimes associated with reduced taste sensitivity (hypogeusia). Our previous study showed that 37% of test subjects over 65 years of age exhibited lower gustatory function, which is generally assessed with the filter paper disk test in Japan. This test uses a filter paper soaked with a taste-inducing chemical solution that is placed on specific areas of the tongue and soft palate. However, because this test only evaluates four of the five basic tastes: sweet, salty, sour, and bitter, we recently developed the umami taste sensitivity test to be able to evaluate umami taste disorders clinically. Umami taste, the fifth taste category, that is a key flavor in the Japanese traditional diet (*washoku*) rich in umami, is also important for the health of older adults. We have reported the specific loss of umami taste sensation in some elderly patients, while the other four taste sensations were normal. These studies further demonstrated that patients who loss the umami taste sensation had less appetite and lost weight, resulting in a poor overall health. Taste disorders are strongly related to reduced salivary flow. Saliva facilitates the diffusion of taste substances to taste receptors, the chemical interaction with food substances, and protects taste buds. When examining the relationship between the rate of salivary flow and the taste threshold, we found that the rate of salivary secretion was lower than the standard level (10mL/10min) in all subjects with gustatory impairment but normal in subjects with normal taste thresholds. These data indicate that hyposalivation is closely related to hypogeusia. Clinical studies have shown that hypogeusia improves by treating hyposalivation, indicating that salivation is essential for normal taste function. The umami compound glutamate was able to increase saliva and thereby improve hypogeusia by enhancing the gustatory-salivary reflex. Our data demonstrates that umami compounds are an effective tool for the relief of hypogeusia without any side effects. In conclusion, our work has proven that since taste function and overall health are associated, salivation and health are also indirectly related.

Keywords: umami taste, hypogueusia, hyposalivation, elderly, healt

The Mediterranean diet effects on health outcomes

J. Alfredo Martinez[1]*, Víctor de la O*[1, 2]*, Miguel Ángel Martínez-González*[2]

1. IMDEA Research Institute on Food&Health Sciences (Spain), 2. University of Navarra Department of Preventive Medicine and Public Health (Spain)

The traditional Mediterranean diet (MedDiet) is defined as the staple food pattern consumed in the early 1960s in Greece, Southern Italy, Spain, and other olive-growing countries of the Mediterranean basin. This frugal diet uses generous amounts of olive oil as main culinary fat and includes a high consumption of plant-derived foods (fruit, vegetables, legumes, nuts and seeds, and whole grain cereals) and fish/seafood; frequent but moderate intake of wine (especially red wine), usually accompanying meals; moderate consumption of dairy products (especially yogurt and cheese, but not butter or cream), poultry and eggs; and low consumption of sweetened desserts or red and ultra-processed meats. Since 16th November 2010, the MedDiet was inscribed into UNESCO's Representative List of Intangible Cultural Heritage of Humanity.The conventional nutritional composition of the MedDiet model provides sufficient fiber, whole grains and starchy vegetables, higher amount of plant-based protein, high quality of the lipid profile (mono- and polyunsaturated fatty acids), and plenty of vitamins, minerals, antioxidants and phenolic compounds such as hydroxytyrosol, tyrosol, and β-sitosterol, which are recognized as main actors in the protection against chronic disease through the modulation of some intermediate metabolic pathways.A huge accrual of worldwide large observational epidemiological evidence has shown that the MedDiet is associated not only with a reduced risk of major chronic disease, but also with health maintenance and illness prevention. An umbrella review concerning the association between MedDiet adherence and multiple health outcomes appraised 13 meta-analyses of observational studies and 16 meta-analyses of RCTs investigating the association of MedDiet with 37 different health outcomes, for a total population of over than 12, 800,000 subjects, which enabled to feature diverse MedDiet and health interactions. Thus, robust evidence was found to support the effects of a higher MedDiet adherence on reduced risks of overall mortality, related-cardiovascular diseases, overall cancer incidence, neurodegenerative diseases and diabetes. Notably, 2 large Spanish RCTs, the PREDIMED trial (n=7,447) for primary

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

prevention and the CORDIOPREV (n=1,002) trial for secondary prevention used hard clinical endpoints found substantial cardiovascular benefits, with relative reductions in major events. Most MedDiet's beneficial effects could be primarily related to anti-inflammatory and antioxidant properties, improvements in insulin sensitivity and endothelial function, anti-clotting properties in addition to interacting with epigenetic mechanisms and gene expression that modify disease risk as well as reducing adiposity and metabolic syndrome manifestations. Furthermore, other benefits related to the long-term adherence to the MedDiet include better quality of life or healthy aging, improved cognition and reductions in the rates of dementia, depression, respiratory diseases, and frailty fractures. Noteworthy, the MedDiet is ecologically sustainable, showing a reduced environmental impact, thus representing another important positive aspect of this dietary model. Further to encourage health and sustainability, MedDiet have additional social, satisfactory/satiety, security, and safety dimensions, which may be shared with other dietary pattern such as Japanese diet.

Integrated programming reduces malnutrition, builds strong families, and reinforces social cohesion in Mali

Meghan Pollak[1]

1. Save the Children (Morocco)

Background and Objectives: In Sikasso, Mali, inadequate consumption of nutritious foods, abnormal loss of nutrients due to illness, and harmful social norms contribute to undernutrition. To improve the nutritional status of children and pregnant and lactating women, the USAID-funded Project Nutrition et Hygiène [USAID/PNH] supported an integrated approach across the health/nutrition, agriculture, and water, sanitation, and hygiene [WASH] sectors by empowering gender transformative community groups to promote small doable maternal and child nutrition and WASH practices at the household level in six health districts in Sikasso Region.

Methods: Community Nutrition Groups [GSANs] facilitate behavior change sessions to help caregivers improve household nutrition and hygiene practices. GSANs, led by female change agents known as Maman Leaders [MLs], collaborate with WASH committees to reinforce links between hygiene and nutrition. MLs negotiate with family members to adopt small doable actions that will lead to better nutrition and fewer cases of illness, while WASH committees work with community members to construct latrines and handwashing stations, and farm field schools [FFS] teach women farmers how to increase yields of nutrient-rich foods. A mid-term evaluation using household survey and program data was conducted to document progress in nutrition and WASH outcomes due to USAID/PNH's multi-sectoral and community approaches and interventions.

Results: The proportion of children below two years who are underweight dropped by 27% from the baseline and wasting in

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

children aged 0-23 months declined by 41%. Community activities have contributed to improved IYCF practices, with exclusive breastfeeding increasing from 35% to 64%. Children aged 6-23 months eating four+ food groups increased from 13% at baseline to 57%. Access to and information on more nutritious foods during community-wide cooking demonstrations, GSAN sessions, and FFS meetings may be having an impact on what people are eating.

Conclusions: USAID/PNH's integrated WASH, nutrition, and agriculture interventions and coordinated gender transformative community platforms have yielded results that positively influence nutritional status in project-supported communities. Because community platforms apply SBC techniques, such as interpersonal communication and hands-on skills building sessions, while working in concert with WASH and agricultural supply chain platforms, they effect greater longstanding change at the community level.

Impact of Enhanced Community Conversations to improve nutrition practices in Ethiopia

Habtamu Fekadu[1], Lioul Berhanu[2], Daniel Abbot[2]

1. Save the Children (USA), 2. Save the Children (Ethiopia)

Background and Objectives: Save the Children, through USAID Growth through Nutrition project, implemented Enhanced Community Conversations (ECCs) to improve maternal dietary and infant and young child feeding (IYCF) practices. ECCs are peer support groups comprised of mothers, fathers, or grandmothers of children under two who meet regularly for ten sessions. Each session covers specific topics that go beyond raising awareness, focusing on promoting the adoption of nutrition-related skills, behaviors, and gender transformative roles during the first 1,000 days. ECCs use a package of multimedia social and behavior change communication (SBCC) materials, including virtual facilitator (VF), games, roleplays and take-home materials to facilitate discussion and learning during the sessions and action afterwards.

We implemented ECCs using two facilitation approaches: 1) frontline health and agriculture workers without a VF, and 2) community change agents (CCAs) recruited from the community by local NGOs, complemented by a VF. The VFs are audio recordings of professional voice actors playing the roles of relatable characters.

Growth through Nutrition conducted an operational research study led by Tufts University to assess the impact of the two ECC approaches and the value added by the VF on IYCF and maternal nutrition practices and the nutritional status of women and children in Ethiopia.

Methods: The project used a quasi-experimental design with a control group in three districts where the project was implemented. In each district, two sub-districts were selected, one to receive ECCs with VF (intervention), and one without VF (control). The control group participants received 10 monthly ECC meetings led by CCAs, take-home materials for action at home, and follow-up household (HH) visits. The intervention group received the same package, with the addition of the VF audio component. The project collected baseline data in December 2018 before the ECCs began and an endline in November 2019 after the completion of 10 ECC sessions. The surveys measured significant differences within groups with a chi-square test and used a difference-in-difference analysis to assess changes between the groups.

Results: ECCs, both with and without VF, resulted in significant improvements in nutrition practices. The percentage of children meeting minimum diet diversity improved from 10.2% to 31.3% (control) and 12.2% to 37.5% (intervention) and minimum acceptable diet increased from 6.1% to 26.9% (control) and 5.6% to 26.8% (intervention). Women with appropriate diet diversity improved from 22.9% to 31.0% (control) and from 22.0% to 37.9% (intervention). The project observed a positive change in the consumption of food groups in line with the promotion of a nutrient-dense and diverse diet. The added value of the VF was assessed, and compared to ECCs without VF, those with VF showed statistically significant improvements in Iron Folic Acid (IFA) intake for more than three months.

Conclusions: ECCs led to improvements in nutrition related behaviors. ECCs without VF were effective and have good potential for frontline workers to take to scale, while ECCs with VF have an added value and can be implemented where operationally feasible. The project has refined this approach to support scalability and sustainability through government systems.

Keywords: IYCF, Behavior Change, Diet Diversity, Enhanced Community Conversations

Field experience around designing adolescent nutrition programming in Ethiopia and Laos

Wossen Assefa Negash[1], Carolyn O'Donnell[2]

1. Results for Development (R4D) (Ethiopia), 2. Save the Children (USA)

Background and objectives: USAID's Growth through Nutrition project in Ethiopia and the USAID Nurture project in Laos were implemented by Save the Children to improve nutrition outcomes among adolescents. In Ethiopia, formative research supported the development of a "whole-household" strategy, which prioritized household members most vulnerable to undernutrition, including adolescents. In Laos, formative research found that a lack of household understanding of the importance of adolescent nutrition perpetuated insufficient quantity and diversity in adolescent girls' diets.

Methods: In Ethiopia, Growth through Nutrition developed adolescent-friendly multi-media materials on optimum adolescent nutrition actions and delivered them through in-school and out of school platforms. Adolescents acted as change agents and shared nutrition information from school with their parents. The project also integrated nutrition promotion activities with existing government systems to ensure sustainability. In Laos, USAID Nurture trained community volunteers to promote ten Small Doable Actions (SDAs) to improve nutrition and WASH behaviors among 1,000 Days Households and those with adolescent girls. USAID Nurture also collaborated with the Ministry of Health to strengthen nutrition counseling in MNCH services, including adolescent nutrition counseling and youth-friendly approaches.

Results: The project reached 301,800 adolescents through in-school and out of school initiatives. Nutrition messages were disseminated through 12 government educational radio stations with a total reach of more than 14 million students. Through home visits and community-wide events, USAID Nurture reached over 6,000 adolescent girls to promote SDAs. The project also supported the training of 126 health workers on adolescent nutrition counseling.

Conclusions: As adolescent nutrition is a relatively new frontier, concepts and approaches need to be constantly tested and adapted to improve program quality.

Formative research is critical to identify the specific barriers to adolescent nutrition in a given context and develop effective SBC approaches.

-Positioning nutrition as a "family affair" resonated well with adolescents, families, and stakeholders.

-Adolescents can change nutrition practices for their entire family.

-Integrating interventions with existing education, health, and agriculture systems helped ensure cost-effectiveness, scalability, and sustainability.

-It is important to address adolescent nutrition at home, in health services, and in schools through capacity strengthening for improved and adolescent responsive counseling.

This publication was made possible through support provided by U.S. Agency for International Development. The opinions expressed herein are those of Save the Children and do not necessarily reflect the views of the U.S. Agency for International Development.

Keywords: Whole household approach

Innovations in enriching complementary food help diversify diets in Cambodia

Carolyn O'Donnell[1], Laura Cardinal[1], Math Srales

1. Save the Children (USA)

Background & Objective: To prevent stunting and give every child a healthy start, children 6-23 months of age need a diverse diet, including daily animal source food. Fish, especially when the head and bones are included, contain most nutrients needed for optimal child growth and development. Although small fish are a staple in Cambodian diets and are available much of the year, only half of children 6-23 months from poor rural communities eat fish due to fears of choking and the time required to cook for children.

Methods: The USAID-funded NOURISH project developed a simple solution by teaching families to make small fish powder [SFP], which could be easily added to any family food. NOURISH worked with food scientists at two regional universities to test its safety, shelf life, and nutritional content and to conduct routine quality control checks. They taught pregnant women and caregivers of children under five years from 475 villages in Cambodia to make SFP at home and coached women entrepreneurs to produce and sell SFP through informal, local markets. This activity was layered on the project's comprehensive social behavior change [SBC] campaign, which promoted 13 key stunting prevention behaviors, including the importance of diet diversity for optimal nutrition and growth, through various communication channels and platforms. Effectiveness of the intervention was measured through routine project monitoring of household SFP production while nutrition outcomes were measured through the project's endline evaluation household survey.

Results: Consumption of small fish/SFP increased from 61% at baseline to 72% at endline, with steady increases as children aged. At endline, among children who had consumed SFP, 81% had minimum diet diversity [MDD] and 80% had minimum acceptable diet [MAD], compared to 19% and 65%, respectively, among children who had not consumed SFP. This increase was also a contributing factor to the 25% increase in MAD.

Keywords: diet diversity, home fortification, fish powder

Conclusion: Promoting small fish powder as a practical activity within a broader SBC campaign in an environment where fish are accessible is a simple and sustainable solution to improve children's nutrition practices, especially diet diversity, which can be layered onto a variety of SBC programs in similar contexts with high potential for impact.

SY(T6)2-02

Age distribution of all-cause mortality among children younger than 5 years – possible implications for VAS programs

Rolf Klemm[1], Andreas Hasman[2], Omar Karlsson, Rockli R Kim, S V Subramanian

1. Helen Keller International (USA), 2. UNICEF HQ (USA)

Coverage of essential child health and nutrition interventions in low- and middle-income countries remains suboptimal. Adverse exposures, such as undernutrition and infections, are particularly harmful during the 1000 days from conception until 2 years of age.

In a cross-sectional study of just under three million children under five years of age in 77 countries we explored whether deaths are concentrated in the first 2 years after birth. A synthetic cohort probability method was used drawing on data from Demographic and Health Surveys and Multiple Indicator Cluster Surveys from 77 low- and middle-income countries surveyed from March 2010 to December 2019. Participants included children younger than 5 years at any point 10 years before survey.

In the pooled sample, 81.5% (95% CI, 81.0%-82.0%) of deaths occurred in the first 2 years after birth—43.0% (95% CI, 42.4%-43.7%) in the neonatal period—ranging from 63.7% (95% CI, 61.6%-65.7%) in Niger to 97.8% (95% CI, 85.9%-99.7%) in Albania. An estimated 18.5% (95% CI, 18.0%-19.0%) of child deaths occurred at 24 to 59 months of age. Countries with higher mortality rates among children younger than 5 years had a lower share of deaths occurring in the neonatal period.

Previous research has highlighted perinatal complications, infections, and undernutrition as primary causes of death among children younger than 5 years. The results of this analysis suggest that coverage of interventions to reduce these adverse exposures should be prioritized during pregnancy and the first 2 years after birth, which is also a crucial period for human development.

Operationalizing: targeting children under 2 with VAS in Senegal as a phased approach to health systems strengthening

Banda Ndiaye[1], Alison Greig[1], Emily Measures[1], Caitlin Gomez[1], Amadou Ndiaye[1]

1. Nutrition International (Senegal)

Objective: Ensure yearly 2 doses VAS coverage is maintained to at least 80% through PHC routine delivery platforms and Improving accessibility and availability of essential child nutrition and health services like Growth Monitoring Promotion, nutrition education, screening for acute malnutrition, diarrhea treatment with zinc and Lo_ORS and catching up for missed essential vaccinations.

Justifications: Decreased funding and opportunities for integration of VAS into immunization campaigns leading to unprecedent slippage of VAS coverage especially in Sub Saharan Africa.

Methods: Assessing the readiness of the national PHC system to deliver VAS to children 6 to 59 months old through the routine PHC contacts and use findings to develop informed plan, guidelines, and tools for implementation of VAS through the routine PHC services. Support to stepwise implementation of the plan including partnering with other nutrition support programs to strength the capacity of the PHC system to deliver integrated nutrition services package including VAS. Regular reviews of progress to identify key challenges and bottlenecks at Primary health care unit (PHCU), districts, regional and national levels for corrective decision making.

Results: high coverage in 6 to 11 months old children throughout the country contrasting to low coverage in children 12 to 59 months old. Districts and PHCU implementing the plan as per operational guidelines including reinforcing community platforms have been successfully reaching over 80% in both age group children.

Conclusions: There is real potential for reaching over 80% VAS coverage in both 6-11m and 12-59m old children and focus should be on ensuring fidelity implementation as per operational guidelines through effective program monitoring and review for quality data driven corrective actions including identification of platforms that can efficiently reach specific age groups.

Vitamin A data that are needed to assess deficiency and excess in order to better target vitamin A supplementation programs

Sherry Ann Tanumihardjo[1], Maria Elena D. Jefferds[2]

1. University of Wisconsin-Madison (USA), 2. Centers for Disease Control and Prevention (USA)

Background: Vitamin A (VA) supplementation (VAS) programs prevent child mortality in populations where VA deficiency (VAD) remains a public health problem. To improve status, VA fortification has been mandated in many countries but reaching young children with sufficient VA can be challenging. Before revising VAS policies, confirmation of adequate VA status and sustained intake are required, among other factors. This presentation describes different methods to assess VA status and how these have been used in different national surveys to drive decisions.

Methods: High under-5 mortality rate (U5MR), symptoms of xerophthalmia and low serum retinol concentrations (SRC) in the population were sufficient evidence to recommend VAS. Other biomarkers to assess VA status exist and are in current use. More recently, retinol binding protein (RBP) has been used to estimate VAD. The modified relative dose response (MRDR) test is more sensitive to total liver VA reserves than ocular signs, SRC, or RBP. MRDR has been used in Nepal, Guatemala, and Malawi, among others, in their national micronutrient surveys (NMS). Fasting circulating serum retinyl ester concentrations can be used with the MRDR test when potential VA excess exists; this was applied in Malawi. Retinol isotope dilution (RID) works along the continuum of VA status but has not been employed in NMS. Nonetheless, RID was applied in a South African cohort study to inform the presence of high circulating retinyl ester concentrations in a population suspected of high intake of VA. Dietary intake data informs VA biomarker results and provide assurances that VA status is not transient. Evaluating actual dietary intake, food frequency of specific foods, including fortified products, and modeling of household expenditure/income data are useful.

Results: Xerophthalmia is rare due to successful programs and general health improvements. Adding the MRDR test to surveys better defines liver VA reserve adequacy. Nepal determined VAD was no longer a public health problem using MRDR in a subsample. However, the seasonality of VA-rich foods suggests that VAS may still be necessary to maintain adequate status. Based on SRC, RBP, MRDR, and sugar fortification quality, Guatemala has chosen to target VAS to younger children. The triangulation of MRDR, serum retinyl esters, and serum carotenoids suggest VA programs are effective in Malawi, yet more targeted evaluation of dietary data is needed before VAS policy will be revised. In South Africa, RID, serum retinyl esters, and liver frequency data suggested no VA deficiency and evidence of excessive liver reserves. Evaluation of VAS policies is on-going.

Keywords: biomarkers, hypervitaminosis A, night blindness, retinyl esters, xerophthalmia

Conclusions: Population data using sensitive VA biomarkers and dietary intake data are needed before VAS can be better targeted to those in need.

Conflict of Interest Disclosure: No conflicts of interest with vitamin A supplementation programs.

SY(T6)3-01

Impacts of ultra-processed foods on health and environment: the scientific evidence

Priscila Machado[2]

1. Deakin University (Australia)

The nutrition literature and authoritative reports increasingly recognise the concept of ultra-processed foods as a descriptor of unhealthy diets. Ultra-processed foods are defined by the NOVA system as formulations of ingredients, mostly of exclusive industrial use, that result from a series of industrial processes. These foods have novel physical structures and chemical compositions that have been identified as providing plausible biological mechanisms to explain associations between ultra-processed foods and adverse health outcomes. At the same time, their production wastes scarce environmental resources which could be used to produce healthy foods. Understanding of the contribution of ultra-processed foods to dietary quality, diet-related diseases and environmental degradation is needed to inform strategies aiming to improve population and planetary health. This presentation will explore the body of scientific evidence on the impacts of ultra-processed foods on health and environment across a range of study designs, populations and country contexts. The range of outcomes, the mechanisms underlying these associations and recommendations for further research will also be explored.

Keywords: Ultra-processed foods, Health, Non-communicable diseases, Environment, Sustainability

SY(T6)3-02

Understanding the global rise of ultra-processed foods: the food systems and commercial determinants

Phillip Baker[2]

1. Institute for Physical Activity and Nutrition, Deakin University (Australia)

Background: Food processing has played an important role in human evolution and the birth of civilizations, in the development of cuisines and food cultures, and in making food safer, more palatable and durable. However, only in recent decades have ultra-processed foods become prominent in human diets, representing a major divergence from dietary patterns of the past. Understanding the determinants of changing ultra-processed food (UPF) consumption is essential, given mounting evidence linking such foods with adverse health and environmental outcomes. It is crucial to informing worldwide food policy responses by governments. Using a food systems approach, this presentation reports the results of a study on trends, dynamics and determinants of worldwide UPF consumption.

Methods: This study adopted a synthesis review method, involving two steps. First, quantification of per capita volumes and trends in UPF sales, and ingredients (sweeteners, fats, sodium, cosmetic additives) supplied by these foods, in countries classified by income and region. Second, a review of the literature on the food systems, commercial and political economy factors that may explain the observed changes in UPF consumption, and differences between regions and countries.

Results: In recent decades, there has been a substantial expansion in the types and quantities of UPFs sold worldwide, representing a transition towards a more highly-processed global human diet, but with significant variations between regions and countries at similar levels of economic development. Sales volumes are highest in Australasia, North America, Europe and Latin America, but are growing most rapidly in Asia, the Middle East and Africa. As countries grow richer and increasingly urbanized, more UPFs and a wider variety of UPFs are sold. These developments are closely linked with food systems transformations at global, national and sub-national levels. This includes the industrialisation of food systems, including the rising production of cheap agricultural input commodities, and technological changes in food production, manufacturing and marketing. Globalization is a key underlying driver, including growth in the marketing and political activities of transnational food corporations, the growing power of financial actors in the food system, and inadequate governance and policy responses by governments.

Conclusions: The scale of dietary change underway, especially in highly-populated middle-income countries, raises serious concern for global nutrition, public health and the environment. The global rise of UPFs reflects major transformations in food systems, including many changes linked with the commercial activities of transnational food corporations, and policy responses that are inadequate in both strength and scope. Responding to this challenge will therefore require a whole of food systems approach, including actions to strengthen the implementation of policy frameworks that attenuate the commercial determinants of the problem.

Keywords: Nutrition transition, Ultra-processed foods, Food systems, Commercial determinants, Transnational corporations

SY(T6)3-03

The social and cultural factors associated to ultra-processed dietary patterns

Jean-Claude Moubarac[1]

1. University of Montreal (Canada)

Ultra-processed foods are formulation of refined substances and additives used to create products that are ready-to-eat, highly palatable, convenient, and cheap. In the last decades, these products have dominated the market in high income countries, and their sales are now growing rapidly in low- and middle-income countries. Epidemiological research has shown that diets high in ultra-processed products are associated to poor diet quality, and several adverse health outcomes. All around the world, diets based on traditional foods and meals are replaced by diets dominated by ultra-processed products with a sharp increase in obesity, chronic diseases and all-cause of mortality. However, less attention has been given to the social and cultural factors associated to ultra-processed dietary patterns. Drawing from studies in anthropology and sociology, as well as some preliminary data on ultra-processed food consumption in Canada and in the world, I will argue that food and ultra-processed food are categories associated to distinct food cultures, with important consequence on health. Food is culture and plays a fundamental role in shaping social norms, values, and beliefs. Indigenous food studies have revealed that the loss of traditional foods impact social cohesion, social relationships, and mental health. We are what we eat, and we also eat what we are. However, if food is culture, then what are ultra-processed products? In this presentation, I will discuss the specific characteristics shared by ultra-processed products and explain how they may negatively affect people's behavior and relationships to food. I will link those characteristics to distinct food cultures and discuss their impact on health. To address the current nutrition transition, I argue that we need to consider the social and cultural implications of ultra-processed dietary patterns. Policies are needed to protect and cherish fresh and minimally processed foods that are traditional and culturally relevant to communities, because beyond their nutritional value those foods have a cultural value that must be consider in public health policies and interventions.

SY(T6)3-04

Policy and regulatory reforms to target ultra-processed foods

Mark Lawrence[1]

1. Deakin University (Australia)

Ultra-processed foods (UPFs) are associated with a range of adverse population and planetary health outcomes. The availability and consumption of these foods are rising around the world as food systems undergo rapid transitions. This increasing availability and consumption of UPFs is occurring despite investment in food and nutrition policy and regulatory systems designed to protect (and promote) public health. How can this be?

This presentation will report the findings of a critical analysis of food and nutrition policy and regulatory system activities in relation to UPFs and propose reforms to help inform the development of 'fit-for-purpose' policies and regulations to target ultra-processed foods.

The critical analysis of food regulatory system activities focused on the nature and scope of their risk analysis frameworks. Consistently, food regulatory systems frame risk assessment disproportionately in terms of toxicological and microbiological risks with limited regard to public health nutrition risks. When nutrition risks are considered the assessment processes generally use methods which are not well-suited for specifying and measuring contemporary risks of the types associated with UPFs. Findings from the critical analysis were used to identify reforms to risk analysis frameworks so they are fit-for-purpose for assessing risks associated with UPFs.

The critical analysis of food and nutrition policy frameworks focused on the scope of policy reference standards such as dietary guidelines and policy actions such as front of pack labelling. Consistently, the scope of these policy activities is framed in a reductionist orientation which privileges nutrient exposures over food exposures as the focus of policy activities. For example, currently the design of front-of-pack labelling is being informed predominantly by nutrient profiling systems which inadvertently are providing 'health halos' for UPFs. Findings from the critical analysis were used to identify reforms to the nature and scope of the evidence synthesis and translation methods used to inform nutrition policy activities so they are fit-for-purpose for attenuating UPF harms.

Reforms to monitoring and evaluation activities so they provide information which is fit-for-purpose to guide food and nutrition policies and regulations to target UPFs are also proposed. These reforms are focussed on the processes for compiling and reporting on food composition and food consumption databases.

Who should think and what should be done to achieve a healthy diet for humans and the planet

Marika Nomura[1,2]

1. Japan International Cooperation Agency (JICA) (Japan), 2. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

The world is in the midst of a transition from undernutrition to overnutrition. This process requires more efficient and sustainable approaches to address double or triple burden of malnutrition. The year 2021 is an important year for the global trend in nutrition. It marked the midpoint of the UN Decade for Nutrition, the UN Food Summit in September, and the Tokyo Nutrition for Growth (N4G) Summit in December. Sustainable healthy diets were discussed in this series of events. Japan has a unique experience in nutrition that can be shared with the world. Japan has dealt with "nutritional deficiencies" due to food shortages and "lifestyle-related diseases" associated with rapid economic growth. Japan has developed nutrition policies to meet the challenges of each era and has become the world's longest-lived nation by practicing a healthy diet in addition to achieving universal health coverage. It has also lowered the prevalence of obesity. Japanese food is listed as one of the territorial diets rooted in the region, and it has an essential double duty to support not only the health benefits but also the transition to sustainable agriculture and food system. We used the EAT-Lancet Diet model to examine the sustainable healthy diet achievement of the Japanese diet using data from the Japan National Health and Nutrition Survey. The results indicated that the Japanese diet almost achieved a sustainable healthy diet, although excessive consumption of red meat was problematic in terms of the EAT-Lancet Diet. In most countries and regions of the world, rapid socioeconomic development has accelerated attractive and convenient food choices. For example, efforts are being made to prevent overnutrition and noncommunicable diseases especially in the Pacific Islands. Diet in small island countries are vulnerable to natural conditions caused by climate change or socioeconomic conditions. The Japan International Cooperation Agency (JICA) is cooperating with low- and middle-income countries facing a double or triple burden of malnutrition to help them achieve a healthy diet, including the capacity development of nutrition experts, policy development, or school meal programs. Stakeholders involved in the supply chain must shift from a one-way food system based on market norms to a people-centered food system based on social norms, where no one is left behind to be healthy in every corner of the world. It is not feasible for a single sector/stakeholder and needs to be a multi-sector/stakeholder effort.

SY(T6)4-02

Equitable and ethical diets for sustainable food systems

Jessica Fanzo[1]

1. Johns Hopkins University (USA)

In the context of the broad global trends of population growth, the climate crisis, and inequitable diets, food systems need to be re-oriented to ensure they can produce enough food that nourishes everyone, leaving no one behind. At the same time, food systems must decrease the pressure on biodiversity loss, conserve land and water resources, minimize air and water pollution, and lower greenhouse gas emissions. The current COVID-19 pandemic has imposed additional pressures on the governance, functionality, efficiency, and resilience of food systems, with potentially long-lasting implications. This re-orientation includes moving towards on-farm sustainable food production practices, lessening food loss and waste, addressing poverty by creating jobs and decent livelihoods, and providing safe, affordable, and healthy diets for everyone. This is a lot to ask of an already entrenched system involving diverse actors with diverging priorities and motivations. Sound food policies are central to changing systems, and bold policies must be applied to accelerate and incentivize economic, societal, and technological transformations towards a more socially just and sustainable global food system. But policy decisions come with trade-offs and ethical challenges, and short- and long-term, often unexpected consequences. In a world of uncertainty, can we have both human and planetary health—can we have it all? This presentation will explore that question through a global lens that takes the audience through a range of sticky debates that plague the world's ability to ensure equitable and ethical diets for everyone.

Keywords: ethics, diets, sustainable, food systems, trade-offs

SY(T6)4-03

The combination of tropical agriculture and insect use for food

Kenichi Nonaka[1]

1. Rikkyo University (Japan)

Insects have been eaten as food from temperate to tropical regions except for Islamic cultures in a long tradition. In recent years, insects have attracted attention as a future food source. Various species of traditional edible insects can be collected through agricultural and rural life. These traditional edible insects have a connection between diverse natural environments and diverse food choices depending on peoples' livelihoods. The amount weights of insects consumed and the labor costs of collecting insects indicate that insects can be a substantial part of the diet among tropical peoples throughout the year. Insects are one of the ingredients that spice up the diets and help in the balance of micro nutrient intake such as Cu, Fe, and Zn. This presentation describes insect food as one of the various uses of natural resources in local subsistence strategies and cultural adaptations and evaluates its value as micro-nutrient resource. Case studies based on geographic and cultural ecological field surveys in which food safety and food security are crucial issues include termite consumption and crop raising on termite hills in Southern Africa (South Africa, Zimbabwe), edible insects associated with rice cultivation in Southeast Asia (Laos, Thailand), and edible forest insects associated with sago palm cultivation in Oceania (Papua New Guinea); health and nutritional transition were crucial issues. Agricultural land is greatly involved in the acquisition of edible insects depending on the growth of crops and the usage of agricultural land. Wild edible insect use can be integrated in agriculture such as growing crops on termite mounds and using the termites as food as well as managing pest insects by collecting them for food. It is necessary to understand the use of insects in the diet by understanding the interrelationship of human activities and insect habitats. In natural resource-dependent societies, the natural resources such as wild leaves, animals, and insects have been suppliers of micronutrients for a long period of time. Therefore, it is necessary to evaluate adaptive aspects of local diets and subsistence activities that provides micronutrients. The relationship among health, nutritional status, diet and natural food resources was elucidated in different ecological settings. Effectiveness for health by micro-nutrients is regarded in the hypothesis of intake of miscellaneous wild food materials such as insects collected by subsistence activities nearby for daily food.

The environmental cost of protein food choices

Kitti Sranacharoenpong[1]

1. Institute of Nutrition, Mahidol University (Thailand)

Background and Objective: Climate change is emerging as a major challenge of the 21st century. Agriculture both affects and is affected by climate change, yet agriculture and food production has been largely overlooked in discussions on climate change policy. A new paradigm is needed for sustainable food system development and climate change mitigation. The objective of this study was to investigate the environmental impact of producing one kilogram (kg) of edible protein from two plant and three animal protein sources.

Methods: Primary source data were collected and applied to commodity production statistics to calculate the indices to compare the environmental impact of producing 1 kg of edible protein from beans, almonds, eggs, chicken and beef. Inputs included land and water for raising animals and growing animal feed, total fuel, and, total fertilizer and pesticide for growing the plant commodities and animal feed. Animal waste generated was computed for the animal commodities.

Results: To produce 1kg of protein from beans required approximately 18 times less land, 10 times less water, 9 times less fuel, 12 times less fertilizer, and 10 times less pesticides in comparison to producing 1kg of protein from beef. Compared to producing 1 kg of protein from chicken and eggs, beef generated 5 to 6 times more waste (manure) to produce 1kg of protein.

Conclusions: The substitution of beef with beans in meal patterns will significantly reduce the environmental footprint worldwide and should also be encouraged to reduce the prevalence of non-communicable chronic diseases. Societies must work together to change the perception that red meat (e.g., beef) is the mainstay of an affluent and healthy diet.

SY(T6)5-01

Poverty and Obesity

Adam Drewnowski[1]

1. University of Washington (USA)

Background and objectives: Obesity in the US follows a socioeconomic gradient. Obesity is more common in more deprived areas and among lower- income groups.

Methods: Although links between prevalent obesity and multiple aspects of the built environment are observed in cross-sectional studies, recent studies of movers show that the built environment has little influence on weight gain over time. Studies on nutrition economics likewise show that food expenditures vary with residential location and socioeconomic status.

Results: Paradoxically, the so-called "obesogenic" neighborhoods do not promote weight gain and have no obesogenic power. Rather, the observed spatial clustering of obesity by neighborhood may be related to residential property values, as opposed to the geographic distribution of supermarkets, fast foods, public transport, or opportunities for physical activity. In essence, obesity is one embodiment of social and economic deprivation. There are further links between obesity, diet quality, and diet cost. In general, diets composed on refined grains, added sugars and fats cost less per 2000 kcal than do healthier diets composed of minimally processed meat and fish, whole grains and fresh vegetables and fruit. Budget driven dietary choices can have physiological consequences. Some lower-cost processed foods that are both energy dense and palatable can promote overeating and subsequent weight gain. Estimated diet cost has also been linked to residential property values and diet quality does vary across neighborhoods.

Conclusions: The long-standing socio-economic disparities in obesity prevalence were brought into sharp relief by the COVID-19 pandemic. The recent rise in food prices was most marked for nutrient-rich foods, including meat, fish and dairy. The reliance of low cost foods of minimal nutritional value, coupled with sedentary lifestyles, will lead to a sharp increase in obesity rates among vulnerable children and adults for years to come.

Keywords: Obesity, Diet quality, Deprivation, Poverty, Property values

SY(T6)5-02

Effects of socioeconomic status on nutrition and nutrition policy studies in Asia

Nobuko Murayama[1]

1. University of Niigata Prefecture (Japan)

Evidence of health disparities has been reported around the world. One of the intermediate factors between socioeconomic status (SES) and health is nutrition. Many studies reported socioeconomically disadvantaged people had more risk of obesity and NCDs than others in western society. In Asia, on the other hand, the economic status of countries is diverse, ranging from low-income to high-income countries, and furthermore, economic status is changing. Therefore, the relationship between SES and nutrition is also considered to be different and changing from country to country. In studies since 2010, the nutritional status of populations with low SES is as follows. In India, undernutrition among children and women has been reported. In China, low energy and nutrient intake and undernutrition are common among children and elderlies, while adults have both obesity and undernutrition. In Japan and Korea, weight faltering of preschool children, low dietary quality among school children to adults, and high obesity among adolescents and adult women have been reported. There are two types of

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

policies to reduce nutrition disparities: those that address the population as a whole and those that focus on households with low SES. For population-wide measures, school environmental interventions have been reported to reduce economic disparities in childhood obesity in high-income countries. It has also been reported that school lunches contribute to improved nutritional status of children in low- and middle-income countries, that school lunches reduce economic disparities in children's dietary quality and that there are no economic disparities in obesity among school children in Japan. As for interventions for low SES households, Supplemental Nutrition Assistance Program (SNAP) in the United States is famous. Several types of intervention to improve the nutritional status of low SES households in low- and middle-income countries were reported. Intervention that improved buying power: unconditional cash transfer (UCT), conditional cash transfer (CCT), income generation intervention, interventions that addressed food prices: food vouchers, food and nutrition subsidies, intervention that addressed the social environment: social support interventions. In India, in addition to CCT by the government, the effectiveness of microfinance by NGOs is also being examined. In China, there are reports on the effectiveness of government-sponsored CCT and the Rural Pension Scheme for the elderly. In South Korea, there are reports on the effects of government food assistance and nutrition education for mothers and children, and food assistance for the elderly. In Japan, there are food banks and home-delivered meals for children provided by NPOs, etc., but there are few policies by the government. Nutrition disparities due to SES disparities in Asia need to be monitored. In Asia, nutrition policy focuses on cash subsidies and food assistance for low SES households, but food environment measures for the population as a whole, such as school lunches, are also needed to reduce not only undernutrition but also overweight/obesity.

SY(T6)5-03

Achieving an equitable healthy society through data-driven community organizing

Naoki Kondo[1]

1. Kyoto University (Japan)

Health and health behaviors are influenced by macro-level factors (e.g., national policies, food systems, income inequality, etc.) and the individual social factors that come from them (e.g., social relationships, participation, income, occupation, neighborhood environment, etc.). Interventions to these social factors are therefore essential. In particular, changing the social environment in a community or a country requires community organizing in collaboration with various non-health sectors, not just medical and health professionals. In addition, in order for diverse organizations to work together, goal setting and evaluation of achievement must be done with objective data. The presenter, a social epidemiologist, will use examples from the Japan Gerontological Evaluation Study Initiative, the collaborative research project with about 60 municipalities across Japan (Haseda et al, Soc Sci Med, 2019; Health Place, 2022), and social experiments we conducted in Adachi Ward, Tokyo (Nagatomo et al, Int J Behav Nutr Phys Act, 2019) and some others, to show how data-driven community organizing strategies can change individual health behaviors, including diet and its equity.

Children's Healthy Living community randomized trial sustainably decreased prevalence of overweight and obesity of young children in the diverse US affiliated Pacific región

Rachel Novotny[1], *Tanisha Aflague*[2], *Patricia Coleman*[3], *Travis Flemin*[4], *Leslie Shallcross*[5], *Lynne Wilkens*[6]

1. University of Hawaii at Manoa (USA), 2. University of Guam (Guam), 3. Northern Marianas College (Northern Mariana Islands), 4. American Samoa Community College (American Samoa), 5. University of Alaska at Fairbanks (USA), 6. University of Hawaii Cancer Center (USA)

Background and objectives: The US affiliated Pacific region includes US states and territories that are not surveyed in US public health surveillance systems, yet there is evidence of nutrition transition in the region. The population is highly diverse with overall high overweight and obesity prevalence and poor diet quality among children, compared to the US contiguous states. The Children's Healthy Living program addressed this gap with nutrition assessments, and a multilevel multicomponent trial with community engagement, capacity building and outreach.

Methods: Twenty-seven communities in 5 Pacific jurisdictions (Hawaii, Alaska, Northern Mariana Islands, American Samoa, and Guam) were randomized. Children, 2-8 years (n=9840), were surveyed, including measured anthropometry and acanthosis nigricans visual inspection at 3 time points - baseline, 2 years (post-trial), and 6 years (maintenance period).

Results: Prevalence of child overweight and obesity decreased in intervention relative to control communities by 4% after the 2 year trial, and by 12.6% 6 years after the baseline measures, and by 8.7% in the 4 years after the trial ended.

Conclusions: A community-based, community-randomized, multilevel, multicomponent, capacity building program resulted in a long-term reduction in the prevalence of childhood overweight and obesity in the diverse US affiliated Pacific region.

Keywords: child, nutrition, Pacific, obesity, community

Capacity building for enhanced research on nutrition and cancer in low- and middle-income countries

Ellen Kampman[1], Cora Busstra[1], Isaac Agbemafle[2], Reggie A. Annan[3], Elom K. Aglago[4], Keiron Audain[5], Alan Jackson[6], Francis Zotor[2]

1. Wageningen University (Netherlands), 2. University of Health and Allied Sciences (Ghana), 3. Kwame Nkrumah University of Science and Technology (Ghana), 4. Imperial College London (UK), 5. University of Ghana (Ghana), 6. International Collaboration on Nutrition in relation to Cancer (UK)

Background: The fast transition in dietary patterns and food production observed in low- and middle-income countries (LMICs), particularly among the poorest people and communities, is leading to more nutrition-related types of cancer. There is an urgent need to better understand the situation and to develop effective approaches to prevention and care requiring high quality research in nutrition and cancer research led by experts from/within LMICs.

Objective: We are working towards building a more extensive capability and stronger and sustained capacity for excellence in research and practice across LMICs. This fundamental and critical challenge is the concern of the International Collaboration on Nutrition in relation to Cancer (ICONIC), which is fostering capacity building as a core ambition. ICONIC is looking to identify the best way to develop and implement training and improve the preparation of grant proposals, especially for the most vulnerable places in LMICs.

Results: Several activities are currently ongoing: 1. Each year, an international course on study designs is provided for scientists who want to gain knowledge in cancer epidemiology and experience with writing grant proposals involving epidemiological studies on nutrition and cancer; A total of 12 scientists from 7 African countries have been initially trained within the scheme of this programme, and a third course is planned late 2022. 2. Together with the founders of the European Prospective Investigation into Nutrition and Cancer (EPIC), the necessary steps are identified to build a major collaborative international study: an international prospective cohort study in Africa ('APIC'). Currently, these activities are coordinated by ICONIC and conducted together with Wageningen University and CANA (Cancer and Nutrition in Africa), a group of African scientists formed within the African Nutrition Society (ANS).

Conclusion: A structured approach to the development of capability and capacity for high quality research related to nutrition and cancer is a high priority for LMICs to improve prevention and treatment. We look forward to sharing experiences and to engage with others interested in and committed to this vision.

The role of nutrition and other lifestyle factors in paediatric oncology

Inge Huybrechts[1]

1. International Agency for Research on Cancer (France)

Background and objectives: Lifestyle factors such as nutrition and physical activity have been related to several chronic diseases, including certain cancer types. However, the role of nutrition and other lifestyle factors in the development of childhood cancers remains unclear. Certain dietary factors, like coffee drinking during pregnancy, have been associated with the risk of developing childhood cancer, while at the same time the nutritional status of children with cancer has been associated with therapy success and survival. We aim to provide an overview of ongoing research projects aiming to investigate the potential role of nutrition and other lifestyle factors in paediatric oncology.

Methods: We will provide an overview of the epidemiological evidence regarding the potential role of nutrition and other lifestyle factors in the development of childhood cancer and more in particular for Childhood Acute Leukemia, the most common type of cancer in children. Secondly, we will give a synopsis of ongoing projects in the Nutrition and Metabolism Branch (NME) at IARC that aim at investigating the role of nutrition and other lifestyle factors in paediatric oncology.

Results: Overall, a recent review of the literature indicates that a maternal diets rich in fruit and vegetables and supplementation with folic acid and other vitamins could potentially reduce the risk of Childhood Acute Leukemia, while coffee drinking during pregnancy may be positively associated with the risk Childhood Acute Leukemia. In addition, several projects have been launched to investigate the role of nutrition and lifestyle factors on cancer prognosis among children with cancer. An information resource is being set up by the International Initiative for Pediatrics and Nutrition (IIPAN) and NME, for advancing high-quality research in nutritional science and pediatric oncology. Data derived from dietary assessments and blood and stool samples taken for monitoring and assessing nutritional status are being used to investigate the metabolic effects of all forms of malnutrition and its impact on treatment efficacy and prognosis. **Conclusions:** This review of the epidemiological evidence together with clinical data and biological specimens will foster future studies on cancer progression and prognosis as well as toxicities during treatment that may impact survivorship and late-effects.

Keywords: Nutrition, Lifestyle, Childhood cancer, Paediatric oncology, Prognosis

Further Collaborators: Projects described are collaborative efforts between the Nutrition and Metabolism Branch at the International Agency for Research on Cancer (IARC), World Health Organization (WHO) and the International Initiative for Pediatrics and Nutrition (IIPAN), as well as the different IIPAN sites where IIPAN-affiliated trained personnel will facilitate the research objectives adhering to standard-operating-procedures set forth by IIPAN and IARC.

Prehabilitation within the management and support of those living with cáncer

Elom K Aglago[1], Alan Jackson[2], Kostas K Tsilidis[1], Stephen Wootton[2]

1. Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London (UK), 2. NIHR Cancer and Nutrition Collaboration, University of Southampton (UK)

The global burden of cancer disproportionately affects low- and middle-income countries (LMICs) with over 11.4 million incident cancer cases diagnosed in LMICs among the 19.3 million cases reported globally in 2020. Likewise, cancer mortality is markedly elevated in LMICs, with over 7 million deaths in 2020. Diagnosis with cancer in LMICs is often associated with malnutrition, anxiety, depression, and even financial toxicity. We know that people with cancer who are under-nourished, physically unfit, and psychologically distressed after diagnosis have poorer outcomes from their cancer and its treatment than those who are better nourished, fitter and more psychologically resilient. Prehabiltation, the process of identifying those individuals most at risk and intervening early through structured exercise, nutritional and psychological support prior to starting treatment, aims to better prepare patients for surgery and/or anti-cancer therapies and improve outcomes. Prehabilitation interventions developed in high income countries (HICs) settings have been shown to result in enhanced recovery, reduced length of stay and treatment complications, improved nutritional status and cardiorespiratory fitness, and overall better quality of life during and after treatment. In contrast to HICs, healthcare care systems in LMICs are less well integrated, often funded and managed vertically, and have multiple challenges in terms of human and financial resources. If the principles and guidance of prehabilitation developed in HICs were applied and translated into culturally-sensitive interventions in LMICs and shown to be feasible and similarly effective, these low-cost approaches may confer important opportunities to improve the response to treatment and the quality of life of cancer patients. The prehabilitation package of care needs to be owned by and with those able to comprehend the complexities and specificities of health systems in LMICs. The implementation of prehabilitation in LMICs will require the development of screening and assessment tools that are fit for purpose in LMICs as well as capability and capacity building using standardized protocols and information management through a trusted network of collaborating centers across countries. Success is dependent on building effective collaborations between HICs and LMICs and South-South collaborations to share experience and understanding which will involve patients, academics, civil societies, services providers, knowledge users and policymakers to determine the factors that will influence the adoption, implementation, impact, and sustainability of prehabilitation interventions within clinical services locally, nationally, and regionally. Work has already started in Africa with Cancer and Nutrition in Africa (CANA), a working group under the umbrella of the African Nutrition Society (ANS) and the International Collaboration on Nutrition in relation to Cancer (ICONIC). For the past two years, CANA has worked collaboratively with Wageningen University, ANS and ICONIC to develop a course on grant writing for cancer and nutrition research in Africa. CANA's agenda involves the development of a community of practice for Africa. This will ultimately lead to research projects on nutrition and cancer, especially on the role of nutrition as an important component of prehabilitation.

Keywords: prehabilitation, cancer, nutrition, collaboration, capacity building

SY(T6)6-04

Supporting better collaboration in nutrition and cancer: A global approach.

Alan Jackson[1,2]

1. University of Southampton (UK), 2. International Collaboration on Nutrition in relation to Cancer (UK)

Background: Cancer prevalence is increasing worldwide, accounting for nearly 10 million deaths in 2020. Inappropriate diet, nutrition and physical activity as major preventable causes. Estimates indicate that cancer will be the most common cause of mortality and morbidity by 2050, increasing greatest in Low and Middle Income Countries (LMIC), where resources for prevention and care are relatively limited.

Objective: The International Collaboration on Nutrition in relation to Cancer (ICONIC), set up in 2018 as Task Force of IUNS, promotes and facilitates collaboration between the scientific communities in nutrition and cancer – for research, education and training, and in clinical and public health practice.

Methods: ICONIC has focused activity on three where the need was evident and possibility for traction appeared greatest: prehabilitation, childhood cancers and capacity building, focussing on LMICs where data are limited.

Results: Firstly, ICONIC recognises the role of prehabilitation (personalised management of exercise, nutrition and psychological support) in preparing patients for treatment, increasing resilience to treatment and improving longer-term health. Secondly, ICONIC is facilitating new and stronger connections amongst multiple stakeholders involved in nutrition and childhood cancer research, with the development of an agreed framework for better enabling collaboration, sharing understanding, identifying knowledge gaps, and setting research priorities for improved care. Thirdly, ICONIC in recognising the need for wider capability and stronger capacity for excellence in research and practice across LMICs, a structured training course has been established with a particular focus on the special needs for Africa in the first instance.

Conclusion: A focus on these three areas in the first instance, is helping to drive forward the ambition to bring change and make a meaningful difference. There is the need for large-scale prospective cohort studies in LMIC, similar in character to European Prospective Investigation into Cancer and Nutrition (EPIC). We are helping establish the base capability with which it will be possible, for example, to conduct studies across multiple sites in LMIC that will capture diversity of cancer sites, diversity

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of dietary patterns, nutritional status and physical activity, with appropriate biomarkers of nutritional status and cancer characteristics.

Keywords: Cancer, Nutrition, Physical activity, Rehabilitation, children and young adults

SY(T6)7-01

Food Loss and Waste: Why it matters to all

Mbuli Charles Boliko[1]

1. Food and Agriculture Organization of the United Nations (Madagascar)

The world produces enough food for all human beings to eat and enjoy a healthy and active life. Yet, over 800 million people on earth do not have access to enough food, in quantity or in quality. At the same time, it is estimated that one third of the food produced painstakingly ends up being thrown away. In addition to its significant economic and health impact, food loss and waste (FLW) is also a major cause of greenhouse gas emissions, the consequences of which can negatively affect anyone, anywhere. This presentation will feature the current situation of FLW, its causes and consequences, before highlighting some recommendations that everyone can implement to contribute to a more sustainable world.

Keywords: Food Loss and Waste (FLW), Food security, Nutrition, Sustainable Development Goals (SDGs), Sustainable behavior

SY(T6)7-02

The Myth of Food Loss: Why this is a problem to solving larger problems

Charles E. McJilton[1]

1. Second Harvest Japan (Japan)

"If I had just one hours to save the world, I would spend 55 minutes defining the problem and five minutes coming up with solutions." Einstein In the case of food loss/food waste (FLFW) this has been turned on its head. Go to any conference or read material related to FLFW and the discussion is focused on either the morality of the issue or how to "solve" the problem. The moral question is framed as, "How can we waste so much food when so many people are hungry in the world?" Then unsubstantiated statistics will be presented to punctuate the question.

"Solutions" to FLFW range from peeling carrots more efficiently to using the last 15 minutes of a party to consume all remaining food (the Japanese government has promoted both of these). Also apps abound claiming they will match surplus food with eager consumers and thus reduce FLFW. And organizations have made it their mission to solve FLFW through awareness campaigns and community engagement. While it is evident people feel their actions make a difference, there is no evidence they have impact. I would suggest that food loss and food waste are natural by-products of our market-driven system. This system rests on the fundamental principal of choice. We freely choose that which we want to consume. The trade-off of choice is not everything is consumed. A world of zero food waste is a world with zero choice. This paper challenges the commonly accepted ideas of FLFW and points to three fundamental overlooked issues. First, the very definition of FLFW is not universal. Each country, and in some cases even within the government, have different working definitions which calls into question how success can be measured. Second, the innate nature of FLFW in the supply chain can be summed up in the equation P> M> C, where P=production, M=market, and C= consumption. We will always produce more than is consumed. Lastly, choice is fundamental from farm to fork. This choice will always create winners and losers (consumption and waste). This paper will address the moral outcry of food waste and when so many go hungry each night. While it is a natural human response to feel pangs of guilt to seeing food thrown away knowing others do not have enough, reducing FLFW will never eliminate hunger or food insecurity. Fundamentally these two issues have very different causes and solutions. Connecting these two issues is counterproductive. We need to decouple the connection between FLFW and hunger/food insecurity. It is time we take an adaptive leadership approach and engage a wider range of stakeholders to reconsider what problem we are trying to solve as well as solutions we can test. There are real consequences of putting resources into campaigns with no hope for meaningful impact. They lead us to believe we are making a difference, when in fact they distract us from what is actually important.

Keywords: Food loss, Hunger, Food waste

Japanese Policies for Enacting and Implementation of Act on Promotion of Food Loss and Waste Reduction

Mizue Naito[1]*, Makoto Tanaka*[1]

1. Consumer Affairs Agency (Japan)

Reducing food loss and waste (FLW) has become a global issue. In light of this, Japan has set a national target of halving FLW from its 2000 total by the year 2030. The Act on Promotion of Food Loss and Waste Reduction, which was enforced on 1 October, 2019, aims to promote the reduction of FLW as a

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

national movement through cooperation between a wide range of stakeholders. This presentation summarizes the current situation on FLW, an overview of the Act, and the Basic Policy on Promotion of FLW Reduction in Japan.

Keywords: food loss and waste (FLW), national movement, national target of halving FLW, national action, SDGs (Sustainable Development Goals)

SY(T6)-04

Global Environmental Issues: Food and Agriculture Education to Address Food Loss and Waste, Aiming at a Sustainable Supply Chain

Mizuho Sato[1]

1. Tokyo University of Agriculture (Japan)

The 2030 Agenda for Sustainable Development adopted at the 2015 United Nations Summit, set a goal to halve global food waste at retail and consumption levels in the Sustainable Development Goals (SDGs). As part of this initiative, governments are required to reflect the SDGs in national planning processes, strategies, and policies with due consideration for the circumstances of each country. It is estimated that food waste of 25.31 million tons and food loss of 6 million tons occurred in Japan during FY 2018. Of this total amount, 3.24 million tons of waste was generated from business including the food manufacturing, wholesale, retail, and restaurant industry, and 2.76 million tons was generated from households. Consequently, it is crucial to mitigate both upstream and downstream food loss. In particular, the consumption patterns of consumers greatly influences not only downstream but also upstream food loss. Special emphasis must therefore be placed on increasing consumers' awareness regarding this global issue, and several programs have been initiated toward this end. Our research reveals that enhancing consumers' skills alongside awareness is of vital importance to efficiently reduce downstream food loss. Additionally, business operators must invest in improving skills of people-in-charge to minimize food loss in commercial set ups. Thus, educating both consumers and businesses with the requisite skills to lessen food loss is equally indispensable. The authors are developing impactful games to aid imparting of such education. Specifically, these include vegetable supply chain games where consumers are players and milk supply chain games where businesses as players. Vegetable supply chain games are games which simulate the vegetable supply chain, demonstrating what type of consumers actions will lead to food loss directly or indirectly and how these effects can be mitigated. In addition, milk supply chain games can simulate the 1/3 rule, a Japanese business practice. These games will examine how the business practice of the 1/3 rule affects the amount of loss at each stage of the supply chain (producer, dairy maker, supermarket, and consumer) and how to reduce the loss. The present talk will introduce some of the studies that have been undertaken by the authors to reduce food loss. During the course of this lecture, "food waste" refers to foods that are still edible and those which were originally inedible, such as meat and fish bones accumulated during food processing. Additionally, “food loss" refers to discarded foods that were originally edible, such as dented canned food or unconsumed food that was procured in large quantities at bargain price (untouched food).

New actions to reduce anaemia and risk of overweight and obesity in infants and young children in low-income urban areas of Peru: The PERUSANO study

Rebecca Pradeilles[1], Rossina Pareja[2], Emily Rousham[1], Rosario Bartolini[2], Michelle Holdsworth[3], Violeta Rojas[4], Nervo Verdezoto[5], Paula Griffiths[1], Hilary M Creed-Kanashiro[2]

1. Loughborough University (UK), 2. Instituto de Investigación Nutricional (Peru), 3. French National Research Institute for Sustainable Development-IRD (France), 4. Universidad Nacional Mayor de San Marcos (Peru), 5. Cardiff University (UK)

Background and objectives Multiple forms of malnutrition coexist in infants and young children (IYC) in Peru. The PERUSANO project aimed to develop new culturally appropriate interventions and policies (actions) to simultaneously reduce risks for micronutrient deficiencies and overweight/obesity in IYC living in low-income urban areas of Peru. The specific objectives were to: i. identify factors influencing infant and young child feeding practices (IYCF) and forms of malnutrition; ii. map and prioritise actions currently in place at national level to target multiple forms of malnutrition; iii. develop and pilot new actions to address multiple forms of malnutrition among IYC through participatory methods and prototyping interventions with families, childcare and health facilities; and iv. work in partnership with local health services and stakeholders to develop capacity to implement participatory IYCF interventions.

Methods: This study included two main phases: i. a formative phase to understand the specific problem of malnutrition in Peru, its drivers and policy landscape, and ii. a design phase to pilot and evaluate new interventions. Here we describe the first phase and how it informed the design phase. The formative phase was divided into four work packages (WP). WP1 assessed the healthiness of IYC diets quantitatively and factors associated with malnutrition via a cross-sectional study of mother-infant dyads (n=244) from Manchay (Lima) and Huánuco district (Huánuco). WPs 2 and 3 aimed at gaining in-depth understanding of family/caregivers (WP2) and health centre/day care centre influences (WP3) on IYCF practices through observations (n=47) and interviews (n=194). WP4 assessed the current implementation of and priority for government actions to tackle multiple forms of malnutrition by conducting in-depth interviews with 16 national experts. To inform the design phase (start date

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

January 2022), we engaged in several steps: i. *step 1*: collate a list of priority challenges from each WP; ii. *step 2*: group similar challenges together to create an affinity diagram; *step 3*: refine the affinity diagram by verifying this classification with WP leads (validation step); and *step 4*: run an online project scoping workshop to enable members to vote on their top four priority challenges from across all WPs (n=29). The top four challenges retained were discussed in small groups using the "how might we" technique to identify barriers/facilitators to their implementation.

Results: The top four challenges to take forward to the design phase included: i. high consumption of unhealthy foods and sugar-sweetened beverages in IYC; ii. Low use of (or difficulties with) iron supplementation in IYC; iii. Issues with nutritional counselling; and iv. Lack of monitoring in the health system to track progress around the double burden of malnutrition in IYC. **Conclusions:** The mixed methods formative work conducted by a team of interdisciplinary researchers was instrumental in identifying and prioritising opportunities to tackle multiple forms of malnutrition among low-income urban communities in Peru. This work also captured the views of stakeholders at different levels of influence (individual, community and institutional, and national level), which is crucial to obtaining a comprehensive appraisal of the problem and to inform the design and implementation of interventions.

SY(T6)8-02

Participatory design to develop prototypes for interventions aimed at tackling malnutrition in all its forms in Peru: The PERUSANO study

Rossina G Pareja[1], Deysi Ortega[2], Hilary M Creed-Kanashiro[1], Rosario Bartolini[1], Rebecca Pradeilles[3], Ines Varela-Silva[3], Paula Griffiths[3], Emily K Rousham[3], Nervo Verdezoto[2]

1. Instituto de Investigación Nutricional (Peru), 2. Cardiff University (UK), 3. Loughborough University (UK)

Background and objectives: The prevalence of undernutrition and overweight/obesity is high in Peru, particularly impacting children of low socioeconomic status. Caregivers play an important role in infant and young child feeding (IYCF) practices. However, their needs, barriers and their voices are not usually considered in the design of interventions aiming to enhance IYCF practices. In this work, we examine the iterative process of designing socio-technical interventions to improve IYCF using participatory methods, that go beyond traditional methods such as interviews and observations. Instead, we brough together interdisciplinary researchers, healthcare professionals, and caregivers to develop more culturally adequate strategies.

Methods: Taking a human-centric approach, we examined the role of different participatory qualitative methods and tools to support the understanding of the context, the user's needs and motivations, and to elicit iterative feedback. We created and validated a set of tools including a storyboard, design cards and a design workbook to support the reflection on IYCF challenges and the early stages of design for and with Peruvian communities (healthcare professionals and families) in Lima and Huánuco. These tools are essential materials to support co-design activities of IYCF interventions.

Results: Based on the iterative design process and early validation of design materials, we will outline the challenges and opportunities to support the early reflection of community IYCF priorities and the material's potential for brainstorming, early ideation, and prototyping of culturally and contextually relevant strategies and interventions to enhance IYCF practices. We found that early identification of sociocultural characteristics of the communities is fundamental to accurately represent the communities' experiences. Additional lessons learned include considering and balancing interdisciplinary perspectives within and beyond the community and facilitating a shared understanding for both the healthcare professionals and the local families.

Conclusions: The use of participatory research methods in Peru has been challenging especially during the pandemic where alternatives to face-to-face participation had to be developed. Participatory research methods are quite new, especially in the healthcare context, where traditional methods often do not involve the community in the design process of health interventions. Our methods have helped us to understand the sociocultural context and the community health priorities giving the opportunity to the local participants to have a voice and engage in the co-design of the most suitable approach. Thus, design materials have the potential to address power imbalances by mediating the interaction among multiple stakeholders with different perspectives.

Community readiness to improve food safety practices among informal food handlers: A qualitative analysis in the three major cities in Ecuador

Angelica Ochoa-Aviles[1], María José Peñaherrera-Vélez[1], Denisse Vásquez[1], Signe Vargas[1], Rebecca Pradeilles[2], Michelle Holdsworth[3], Paula Griffiths[2], María José Molina Cando[1], Johana Ortiz-Ulloa[1]

1. University of Cuenca (Ecuador), 2. Loughborough University (UK), 3. French National Research Institute for the Development (France)

Background and objective: Food safety is a critical issue in low- and middle-income countries and is a barrier to healthy eating in Ecuador. This study aimed to explore community readiness to implement strategies to improve food safety among informal food handlers in urban Ecuador.

Methods: Using the **Community Readiness Model** (CRM), 40 in-depth interviews were conducted with key informants in the urban area of the three major cities in Ecuador (Quito, Guayaquil and Cuenca). Data collection was conducted from September to December 2020. The informants included governmental officials involved in regulatory actions regarding food safety among informal food handlers and non-governmental community members related to the preparation, transportation, and consumption of informally produced foods. The governmental informants belonged to the Ministry of Health, Food Safety Regulatory Agencies and the City council; the non-governmental informants comprised informal food handlers, consumers' advocacy groups, health professionals, food deliverers, and cleric representatives. The CRM determines the communities' willingness to implement preventive strategies for a specific problem (i.e., unsafe foods sold by informal food handlers) by exploring five critical dimensions (community knowledge of efforts, leadership, community climate, knowledge of the issue and resources). A score was assigned for each dimension (from 1 = no awareness to 9 = high level of community ownership), which was then used to generate an overall readiness score for each city. A thematic analysis was undertaken to understand the scores and identify critical factors (i.e., barriers or facilitators) for preventive strategies.

Results: The three cities were in a "denial/resistance" stage (Cuenca: 2.9 ± 0.4; Quito 2.9 ± 0.4; Guayaquil 2.8 ± 0.5), regarding the need to implement strategies to improve food safety among informal food handlers. In Cuenca and Quito, the scores ranged from denial to vague awareness for all the dimensions, with community knowledge about the efforts receiving the lowest score (Cuenca: 2.4 ± 0.8; Quito: 2.3 ± 1.4). In Guayaquil, the community knowledge about the efforts was in a "no awareness" stage (1.8 ± 0.8), while the other dimensions ranged from denial to vague awareness. Straightforward strategies to promote food safety among informal food handlers were not identified. Training sessions were mentioned as the primary strategy but seemed to be improvised. The governmental entities share roles in monitoring the food safety of informal handlers, resulting in unclear responsibilities and overlappings. Potential conflicts of interest of decision-makers were identified, and the community has several misconceptions and knows little about the problem and its consequences.

Conclusions: Food safety is not recognized as a priority in these three cities in Ecuador, even though it can have critical implications for healthy eating and overall health. Strategies aiming to improve community awareness of the consequences of consuming unsafe foods are urgently needed to pave the way for implementing appropriate preventive strategies to promote healthy diets in urban Ecuador. The generated data enables a clear understanding of existing strategies, stakeholder roles, and community perceptions, which can be the basis to co-design appropriate strategies.

How ready are community stakeholders to implement interventions to address the marketing and availability of unhealthy foods and beverages in and around schools in the Greater Accra Region of Ghana?

Akua Tandoh[1], Amos Laar[1], Rebecca Pradeilles[2], Agnès Le Port[3], Hibbah Osei-Kwasi[2, 4], Gideon Amevinya[1], Richmond Aryeetey[1], Charles Agyemang[5], Michelle Holdsworth[3], Wilhemina Quarpong[6]

1. University of Ghana (Ghana), 2. Loughborough University (UK), 3. French National Research Institute for Sustainable Development (France), 4. University of Sheffield (UK), 5. University of Amsterdam (Netherlands), 6. Emory University, (USA)

Background and objectives: Ghana has reached an advanced stage of nutrition transition, contributing to increasing overweight and obesity, including in children and adolescents. There is widespread marketing and availability of unhealthy foods and beverages that have, in part, led to changes in dietary habits towards processed foods high in saturated fats, sugar, and salt. Emerging evidence shows a need to improve school food environments such that they promote the consumption of safer and more nutritious diets. The readiness of communities to accept a range of interventions to tackle this issue needs to be understood before appropriate interventions can be implemented. Therefore, this study assessed how ready the 'community' is to implement actions to address the marketing and availability of unhealthy foods and beverages in and around schools in the Greater Accra Region of Ghana.

Methods: The Community Readiness Model (CRM) protocol was used to conduct in-depth interviews with 18 key informants from various school/education/citizen sectors in Greater Accra, Ghana, which together represent the 'school community'. The CRM tool consists of 36 open questions addressing five readiness dimensions (community knowledge of efforts, leadership, community climate, knowledge of the issue and resources). Interviews were scored using the CRM protocol with a maximum

of 9 points per dimension (from 1= no awareness to 9=high level of community ownership). Thematic analysis was undertaken to gain insights into community factors that could influence the design and implementation of interventions to reduce the marketing and availability of unhealthy foods and beverages to improve diets among children and adolescents.

Results: The mean readiness scores indicated that the 'school community' was at the "pre-planning" stage (4.44 ± 0.98) to address the marketing and availability of unhealthy foods and beverages in and around schools. CRM scores across the five dimensions ranged from 3.19 (vague awareness) to 5.36 (preparation) on the 9-point scale. The mean readiness score for 'leadership' was the highest of all dimensions (5.36 ± 1.60), corresponding to the "preparation" stage. The lowest scores were found for 'community knowledge of efforts' (3.19 ± 2.45) and 'resources' (3.64 ± 0.87), both of which correspond to a "vague awareness" stage. This relatively low readiness level could be explained by challenges with limited resources, such as poor funding for programmes. Additionally, while some efforts are ongoing to address unhealthy food marketing and availability, only a few community members had heard about them or knew about the scope of local efforts.

Conclusions: There is awareness among community members about the occurrence of marketing and availability of unhealthy food and beverages in and around schools and a high level of active leadership for improving food environments for children and adolescents. However, for any intervention to have maximum impact, initial actions must focus on increasing the community's knowledge of existing efforts and securing resources (e.g. funding) to initiate and sustain efforts.

Using participatory photography to identify drivers of dietary behaviours in adolescents and women living in urban Ghana

Julia Ligouri[1], Rebecca Pradeilles[2], Amos Laar[3], Francis Zotor[4], Akua Tandoh[3], Hibbah Osei-Kwasi[5, 2], Agnès Le Port[1], Richmond Aryeetey[3], Paula Griffiths[2], Michelle Holdsworth[1]

1. IRD-French National Research Institute for Development (France), 2. Loughborough University (UK), 3. University of Ghana (Ghana), 4. University of Health and Allied Sciences (Ghana), 5. University of Sheffield, United Kingdom (UK)

Background and objectives: Evidence on the individual-level drivers of dietary behaviour in deprived urban contexts in Africa is limited. Understanding how to best develop and deliver interventions to promote healthy dietary behaviour is needed, especially in Ghana, where there is evidence of rising diet-related non-communicable diseases (DR-NCDs) amidst persistent food insecurity and micronutrient deficiencies. The study aimed to identify individual-level factors (biological, demographic, cognitive, practices) influencing dietary behaviours amongst adolescent girls and women at different stages of the reproductive life course in urban Ghana, with the goal of building evidence to improve targeted interventions.

Methods: Participatory photography can be used as a tool to increase understanding of communities' and citizens' everyday life, helping to facilitate communication between communities, researchers and decision makers. Qualitative participatory photography (Photovoice) interviews (n=64) were conducted in two low-income urban neighbourhoods in Accra and Ho with adolescent girls (13-14y) and women of reproductive age (15-49y). An exhibition was also held to display participant's photographs and foster discussion within these neighbourhoods, so that participants' voices could be heard. Interviews were transcribed verbatim and coded in NVivo (version 11) using both theoretical a priori themes and a data-driven coding scheme to allow for emerging themes. The African Food Environment framework was used to structure the synthesis.

Results: Thirty-seven factors, across four domains within the individual-level were identified as having an influence on dietary behaviours: biological (n=5), demographic (n=8), cognitions (n=13), and practices (n=11). Several factors emerged as facilitators or barriers to healthy eating, with income/wealth (demographic); nutrition knowledge/preferences/risk perception (cognition); and cooking skills/eating at home/time constraints (practices) among the most frequent. Pregnancy/lactating status (biological) was also observed to influence dietary behaviours mainly through medical advice, awareness and willingness to eat foods to support foetal/infant growth and development. The ability to eat nutritious, safe food was largely mediated by income and wealth. Time constraints, eating at home/out, cooking skills, food preferences and food safety concerns were identified as key factors influencing dietary behaviours at the individual level.

Conclusions: Many individual-level factors influencing dietary behaviour were perceived as important and are intertwined with the wider food environment. Using photovoice as a method helped shed light on these multiple factors in people's lived food environments. All these individual and environmental factors need to be taken into account when designing interventions and policies within Ghana.

Policy mapping of double-duty actions that address multiple forms of malnutrition in Peru

Violeta Rojas[1], Rebecca Pradeilles[2], Hilary M Creed-Kanashiro[3], Emily Rousham[2], Doris Delgado[1], Rossina Pareja[3], Edwige Landais[4], Nervo Verdezoto[5], Emma Haycraft[2], Michelle Holdsworth[4]

1. Universidad Nacional Mayor de San Marcos (Peru), 2. Loughborough University (UK), 3. Instituto de Investigación Nutricional (Peru), 4. French National Research Institute for Sustainable Development-IRD (France), 5. Cardiff University (UK)

Background and objectives: Multiple forms of malnutrition co-exist in infants and young children (IYC) in Peru. Double-duty actions (DDAs) have been proposed to simultaneously tackle undernutrition and overweight/obesity. We assessed current implementation of- and priority for- government-level actions to tackle multiple forms of malnutrition in IYC in Peru.

Methods: Mapping of current policy activity was undertaken against 47 indicators of good practice for 5 DDAs (exclusive breastfeeding, complementary feeding, food marketing, maternal nutrition, preschool nutrition; assessed by 27 indicators) and for the enabling policy environment, i.e. 'infrastructure support' (health in all policies, platforms for interactions, financing, monitoring, governance, leadership; assessed by 20 indicators). In-depth mixed methods interviews with 16 national experts explored their views on the level of and barriers to implementing DDAs and infrastructure support. Experts also prioritised the DDAs and infrastructure support indicators for their likely impact and feasibility. The mean rating for each good practice indicator was used to determine an overall percentage level of implementation (quantitative) and verbatim transcripts from interviews were analysed using NVIVO (qualitative).

Results: Only 5/27 of DDA indicators were seen as fully implemented by all national experts (international code of breastmilk substitutes marketing, iron supplementation, micronutrient powders in infants, iron/folic acid supplementation in pregnant women, paid maternity leave). More than half (14/27) of DDA indicators were rated as fully implemented by > three-quarters of experts. Only one infrastructure support indicator (access to nutrition information) was rated as fully implemented by all experts, and a further 8 indicators by more than half of experts. Barriers to implementation of the poorly implemented indicators for DDAs (13/27) and infrastructure support (11/20) included: legal feasibility or lack of regulations, inadequate monitoring/evaluation to ensure enforcement, commercial influences on policymakers, insufficient resources, shifting public health priorities with the Covid-19 pandemic and political instability. Going forward, experts prioritised 11 indicators across all 5 DDAs: breastfeeding (5 indicators), maternal nutrition (3 indicators) and 1 indicator each for complementary feeding, food marketing and preschool nutrition. Eight indicators for improving infrastructure support were prioritised for: strengthening leadership (3 indicators), monitoring and evaluation (3 indicators), and prevent multiple forms of malnutrition by increasing funding for interventions (1 indicator) and implementing policies (1 indicator).

Conclusions: Experts observed the need to improve implementation of all DDAs to address multiple forms of malnutrition and identified a range of ways that the enabling policy environment could be strengthened.

Addressing multiple forms of malnutrition through double-duty actions: Evidence-to-policy action from Ghana

Amos Laar[1], Emmanuel Odame[2], Percy Agyekum[3], Mary Mpereh[4], Sebastian Sandaare[5], The DFC/MEALS4NCDs Projects[6]

1. University of Ghana (Ghana), 2. Ministry of Health (Ghana), 3. Food and Drugs Authority (Ghana), 4. National Development Planning Commission (Ghana), 5. Coalition of Actors for Public Health Advocacy (Ghana), 6. The DFC & MEALS4NCDs Projects (Ghana)

Introduction: Non-communicable diseases are predicted to become the leading cause of death in Ghana by 2030, amidst prevailing challenges of infectious diseases, undernutrition, and micronutrient deficiencies. Unhealthy food environments hinder progress to overcoming malnutrition in all its forms. Policies that aim to inform and empower; guide and influence; incentivize consumption of healthier diets, while disincentivizing less healthy ones are urgently needed.

Objective: We aimed to address the multiple forms of malnutrition in Ghana through context-appropriate and evidence-informed policy measures.

Methods: We engaged people in their communities, assessed communities/neighborhoods, and engaged relevant national-level food environment stakeholders to identify priorities for national action. We assessed how food and beverages are advertised, sold, and consumed in urban Ghana; assessed the healthiness of foods and beverages across food retail outlets and media channels; identified social and physical environmental drivers shaping dietary behaviors; identified priorities for policy and interventions to improve the food environment in Ghana, and determined how ready Ghanaian stakeholders are to reduce unhealthy diets and beverages consumption.

Results: The engagements, assessments, and evidence show that to improve the Ghanaian food environments, fit-for-local purpose double-duty policies, as well as strong leadership and accountability, are required to combat malnutrition in all its forms. Such policies include those that limit the availability of unhealthy diets in public institutions and markets, adjust the relative price of foods to equitably promote health and economic value, and ensure that food products have bold and truthful information for all consumers. The Ghanaian stakeholders pay heed. A coalition of government agencies, academia, and civil society are currently delivering multi-stakeholder action toward

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

a double-duty policy bundle for healthier and more equitable consumer food environments.

Conclusion: Evidence-informed advocacy and scholar activism have valorized demand for the policy bundle; the Ghanaian government is leading politically, and there is a national consensus that enactment and implementation of the policies will make unhealthy diets unattractive and unavailable while making healthier diets available, and attractive.

Framework for development of the Dietary Reference Intakes

Susan Irene Barr[1]

1. University of British Columbia (Canada)

The Dietary Reference Intakes (DRIs), supported by the United States (US) and Canadian governments, were initiated in 1994 by the Institute of Medicine (IOM) in Washington DC in response to expanding needs for nutrient reference standards beyond the single-value Recommended Dietary Allowance (RDA). As a result, the DRIs include the Estimated Average Requirement (EAR; an estimate of the median or average requirement for the specified indicator of adequacy for an age/sex/life-stage group), the RDA (an intake that that meets or exceeds the requirements of almost all (97-98%) members of an age/sex/life-stage group), the Tolerable Upper Intake Level (UL; an intake level above which the potential risk of adverse effects may increase), and an Adequate Intake (AI; an intake level thought to meet or exceed the needs of almost everyone in an age/sex/life-stage group that is used when an EAR/RDA cannot be established). The process of developing the DRIs, which has come to be known as the DRI Framework, is intended to ensure transparency of the decision-making process and also to recognize the need to make decisions based on limited data. A 4-step risk-assessment approach is used, beginning with the identification and review of potential indicators of both adequate and excessive nutrient intake for age/sex/life-stage groups, followed by selection of the most appropriate indicators based on strength and quality of the evidence. The second step includes determining the intake-response relationships between the nutrient and the selected indicator(s) and specifying the DRIs. This includes consideration of uncertainty factors, variance in requirements, nutrient interactions, bioavailability and the need to scale or extrapolate when data are limited. In the third step, data on intake of the nutrient (and as available, on biochemical and clinical measures of nutrient status) are compiled and assessed in preparation for the final step of risk characterization. This final step includes a discussion of the public health implications of the DRIs (e.g., whether particular age/sex/life-stage groups are at risk of inadequacy or excess) as well as whether the reference values may need to be modified for particular subgroups within the population. In 2017, the DRIs were expanded to include the Chronic Disease Risk Reduction Intake (CDRR), which is an intake range for a nutrient that can be set when there is at least moderate strength of evidence for both a causal and an intake-response relationship between intake of the nutrient and risk of a chronic disease. It is likely that the DRI process will continue to evolve in the future.

Dietary Reference Intakes for Japanese (2020)

Satoshi Sasaki[1]

1. The University of Tokyo (Japan)

"Dietary Reference Intakes for Japanese (2020)", DRIs-J (2020), was issued from Ministry of Health, Labour and Welfare, in 2019 and will be officially used until March of 2025. In 2005, Japan abolished Recommended Dietary Allowances and issued DRIs. Since then, the revised edition has been issued every 5 years. DRIs-J (2020) describes recommended intake values by sex and age-class and the explanations for energy and 34 nutrients (note: dietary cholesterol only has explanation, but shows no value). Estimated energy requirement (EER) is used for intake values of energy. For those of nutrients, either estimated average requirement (EAR), recommended dietary allowances (RDA), adequate intake (AI), upper tolerable intake value (UL), tentative dietary goal for preventing lifestyle-related diseases (DG), or some of them are used. DG has uniquely been developed and been introduced to the DRIs-J (2005) by considering a serious need for prevention of lifestyle-related disease in Japan. At the same period, DRIs-J (2005) has introduced the chapter "basic concepts" that described basic knowledge on developments of and how to use DRIs. The chapter "basic concepts" has still an important role in DRIs-J (2020). DRIs-J (2015) has introduced "preferred body size for adults" as energy control in addition to EER. It stated that optimal body size expressed as body mass index was between 21.5 or 22.5 (which depends on age-class) and 25.0 kg/m2. DRIs-J (2015) has also introduced a new chapter called "relation between chronic diseases and nutrients". This chapter summarized the relationship between four major chronic diseases such as high blood pressure, dyslipidemia, type-2 diabetes, and chronic kidney disease and intakes of selected nutrients. In DRIs-J (2020), relation between frailty and selected nutrients has been added considering a social need, but the description was short and no concrete intake values were

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

suggested because of scarcity of the scientific findings. DRIs-J has consistently kept the importance of avoidance of insufficiency and of excess of tolerable intake level for nutrients and the importance of adequate energy intake, and at the same time has gradually increased information on chronic disease prevention and control. We would like to keep this high scientific level and change it more easy to use for users such as dietitians.

Vietnam Recommended Dietary Allowances: current and challenges

Le Danh Tuyen[1], Thu Nguyet Nghiem[1], Nga Thuy Tran[1], Nhung Thi Bui[1]

1. National Institute of Nutrition (Viet Nam)

With the increase in the country's economic growth, food supply has improved. Vietnamese diet has significantly changed. National Survey on Food Consumption 2020 showed that the average daily energy intake was 2023kcal per day, slightly increased in comparison with that in the year 2010 (1925kcal). The proportion of energy from protein, fat and carbohydrate is 15.8%, 20.2% and 64%. The quantity of vegetable intake is 231gr/day and that of fruit is 140.7gr/day, meat intake is 136.4gr/day, that in rural area is 155.3gr/day, the consumption of fast-food and sweetened drink is increased. Stunting is prevalent among children under 5 and micronutrient deficiencies is still common but overweight/obesity, metabolic syndrome and other chronic diseases related to nutrition and lifestyles is raising. The most updated Recommended Dietary Allowances (RDA) for Vietnamese population was developed in 2016. It is therefore necessary to revised the RDA for the Vietnamese population with the change of the current morbidity and mortality, and the current eating habits and food consumption. The revised RDA would be an important science-based tool for the development of healthy Vietnamese dietary guidelines and the evaluation of food and nutrition security in Vietnam. It is expected that the revised Vietnam RDA and its conversion to food-based dietary guidelines will be the basis for the policy implementation of programs for prevention the double burden of both under and over nutrition as micronutrient deficiencies, stunting and noncommunicable chronic diseases.

Current issues of DRIs and RDAs in German-speaking countries

Ibrahim Elmadfa[1], Alexa Leonie Meyer[2], Helmut Heseker[3]

1. University of Vienna (Austria), 2. Haus der Barmherzigkeit, Long Term Care Hospital, Vienna (Austria), 3. University of Paderborn (Germany)

The DRIs in the German-speaking countries date back to the year 1956 when the German Nutrition Society published its dietary reference values for energy, protein, fat, calcium, iron, iodine, and the vitamins A, D, B_1, B_2 , and C. Regular revisions followed over the next decades, taking into account new evidence on nutrient requirements and the changing lifestyle of the population. Since 2000, the D-A-CH reference values are published and regularly updated as joint intake recommendations for Germany (D), Austria (A) and Switzerland (CH) and were also adopted by Hungary, the Czech Republic, Slovenia, and Serbia. At the regional level, the D-A-CH reference values have also served as a basis for the development of some RDIs of the European Food Safety Authority (EFSA) but some discrepancy exists. A hallmark of the D-A-CH DRIs, which was introduced in 1995, is the differentiation between recommended intake levels, estimated intake levels and values given as orientation depending on the scientific evidence available for a given nutrient. Some uncertainty as to the appropriate levels for some nutrients still remains as shown for folate, for which analyses in the frame of the Austrian Study on Nutritional Status 2012 revealed a notable discrepancy between dietary intake and the biochemical status of this nutrient that led to the lowering of the DRI from 400 μg/d to 300 μg/d in the following revision of the D-A-CH reference values. Recent adaptations include the introduction of varying recommended intakes for zinc depending on the diet's estimated phytate content, an approach that was proposed by the WHO and is also found in the EFSA DRIs, and the adoption of a conversion factor of 12:1 for beta-carotene to vitamin A. New evidence underlines the importance of preventive aspects of nutrient intake. This has, for instance, entailed higher recommendations for protein intake in elderly persons aged ≧65 years and a DRI for potassium above basal requirements to account for the antihypertensive effect of this mineral. For future revisions of the D-A-CH reference values, more studies on the nutritional requirements of infants and young children are particularly needed, for whom most DRIs are estimations.

Revisiting the potential of growth monitoring and promotion

Edward A. Frongillo[1], Jef L. Leroy[2], Leila M. Larson[1], Marie T. Ruel[2]

1. University of South Carolina (USA), 2. International Food Policy Research Institute (USA)

Background and objectives: Growth monitoring means following the growth of children by periodic, frequent anthropometric measurements that are used to assess the adequacy of the child's growth. Growth monitoring and promotion programs include healthy growth promotion activities, mostly as tailored, individual counseling based on the child's growth results. Some programs also include group counselling and are used as a platform to bring communities together to discuss child growth and nutrition topics. Three broad categories of purposes, which may overlap, are screening, providing a source of data, and providing a platform to deliver or promote other health and nutrition services. Although growth monitoring and promotion programs have been widely implemented for many decades, their appropriateness and effectiveness are uncertain and questionable. The objective of this introduction is to provide an overview of what is known about the appropriateness and effectiveness of growth monitoring and promotion, what are the issues that have been raised, and how to frame intellectual and empirical analyses to resolve these issues to indicate a path forward.

Methods: The literature on growth monitoring and promotion programs was reviewed. Evidence of effectiveness was compiled, and relevant concerns and questions were identified. **Results:** Five main issues concerning growth monitoring and promotion programs were identified. First, the epidemiological underpinnings of growth monitoring and promotion programs are not clear. Second, the data from growth monitoring and promotion programs may not be representative (i.e., subject to selection bias) and may not be reported in an adequate time frame, if reported at all. Third, the programs have poor implementation and coverage. Fourth, most countries implement growth monitoring and promotion programs despite the lack of evidence on effectiveness. Fifth, rigorous evidence on the usefulness of growth monitoring and promotion as a platform for delivering other services is missing.

Conclusions: Critical examination of the bases and potential of growth monitoring and promotion is needed to help redirect how these programs may be used to improve the nutrition and health of children and families.

Growth Monitoring and Promotion: A Global Perspective

Julie Catherine Ruel-Bergeron[1]

1. Global Financing Facility, World Bank (USA)

Introduction: Regular assessment of growth and development is critical during infancy and early childhood and is standard practice in an estimated 178 countries. Over the last four decades, countries have implemented various types of growth monitoring and promotion (GMP) programs, based in communities and/or health facilities, and offering a range of services and growth measurements. Despite lack of detailed information on global costs and mixed evidence of effectiveness, the widespread implementation of GMP raises important questions on costs, benefits, and value for money given the slow progress in key anthropometric indicators for children over time. Nevertheless, GMP provides unique access to vulnerable communities, promoting frequent contact with health workers and serving as a potential entry point for the delivery of other timely child health and development interventions, and especially so when delivered at scale.

Methods: A global convening that included eleven countries and over 60 thought leaders was co-hosted by The Global Financing Facility, The World Bank, The Bill & Melinda Gates Foundation, UNICEF, and The Manoff Group in 2018 to review the empirical and experiential evidence on GMP, and elaborate on implementation and data gaps hampering effective GMP implementation. Four years later, we conducted a desk review to revisit the status of GMP globally, and incorporate perspectives of The Global Financing Facility vis a vis implementation and progress in supporting countries to strengthen GMP programming.

Results: Costs of implementation are highly variable, dependent on level of coverage and diversity of activities. Program data from 5 countries who participated in the 2018 global convening shared annual program costs that ranged from 2 to 200 million in Madagascar and Ethiopia, respectively. The intersection between scale of implementation and questionable impact signals the need for a paradigm shift in GMP programming, especially in the context of renewed global attention to and financing of nutrition scale-up driven and supported by global initiatives. The paradigm shift includes: (1) a clear definition of which types of measurements to focus on, if any, and potential variations in program typologies based on country epidemiology and implementation arrangements and capacity; (2) the inclusion of overweight measurement and counseling; (3) the development and deployment of new tools, training, and skills development to improve the quality of GMP, particularly the use of data for decision-making at all levels; and (4) strengthening of links with referral services and incentives. Large donor institutions and financing mechanisms that support the strengthening of country systems to improve nutrition delivery at scale will continue to finance GMP in alignment with national priorities and plans, and government requests to do so.

Conclusion: There remain several fundamental, unanswered questions on operational aspects of GMP implementation. Clarity and attention to these is needed for institutions to more

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

effectively support the large-scale implementation of the needed paradigm shift in GMP, and to maximize the impact of GMP as a platform to promote child development and nutrition outcomes.

The epidemiological underpinnings of growth monitoring and promotion

Jef L. Leroy[1], Marie T Ruel[1], Edward A Frongillo[2]

1. International Food Policy Research Institute (USA), 2. University of South Carolina (USA)

Background and objectives: Growth monitoring is the process of following the growth of children by periodic, frequent anthropometric measurements that are compared to an appropriate standard to assess the adequacy of the child's growth. Growth monitoring and promotion (GMP) programs also include promotion activities, mostly in the form of individual counseling based on the growth results. The primary objective of GMP is screening and promotion, i.e., the early detection of inadequate child growth followed by counseling using a growth chart as an educational and promotional tool. GMP is also used as a source of data for decision-making and as a platform to promote the use of other nutrition and health services. Even though growth monitoring and GMP programs have been widely implemented for many decades, there is little evidence from rigorous research on their effectiveness. The widespread implementation of GMP around the world is largely motivated by the assumption that visualizing growth faltering using a growth chart will help parents recognize the problem and will make them more responsive to advice aimed at improving their child's growth, nutrition, and health. Praise for healthy growth is also expected to motivate parents to continue their positive practices. Examples of children growing well can be used as a model for other parents from the same community. Research on GMP, however, has almost exclusively focused on program implementation. Very few studies have looked at the effect of GMP on parents' nutrition knowledge and practices or on child growth. Most importantly, the epidemiological foundation of GMP has not been carefully studied.

Methods: We critically assessed the epidemiological underpinnings of the first GMP purpose (screening and promotion) and reviewed the evidence for the remaining two purposes (as a source of data for decision-making and as a delivery platform for other nutrition and health services).

Results: The rationale for screening (first purpose) is that the early detection of a health problem followed by an effective intervention increases the chance of a positive health outcome. Many of the requirements of a screening program, however, do not seem to be met in GMP programs. It is unclear whether growth faltering is a useful early marker of undernourishment or rather an advanced consequence of the health (or undernutrition) problem that is being screened for. Second, there are no generally accepted quantitative cut-offs to identify growth faltering at the individual level. And finally, there is no currently available treatment that can bring the child back to the "healthy" linear growth trajectory. Relative to the second purpose, a key challenge is the lack of representativeness since children taken to the GMP session are not necessarily representative of the whole population or community. Rigorous evidence on the effectiveness of GMP as a platform to promote the use of health and nutrition services (the third purpose) is missing.

Conclusion: We conclude that the epidemiological foundations of GMP may not provide the necessary justification to continue with GMP in its current form. It is thus necessary to critically revisit the potential of GMP to improve the nutrition, health, and development of individual children.

Rethinking growth monitoring and promotion as an opportunity to improve early childhood development

Leila Larson[1], Fahmida Akter[1], Edward A. Frongillo[1], Jef L. Leroy[2]

1. University of South Carolina (USA), 2. International Food Policy Research Institute (USA)

Background and objectives: Growth Monitoring and Promotion (GMP) is broadly regarded as an essential component of primary health care. It is widely used to screen children for nutritional or health problems, but there is limited evidence on the effectiveness of GMP on nutritional status of children. One strength of GMP visits is the frequent contact between caregivers and health workers. This point of contact may provide an opportunity to screen for children at risk of developmental delay and, if necessary, intervene with the aim of improving child development. Our study's first objective is to examine the potential of GMP's established platform to identify children at risk of poor development. Second, we will evaluate whether GMP can be used to deliver responsive parenting education to caregivers of young children in need.

Methods: We will conduct a literature review to determine the sensitivity and specificity of anthropometric indices in identifying children at risk of developmental delay. We will review the evidence of the validity of child development measurement tools that are easy to implement, free of cost, and which could be used to screen children for developmental risk during GMP visits by trained unskilled health workers. We will

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

assess the sensitivity and specificity of anthropometric indices using existing data, including data from the Multiple Indicator Cluster Surveys and other studies that used standard measurement tools for child development, such as the Bayley Scales of Infant and Toddler Development. We will identify light-touch versions of existing early childhood development programs which could feasibly be delivered by health workers during GMP visits.

Results: Drawing on both studies in the literature and our own analyses of available data, we will document the accuracy of anthropometric indices in identifying children at risk of developmental delay. Through a review of peer-reviewed and grey literature and through discussions with key experts in the early childhood development field, we will identify the characteristics of early childhood development programs that make them feasible and effective for implementation during GMP visits (i.e., group vs individual sessions, home vs clinic-based sessions, number of visits, adaptation requirements, etc.).

Conclusions: We will conclude with an appraisal of the potential of GMP to serve effectively as a platform to identify children at risk of poor development and deliver responsive parenting education to caregivers of young children in need.

Implementation of growth monitoring and promotion: Lessons from India

Rasmi Avula[1], Sumati Bajaj, Anjali Pant[1], Phuong H Nguyen[2], Purnima Menon[1]

1. International Food Policy Research Institute (India), 2. International Food Policy Research Institute (USA)

Background and objectives: Growth monitoring (GM) and promotion is a routine part of primary healthcare for children in > 80% of countries. In India, 57.5 million children are measured every month by frontline workers to assess their growth and to trigger preventive or curative services. Standard guidance for anthropometry suggests quality can be compromised by the choice of measurement equipment, placement of equipment, and positioning of children during measurement. Little is known about the quality of measurement processes during GM.

Methods: We compared child height and weight measurement processes with standards for anthropometry to assess GM quality. We observed the process of measuring weight and height of children under 5 years of age (N=681) in 4 states in India, using a checklist. We summarized data along critical measurement falter points that could affect quality. Open-ended interviews were conducted with caregivers to assess how they value GM.

Results: Nearly 75% children were weighed using age-appropriate weighing scales. However, the scales were not used appropriately in all cases. However, for Salter scales, only 44% of children were placed in sling/pants as appropriate for their age. Nearly 30% of children wore heavy clothing and 45% of children were not calm during weighing; > 60% were weighed in a sitting/standing position on a baby-weighing scale. More than 50% of infants were not measured using age-appropriate height equipment. Height equipment was placed on a stable surface while measuring majority of children, but a large proportion of children were incorrectly positioned on the equipment. Caregivers valued GM and reported having children routinely weighed to learn about any changes; nearly half the caregivers considered weight as a marker for child growth.

Conclusion: Multiple measurement-related falter points were observed during GM. Incorrect measurements increase the potential for under-or over estimation of weight/height and consequent misclassification for screening and referrals. GM results are used to refer children diagnosed with malnutrition to additional health and nutrition services. Routine GM appears to be an assurance of child growth to caregivers. Therefore, it is imperative to strengthen the quality of measurements, focusing on the falter points, to ensure better data for programmatic and for caregiver use.

Introduction to the Whole Grain Initiative: Goals and Vision for Healthier Dietary Lifestyles

Kevin Burke Miller[1], Jan de Vries[2]

1. General Mills, Inc. (USA), 2. DeVries Nutrition Solutions (Netherlands)

Dietary lifestyles that include higher intakes of whole grain have been correlated with reduced risk of disease, healthcare cost savings, and potentially even lower environmental impacts. Although whole grains are recognized in dietary guidance recommendations around the globe, these recommendations can be vague and consumption remains low. The Whole Grain Initiative (www.wholegraininitiative.org), which arose from the 6th International Whole Grain Summit (Vienna, 2017), seeks to improve consumer and planetary health through a transition from the consumption of mainly refined grains to whole grain. To accomplish this goal, expert working groups were formed each tasked with pursuing unique, independent strategies that contribute toward the case for whole grain. Working groups include whole grain definitions group, economics group, communications group, sustainability group, and a policy group. Ultimately, products from each working group will contribute to a comprehensive dossier on whole grain to spur government and non-government organizations to invest in policies and programs that encourage the public to swap whole for refined grains in their diet. Dietary guidance and recommendations for whole grain consumption around the globe are inconsistent and often vague. The whole grain definitions working group was formed

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

develop a consistent definition of whole grain, both as an ingredient and also a whole grain food. The working group's consensus definition was developed through collaboration by private and public sector experts and recently published, a link to the paper is available at the WGI website. Promoting changes in public attitudes and behaviors around diet requires investment by government and authoritative bodies to help educate the public. The economics working group was charged with developing compelling evidence for the return on the investment policymakers and government stakeholders might recognize from their investment in programs promoting whole grain. Results from several health economic studies developed with members of the WGI economics working group will be presented. Promotion of whole grain requires consumer education; the communications working group was formed to increase awareness to whole grain and develop resources for use in educational campaigns targeting stakeholders and the public. Globally, grains represent the principal source of energy in the diet. The sustainability working group is exploring the value of whole grain as an efficient, quality carbohydrate that fits within planetary boundaries. Lastly, a whole grain recommendation working group is being formed with the task of identifying a pragmatic intake recommendation for whole grains. The introductory presentation of the Whole Grain Initiative organization, member composition, and mission and vision will provide the audience context for the presentations that follow by representatives of the individual working groups. The presentation will conclude with an invitation to engage during the conference and encourage the audience to join and participate.

SY(T6)11-02

Whole grains and whole grain foods - new global consensus definitions and the role of fibres and other bioactive compounds

Jan-Willem van der Kamp[1], Maria Wiese[1]

1. TNO Healthy Living (Netherlands)

Whole grains are an important pillar of healthy and sustainable diets. However, actual intake in most counties remains well below recommended levels, due to a lower acceptance of products high in whole grains and a lack of clear definitions. Internationally accepted credible whole grain definitions are necessary to ensure that all global stakeholders have shared standards, and that consumers find them clear, credible, and useful. Such definitions may also play a role in a wider acceptance of whole grain products.

Based on widely accepted definitions and new developments, the Whole Grain Initiative published (*Nutrients 2022 14 (1)* https://doi.org/10.3390/nu14010138) generic definitions for whole grain as a food ingredient and for whole-grain foods, definitions ratified by the leading global scientific associations: International Association for Cereal Science and Technology (ICC), Cereals & Grains Association, and the Healthgrain Forum.

The definition of whole grain as food ingredient sets criteria for grain species to be included and for processes. All cereal grains of the Poaceae family used for human consumption are included as well as the widely used pseudo-cereals amaranth, buckwheat and quinoa, seeds that are similar in use and composition to cereal grains. For processing the definition requires that whole grains shall consist of the intact, ground, cracked, flaked or otherwise processed kernels. These other processes include fermentation, a technology increasingly used for preparing appealing whole-grain products.

For ensuring that whole grain is only indicated front-of-pack when the actual whole grain level is dietarily significant, the whole grain food definition sets a minimum level of 50% whole grain ingredients for calling a product a whole-grain food and of 25% for designating whole grain front-of-pack. These levels are calculated on a dry-weight basis. In this way whole grain can also be mentioned front-of-pack in products with a high moisture level (e.g. whole-grain porridge). The definition is also recommending the quantitative reporting of the amount of whole grain front-of-pack.

The Whole Grain Initiative urges adoption of these consensus definitions by national regulatory authorities and health promotion organisations worldwide. With a global definition setting credible minimum criteria, more lenient conditions, for example for the required levels of whole grains, should not be accepted.

In many dietary guidelines the presence of dietary fibre in whole grain products is highlighted for their contribution to meeting the recommended daily intake of at least 25-30g fibre, being adequate for normal laxation and contributing to reduced risks for lifestyle related diseases. Recommended intake levels for whole grains for realizing similar risk reductions range from 50 to 90 g/day, containing for wheat, the most widely consumed whole grain, 5–10g fibre. This indicates the beneficial role of the wide range of other bioactive compounds in whole grains such as minerals, vitamins, choline, betaine, phytosterols, tocopherols and last but not least polyphenols, compounds with anti-oxidant and increasingly recognized prebiotic properties. It should also be noted that such compounds, when present together in the food matrix may result in broader beneficial effects (Kristek A, Wiese M. *BJN*. 2019; https://doi.org/10.1017/S0007114518003501)

SY(T6)11-03

Healthcare cost savings with increased whole grain intake

Sara Grafenauer[1], Kevin Miller[2], Janne Martikainen[3]

1. University of New South Wales (Australia), 2. General Mills (USA), 3. University of Eastern Finland (Finland)

Background: Dietary patterns including higher intakes of whole grain have been consistently associated with reduced incidence of cardiovascular diseases, type-2 diabetes, and certain gastric cancers, yet consumption is often low. Economic healthcare analyses are of interest, providing data to justify support for government guidance, policy, and consumer information. The aim of this research was to draw together analyses from the US, Australia, and Finland, assessing the potential healthcare and/or lost productivity cost savings associated with reductions in relative risk of these common chronic diseases.

Methods: To assess expected cost savings from increasing whole grain intakes over time, the American and Australian studies both employed arithmetic models whereas the Finnish study design included the more robust Markov-type cohort transition model with probabilistic sensitivity analysis (PSA). The studies utilised common input parameters from: 1) data on costs of healthcare (and if available, productivity loss) based on monetary figures by national healthcare authorities 2) relative reductions in risk of disease (with 95% confidence intervals) associated with specific whole grain consumption, as reported in meta-analysis studies 3) each study proposed pessimistic and optimistic scenarios 4) Three of the four studies applied a discounting rate to take into account the passing of time regarding costs.

Results: Healthcare cost savings ranged from USD $4516-$10,624/ person annually representing between 9.04%-16.89% of gross domestic product. Calculations based on the adult American population aimed to achieve the Dietary Guidelines for Americans recommendation 'make half your grains whole grain', and direct cost savings from CVD and CHD combined could reach USD $36 billion annually. In Australia, where only 27% meet the recommended 48g Daily Target Intake (DTI), if one-half met the DTI, there could be savings AUS $734 million ($560MM USD) and more than AUS $1.4 billion ($1 billion USD) in savings from T2DM and heart disease combined. In contrast, the Finnish population has a higher intake of whole grain, so modelling was based on a 10%-unit increase (from 70% to 80% of the population), and increasing the number of daily servings (i.e., two or more) among those who already use at least one serving a day, as well as the combination of those two scenarios on incidence of T2DM. This reduced total costs €286MM and 989MM ($340MM and 1.2 billion USD) over 10 years with additional improvements in Quality-Adjusted Life Years.

Conclusions: The analyses point to significant economic value in reaching target levels of whole grain consumption through simple nudges, exchanging refined flour products with as little as a slice of wholemeal/ whole grain bread or bowl of whole grain breakfast cereal daily. By focusing on the largest sources of whole grain within diets, for example, breakfast cereals and bread, the DTI could be achieved with a minimal burden on consumers. Future models of this type should consider age stratification and socio-economic status. Likewise, focusing on the lowest consuming age groups where there would be a greater benefit in correcting whole grain intake.

Which food policies to promote whole grain consumption?

Kevin Burke Miller[1], Gabriel Masset[2]

1. General Mills, Inc., (USA), 2. Nestle SA (Switzerland)

Globally, consumption of whole grain is below recommended levels and low whole grain intake has been identified as the first dietary risk factor for global DALYs attributable to diet [1]. Several food policy tools exist that could help promote the consumption of whole grain. The symposium will cover several examples of food policies and programs that have targeted whole grain intake. Proposals from the Whole Grain Initiative will be presented, together with current gaps in knowledge that can prevent the adoption of policies.

Firstly, the promotion of whole grain in food-based dietary guidelines will be discussed, highlighting the variety of messaging on whole grain, in particular for quantitative intake recommendations. Secondly, a brief overview of educational and promotional campaigns regarding whole grains will be presented. The possibility of front-of-pack labelling including whole grain as well as whole grain content claims will be analysed in various jurisdictions. Finally, the challenge of reformulation will be assessed, and some concrete examples presented.

The coordination and harmonisation of such policies and the participation of all stakeholders is necessary to have an impact in terms of whole grain product availability and consumption. The example of the Danish Whole Grain Partnership will be presented as a successful campaign on whole grain. This public-private partnership led to an increase of the average whole grain intake within the Danish population from 36 to 82 g/day in 15 years [2].

By collecting scientific evidence on the health benefits of increased whole grain consumption as well as providing the means to translate such evidence into food policy tools (e.g. whole grain definitions), the Whole Grain Initiative's aim is to ensure whole grains are adequately and consistently considered in all food policies. A harmonisation of measures and guidelines on whole grain will enable an environment that incentivises manufacturers to propose products with higher whole grain content while providing clear and consistent messages to the general population.

Aligning dietary guidance – including whole grain in front of pack labelling schemes

Eleanor J Beck[1,2] , Elizabeth P Neale[1,2] , Katrina R Kissock[1,2]

1. University of Wollongong (Australia), 2. Illawarra Health and Medical Research Institute (Australia)

Background and objectives: Intake of whole grains is associated with multiple health benefits however remains significantly below recommendations on a global scale. The priority worldwide for the consumption of less processed, whole-grain foods is recognised in national dietary guidelines. Whole-grain foods are encouraged together with high fibre grain varieties in almost all guidelines, with words such as “make at least half your grains whole grain”. Guidelines translate to front-of-pack labelling, including content claims, where manufacturers aim to guide consumers to choose whole grains. Food regulators develop nutrient profiling systems aimed to guide consumers in their food choices. Our work aimed to consider translation of the Whole Grain Initiative's whole-grain food definition[1] into practice. Specifically, we modelled whole-grain food definitions in nutrient profiling algorithms where whole grain was previously ignored and secondly, we explored how consumers might understand messages such as “whole-grain food” or “contains whole grain”.

Methods: We considered all foods in the 2011-2013 Australian Food, Nutrient and Supplement Database, applying cut offs from the Whole Grain Initiative's new whole-grain food definition of ≧25% and ≧50% whole grain in nutrient profiling systems, awarding higher points to foods with ≧50% whole grain[2]. Foods changing categories based on the new algorithm were explored. Focus groups with consumers explored their knowledge of whole grains, health benefits and their preferences for whole-grain labelling, which they considered likely to assist them in making positive food choices.

Results: Where whole grain is considered as a relevant measure of dietary quality, aligning nutrient profiling with dietary guidelines and including whole grain in profiling systems improved consistency with guidelines. Consumers had limited knowledge of whole-grain health benefits although they understood whole grains were positive dietary choices. They preferred specific messaging on packaging such as provision of a precise percentage of whole grain in a food and avoidance of more vague messages such as “high in whole grain”.

Conclusions: The modern consumer is sceptical of health messaging and therefore aligning of food regulatory systems (such as nutrient profiling and front-of-pack claims) may assist in promoting whole-grain intake. The global definition of whole-grain foods may assist in promoting consistent messaging.

SY(T6)12-02

Identifying socio-cultural conversion factors underlying maternal capabilities for child growth using ethnographic methods in Tanzania

Zaina Mchome[1], Ajay Bailey[2], Hinke Haisma[3]

1. NIMR Mwanza (Tanzania), 2. Utrecht University (Netherlands), 3. University of Groningen (Netherlands)

Background: The magnitude of childhood stunting in Tanzania is persistently high, even in high food-producing regions. This accentuates the critical need for a paradigm shift in Child Growth Monitoring (CGM) to a multi-dimensional approach that also includes the contextual information of an individual child and her/his caregivers. We engaged the Capability Framework for Child Growth (CFCG) to identify socio-cultural conversion factors that underly the mothers' capability to achieve their ability to ensure healthy child growth.

Methods: An ethnographic study was conducted in rural Tanzania to investigate the socio-cultural conversion factors shaping maternal capabilities for healthy child growth. Data for the study were collected through in-depth interviews, key informant interviews, participant observation, and focus group discussions with caregivers for under-fives. The topic guides with open-ended questions and probes were used. The issues related to conversion factors underlying maternal capabilities were captured using questions on the mother's daily responsibilities in the family, mothers' roles in promoting healthy growth, what mothers can do to make their children grow well, what caregivers think a mother would need to make their children grow well, the environments that contribute to mothers' ability and/or inability to provide good care for their children, and stories about moments when they wanted to take care of their children but could not. Both inductive and deductive approaches were used in the data analysis.

Results: Being able to feed children, being able to control and make decisions on farm products and income, and being able to ensure access to medical care emerged as important capabilities

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

for mothers related to promoting healthy child growth. A mother's capability to (breast)feed her infant was constrained by an interplay of multiple socio-cultural conversion factors, including (i) gendered patterns in childcare, (ii) the cultural belief that parents' resumption of sexual intercourse while a baby is still breastfeeding can harm child growth, (iii) cultural schema that a new pregnancy during lactation period spoils a mother's breast milk, (iv) the cultural schema that an infant's persistent crying at night indicates that the child is "born with hunger" and therefore cannot be satisfied by the mother's breast milk; and (v) the belief that a child's reduced interest in breastfeeding is caused by threats from *mdudu* (unseen evil spirit) residing in the mother's body. The patriarchal cultural norms restricted women's control of farm products and decision-making on household purchases and their capability to ensure a child's access to and utilization of medical care.

Conclusions: Our findings accentuate the need for the current child growth monitoring charts and tools to be aligned with the context, thus, include the indicators at the parental / household level. Capturing contextual information that embeds child growth would facilitate the identification of the root causes of childhood malnutrition, and would thus enhance the development of interventions that are effective in addressing inequalities among children. The CFCG could give direction to the paradigm shift needed for child growth monitoring, as it goes beyond biometric measures, and considers mothers' real opportunities for achieving healthy child growth.

Keywords: Capability approach, Conversion factors, Child growth, Growth monitoring, Ethnography

SY(T6)12-03

Achieve scientific rigour using a participatory approach for identifying capabilities for child growth: an example of haor areas of Bangladesh

Barnali Chakraborty[1, 2], Haisma Hinke[2], Shrinivas Darak[3]

1. BRAC University (Bangladesh), 2. University of Groningen (Netherlands), 3. Prayas Health Group (India)

Introduction: The multidimensional approach to child growth developed based on the constitutive elements of the capability approach, describes child growth as the achievement of a certain set of child and parental capabilities needed for a child to grow well.

Method and objective of the presentation: We used qualitative research in a participatory approach to identify capabilities in hard-to-reach *haor* areas of Bangladesh. In this presentation, we will illustrate how we assured scientific rigour and validated our initial findings.

Process of operationalizing capability approach: Firstly, we made use of criteria for identifying capabilities as suggested by Robeyns who is a renowned scholar on the capability approach. In addition, we had identified a universal list of capabilities based on a workshop with experts. Secondly, we conducted our research in two phases. In the first phase, we contextualised the universal list of capabilities for child growth in the context of Bangladesh, by incorporating feedback from the local experts that later shaped our interview guides to explore the contextual dimensions of child growth in *haor*. Then, we contextualised the capabilities in *haor* regions employing a participatory approach by combining doxastic and epistemic interviewing methodology. The doxastic interviews focused on "understanding" the interviewees that were done using specific interview guides for parents of children less than 2 years of age. The epistemic interviews were dialogues in which the interviewee and interviewer communicated from a position of equality to co-create knowledge and were done employing visual methods. An inductive coding method using an emic approach generated the codes close to the actual data. For example, in response to the question, what kinds of abilities a mother or a father needs to have to take good care of his/her children, a participant said: "...*She must have maya (affection) and mohabbat (love) for her child. If she doesn't have that she would not able to take care of her child". We coded this response as "mother's capability to express maya and mohabbat".* When the participants pointed to the importance of the collective capabilities of all household members, we categorized that *"household's* capability"; e.g., "*household's* capability to overcome the struggle with the earth to keep the child neat and clean". The stories for each of the capabilities that emerged from the doxastic interview were later discussed with the participants using the visual method. For example, a drawing of "a husband attempting to beat his wife" was used to invite people to talk about a mother's capability to stay away from domestic violence in connection with child growth. Thus, the analysis provided nuance to the capabilities and generated a set of valid lists of capabilities at child, mother, father, and household levels that affect children's healthy growth.

Conclusion: Our example will provide guidance to nutritionists and capability scholars on how to apply a capability approach in a participatory way in a vulnerable setting while assuring scientific rigour and meeting requirements for validity, by combining doxastic and epistemic interview methods and by applying an emic approach.

Constructing a Multidimensional Index of Child Growth for Ethiopia, Perú, India and Vietnam: Quantitative results

Rolando Gonzales Martinez[1], Hinke H.H. Haisma[1]

1. University of Groningen (Netherlands)

Background and objectives: Child-specific indicators were developed by UNICEF and by researchers worldwide to capture the physical causes of malnutrition. The objective of the research was to calculate a Multidimensional Index of Child Growth (MICG) with physical and non-physical indicators that measure the direct and indirect causes of malnutrition for children living in four countries: Ethiopia, India, Vietnam, and Peru.

Methods: The MICG is based on the operationalization of the capability approach for children and the theoretical and conceptual framework of child growth formulated by the members of the Task Force "Toward Multidimensional Indicators of Child Growth and Development". Bayesian methods were applied to recover children's capabilities from observed indicators.

Results: Poorer physical health, less freedom from paid and unpaid work, and less freedom from domestic tasks was found for children living in rural areas of Ethiopia, Vietnam, and Peru. In Vietnam, female children in rural areas not only have poorer physical health but also lower opportunities for multidimensional growth.

Conclusions: To properly identifying children that could be left behind during the development process it is necessary to enrich the datasets that aim to measure the situation of children worldwide.

Keywords: Child growth, Multidimensional indexes, Capability approach, Bayesian methos

Conflict of Interest Disclosure: None

Implementation of the multi-dimensional index for child growth - Implications for policy and practice

Hinke Haisma[1], Ali Dhansay[2], Gretel Pelto[3]

1. University of Groningen (Netherlands), 2. IUNS Council (UK) / South African Medical Research Council and Stellenbosch University (South Africa), 3. Cornell University (USA)

Background: As a Task Force we worked on the development of a Multi-dimensional Index for Child Growth that is based on knowledge on child and parental capabilities. As a first step we conducted ethnographic research in Tanzania and in Bangladesh to obtain the perspectives of local populations. Next, we constructed an index for child growth using data from the Young Lives Survey of the University of Oxford. This survey contains information on the physical dimension of child growth and on the social and cultural domains, of the contexts in which children live from Peru, Ethiopia, Vietnam and India. A spiderweb with 14 dimensions was used to compare multidimensional child growth between those countries. Bayesian stochastic frontier analysis was applied to assess children's and parental capabilities for child growth. Stakeholders from international organisations and universities were also involved in the process of developing the index.

Objective: A next step will be to test the index in the field, as a tool to make comparisons between countries, to monitor achievement towards SDG targets, to evaluation interventions, and ultimately to inform the development of manuals for child growth monitoring so that malnutrition can be combatted in all its forms at the community level as well. The spiderweb will be tested as a communication tool at wellbaby clinics.

We identified a number of challenges for implementation of the index as a measurement tool: 1. Lack of quantitative data on the root/indirect causes of malnutrition; 2. Resistance towards complex indices on the part of intended program users, and the need to simplify the index; 3. Competition with other frameworks planners are familiar with. The Task Force will use concepts from implementation science to study these challenges and ways to overcome them and identify compromises to improve current mono-dimensional measuring tools. The Task Force will then test the index as a monitoring and evaluation tool in nutrition programmes, for example, in Bangladesh, as this is one country where there is a depth of insight related to parental capabilities for child growth.

Food safety and nutrition: exploring the linkages

Stella Nordhagen[1]

1. GAIN (Switzerland)

To further human health, diets must be comprised of foods that are both nutritious and safe: that is, they must enable people to meet their micro- and macronutrient requirements (while not exceeding them) and not expose them to foodborne illness. Currently, this is not the case for a large share of the global population—burdens of malnutrition and of foodborne disease remain large. The two challenges are interlinked: efficient and effective food-systems action to improve nutrition and reduce foodborne disease requires synergies that seek to improve access to nutrient-dense foods while simultaneously improving their safety. However, the two issues are often addressed in isolation. They are not monitored, analysed, or tackled jointly, be it in legislation, guidance, or research. This presentation will examine how food safety and nutrition are inextricably linked, focusing on four pathways: physiological, consumer behaviour, food supply chains and markets, and policy and regulation. It will discuss the implications of a more interlinked view of food safety and nutrition for policy and programming.

Keywords: food safety, nutrition

Conflict of Interest Disclosure: None

Research Strategies Addressing Food Safety in LMICs

Haley F. Oliver[1]*, Randy W. Worobo*[2]*, Amanda J. Garris*[2]*, Molly Webb*[1]*, Julie Hancock*[1]

1. Purdue University/USAID Food Safety Innovation Lab (USA), 2. Cornell University (USA)

Foods can be nutritious and available, but if those foods are unsafe, there is no food security. Contaminated foods are estimated to sicken 600 million people a year, contributing to impaired growth and development in children, food insecurity, and barriers to entry into the global food trade. By investing in data-driven approaches to identify the key points for intervention, we support countries in transforming the handling and processing of foods at the household, farm, and market level. Funded by the United States Agency for International Development (USAID), the Feed the Future Innovation Lab for Food Safety (Food Safety Innovation Lab) is jointly managed by Purdue and Cornell Universities. We leverage extensive experience in international food safety research, education, and extension to develop and manage a portfolio of food safety and capacity development projects to meet the following objectives: (i) Increasing awareness of food safety, (ii) Enhancing capacity to conduct food safety research, (iii) Developing policies that enable conditions for food safety research, translation, and practice, and (iv) Accelerating translational research technologies and practices for households, communities, and the food industry. In this presentation, we will showcase the Food Safety Innovation Lab ongoing research portfolio in Bangladesh, Cambodia, Kenya, Nepal, Nigeria, and Senegal, highlighting the importance of local partners and university collaborations. We will also highlight major outcomes from a USAID-funded COVID-19 response program to improve awareness and safety among food industry professionals in LMICs. Lessons learned, barriers, and opportunities will be shared.

How consumer behaviour interface food safety and nutrition: a case of the Ghanaian consumer

Angela Parry-Hanson Kunadu[1]

1. University of Ghana (Ghana)

Background and objectives: Consumer perceptions of food safety affect food choice. Food safety perceptions are shaped by consumer experiences, food environment, subjective food safety knowledge, food safety communication through popular media or extension of food safety knowledge or experiences of family, friends and loved ones. These perceptions influence consumer behaviour and diet choices either positively or negatively and they have overall implications on the nutritional status of the consumer. There is little evidence of the interplay between nutrition and food safety. This study presents pieces of evidence from Ghana on the linkage between food safety and nutrition in the context of consumer behaviour.

Method: Desk top review on available studies conducted in food safety and nutrition in Ghana.

Results: A recent study that investigated consumption of traditional dairy products in fifteen dairying communities in Ghana, revealed that poor safety perception of the traditional dairy products (boiled milk, *brukina and wagashie)* hindered patronage and consumption in the dairying communities. One of the focused group participants suggested that "his brother's wife drank *brukina* and died, so in their household no one drinks *brukina*." *Brukina* is a fermented milk beverage mixed with cooked agglomerated millet. It is consumed as a snack in Ghana and neighbouring countries. Microbiological survey of these

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

products revealed that boiled milk and fried *wagashie* were erroneously perceived as unsafe and thus these products are underutilized although they are affordable, nutritious and safe. Another food product commonly consumed nationwide, is kenkey. Kenkey is a soft fermented maize dumpling that are rolled into balls and cooked in maize husks (Ga kenkey) or plantain leaves (Fante kenkey). Kenkey is a common source of energy for most Ghanaians as it is a staple, affordable and accessible as a street vended food. A study in year 2000 revealed high levels of aflatoxins in kenkey which was communicated in common press as "*kenkey causes cancer*". This was very alarming to the public, and many averted consumption of kenkey. However, risk communicators and relevant government agencies intervened. Aflatoxins in grains and legumes, which are staples for Ghanaians and other West African countries, continue to present significant chemical hazards in our food supply. Studies in four villages in Ghana identified AFB1 albumin levels ranging 0.12-3.00pmol/mg among 140 participants and AFM1 ranging undetectable levels – 11562.36pg/mg in urine samples among ninety-one participants. There have since been various intervention efforts to minimize risk. There are evidence of several other food safety concerns the influence consumer choice. For example, consumers in Ghana worry about pesticide residues in green leafy vegetables consumed raw or minimally processed, and risk of cholera, typhoid fever, diarrhoea and other forms of food poisoning associated with fast foods and ready to eat foods. One typical street vended food, known as *waakye*, is made up of rice, beans, vegetables, sauce and eggs, fish or meat. *Waakye* is common in urban and peri-urban communities in Ghana, but it is associated with cholera. Most consumers of waakye are aware of this risk but they conduct their own individual risk assessments in deciding whether, and from who, to purchase this delicacy. **Conclusion:** Food safety influences consumer choice of diets and can thus enhance positive or negative nutritional outcomes. Further evidence is needed to fully understand the bidirectional linkages between nutrition and food safety. Such evidence will support appropriate programming and policies to improve food safety and nutrition outcomes.

Food Safety in Street Food in India

Pawan Agrawal[1]

1. Government of India (India)

India has innovated and created a unique model for the safety of street food. This model adopts a 5-E (Engage-Excite-Empower-Enable-Entice) approach. Training and capacity building and third-party audits are important parts of the protocol. Local municipal authorities and state administration provide requisite civic infrastructure. This has created a mutually reinforcing process of change and created a strong and sustainable food safety culture in India.

Keywords: food safety, street food

Commentary – What is the way forward for improving food safety, in a nutrition-sensitive way, via policy and programming in LMICs?

Carol J Wilson[1]

1. USAID (USA)

USAID recognizes the need for a holistic, nutrition-sensitive food systems approach that addresses food safety risks and allows our investments in programs around the world to achieve inclusive and sustainable progress. We encourage strengthening the multi-sectoral enabling environment for safe, nutritious foods. We also emphasize collaboration with governments, the private sector and all stakeholders to support the most vulnerable, but in particular women and children under five.

Keywords: Nutrition, Multi-Sectoral

Current status and issues of national nutrition monitoring in German-speaking countries

Ibrahim Elmadfa[1], Alexa Leonie Meyer[2], Carolin Krems[3], Ingrid Hoffman[3], Petra Rust[1], Christine A. Zuberbuehler[4], Urs G. Stadler[4]

Regular monitoring of the population's health and nutrition status is important to identify critical nutrients and risk factors

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

for obesity and chronic diseases as well as population groups with specific nutritional risks. Nutrition surveys provide the basis for the development of nutrition and health policies to address problems. The first national nutrition survey in the German-speaking countries, the German National Food Consumption Survey (Nationale Verzehrsstudie I, NVS I) dates to 1985-1989. In a sub-sample, biochemical parameters were assessed. Twenty years later, from 2005-2007, the NVS II, was based on dietary assessment only. A follow-up (NVS III) planned for 2023 will include analyses of critical nutrients in blood and urine. It was scheduled for spring 2020 but was postponed due to the COVID-19 pandemic. The Austrian Study on Nutrition Status (ASNS) started in 1991 and was first published in 1998, with follow-up reports in 2003, 2008, 2012, and 2017 (adults only). Among these, ASNS 1998 and 2012 included biochemical analyses of nutrients. Switzerland reported consumption estimates based on agricultural statistics until 2012. In 2014/15 the first Swiss national nutrition survey (menuCH) was realised in adults relying on dietary assessment only. A survey with children and adolescents (menuCH-Kids) planned for 2023 will include biological samples. In general, nutrition monitoring faces challenges to depict an increasingly complex and rapidly changing nutrition situation. One challenge is the increasing differentiation of food market and eating situations, which may be addressed by digitalisation of dietary assessment. This should include barcode scanning and photographs of packaged products to support assessment of portion size and food composition of branded foods. Moreover, harmonised European Nutrition Monitoring needs to be addressed. For the estimation of nutrient intake of the population, nutrient databases continually need to be further developed, e. g. secondary plant compounds should be included. Another issue is the underrepresentation of population groups like older persons (≥ 80 y), pregnant/lactating women and ethnic minorities in nutrition monitoring of German speaking countries. Besides a stronger focus on biochemical analyses and improved dietary assessment, upcoming nutrition surveys will also have to focus on environmental aspects of nutrition and the food system.

National health and nutrition surveys in Finland

Liisa M. Valsta[1]

1. Finnish Institute for Health and Welfare (Finland)

Altogether 13 health surveys including a dietary component in a sub-sample, have been carried out in Finland, since the late 1960's. One driving force in the long history of national health and risk factor monitoring in Finland has been the highest coronary heart disease mortality among men in the world. Health examination surveys with a follow-up, cross-sectional health and risk factor monitoring surveys, and postal surveys on health behaviour have been included.

The National FINRISK Studies carried out every 5th year by the Finnish Institute for Health and Welfare (THL) have included a dietary survey in a 30% sub-sample. For over two decades, food consumption data have been collected using an in-house developed, computerized data collection and calculation software (Finessi), with the national food composition database Fineli® incorporated. In addition, a validated food frequency questionnaire (FFQ) has been used for dietary data collection in population surveys.

The most recent health examination effort, the FinHealth Study (N=10247, > 18 years) was carried out in 2017 in a nationally representative random sample to produce reliable and up-to-date information on health, well-being, health behaviour and functional capacity as well as their determinants in the Finnish adult population. The FinDiet 2017 dietary survey was carried out in a sub-sample according to the harmonized EU Menu methodology recommended by the European Food Safety Authority (EFSA).

Today, the diverse background data, measurements and samples collected during the past decades are nationally and internationally used to carry out complex sets of analyses to provide information for health and welfare monitoring and policy planning purposes and to further harmonize health surveys. Register based follow-up has further increased possibilities for services development and scientific research. In the future, the main aim is to use different modules of data collection to cover the national health and dietary data needs. Utilization of register information in monitoring the health and well-being of the population may be increased. A nationally representative nutrition survey among children and adolescents has been lacking and is a major priority in the coming years. In the coming surveys, the participation rate continues to be a major challenge. Renewal of the dietary research infrastructure is ongoing.

Since the early 1970's in Finland, the reduction of cardiovascular disease risk factor prevalences have been pronounced due to a decrease in smoking prevalence and blood pressure levels as well as improved serum lipid values. These developments have resulted in a major decrease in cardiovascular disease morbidity and mortality. On the other hand, during the past 25 years, a significant increase in both obesity and Type2 diabetes has been observed. The diet of Finnish adults has generally improved. However, the quality of fat and carbohydrates as well as the high salt intake and low intake of folate remain key challenges. Vitamin D and iodine intakes have improved due to updated food fortification programs. The main disparities in nutritional adequacy are seen between genders and less between socio-economic population groups.

Nutrition Monitoring in the United States -- What We Eat in America, National Health and Nutrition Examination Survey

Alanna J, Moshfegh[1]

1. US Department of Agriculture (USA)

National dietary surveillance of the United States (U.S.) population is essential for informing and evaluating national policies in food and nutrition. Continuous monitoring of the dietary patterns of the U.S. population is critical to evaluate dietary status and diet-related health characteristics and to identify future Federal nutrition and related regulatory and program needs. National dietary data collection in the U.S. is accomplished by one national food and nutrition survey, What We Eat In America (WWEIA), launched in 2002 through the collection mechanism of the National Health and Nutrition Examination Survey (NHANES). WWEIA consists of 2 recalls on 5,000 respondents per year, one in-person and the second by telephone. The two components of dietary data collection in WWEIA are U.S. Department of Agriculture's (USDA) validated 24-hour dietary recall instrument, the Automated Multiple-Pass Method (AMPM) and its companion component, the USDA Food and Nutrient Database for Dietary Studies (FNDDS), used to convert foods and their amounts reported in the AMPM into gram amounts and determine their nutrient values. **The design of the AMPM**, based on the guiding principles of enhancing accuracy and reducing respondent burden, includes multiple recall strategies and memory cues within its structure of 5 steps that progress in logical order. USDA's AMPM and its related data processing programs and databases are made available for use by other government agencies and by partial support from outside research institutions through collaborative agreements. The WWEIA, NHANES data are made publicly available, providing the critical linkage of data on food and beverage intakes to data on health status. Survey products including data tables, data briefs, and research papers summarize major findings. Additional specialized survey databases provide detailed characteristics to evaluate dietary intakes based on dietary guidance or retail food commodities. The survey data and research products are available at the Food Surveys Research Group website at www.ars.usda.gov/nea/bhnrc/fsrg. The AMPM, dietary data collection methodology and instrumentation, dietary databases, data review and public release, and data reporting will be detailed. Advancements in dietary data collection and related food/beverage databases to meet data user needs will be highlighted.

Current State and Issues of National Health and Nutrition Survey in Japan

Hidemi Takimoto[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

The National Health and Nutrition Survey, Japan (NHNS-J) is a nation-wide household-based survey conducted annually since 1946. Participants are household members aged 1 year or older of households living in the 300 unit blocks (about 5700 households and N=15000) that were randomly selected from the unit blocks of the Comprehensive Survey of Living Conditions of each year except for 2012 and 2016, where an expanding survey was conducted. It currently consists of three components, the one-day dietary survey, physical examination survey, and the lifestyle questionnaire survey. The surveys were conducted in November except for 2012 and 2016 where it was conducted from 25 October to 7 December and 1 October to 30 November, respectively. Overall response rates for the NHNS-J ranged 44.4% (2016) to 68.6% (2003). Dietary intake data were collected using a 1-day semi-weighed household-based dietary record, and food consumption is recorded for a usual day excluding trip or festivity days. Trained fieldworkers (mainly registered dieticians) at the public health centers in charge, give instructions to participants about the survey purpose and how to complete the dietary record. The main record-keepers in a household (members who are usually responsible for preparing meals) were instructed to weigh all the foods and beverages consumed by the household members and record their names and weights on open-ended recording forms, including the amounts of food waste and leftovers, in a separate sheet for breakfast, lunch, dinner, and snacks. The approximate proportions of the food taken by each household member for a shared dish is recorded so that the dietary intake of each member could be calculated. Trained fieldworkers visit each household and checked the completeness of recording forms and, if necessary, confirmed portion sizes using commercially available food models or food booklets, and corrected any missing information. After intensive checking, the dietary intake data is collected through the online data entry system, named “Shokujishirabe” (meaning meal checker). The current survey method requires much manpower, as well as experienced fieldworkers (dieticians) in conducting in-person dietary surveys. Already before the COVID-19 pandemic since 2020, the survey faced difficulties in collecting data from young, working age participants. Since then, it has become extremely difficult to conduct home visits as well as physical examinations. In this lecture, we report the current difficulties we face in conducting nation-wide dietary surveys, as well as applying other methodologies.

Inflammatory Food Consumption and Age-related Hearing Impairment in a Prospective Observational Cohort: Results from the Salus in Apulia Study

Luisa Lampignano[1], Rodolfo Sardone[1], Nicola Quaranta[2]

1. National Institute of Gastroenterology Saverio de Bellis, Research Hospital (Italy), 2. University of Bari Aldo Moro, Bari (Italy)

The aetiology of age-related hearing loss is extremely complex and currently being researched in modern science. A growing body of data has connected age-related hearing loss to various aging conditions, including cerebrovascular diseases (CVDs) and physical frailty. In older persons, the prevalence of age-related hearing loss or age-related central auditory processing disorder (CAPD) is higher. These disorders frequently coexist, implying some similar underlying mechanisms, such as systemic inflammation. To reduce the occurrence of ARHL and CAPD, preventing systemic inflammation and microcirculation anomalies could be a public health strategy. It is also well documented that the consumption of unusual foods and specific dietary patterns can reduce or raise systemic inflammation. As a result, nutritional variables may play a role in repairing the first damage to the hearing before it becomes irreversible, and so maybe a step toward preventing hearing loss. This study aimed to see if eating pro-inflammatory foods was linked to age-related hearing loss (ARHL) and age-related central auditory processing disorder (CAPD) in a population-based cohort of older adults from a Mediterranean area.

Participants of the present study were enrolled from the electoral rolls of Castellana Grotte, Bari, Southern Italy. The baseline data were recorded from 2003 to 2005, and the follow-up data from 2013 to 2015. All those studies were conducted within the “Salus in Apulia Study” a public health survey funded by the Italian Ministry of Health and Apulia Regional Government and conducted at IRCCS “S. De Bellis” Research Hospital. We selected 734 participants (425 males). Dietary habits were assessed by a Food Frequency Questionnaire. Peripheral ARHL was defined with a pure tone average threshold greater than 40 dB hearing level in the better ear. CAPD was defined with a Synthetic Sentence Identification with Ipsilateral Competing Message (SSI-ICM) or a Contralateral Competing Message (SSI-CCM). The association between ARHL or CAPD and food groups and micro/macronutrients was examined with adjusted logistic regression models.

There were mean differences in terms of increased consumption of fruit juices (10.0±5.9 vs 5.6±2.0), sugary foods (15.2±4.3 vs 11.8±1.9), caloric drinks (16.2± 16.2 vs 9.2±5.6), beer (39.7±42.2 vs 27.3±23.9), and spirits (2.5±2.9 vs 1.5±1.4) in the ARHL group compared to the normal hearing group. Only a significant increase in vitamin A dietary intake was evident in the normal hearing group (1177.7±99.7) compared to the ARHL subjects (1042.0± 116.6). In the CAPD group compared to the normal hearing subjects, there were mean differences in terms of increased consumption of grains (215.2±35.2 vs 196.2±37.5), sugars (15.1±4.5 vs 11.7±1.9), spirits (1.8±2.3 vs 1.1±0.7) and in term of decreased consumption of fruits (535.7±80.3 vs 651.4±98.1).

Anti-inflammatory dietary patterns and the avoidance of inflammatory foods such as sugars and alcohol can be part of a healthy lifestyle program for ARHL prevention. Consuming vitamin-rich foods, such as fruit, while avoiding sugar-rich food, alcohol, and grains can help to prevent CAPD.

SY(T6)15-02

The role of diet in the increase of cardiovascular risk in the prospective cohort of Moli-Sani Study

Licia Iacoviello[1], Maria Benedetta Donati[2], Giovanni de Gaetano[2], Marialaura Bonaccio[2]

1. IRCCS Neuromed and University of Insubria (Italy), 2. IRCCS Neuromed (Italy)

Poor diets are responsible for more deaths than any other risk factor globally, and are the leading cause of obesity and non-communicable diseases. In light of this, much of the research efforts in large-scale cohort studies are directed to disentangle the association between diet and disease risk on a long term. The Moli-sani Study is one of the largest population-based cohorts established in Europe in the last decades. It consists of 24,325 men and women (aged more than 35 y) who between 2005-2010 were randomly recruited from the general population of Molise, a Southern Italian region, with the purpose of investigating genetic and environmental risk factors in the onset of major non-communicable diseases, with a special attention being paid to diet and dietary habits of the population. The research questions have been mainly directed to analyse the association of a traditional Mediterranean diet, which emphasizes high intake of plant foods, olive oil, high-to-moderate intakes of fish and seafood, moderate consumption of poultry and dairy products, low consumption of red meat, and moderate intake of wine during meals, with different health outcomes, in particular cardiovascular disease (CVD). Results from analyses conducted in this cohort point to a reduced mortality risk in the general population, but also in some high-risk groups, as the elderly, people with type 2 diabetes and also for those with pre-existing history of CVD. Of interest, our data also suggest that the protection associated with a close adherence to a Mediterranean Diet may vary substantially across socioeconomic groups, and therefore suggesting a role for food quality beyond the quantity of food consumed. More recently, analyses conducted in the Moli-sani Study were aimed to investigate the potential implications of food processing to human health. Actually, the diet–health relationship has been traditionally explained almost exclusively by food composition, therefore leading to recommendations of reducing sugar, salt and fat in the diet, with no or little attention paid to degree of food processing. However, such a nutrient-driven approach, also referred to as the ‘nutrient gate', has some important limitations, since other aspects in the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

diet-health relationship are increasingly acknowledged as important as nutrients in shaping health risk at population level. More recently, data from the Moli-sani Study reported a 58% increased risk of CVD mortality associated with an elevated UPF intake, as compared to less UPF, in the general population, and this was confirmed also among individuals with pre-existing CVD. Of interest, these associations were independent from the overall diet quality and this means that the detrimental health impact of UPF should be understood as net of its nutritional quality. If on the one hand it is undeniable that these foods are nutritionally inadequate (i.e. having a low content of fibre, vitamins and other nutrients, while being rich in calories, unhealthy fats and salt), on the other it is necessary to search for other possible mechanisms, other than the nutrient pathway, which may explain the link between heavy UPF intake and non-communicable chronic diseases.

Scoping the potential to integrate local agriculture in the provision of food in schools in the Pacific Islands

Sarah J Burkhart[1], Jessica Evelyn Raneri[2], Danny Hunter[3]

1. University of the Sunshine Coast (Australia), 2. Advisor to the Australian Centre for International Agriculture Research and Department of Foreign Affairs and Trade (Australia), 3. The Alliance for Bioversity International and CIAT (Italy)

Food provision in schools based on home-grown models can serve as platforms for food system transformation, while simultaneously improving the quality of education. Locally grown and procured food is a nutritious, healthy, and efficient way to provide schoolchildren with a daily meal while, at the same time, improving opportunities for smallholder farmers. Despite the significant global development of home-grown school feeding types of approaches linking to local producers and aimed at improving farmer livelihoods and other related job creation, there has been very little attention on these models in the Pacific Islands region or indeed on school feeding programmes in the region generally. The aim of research is to provide an understanding of the current extent and status of school food provision and environments in Pacific Islands countries, with a focus on better understanding the enabling policy environment, institutional and farmer capacity to better support the integration of local agriculture into school food provision. A desk-based scoping study and interviews will develop an understanding the current state of integration of local agriculture into school food provision in the region, and the development of a database of activities. Based on these findings, a subset of countries will be selected for a deep-dive of the policy landscape to identify policy enablers and to document case studies. Furthermore, sustainable options for integrating local agriculture into school food provision and recommendations for action and research opportunities will be identified through workshops and discussions with key stakeholders and organizations. This symposia presentation will provide a description of the current landscape, an overview of the policy enablers and research opportunities identified.

Morobe School Garden's potential to Provide Nutritious Food: A pilot

Helmtrude Sikas-Iha[1], Jessica Evelyn Raneri[2]

1. Program Implementation Manager, Morobe School Gardens Project (Papua New Guinea), 2. Nutrition-Sensitive Agriculture Advisor to both Australian Centre for International Agriculture Research and Department of Foreign Affairs and Trade (Australia)

Papua New Guinea (PNG) has some of the highest global rates of chronic child malnutrition. At the same time, the majority of PNG youth are not attending school, with the primary school net attendance ratio for primary school students at 50%, dropping to 21% for secondary school. The combination of malnutrition and poor formal education results in significant economic impacts, including loss of productivity and intergenerational poverty. As well, employment prospects are poor for the school leavers who constitute 60% of the population. PNG youth are struggling to complete their schooling, with 80% pushed out of the formal education system annually. Agriculture is the main livelihood for rural populations hence if the current trend continues, rural youth are likely to similarly depend on agriculture-based livelihoods. Schools provide clear entry points for both agriculture and nutrition interventions, yet the school system no longer prepares them well for agriculture-based livelihoods, nor does it seek to engage their interest in agriculture. Agriculture and nutrition have been a part of PNG's curriculum since before Independence, including versions of the school garden (SG) model. However, these parts of the education system have fallen into disrepair due to resource and capacity constraints. Revitalizing of school farms and teaching students practical farming skills would help address the lack of agricultural extension services in PNG. The Morobe School Gardens Project implemented in Morobe province, PNG, is based on the fundamental concept which provides a model to promote school gardens as a way to engage youth in agriculture. The project established integrated-gardens at the primary and secondary schools and education resources for teachers to utilize the gardens to deliver the mechanism. The pilot project implemented so far 15 gardens, 10 chicken sheds, and 1 fish pond in 15 primary and secondary schools. A survey was administered to 185 students and 6 teachers from 2 schools to provide data on understanding the school food environments, knowledge, and attitudes regarding nutrition and agricultural livelihoods, and students' diet quality through a qualitative 24hour recall. Boarding school menus were documented, and

recommendations on how to improve their nutritional quality using the garden outputs were developed. Cost-benefit analysis models were developed to evaluate how these gardens could be financially self-sufficient, and their capacity to provide surplus produce and/or income to provide and/or procure nutritious foods. These data were used to develop a set of school food provision models utilizing the school garden. The project also took a proactive role in engaging the PNG Government on the topics of school gardens, nutrition, and the SG model, which is now recognized by the PNG Government and was endorsed in 2021 with an SG Policy. In this connection, the model SG project aims to bridge the gap in the curriculum in agriculture and nutrition education and low-cost agriculture production as a basis for a school food provision model.

Palau's School Service Program (Food Service Program at a Glance)

Brynn Demei[1]

1. Palau Ministry of Education (Palau)

The Food Service Program (FSP) is a Program that provides food and kitchen supplies to all eighteen public schools under the Ministry of Education in the Republic of Palau. The idea is not only distributing food supplies to cafeterias where about thirty cooks prepare hot meals for students, but also providing cook workshops to enhance their cooking skills and services while utilizing local and nutritious food.

However, about seven years ago when I came on board, there was a limited budget of about $821K per year (current budget is $946K per fiscal year), serving all public elementary schools while Palau High School meals were from restaurant vendors, which was using a big chunk of the limited yearly budget. There was barely local food utilized in the menu, as well as limited usage of fruits and vegetables. Thus, the direction taken was figuring out how to increase the limited budget while being creative enough to accomplish objectives of a healthy eating for all public school students. Several approaches had to take place to achieve this task.

For instance, study was made and concluded that by hiring cooks to prepare meals, it would be more cheaper, so the kitchen was constructed as well as five cooks hired to prepare meals. Thus, the budget saved every month was then used to buy local vegetables and fruits as well as store food items when necessary. FSP realized that in order to provide nutritious food, the cooks have to be trained to cook these healthy food items. Thereby, Nutritionist volunteers (one from JICA and one from ICDF-Taiwan) were requested to come on board and conduct cook workshops and trainings to enhance the cooking skills and improve nutrition and sanitation management. In addition, the Nutritionists also conduct cafeteria inspections as well as food education for the students and parents to promote healthy eating in the school setting. FSP conducts cafeteria visitations and monitoring in order to make sure that the given food supplies are being utilized.

Moreover, collaboration and networking are important in order to request partner agencies to help with technical assistance as well as providing professional development. Alongside these solutions, FSP has reached out to fishing cooperatives in order to promote sustainable fishery, as well as having local partners to provide local fish, taro, fruits and vegetables, eggs and other food that are cheaper and lessen the carbon footprints.

The major results of these endeavors are as follows:

· By utilizing the local food systems, FSP is saving its budget in order to promote yearly improvements.

· Nourishing children with local nutritious food has brought awareness to student healthy eating.

· Yearly budget has increased to $946K in order to provide student breakfast.

· Nutritionists also conduct nutrition education for the community.

· Health and nutrition initiatives are currently being developed due to networking with partner agencies in the government and non-government sectors.

The results have been positive and effective. FSP will continue its important mission to nourish children through healthy eating while sustaining local food systems.

1. Pacific Blue Foundation (Fiji), 2. Fung's Farm (Fiji)

Pacific Blue Foundation has established the 'Beqa Lagoon Initiative' which forges strong partnerships to implement cross-sectoral sustainable development of a remote Fijian seascape that is home to 1500 indigenous people. The Green Schools program is a fundamental element of the initiative.

The Green Schools Program has been piloted at remote boarding school locations on two Islands in Beqa Lagoon and has been successful in integrating small commercial scale organic farming with the school curriculum. The project has demonstrated how the nutrition of school age students can be directly and tangibly improved using this practical educational model.

School age children in remote islands of Fiji have limited access to fresh produce due to isolation and costs. As a result, their diets consist mainly of rice, cassava and tinned food, with occasional leaf vegetables provided by student parents. This has led to malnourishment of youth attenuating from vitamin and mineral deficiencies. As part of the Green Schools Program in

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Beqa Lagoon, organic farms have been established in and around school compounds and students are educated in the application of traditional and innovative agricultural practices to cultivate high-yielding nutritional crops. These crops include cabbage, beans, lettuce, eggplant, tomato and cucumber which are attended by students supervised by dedicated community members and the academic staff, harvested and cooked at the school's kitchen and consumed during school hours. As part of the school's activities, students are responsible for expanding and maintaining the school's organic farm, taught the nutritional value of consuming a range of fresh vegetables and the importance of a healthy, balanced diet.

The Green Schools Program has improved the health, nutrition and well-being of school age children and the broader islands' community in the following ways:
· Direct nutritional benefits associated with consuming a wide variety of organic vegetables during school hours

· Integrating a variety of vegetables into the staple diet of children that they otherwise would have limited access to

· The opportunity to sell excess local produce, therefore providing financial-returns to the school supporting the farm maintenance

· Upskilling students with farming skills resulting in positive flow on effects as skills and learnings are shared with the farming community of the islands

· Providing the capacity and capability for students to grow commercial scale fresh produce using an organic closed system model therefore enhancing long-term income generating opportunities for youth as they transition into young adults

· Provision of sustainable livelihoods in the form of high yielding organic farming that can replace unstainable fishing and agriculture therefore enhancing environmental and ecological outcomes.

This presentation will showcase the successes of the Green Schools program and highlight the importance of engaging students through hands on learning opportunities and practical farming solutions to improve nutrition. It will explore the important roles of the different stakeholders play in the inclusive education system of remote island settings in assuring the long-term educational and nutritional benefits for children and youth so they can become the role models and custodians of community health.

Framing food choice, creating demand for healthy diets, and engaging with actors to respond to emerging nutritional challenges

Edward A. Frongillo[1], Christine E. Blake[1], Eva C. Monterrosa[2], Suneetha Kadiyala[3]

1. University of South Carolina (USA), 2. Global Alliance for Improved Nutrition (Switzerland), 3. London School of Hygiene & Tropical Medicine (UK)

Background and objectives: Globalized food systems, urbanization, climate change, and expansion and alteration of retail markets are rapidly changing food environments in low- and middle-income countries. Sub-Saharan Africa and South Asia are experiencing unprecedented economic growth with concomitant increases in wages and availability of consumer goods, including locally and industrially processed foods and beverages of low nutritional value. Displacement of healthy foods threatens the development of a high burden of nutrition-related non-communicable diseases such as diabetes, hypertension, and cancer. The objective is to frame why countering this trend requires understanding how and why people make food choices in the context of rapidly changing food environments; how to assess food environments; how to create demand for healthy diets; and how to engage among nutrition, health, public, and private-sector actors to assess and respond to this emerging nutritional challenge.

Methods: Recent developments in thinking and empirical research about food choice, demand creation, food environments, and engagement in countries were reviewed.

Results: Understanding how and why people make food choices in the context of rapidly changing food environments requires quantitative and qualitative research on the drivers and decision-making processes involved in different contexts. Assessment of food environments requires conceptualization of the attributes of food environments, judging how these attributes reflect healthiness, and determining how to construct an assessment method to collect needed data. Creating demand for health diets requires understanding the cognitive and emotional bases of generating intent and desire.

Conclusions: Well-designed research and development of actions to achieve goals for health in preventing an upswing in non-communicable diseases and for mitigating and adapting to climate change is needed. This research and development of actions must be based on solid understanding of food choice, food environments, and demand creation as well as realistic judgment of priorities and what can be achieved working closely with country partners.

Keywords: Food choice, Demand creation, Healthy diets, Low- and middle-income countries

Advances in methods and metrics in measuring food environments and implications for healthy food choices

Suneetha Kadiyala[1], Gregory Cooper[2], Umi Fahmida[3], Edward A. Frongillo[4], Archana Konapur[5], Indriya Laras Pramesthi[3], Dominc Rowland[6], Kiruthika Selvaraj[5], Bhavani Shankar[2], Nur Lailatuz Zahara[3]

1. London School of Hygiene & Tropical Medicine (UK), 2. University of Sheffield (UK), 3. Southeast Asian Ministers of Education Organization Regional Center for Food and Nutrition (Indonesia), 4. University of South Carolina (USA), 5. Indian Council of Medical Research-National Institute of Nutrition (India), 6. SOAS University of London (UK)

Background and objectives: Given their highly dynamic and informal attributes, food environments in low- and middle-income countries (LMICs) are traditionally difficult to characterise. Further, the concept of food environment encompasses multiple constructs making measurement, to underpin effective policy actions, difficult. The objective of this presentation is to provide an overview of the state-of-the-art developments in methods and metrics to measure and characterise food environments to underpin effective actions for healthy food environments.

Methods: This presentation will include a critical evaluation of food environment methods and metrics and will introduce the latest food environment experience survey tool (FEST), which is currently being piloted in India, Indonesia and Senegal. This tool, developed under the UKRI-GCRF Action Against Stunting Hub, aims to (i) characterise the extent to which nutrient-dense foods are available and affordable within different food environments, and (ii) explore the relative importance of external and personal food environment domains on household food choices.

Results: Existing measures have trade-offs between contextual understanding and scale. Food-system interventions to improve diet quality require actionable data about food environments that is sensitive to context, can be collected at scale, and adaptable for specific foods and food groups of interest. Cognitive testing of FEST highlighted variable levels of understanding around food environment constructs and prompted the adoption of additional contextual information. The results of pilot testing will be available by June 2022 and the presentation will include the results of pilot testing in all three countries and our approach to FEST metric development.

Conclusions: Rapid advancements in developing, testing, and establishing cross-contextual equivalence of food environment metrics are critically needed to underpin effective policy actions. While geospatial tools and observational surveys have gained prominence, promising methods (quantitative and mixed-methods) and metrics to assess how people experience food environments and which constructs of food environments are important for food choices in diverse contexts are rapidly emerging.

SY(T6)17-03

Changing drivers of food choice in relation to changing food environments

Christine E. Blake[1], Edward A. Frongillo[1], Krystal K. Rampalli[1], Shiva Bhandari[1], Sharraf Samin[1], Emma Kenney[1], Shiny Drew[1]

1. University of South Carolina (USA)

Background and objectives: People are central to any food system, and how they interact with food environments has broad implications for human and planetary health. Dramatic changes in daily life of people in low-and middle-income countries (LMICs), including changes in how people make a living, drives changes in food choice behavior. The objective of this presentation is to provide a conceptual overview of the pathways of food choice behavior in the context of changing livelihoods that can be used to guide food environment interventions.

Methods: Recent developments in thinking and empirical research about food choice behavior, livelihood change, and food environments in LMIC were reviewed.

Results: Livelihood changes in LMIC that impact food choice behaviors include shifts to wage-based work as people migrate to urban areas, changes in the type and environment of work (e.g., rise in sedentary, technical jobs), and women in the workforce. Income, time use, social interactions, and physical location alterations that come with livelihood change have occurred in tandem with changes in food environments primarily through land use and food choice behavior. Food choice involves the processes by which people produce, acquire, prepare, distribute, and consume foods. Examples of pathways between livelihood changes and food choice are less food produced for household consumption with more market-oriented livelihoods; acquisition of higher cost convenience foods with increased income and further work distance; preparation of processed foods when longer work hours; alterations in intra-household food distribution to accommodate varied work schedules; and consumption of food prepared away from home with increased access during commutes. Livelihoods changes shift social norms, values, and preferences for both healthy and unhealthy foods.

Conclusion: Results highlight the importance of addressing the intersection of food environments and food choice from a dynamic perspective that considers rapid social and environmental changes in the context of history. Understanding the patterning of daily life as determined by livelihood strategies provides insight into pathways between macro-level forces and food choice behaviors that have implications for human and planetary health. Such insight is necessary for contextually grounded and practicable policies and interventions.

A model for creating demand for nutritious diets and foods in Low- and Middle-Income Countries (LMICs)

Eva C. Monterrosa[1], Ashish Deo[1], Chris Holmes[2], Wendy Gonzalez[1]

1. Global Alliance for Improved Nutrition (Switzerland), 2. Independent Consultant (UK)

Background: 'Demand' as a concept is underconceptualized in public health nutrition but is a well-known concept in business and economics. Demand can be broadly understood as what consumer want or desire and is manifested through usage or purchase. There is increasing agreement in LMICs that to address micronutrient malnutrition and the growing obesity burden, countries need to invest in creating demand for healthy diets. Methods: We conceptualized demand around 'desire' and 'influencing choice'. We focused on lower-middle income parents in Nairobi, Kenya on the assumption that these families have some purchasing power. Drawing from Kok et al. 2011 framework, we applied a 3-phase process: (1) to identify cognitive, emotional, situational determinants affecting desire for nutritious diets, (2) ability of an intervention to change the determinant(s), and (3) programmatic applications. The first phase drew from parenting identity literature and our ethnographic research on parenting and food practices. The second phase consisted of identifying an insight and research to confirm its validity. The third phase was translating the insight into communication materials (radio, TV), to deliver the emotional benefit and drive intentions. Results: Our research found cognitive and emotional dissonance among parents. A peaceful meal was the immediate goal but giving in to children's preferences brought negative parental feelings. The insight that solved the tension among preferences, emotions, and values was: *It is a relief to realise that I am not the only one [parent] struggling. It restores my desire to persevere. To be the parent I want to be. To nourish my family.* The advertising agency converted the insight to the 'Together We Step Up to the Plate' campaign and the FitFood Brand. Conclusion: The research and development culminated in an evidence-based marketing strategy. It was necessary to draw on several disciplines, theories and multiple rounds of research to develop a programme to re-activate parents' innate desire for healthy diets and support their good intentions. The next steps are to deploy the FitFood Brand and campaign and track purchase of vegetables in Nairobi.

SY(T6)18-01

A strategy for further wellness for all: population approach to prevent cardiovascular diseases in Japan

Tomonori Okamura[1]

1. Keio University School of Medicine (Japan)

The population approach may be effective in reducing cardiovascular disease (CV) in the entire population. In Japan, the first public population approach is Health Japan 21 from 2000 to 2012. In 2013, it was revised as Health Japan 21 (the second term) that was promoting the health of all citizens until 2022. Concerning CVDs, high blood pressure, dyslipidemia, diabetes, smoking is set as the main risk factor, of which target was 1) a 4 mmHg decrease in mean systolic blood pressure (SBP), 2) a 25% reduction in prevalence of hypercholesterolemia, i.e., total cholesterol (TC) level being 240 mg/dl and greater, or LDL cholesterol (LDLC) being 160 mg/dl or greater, 3) prevention of increase in prevalence of diabetes, 4) decrease in smoking rate (19.5% to 12%). Especially, regarding blood pressure, the target value of nutrition and diet (salt intake, vegetable and fruit intake, i.e., potassium intake, and proportion of over-weight), physical activity, alcohol drinking, and increase of antihypertensive medicine users in hypertensive patients were placed as the first step of the three-layer structure; and from there, a target value of a 4 mmHg decrease in SBP was set as a second-layer target goal. In the final assessment recently performed, although a significant decrease in age-adjusted CVD mortality is observed, it is unclear why these findings occurred. In the future, multifaceted efforts are needed for decrease in blood pressure level, including not only salt reduction, but also evaluation using sodium/potassium ratios, food ingredient labelling and development of foods with enhanced functions. In addition, blood pressure can be easily measured at home, and it is considered effective to strengthen self-monitoring by promoting home blood pressure measurement and linking it to personal health records. With regard to dyslipidemia, because method of health promotion differs between triglyceride and HDL cholesterol, which are lipids related to the metabolic syndrome (closely related to obesity and diabetes), and LDLC, which is weakly related to metabolic syndrome but strongly related to quality of fatty acid. Therefore, it is necessary to promote awareness-raising projects. Furthermore, it is essential to urgently establish an incidence registry system for CVDs to assess the effect of prevention program.

SY(T6)18-02

Population level approaches to improve diet quality and reduce cardiovascular disease risk in the U.S.

Kristina Petersen[1]

1. Texas Tech University (USA)

Poor diet quality is a leading risk factor for cardiovascular disease (CVD) in the United States. At a population level, small incremental improvements in diet quality improve CVD risk factor burden and lower risk of incident CVD. However, at the individual level, sustained dietary change is challenging. Therefore, intervention at the government (policy), food system and community level is needed to affect population level dietary intake. In this presentation, recent evidence for population-based approaches to improve diet quality will be reviewed. Specifically, food product labeling reform, economic incentives, school and workplace initiatives as well as strategies to address nutrition security will be discussed. Social and environmental factors are key determinants of dietary intake and therefore addressing barriers to intake of a healthy diet at these levels is critical to improving population-wide diet quality.

Keywords: Nutrition, Cardiovascular disease, Dyslipidemia, Hypertension, Diet quality

SY(T6)18-03

Salt Reduction – Experience from the UK

Feng J He[1]

1. Queen Mary University of London (UK)

It is well established that dietary salt intake is the major cause of raised blood pressure, which is the underlying cause of cardiovascular disease (CVD). The World Health Organisation (WHO) has listed salt reduction as one of the 'best-buy' interventions to prevent high blood pressure and CVD. The UK initiated a voluntary salt reduction strategy in early 2000s, led the Food Standards Agency (FSA) and CASH (Consensus Action on Salt and Health), a Non-Governmental Organisation. As 70-80% of the salt in the UK's diet comes from packaged and prepared foods, e.g. bread, breakfast cereals, FSA and CASH developed incrementally lower salt targets for over 85 food categories with a clear timeframe for the food industry to achieve. This strategy was very effective, leading to a reduction in salt content by 20-50% in most foods and a fall in population salt intake from 9.5 g/d in 2003 to 8.1 g/d by 2011, as measured by 24-hour urinary sodium excretion. The reduction in salt intake led to a fall in population blood pressure, and prevented approximately 9000 CVD deaths each year and saved the healthcare service about £1.5 billion in annual costs. As the reductions in salt have been made gradually, the public has not noticed any change in taste and crucially no loss in sales of products for the food industry, a true win-win for industry and public health.

The UK's salt reduction model has now been adopted by many countries. To date, almost 60 countries have set salt reduction targets and about a third of these countries have mandated the targets which are more effective than voluntary targets. In 2021, the WHO published global benchmarks for salt levels in over 60 food categories which provide a guide for countries to set salt targets.

Salt reduction is one of the most cost-effective ways to prevent CVD, which is the leading cause of death and ill-health both in the UK and worldwide. Yet, sustaining salt reduction requires considerable persistence in the face of food industry resistance and the current government's indifference.

Keywords: Salt reduction, targets

SY(T6)18-04

Strategies to reduce salt intake in Japan

Takuya Tsuchihashi[1]

1. Steel Memorial Yawata Hospital (Japan)

Salt reduction is the most important lifestyle modification, especially in Japanese individuals who still consume a significant amount of salt. The Dietary Reference Intakes for Japanese 2020, issued by the Ministry of Health, Labour and Welfare, propose a salt intake goal of < 7.5 g/day for men and < 6.5 g/day for women. Regarding the goal of salt reduction in hypertensive patients, the hypertension guideline by the Japanese Society of Hypertension 2019 (JSH2019) proposes a goal of < 6 g/day. Although the average salt intake in Japan gradually decreased in the early 2000s, the declining trend has not been seen in recent years, and thus, it seems difficult to achieve these target salt intake levels. To overcome this challenge, the JSH announced the 'JSH Tokyo Declaration' and pledged to create a specific action plan to achieve the target salt intake level of < 6 g/day. The six strategies to achieve the target salt intake level are as follows: (1) educating citizens on the harms of excessive salt intake and the importance of reducing salt intake; (2) recommending the assessment of the salt intake of individuals or populations and proposing adequate methods to reduce salt intake; (3) promoting salt reduction for children as a part of dietary education at school; (4) promoting salt reduction in takeout food, prepared dishes, canteens, and school lunches; (5) encouraging companies to develop and promote low-salt foods; and (6) encouraging the government to take measures to promote salt reduction. The JSH is conducting a project to reduce salt intake in the general population with the support of the Ministry of Health, Labour and Welfare and the Ministry of Economy, Trade and Industry. In particular, estimated 24-hour urinary salt excretion is measured for the participants in specific health checkups, and guidance regarding salt reduction is provided to them. Additionally, efforts to improve the food environment are underway so that local residents can easily obtain information on low-salt foods and access stores for

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

purchasing them. Through these activities, a society with a low salt intake will be expected in the near future.

Keywords: Dietary salt intake, Guidelines, Japanese Society of Hypertension, Population approach

SY(T6)19-01

Food Labeling Systems in Japan -Nutrition and Health Claims-

Tsuyoshi Chiba[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Japan is one of the countries with the highest life expectancy in the world. However, there is a gap between life expectancy and healthy life expectancy, that is nearly 9 years in males and 12 years in females. In order to reduce this gap, maintaining good health is important. According to World Health Organization (WHO), self-care is the ability to promote health, prevent disease, maintain health, and so on. Adopting self-care, in other words, practicing healthy life habits including healthy dietary habits would reduce the risks of non-communicable diseases. In Japan, food labeling has been regulated under three laws that were “Food Sanitation Act”, “Health Promotion Act”, and “Act on Japanese Agricultural Standards”. This regulation system was complicated for both consumers and food business operators. To dissolve this problem, “Food Labeling Act” has enacted in 2015. It is stated that food labeling plays a role “to contribute to the protection and promotion of the health of the people” in the Food Labeling Act. Food label is consisted in nutrition claim and health claim with health protect information. Nutrition claim exhibits the contents of energy, protein, fat, carbohydrates, and salt equivalent, which are mandatory, and saturated fat and dietary fiber, which are recommended in Japan. At this time, *trans*-fatty acid is not listed up because of lower amount of consumption among Japanese consumers than WHO recommendation. On the other hand, health claim exhibits health maintenance and health promoting by nutrients/ingredients in foods. Under the Food Labeling Act, foods allowed to label health claims, are specified as “Foods with Health Claims” that include three categories, “Foods with Nutrient Function Claims (FNFC)”, “Foods for Specified Health Uses (FOSHU)”, and “Foods with Function Claims (FFC)”. Consumer Affairs Agency reported that 72% of consumers knew that there was a nutrition label on the packages. Among them, 53.4% checked the fat contents, and 46.7% checked the protein contents. Only 20.4% checked salt equivalent. Nutrition label serves as a parameter for a healthier food choice, but consumers cannot use food label to select low-salt equivalent foods that is the major issue in Japan. In addition, consumers could not understand properties of “Foods with Health Claims”. Some of them could not recognize a distinction between medicines and “Foods with Health Claims”, and use them to treat diseases. In this situation, some consumers experienced adverse events. Food label is a beneficial tool which encourages people to conduct self-care and maintain their health. However, both nutrition claim and health claim are underutilized by consumers. In this regard, front-of pack labels (FOPLs), is a beneficial tool which encourages people to choose healthier foods. However, FOPLs is still unfamiliar in Japan, so we have to investigate which nutrients and which type of FOPLs are the best for Japanese people. In addition to FOPLs promotion, education is important to get consumers using food labels for extension their healthy life expectancy.

Keywords: Food label, Front-of-pack labels, Nutrition, Foods with Health Claims, Healthy life expectancy

SY(T6)19-02

Current Status of Nutrition Labelling and Claims in SEA Region

Pauline Chan[1]

1. International Life Sciences Institute SEA Region (Singapore)

Nutrition labels, as well as nutrition and health claims, are important tools to communicate the nutritional quality and health benefits of prepackaged food to consumers. They provide point-of-sale information to help consumers make informed choices to keep themselves healthy. Recognizing this, most regulatory authorities in Southeast Asia have enacted regulations on nutrition labelling and nutrition and health claims. However, there is wide disparity in the regulations on nutrition labelling and claims in the region. The number and types of nutrients to be declared on nutrition information panels (NIP) or Nutrition Facts as well as the format and expression for nutrient declaration are quite different among the countries. In addition, differences in the types of health claims permitted, the criteria for the claims and the regulatory systems related to these claims are also observed. These differences may cause confusion among consumers and are technical barriers to the distribution of commercial prepackaged food products. The ASEAN Committee for Harmonisation of Prepared Foodstuff Standards (ACHPFS), under the Prepared Foodstuff Products Working Group (PFPWG) of ASEAN Consultative Committee on Standards and Quality (ACCSQ), is the main body for making recommendations for the harmonization of priority standards for the prepared foodstuff sector. It is currently facilitating the harmonization of nutrition labelling which includes the development of ASEAN Guidelines on Nutrition Labelling, and harmonization of Nutrient Reference Value (NRV). In this presentation, the regulatory status of the nutrition labelling and various types of health claims permitted in selected SEA countries, including the regulatory framework for application and review of claim applications, as well as the scientific substantiation requirement will be shared.

Keywords: Nutrition Labelling, Nutrition and Health Claims, Current status, Harmonization

Consumer use and understanding of Health Star Rating (HSR) nutrition labels, and the impact of HSR labelling on dietary habits

Cliona Ni Mhurchu[1]

1. University of Auckland (New Zealand)

Background and objectives: Front-of-pack nutrition labelling (FoPL) of packaged foods aims to promote healthier diets. New Zealand (NZ) and Australia adopted the voluntary Health Star Rating (HSR) scheme in 2014. We aimed to examine the effect of the HSR on population diets via two pathways: consumer food purchasing behaviour and industry reformulation of labelled foods relative to unlabelled foods.

Methods: We undertook three research studies: (1) a randomised controlled trial (n=1357 New Zealand shoppers) of the effects of HSR and traffic light labels versus a control on short-term food purchasing behaviour; (2) fixed effects analyses of Nielsen Homescan household-purchasing panel data to estimate the association of HSR with product and nutrient purchasing over time (2013-2019); and (3) a difference-in-differences analysis of packaged food composition over time (58,905 unique products across 14 major food groups) to estimate product reformulation associated with voluntary HSR adoption.

Results: At the relatively low level of use observed in the randomised controlled trial, neither HSR nor traffic light labels nutrition labels had any significant effect on food purchases. In 2019, 24% of all products in the Nielsen NZ Homescan dataset were labelled with HSR (25% of purchasing volume). Adoption of HSR was selective however with 46% of HSR-labelled products displaying a rating of 4.0-5.0 stars compared with 19% displaying a rating of 0.5-2.0 stars. We found little or no association between HSR labelling and the quantities of different foods purchased by NZ households over time. Introduction of HSR was, however, associated with lower sodium, lower protein, and higher fibre purchases when purchased products displaying an HSR were compared to the same products prior to introduction of the program. **Conclusions:** Robust evidence of HSR labels changing consumer purchasing behaviour was not observed. However, because of industry reformulation of foods in response to the HSR, it was associated with net changes in nutrients purchased: 9% lower sodium, 3% lower protein, and 5% higher fibre. We conclude that FoPL is justified, and should arguably be mandatory, given it alters product composition to be healthier and consumers have a right to clear information on the healthiness of foods.

Keywords: Nutrition labels, Health Star Rating, Effectiveness, Population diets

Conflict of Interest Disclosure: Cliona Ni Mhurchu is a member of the Health Star Rating Advisory Committee. The Committee had no role in study design, data collection and analyses, decision to publish, or preparation of manuscripts and presentations.

SY(T6)20-01

Climate Change and Nutrition

Saskia Osendarp[1]

1. Micronutrient Forum (Netherlands)

While much attention has been devoted to how climate change threatens food supplies and food security, there has been less focus on the effects of climate change on human nutrition. In the climate change-nutrition discourse, micronutrients play a core role. The impacts and disruptions associated with climate change—including the rise in atmospheric carbon dioxide, greater land degradation, more extreme weather, and rising sea levels, to name just a few—are jeopardizing people's micronutrient status. In addition, at the same time that climatic shocks and crises threaten individuals' nutrition security, climate change-induced rises in the prevalence of waterborne diseases may increase human micronutrient needs.

Micronutrients are thus key to mitigating the impacts of climate change on human nutrition. Improving micronutrient resilience in the face of climate change will mean promoting context-specific, sustainable, diverse diets through both food production and connections to markets and trade. It will entail advancing large-scale food fortification as well as investing in the development of climate-resilient, more nutritious key crops (biofortification). And, importantly, it will call for ensuring access to micronutrient-rich foods at the heart of social protection systems and humanitarian activities.

Keywords: Climate change, nutrition security, micronutrients

SY(T6)20-02

The Role of Micronutrients on Immune Function

Jose M. Saavedra[1]

1. Johns Hopkins University School of Medicine (USA)

Nutrition is a determining factor of an adequate immunologic response. Protein and energy undernutrition impacts all immune-related functions. However, even in the face of adequate macronutrient supply, micronutrients in general, and some vitamins and minerals specifically, can significantly affect the protective and recovery immune mechanisms necessary for prevention and recovery from infectious disease. The dependence on nutrition for an adequate immune response is accentuated both in early life and in the elderly, and in those with underlying conditions associated with increased demands, higher nutrient losses, or inadequate metabolism. In situations with underlying poor micronutrient intakes, the effect is compounded by increased requirements in the face of infection, stress, and pollution. Poor micronutrient status, in general, is a

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

risk factor for an increased rate of infections, poor outcomes, and increased mortality. The recent COVID pandemic is an instance where the adverse impact of inadequate nutrition on the immune system, including its inflammatory components, may explain the higher risk of severe outcomes and mortality from viral infections like SARS CoV2 in the elderly, as well as those with obesity, including obese children. Specific micronutrients, namely vitamins A, D, C, E, B6, and B12, folate, zinc, iron, copper, and selenium, play key roles - individually and synergistically - in all phases of the immune response. Individual and combined deficiencies will reduce immune competence and/or disrupt systemic inflammatory regulation. Whether part of the innate or adaptive immune response, in varying degrees, these micronutrients are central to the integrity of physical and chemical barriers and immune cell function. Their roles are broad and interconnected, including supporting integrity of mucosal, skin, and epithelial surfaces, differentiation, proliferation, functioning, and movement of innate immune cells, defensive cytotoxic leukocyte function, antibody secretion, and modulation of pro- and anti-inflammatory cytokines. Thus, individual and combined deficiencies increase vulnerability to infections in general. Although the data is inconsistent, some evidence suggests that supplementation with some micronutrients, particularly vitamins C and D, and zinc, in some circumstances can help reduce the risk of infection. Or, they can serve as therapeutic adjuvants, attenuating infection symptoms and severity, and accelerating recovery, especially in viral respiratory infections, including influenza and possibly SARS CoV2. However, nutrient supplementation during active infections should be treated cautiously and should avoid exceeding safe limits. Finally, malnutrition in general, and micronutrient deficiencies in particular, are likely to play a role in the quality of a protective response to various vaccines. While the data is limited, such responses can be elicited, albeit with lower protection levels than those who are adequately nourished.

Keywords: Nutrition, Immunity, Micronutrients, Infection, Malnutrition

SY(T6)20-03

Learning in crisis: gathering recent [data and] evidence to inform resilient micronutrient policies

Rebecca Heidkamp[1]

1. Johns Hopkins Bloomberg School of Public Health (USA)

Almost three years into the pandemic, actual data on nutritional status are emerging unevenly. Few countries have anthropometric data, and accurate infant and child mortality data from LMICs are limited. However, there are evidence for a dramatic increase in food insecurity and disturbing declines in dietary diversity for households and children. Governments responded to the crisis with an unprecedented range of policies, including adaptations to continue to deliver nutrition and nutrition-sensitive programs, and the initiation of expanded or new social protection programs to build resilience among the most vulnerable households. An analysis of these programs by sector, with a gender lens, will illustrate examples of nutritional resilience capacities (absorptive, adaptive, and transformative capabilities). Importantly, it will also identify data and knowledge gaps that are limiting our ability to advance resilient policies and programs across sectors.

The world is now experiencing a 'crisis on crisis' with severe climate events, conflict and the global food crisis – perhaps a 'new normal'. As a nutrition community, we must work together to identify and analyze evidence to provide policy guidance to promote nutrition resilience. Policy-makers and funders must bridge the gap between humanitarian and development responses to facilitate nutrition resilience.

SY(T6)20-04

Nutrition & Resilience: Program Challenges, Research Gaps and Opportunities

Patrick Webb[1]

1. Tufts University (USA)

The 2020s have so far exposed the stark fragility of our global and local food systems in dramatic, previously unexpected ways. The shocking impacts of climate change were compounded by the Covid pandemic, and then amplified by the Ukraine crisis. Once again, food price hikes, supply chain bottlenecks, and concerns about reliance on international trade have all focused the minds of policymakers and business investors on the hurdles involved in making sustainable healthy diets available and affordable to all. This presentation will discuss the dynamic nature of these challenges and policy reactions to such unstable processes. It will also explore implications for nutrition and health from both programmatic and research perspectives. Will the world revert to self-sufficiency goals and technocratic approaches to securing supplies of low cost calories? Or will this moment in time be seized to achieve transformational change?

Impact of rising global food prices on vulnerable populations

Matin Qaim[1]

1. University of Bonn (Germany)

More than one-quarter of the world population cannot afford a sufficient, healthy, and nutrient-adequate diet. The poorest ones, around 800 million, suffer from insufficient access to staple foods and calories. Beyond calories, more than 2 billion people suffer from micronutrient malnutrition due to insufficient intakes of higher-value, nutritious foods. Women and children are often particularly affected by malnutrition with long-term negative health consequences, including weakened immune systems, physical and mental development problems, and premature deaths.

Reducing malnutrition and improving dietary quality will require higher incomes among poor and vulnerable population groups. Hence, pro-poor income growth must be an integral part of any longer-term strategy to fight undernutrition. At the same time, downside income shocks among the poor must be avoided or cushioned to the extent possible, as income losses exacerbate dietary quality.

Beyond income, food prices determine the affordability of healthy diets. Poor people have to spend a large fraction of their income on food anyway, so that low food prices are conducive whereas rising food prices make it harder to afford diets that are sufficient in quantitative and qualitative terms. When food prices rise, poor people tend to reduce the consumption of higher-value, nutritious foods first, as these are more expensive sources of calories needed to fill the stomach. However, higher-value foods such as fruits, vegetables, and animal-sourced products are rich sources of micronutrients, so that their reduced consumption exacerbates micronutrient deficiencies. If changes in the types of foods consumed are not enough to cope with food price rises, the consumption of staple foods is also reduced, leading to additional calorie and nutrient deficiencies. Even temporary nutritional deficiencies during early childhood are often associated with irreversible development impairments.

Over the last two years, the COVID-19 pandemic has contributed to widespread job and income losses in the global south. At the same time, global food prices have been rising due to high energy prices, high transportation costs, high fertilizer prices, supply chain disruptions, and weather-related harvest failures in some major food-producing regions. The Russian attack on the Ukraine has further increased food prices dramatically, as both Russia and the Ukraine are major exporters of cereals and oilseeds, so reduced exports during the war are associated with food shortages in many other parts of the world as well. In the first half of 2022, global food prices were higher than ever before during the last 60 years. This is extremely worrisome and threatens to reverse recent nutritional improvements especially in Africa and Asia.

The world must act to avoid further nutritional crises. First, better social protection measures need to be put in place in order to cushion poor and vulnerable population groups. Second, sustainable productivity and efficiency growth in food production and distribution are needed to increase the stability and affordability of diverse and healthy food supplies. Third, more sustainable consumption styles need to be promoted to reduce food waste and inefficient resource use.

Micronutrient Deficiencies and Resilience in Asia

Emorn Udomkesmalee[1]

1. Institute of Nutrition, Mahidol University (Thailand)

The remarks will focus on policy-enabling environments for micronutrient resilience including ways to integrate nutrition and micronutrients into food systems transformation and will highlight pro-micronutrient policies undertaken across South and Southeast Asia.

Today, South Asia, and Southeast Asia countries disproportionately suffer from the impact of global climate crisis particularly relating to decreased yields of micronutrient-rich foods and fisheries catch. Communities across the region are mitigating and adapting to the impacts through various nutrition sensitive policies and actions.

In Bangladesh, a policy focus to improve the bioavailability of micronutrient-rich foods and high-quality protein was included in the Third Country Investment Plan for Sustainable, Nutrition-Sensitive, and Resilient Food Systems. The Plan focuses on dietary diversity food safety, food loss and waste, gender sensitivity, and resilience to the effects of climate change.

The 1995–2000 National Plan of Action for Nutrition of Vietnam promoted traditional farming system. This resulted in higher household incomes and greater production of micronutrient-rich foods (meat, fish) and rice; and improved dietary intake and reduced the prevalence of anemia and vitamin A deficiency.

Thailand's reduction in hunger and undernutrition indicators was achieved through community-based nutrition programs. Local production of vegetables, fruits, rice, fish, and chicken; supplementary food for pregnant mothers; complementary food for infants and young children; food preservation and processing; and cooperatives and microcredit have improved the nutrition security of the population.

Nepal recovery after a severe earthquake in 2015, reduced child wasting, child stunting, and household food insecurity involved interventions focused on childhood nutrition.

A clear lesson is that merging micronutrient and resilience agendas requires the alignment of local and national policies; the coordination of human and material resources; and strengthening local food production to support for climate-resilient dietary diversity.

SY(T6)20-07

Transforming food systems to nourish and build resilience

Namukolo Covic[1]

1. International Livestock Research Institute (Ethiopia)

Under existing food systems, about 3 billion people cannot afford a healthy diet and malnutrition in all its forms is the largest preventable burden of disease for individual countries and globally. This includes widespread micronutirent deficienies. In addition, it is estimated that current food systems account for 25% of all greenhouse gas emissions and 70% of biodiversity loss. Adequate nutrition for resilience, a desired outcome from food systems that provide the required nutrients across the life cycle, from conception to old age, is not accessible to many. Healthy and sustainable diets should be at the heart of providing the needed nutrients. But current food systems present multiple challenges resulting in inadequate diets that fail to nourish populations optimally for both rich and low- and middle-income countries (LMICs). For LMICs food insecurity, low production diversity, non-affordability of healthy nutritious diets and conflict, are significant challenges, further compromised by increasing environmental degradation and climate change that threaten present and future food security. For rich countries, unsustainable production and consumption practices and environmental degradation present, nutrition and health risks and negative environmental impacts threaten future food security. All settings would benefit from appropriate food systems transformation that can make healthy nutritious diets from more sustainable food systems accessible to the majority while mitigating against climate change and improving resilience. Given the enormity of the challenges faced the United Nations Food Systems Summit 2021 (UNFSS-2021) was convened to promote accelerated progress on the needed food systems transformation - led by UN member countries. Majority of the UN member states responded to this call. However, significant challenges need to be addressed for the magnitude of transformation needed to be realized. This symposium presentation will address the existing challenges, recommending that transformation to food systems that nourish and build resilience calls for a nuanced approach under different settings.

Symposium Overview: Building momentum for the rights of children to healthy diets and a sustainable future

Kjørven Olav[1]

1. EAT (USA)

The presentation will provide an overview of why improving children's access to healthy and sustainable diets needs to be prioritized as an integral part of a larger strategy towards food systems transformation. It will present EAT's work in this area, particularly through the Children Eating Well (CHEW) collaboration with UNICEF and other partners; our work as lead of Action Track 2 (Shifting to Sustainable Consumption Patterns) of the UN Food Systems Summit held in 2021; and, continuing on from that work, the building of the Coalition for Healthy Diets from Sustainable Food Systems for Children and All (HDSFS) and the School Meals Coalition. The presentation will draw attention to the framework for action that was developed by CHEW and, in important ways, adopted by UNICEF, and will show how this work has informed EAT's engagement towards the UN Food Systems Summit and its contributions to the creation of HDSFS. Finally, the presentation will draw attention towards priority issues, challenges, and opportunities when it comes to making real progress in improving nutritional outcomes for children in such a way that the rights, needs, and voices of children today and in the future are front and center—including when it comes to ensuring that they can inherit a healthy planet.

Keywords: Children, health, nutrition, sustainability, coalition

Priorities for Action: What do the framework and evidence say about how to transform food systems to provide healthy diets for children?

James Garrett[1]

1. Alliance of Bioversity and CIAT / CGIAR (Italy)

The presentation will review the CHEW framework and current evidence in greater depth, using a systems lens, noting impact pathways, connections among framework elements, key entry and leverage points, and priority areas of action for policies and programs. The presentation will also relate the framework and areas for action to current evidence and experiences and note critical knowledge gaps. It will also note key principles and challenges undergirding the transformation of agri-food systems to provide healthy and sustainable diets for children.

Keywords: Food system transformation, children, diets

After the UN Food System Summit: The Coalition of Action on Healthy Diets from Sustainable Food Systems for Children and All (HDSFS) takes off

Stineke Oenema[1]

1. UN Nutrition (Italy)

The presentation will highlight the creation, membership, governance, and activities of the Coalition of Action on Healthy Diets from Sustainable Food Systems for Children and All (HDFSF), which was formed following the UN Food System Summit in 2021 and can serve as a leading platform to support global and country efforts to achieve healthy diets for children. The Coalition membership includes governments as well as global NGOs, research organizations, and development agencies. Its secretariat is administered by WHO, FAO, and UN Nutrition. The Coalition has established principles of engagement and was officially launched in May 2022. It has three core functions: mobilize relevant expertise, especially in partner countries themselves; facilitate peer-to-peer learning; and manage special projects. Already, several learning events have taken place and a number of frontrunner countries have joined from all over the world. Currently the Coalition has two special projects underway: promotion of food-based dietary guidelines that include sustainability criteria; and the inclusion of food and nutrition in Nationally Determined Contributions (NDCs). For the coming year another project will take off, focusing on healthy diets in fragile contexts.

Creating Sustainable Agri-Food Systems that Provide Healthy Diets for Children: Ghana's experiences

Francis B. Zotor[1]

1. University of Health and Allied Sciences (Ghana)

In sub-Saharan Africa, the food and nutrition security situation is dire and portends serious consequences for public health and sustainable development. The rate at which non-communicable diseases (NCDs) are increasing in sub-Saharan Africa (SSA) is alarming. By 2030, NCDs are predicted to become the leading cause of death in Africa. Incorporating healthy eating into the diets of children is important for ensuring a healthy life for them, including helping to prevent NCDs and other diet-related diseases later in life. In Ghana's current situation the high costs of food, especially fruits and vegetables and animal-source foods, which constitute important aspects of healthy diets, make it difficult for most people to afford healthy diets. It is important to put children at the center of the needed food systems transformation. Early initiation and education of children with respect to healthy diets and healthy eating will ensure these become an integral part of their lifestyle. Ensuring children eat healthy diets will have a lifelong impact on their health, nutrition, and overall well-being and also, over the course of their lives, have a positive impact on the shape and sustainability of the food system itself. Most children these days are used to the consumption of sugar-sweetened beverages, which pre-exposes them to various kinds of NCDs, malnutrition, and other nutrition-related diseases. One of Ghana's efforts toward achieving sustainable food systems and providing healthy diets for children is increasing awareness among communities and policymakers of these issues and of the policies and tools they can use to promote healthy diets for children. For example, greater involvement of community members will enable community ownership and an increased sense of responsibility toward transforming food systems to be sustainable and ensure healthy eating among children. Tools such as food-based dietary guidelines can direct and influence the dietary habits of individuals and provide nutritional recommendations for various age groups, including children. Currently, Ghana does not have active food-based dietary guidelines and therefore finds it difficult to alter the dietary behaviors of individuals. Ghana should also intensify nutrition education in the school curricula at all levels (from kindergarten through tertiary level), making sure children have the knowledge to eat healthy diets but also recognizing their roles as change agents.

Transforming Food Systems to Provide Healthy Diets for Children: Insights on 'what' and 'how' from country experiences

James Garrett[1]

1. Alliance of Bioversity and CIAT (Italy)

Drawing on country experiences in Africa, Europe, and Latin America, the presentation will focus on what countries are doing to shape food systems to provide healthy diets for children and the lessons learned from those experiences. As with food system transformation generally, food system transformation focused on benefiting children can engage elements of production, transportation, storage, food safety, processing, marketing and the food environment, and consumer knowledge and consumer choices. But what does it mean to shape the food system *for children*? How does this differ from more general "food system transformation"? What have countries decided are their priority actions in terms of policies, programs, and "targets for change"

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

to promote healthy diets for children, and why? What are their strategies, their steps to transformation, and how do they envision engaging the system as a whole? What institutions, platforms, and institutional and program settings do they use, and why? What are some of the challenges they have encountered in their initiatives – say, in terms of political interest, bringing key actors together, program design and implementation, or just getting started using this perspective? And how do they deal with these challenges? What are the key lessons they want to highlight for others wanting to do similar work?

Advancing methods and tools to assess and monitor healthy diets

Edward A. Frongillo[1]

1. University of South Carolina (USA)

Unhealthy diets are responsible for one in five deaths worldwide. Households and individuals, to achieve good nutrition and health, must consistently access and consume a healthy diet that provides optimal amounts of nutrients and other dietary constituents (e.g., dietary fiber) required for good health.

Routine dietary assessment and monitoring of the healthfulness of dietary intake is needed at global and national levels to support policies and programs that promote healthy diets and evaluate their effectiveness. Few countries assess and monitor diets, in part because of the lack of harmonized methods, tools, measures, indicators, and data platforms to do so.

Knowing what to assess and monitor means knowing what are the sub-constructs that make up the construct of healthy diets. Furthermore, methods and tools are needed that yield measures and indicators that reflect the sub-constructs of healthy diets and are valid and cross-context equivalent. Finally, data platforms must be available that can accommodate the methods and tools to collect the needed data.

In May 2021, WHO-UNICEF Technical Expert Advisory Group on Nutrition Monitoring and the Food and Agriculture Organization of the United Nations, with technical and logistical support from US Agency for International Development Advancing Nutrition, organized a technical consultation to catalyze progress toward identifying a parsimonious set of methods and tools for global assessment and monitoring of healthy diets. Eighty-five experts engaged in the consultation, representing a wide range of institutions, geographic areas, and roles in the data value chain. Building on the outputs of the 2021 Technical Consultation, work is being undertaken in 2022 to 1) identify, and reach consensus on, the sub-constructs of a healthy diet that should be measured, 2) scientifically assess the validity, usefulness, and fitness-for-purpose of existing healthy diet methods and tools, and 3) identify gaps in knowledge and in the existing methods and tools that will require additional research. This work will contribute to guiding governments and others seeking to assess and monitor healthy diets and provide the basis for selecting one or more assessment methods for global and country dietary assessment and monitoring through the next set of Sustainable Development Goals.

Food environment assessments in low- and middle-income country settings: an overview of their use and application for informing healthy diets

Shauna Downs[1]

1. Rutgers University (USA)

Food environments are rapidly changing in low- and middle-income countries (LMICs), contributing to poor quality diets as well as a growing burden of obesity and diet-related non-communicable diseases. While many food environment assessments have been developed for use in high-income countries, few have been designed, or adapted for, LMIC contexts. Given the dynamic and informal nature of these food environments, assessments that are designed to capture the dimensions (i.e., availability, affordability, promotion and quality, convenience) of these environments in a practical way are needed. This presentation will provide examples of food environment assessments that have been piloted in LMICs to date and provide insight into their strengths and weaknesses. It will also identify areas for future research aimed at filling existing gaps in food environment assessments in LMICs. By improving our ability to measure the different dimensions of food environments in diverse settings it will enable researchers and practitioners to better identify the ways in which food environments can be leveraged to support healthy diets.

Understanding diets and micronutrient adequacy at sub-national scales using Household Consumption and Expenditure Survey tools

Kevin Tang[1]

1. London School of Hygiene and Tropical Medicine (UK)

Addressing diets that are inadequate to meet micronutrient needs across LMICs is challenging as they require detailed sub-national assessment to evaluate whether populations with the greatest risks for micronutrient deficiencies are being adequately reached within a country. Dietary data collected via Household Consumption & Expenditure Surveys (HCES) contribute key insights into the quality of diets and can be used to model the potential for micronutrient interventions to help meet the micronutrient needs of at-risk populations. Integrated within nationally representative household surveys, this style of dietary data quantifies foods reportedly consumed by households through a recall using a standard list of commonly consumed food items. When combined with food composition data, these dietary data can generate metrics to provide insights into whether households' dietary micronutrient supplies are sufficient to meet micronutrient requirements. Additionally, adjustments to the composition of key food vehicles can model the potential micronutrient contributions from micronutrient interventions. HCES-based modeling estimates contribute valuable sub-national insights that can characterize dietary quality, coverage of food vehicles, and the potential for filling nutrient gaps. The use of HCES data to contribute to data-driven nutrition decision-making is being facilitated by the development of open-source nutritional assessment tools aimed at making HCES data more widely accessible to inform policies and programs to improve diet quality.

Methodology to Assess Needs and Use Data to Design Large-Scale Food Fortification Programs to Improve Diets

Monica Woldt[1,3], *Mike Foley*[1,4], *Jennifer Yourkavitch*[1,5], *Ingrid Weiss*[2], *Timothy Quick*[2], *Omar Dary*[2]

1. USAID Advancing Nutrition (USA), 2. USAID (USA), 3. Helen Keller International (USA), 4. Save the Children (USA), 5. Results for Development (USA)

Objective: Large-scale food fortification (LSFF)—the addition of vitamins and minerals while processing commonly consumed staple foods and condiments—is a cost-effective strategy when designed and implemented appropriately. LSFF can deliver nutrients to improve micronutrient intakes without changes in dietary habits or food delivery systems. However, barriers at various stages prevent LSFF from reaching its full potential, including access to and effective use of data to inform the choice of food vehicles and fortification formulation. USAID and USAID Advancing Nutrition developed a methodology using existing data to assess food consumption and micronutrient intake to determine potential fortifiable food vehicles for micronutrients found to be insufficient in the diet. The methodology aims to model the potential contribution of fortifiable foods to micronutrient adequacy and reducing the cost of an adequate diet. It is designed to be a feasible and cost-efficient methodology to guide programming and policy actions.

Methods: We first conducted a literature review to design the methodology. We are piloting the methodology in Zambia using existing data from the 2013/2014 Zambia Food Consumption and Micronutrient Status Survey, along with data from the 2015 Zambia Living Conditions Monitoring Survey. To estimate micronutrient adequacy of the diet, we will use the estimated average requirement (EAR) cut-point method for all micronutrients except iron, for which we will use the full probability approach. We will use harmonized average requirements (H-ARs) to determine adequacy levels. We will estimate consumption of centrally processed fortifiable foods in grams per adult female equivalent per day. We will then use these data to model the potential contribution of food fortification to micronutrient adequacy and the cost of an adequate diet for different strata of the population using various feasible food fortification formulations. We will use the Save the Children Cost of the Diet tool to model diet cost.

Findings: We will share the preliminary findings from our analyses, including the prevalence of inadequate micronutrient intake among different strata of the population and modeling the potential contribution of centrally processed fortifiable foods to micronutrient intake. We will also share the cost of an adequate diet with and without the contributions from fortifiable foods, and with various feasible food fortification formulations.

Conclusions: We will share the conclusions from our preliminary findings and recommendations regarding using the methodology to assess micronutrient needs and design LSFF programs to address the needs, as well as implications for use with other programs that aim to improve diets.

The Diet Quality Questionnaire (DQQ): Development, validation, and application as a 5-minute data collection tool for dietary diversity and other diet quality indicators

Anna Herforth[1]

1. Harvard T.H. Chan School of Public Health (USA)

Poor diets are a cause of malnutrition in all its forms, including undernutrition and diet-related non-communicable diseases (NCDs). As one of the largest public health risk factors in the world, diet has been one of the most poorly tracked. Until recently, basic and current data about what people eat has been difficult to collect, and has never been collected comparably across countries globally. Quantitative dietary intake surveys are costly and require a high input of time and expertise to carry out, and therefore are rarely done at national scale. The Diet Quality Questionnaire (DQQ) was developed to fill the gap in scalable data collection tools for monitoring and nutrition surveillance: it is a low-burden, low-cost survey module designed to capture the data needed for validated indicators of diet quality. It is a set of yes/no questions about the consumption of food items that represent 29 food groups, including food groups including healthy foods and foods to limit. The food groups are universal, while the questions have been rigorously adapted to each country. Each country-adapted DQQ is read aloud by survey enumerators, taking approximately 5 minutes and minimal training. Country-adapted DQQs are available for over 100 countries as a global public good at dietquality.org. These can be used to gather standardized data on diet quality indicators including the minimum dietary diversity score for women (MDD-W), consumption of food groups recommended in food-based dietary guidelines, and the Global Dietary Recommendations score as an indicator of adherence to WHO recommendations and dietary risk factors for NCDs. Companion DQQs adapted for infants and young children (IYC) are also available for monitoring WHO and UNICEF indicators of IYC feeding. The DQQ was implemented in nationally representative surveys carried out by the Gallup World Poll in 40 countries in 2021, and the questions are also being used in the core module of DHS. This presentation will provide an overview of DQQ design, validation, and demonstration of the indicators derived from DQQ data.

Potential role of multifunctional food protein-derived peptides in human health

Rotimi Emmanuel Aluko[1]

1. University of Manitoba (Canada)

Food protein-derived peptides have gained increasing attention as potential therapeutic tools for the management of various human diseases. One of the unique features of these peptides is their ability to modulate various metabolic reactions involved in the pathogenesis of chronic diseases. Peptides with simultaneous effects on more than one metabolic reaction are termed multifunctional and represent a new generation of therapeutic tools that could enable the use of a single compound or product for effective prevention and treatment of multiple diseases. In this presentation, novel multifunctional peptides derived from the enzymatic hydrolysis of pea proteins are presented. To obtain these peptides, pea protein isolate was hydrolyzed with alcalase, chymotrypsin, pepsin or trypsin followed by membrane ultrafiltration separation of the hydrolysate peptides into < 1, 1-3, 3-5, and 5-10 kDa fractions. Alcalase was the most effective catalyst in producing low-molecular weight peptides that were dominated mainly by di- and tripeptides. In contrast, pepsin, chymotrypsin, and trypsin produced longer chain peptides. The protein hydrolysates and peptide fractions were tested as inhibitors of α-amylase, α-glucosidase, pancreatic lipase, trypsin and chymotrypsin. Results indicated stronger inhibition ($p < 0.05$) of α-amylase through competitive binding to the enzyme active site when compared to α-glucosidase, which was inhibited non-competitively. Membrane ultrafiltration fractionation led to reduced inhibition of lipase activity and the unfractionated hydrolysates were more effective than the peptide fractions. In contrast, the fractionated peptides had stronger inhibition ($p < 0.05$) of trypsin activity with mean IC_{50} of 2.2 mg/mL when compared to 6.8 mg/mL for the unfractionated hydrolysate. Similarly, peptide inhibition of chymotrypsin activity was significantly ($p < 0.05$) enhanced by ultrafiltration, especially peptide sizes > 3 kDa. Kinetics of enzyme inhibition indicated that the peptides inhibited trypsin and chymotrypsin activities through competitive mode, which reduced substrate access to the enzyme active site. It can be concluded that the pea protein hydrolysates and peptide fractions have potential uses as agents against obesity and diabetes as a result of their effective inhibitions of α-amylase, α-glucosidase, and pancreatic lipase. The same peptides could also serve as protease inhibitors against trypsin and chymotrypsin activities with potential uses in the prevention or treatment of virus infections and cancer.

The potential use of a food-derived peptide IRW against osteoporosis

Jianping Wu[1], Nan Shang[1, 2], Khushwant Singh[1]

1. University of Alberta (Canada), 2. China Agricultural University (China)

Osteoporosis, due to an imbalance between bone formation (osteoblastic activity) and resorption (osteoclastic activity), affects millions of people worldwide. Most current pharmacological therapies are targeting to inhibit osteoclastic activity, which are associated with side effects and are limited in their ability in restoring new bones. IRW (Ile-Arg-Trp), a tripeptide derived from egg white ovotransferrin, was previously shown to exert various biological activates in cells and in animals. In our recent work, we have shown that IRW inhibits osteoclastogenesis and promotes osteogenesis in the mouse macrophage RAW 264.7 and MC3T3-E1 cells. IRW (25 and 50 μM) significantly inhibited the osteoclastogenesis-associated factors [TRAF6 (TNF Receptor Associated Factor 6), c-fius protein (c-Fos), Nuclear Factor of Activated T Cells 1 (NFATc1), and cathepsin K] and upregulated osteogenesis-associated factors [RUNX2 (Runt-related transcription factor 2) and RANKL (Receptor activator of nuclear factor kappa-B ligand)] in the two cell lines. Using ovariectomized (OVX) Sprague-Dawley rats, which mimic to postmenopausal osteoporosis due to a lack of estrogen. Oral administration of IRW did not affect body weight, food intake and organ weight, indicating a lack of toxicity of IRW. After 12-week treatment, feeding IRW at a dose of 45 mg/kg body weight prevented OVX-induced bone loss and maintained relatively high bone mineral density and integrated bone microarchitecture. The serum concentration of biomarkers indicating bone formation was increased in IRW treated groups, while the bone resorption biomarkers were decreased. Our research supports a potential use of a food-derived peptide against osteoporosis.

Keywords: bioactive peptide IRW, Osteoporosis

Cholesterol-lowering food peptides

Satoshi Nagaoka[1]

1. Gifu University (Japan)

1] IIAEK

IIAEK (Ile-Ile-Ala-Glu-Lys, lactostatin) is a novel cholesterol-lowering pentapeptide derived from bovine milk β-lactoglobulin. We identified the target protein interacting with IIAEK and evaluated whether IIAEK specifically interacted with the target protein to improve cholesterol metabolism. We tested the effect of IIAEK on intestinal cholesterol metabolism using Caco-2 cells. We used photoaffinity labeling and nano LC-MS/MS analyses using IIXEK to capture and identify the target protein that interacted with IIAEK (1). We evaluated the specific interaction between IIAEK and the target protein using surface plasmon resonance (SPR). We studied whether IIAEK targets intestinal alkaline phosphatase (IAP) to improve cholesterol metabolism using IAP siRNA. We found that IIAEK significantly reduced the expression of intestinal cholesterol metabolism-associated genes, particularly ATP-binding cassette transporter A1 (ABCA1). Through photoaffinity labeling and MS analysis with IIXEK for intestinal lipid raft fractions of Caco-2 cells and rat intestinal mucosal proteins, we identified IAP as a specific molecule interacting with IIAEK (1). Surprisingly, SPR study showed the specific interaction of IIAEK with human IAP was 2.63 times stronger than that of *in vivo* substrate of IAP (vitamin B_6). Interestingly, IAP siRNA treatment counteracted the IIAEK-induced decrease in ABCA1 mRNA level in Caco-2 cells. We found that IIAEK specifically interacted with IAP in the amino acid sequence-dependent manner to improve cholesterol metabolism with a specific activation of IAP and downregulation of ABCA1 (1).

2] FP

We discovered a novel cholesterol-lowering dipeptide FP (phenylalanine-proline) from 400 dipeptides. We evaluated cholesterol-lowering effects of FP *in vivo and in vitro*, including *PepT1 KO mice.* Wistar male rats, wild-type C57BL/6J male mice and *PepT1* KO mice were fed a high-fat, high-cholesterol diet with a FP treatment to evaluate its effects on lipid metabolism (2). Cholesterol absorption, serum and liver cholesterol, liver lipids were significantly decreased by FP treatment in rats and mice. FP significantly decreased ABCA1 mRNA in the rat jejunum and reduced cholesterol absorption in Caco-2 cells. The cholesterol-lowering action induced by FP was disappeared in *PepT1* KO mice. We found that the cholesterol-lowering action of FP is mediated by PepT1 (2).

3] RPR

Dietary protamine can ameliorate hyperlipidemia; however, the protamine-derived active peptide and its hypolipidemic mechanism of action are unclear. We attempted to identify novel anti-obesity and hypocholesterolemic peptides derived from protamine in animal studies. We attempted to identify novel anti-obesity and hypocholesterolemic peptides derived from protamine in animal studies. We also investigated the effects of the novel anti-obesity and hypocholesterolemic peptide, Arg-Pro-Arg (RPR) derived from protamine, in mice.
C57BL/6J male mice were fed a high-fat diet with a RPR or protamine treatment to evaluate its effects on lipid metabolism (3).

The anti-obesity effects of protamine are linked to the upregulation of adipocyte PPARγ1 and hepatic PPARα and the downregulation of hepatic SCD1 via SREBP1 and adipocyte FAS.

RPR derived from protamine has a crucial role in the anti-obesity action of protamine by evaluating the effective dose of adipose tissue weight loss (3).

Brain barrier transportable peptides and functions in mouse brain

Toshiro Matsui[1]

1. Kyushu University (Japan)

There have been few evidential *in vivo* studies that peptides can cross the blood-brain barrier (BBB) in their intact forms and their functions in brain. By *in situ* mouse perfusion experiments, peptides that can be transported across the BBB were screened and investigated about their functions in the brain. Freshly prepared perfusion fluid containing fluorescein isothiocyanate conjugated (FITC)-albumin or peptides (200 nmol/mL) was infused in the left ventricle of the heart by inserting a 26-gauge butterfly needle at a rate of 2.0 mL/min for up to 10 min. After the perfusion, the whole brain was removed from the mice by decapitation. By liquid chromatography-time-of-flight/mass spectrometry (LC-TOF/MS) and matrix assisted laser desorption ionization (MALDI)-MS imaging analyses, a significant influx of 13^{C}_{2}, 15^{N} Gly-Sar into the brain was obtained in the 10-min perfusion. Among 18 synthetic dipeptides based on the Gly-Sar skeleton, we found that Gly-Pro and Tyr-Pro can cross the BBB with K_i values of 3.49 and 3.53 µ L/g·min, respectively. No detection of Pro-Tyr, a reversed sequence of BBB transportable Tyr-Pro, also revealed the importance of peptide sequence for the transport. MALDI-MS imaging analysis of Tyr-Pro-perfused brain demonstrated that perfused Tyr-Pro was accumulated in the hippocampus, hypothalamus, striatum, cerebral cortex, and cerebellum of mouse brain. It was also demonstrated that the dipeptide improved an impaired memory by spontaneous alternation and shortened step-through latency in amyloid β-induced mice after daily administration for 16 days. In conclusion, Tyr-Pro is a brain-transportable peptide across the BBB and has a potential to improve amyloid β-induced memory dysfunction in mice by its oral administration.

Collaborative immunomodulation by food components and microbiota in the small intestine

Satoshi Hachimura[1]

1. The University of Tokyo (Japan)

Recent studies have revealed that various food components affect the immune response. These components act on various immune cells, and their effects are mediated through the intestinal immune system and, in some cases, the intestinal microbiota.

Chronic inflammation leads to various diseases. For example, obesity can cause chronic inflammation and this may lead to lifestyle diseases such as diabetes. Feeding high-fat diet (HFD) to mice elicits inflammation in adipose tissue, and can be utilized as a model for chronic inflammation. We have been using this model to investigate the anti-inflammatory effects of food components via the intestinal immune system.

We demonstrated in this model that feeding β-elemene, contained in herbs, alleviated inflammation in adipose tissue. Oral administration of β-elemene induced $Foxp3^{+}$ T cells, known to have anti-inflammatory functions, and decreased inflammatory M1 macrophages in adipose tissue. Furthermore, β-elemene acted on intestinal dendritic cells to induce $Foxp3^{+}$T cells in the intestinal immune system. Our study demonstrated the effects of β-elemene in treating experimental obesity-induced chronic inflammation by adjusting the balance of immune cell populations in fat tissue through the generation of regulatory T cells in the intestinal immune system by modulating dendritic cell function.

A different food material, namely a heat-killed lactic acid bacteria (LAB) preparation also inhibited inflammation of adipose tissue in HFD-fed mice. In this case, intestinal inflammation was alleviated, accompanying increase in gut barrier function which decreased by HFD-feeding. HFD feeding is known to cause dysbiosis of intestinal microbiota which was reversed by feeding this LAB strain. Our study demonstrated that the oral administration of the LAB strain regulated gut microbiota, suppressed intestinal inflammation, and improved the gut barrier. It was suggested that this inhibited translocation of products of obesity-induced gut dysbiosis, and through such mechanisms inflammation in adipose tissue was alleviated. We consider this as a case of collaborative immunomodulation by food components and microbiota in the small intestine and are now investigating the mechanisms.

These and other studies show that food components could act on the intestinal immune system directly, indirectly through intestinal microbiota, or through collaborative immunomodulation by both.

Microbiome Targeted Therapy for Immune Disorders

Sin-Hyeog Im[1, 2]

1. POSTECH (Korea), 2. ImmunoBiuome Inc (Korea)

Our immune system controls immunity toward pathogens and suppresses destructive hyper-immune responses. This immune homeostasis is maintained by concerted crosstalk between genetic factors and environmental cues, including intestinal gut microbiota. Dysregulation of the commensal flora

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

is closely linked to functional changes in the immune system and subsequently contributes to the development of immune disorders (such as autoimmunity, allergies), neuronal disorders (depression, Autism Spectrum Disorders), and metabolic syndromes. Moreover, altered gut microbiota affects differential responsiveness to immune checkpoint inhibitors, including anti-PDL1 or anti-PD-1 inhibitors. The candidates of microbiome therapeutics include bioactive molecules derived from the microbiome (metabolites and cellular components) and the bug itself (live biotherapeutic products, LBP). We have developed screening systems to identify anti-inflammatory and immune-stimulatory microorganisms to restore the dysregulated immune responses in various disorders. Furthermore, we have characterized the effector molecules from the selected bacteria and elucidated their mechanism of action. I will discuss the current status of microbiome therapeutic and our work on how we have identified B. bifidum PRI1 and CSGG (as the key effector molecule) that show anti-inflammatory properties to treat autoimmunity and neuronal developmental disorder in a pre-clinical model. I will also discuss immunostimulatory bacteria and their effector molecule that show synergic anti-cancer effects combined with immune checkpoint inhibitors.

Essential nutrients control the host immunity through collaboration with bacteria in the gut and fermented food

Jun Kunisawa[1, 2, 3, 4, 5, 6]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 2. Osaka University (Japan), 3. The University of Tokyo (Japan), 4. Kobe University (Japan), 5. Hiroshima University (Japan), 6. Waseda University (Japan)

Nutrition and commensal bacteria play a major role in the maintenance of immune function. Indeed, low nutrition, especially in essential nutrients, leads to a compromised immune system, which in turn leads to an increased susceptibility to infection. We are studying the immune functions of vitamins and oils, focusing on food and intestinal bacteria. For example, vitamin B families are involved in energy metabolism and are closely related to the maintenance of immune cell functions. In fact, when mice are maintained with a vitamin B1-deficient diet, impaired development and dysfunctions of immune cells with shrinkage of various lymphoid tissues such as Peyer's patches and thymus is observed. Even a deficiency of a single nutrient can cause significant immune dysfunction, but in some cases, it is not only the "quantity" of the nutrient but also its "quality" is important. One example is oil. Omega-3 and omega-6 fatty acids are known as essential fatty acids which cannot be synthesized by the body, so they are strongly influenced by food. They are known to be associated with immune regulations including inflammation and allergies, and recent developments in metabolome analysis have made it possible to reveal the effective lipid metabolites produced from each fatty acid. More recently, we show that beneficial lipid metabolites are produced not only by the body, but also by microorganisms such as bacteria in the gut and fermented food. These findings would lead to the clarification of the immune effects of nutrition from the perspective of "nutrition - bacteria - metabolism" is expected to make the realization of stratified/individualized nutrition that provides an optimal immune environment according to individual characteristics.

Novel roles of the aryl hydrocarbon receptor in the control of intestinal inflammation

Francisco J Quintana[1]

1. Brigham and Women's Hospital, Harvard Medical School / The Broad Institute of Harvard and MIT (USA)

Genome-wide association studies have identified risk loci linked to Inflammatory Bowel Disease (IBD), a complex chronic inflammatory disorder of the gastrointestinal tract. The increasing prevalence of IBD in industrialized countries and the augmented disease risk observed in migrants who move into areas of higher disease prevalence suggest that environmental factors are also important determinants of IBD susceptibility and severity. However, the identification of environmental factors relevant to IBD and the mechanisms by which they influence disease has been hampered by the lack of platforms for their systematic investigation. Here, we describe an integrated systems approach, which combines publicly available databases, zebrafish chemical screens, machine learning and mouse pre-clinical models to identify environmental factors that control intestinal inflammation. This approach established that the herbicide propyzamide boosts inflammation in the small and large intestine. Moreover, we identified a novel AHR-NF-κB-C/EBPβ signaling axis that operates in T cells and dendritic cells to promote intestinal inflammation and is targeted by propyzamide. In conclusion, we developed a pipeline for the identification of environmental factors and mechanisms of disease pathogenesis in IBD and potentially, other inflammatory disorders.

Anthocyanins and curcumin: Possible abilities to prevent diabetes and obesity by stimulating glucagon-like peptide-1 secretion and inducing beige adipocyte formation

Takanori Tsuda[1]

1. Chubu University (Japan)

There is growing interest in the health benefits of natural plant pigments such as anthocyanins and curcumin. Anthocyanins are a group of naturally occurring phenolic compounds responsible for the color of many flowers, fruits (particularly berries), and vegetables. Curcumin is a polyphenol found in turmeric and is used as a spice, food coloring, and herbal medicine. At this symposium, I will describe how these pigments can help prevent diabetes and obesity by stimulating glucagon-like peptide-1 (GLP-1) secretion or by inducing beige adipocyte formation.

(Anthocyanins)

Our screening of the GLP-1 secretagogue suggested that delphinidin 3-rutinoside (D3R) increases GLP-1 secretion in vitro. Pre-administered D3R-rich blackcurrant extract (BCE) significantly ameliorated glucose tolerance after intraperitoneal glucose injection in rats by stimulating the secretion of GLP-1 and subsequently inducing insulin secretion. Dietary BCE significantly reduced blood glucose concentration and improved glucose tolerance, in association with increased basal GLP-1 concentration in plasma. This effect was accompanied by the upregulation of prohormone convertase 1/3 expression, which is essential for intestinal proglucagon processing and the production of GLP-1 in type 2 diabetic mice. An increase in endogenous GLP-1 secretion induced by food-derived factors may help to reduce the dosages of diabetic medicines and to prevent diabetes.

(Curcumin)

Curcumin has various biological functions, including anti-obesity and anti-diabetic properties. Several experimental animal and clinical trials indicate that curcumin has a suppressive effect on the accumulation of body fat. However, the molecular mechanisms by which curcumin exhibits anti-obesity and anti-diabetes properties through beige adipocyte formation are unknown. In addition, high doses of curcumin have been administered in most animal and human trials to date, due mainly to the poor water solubility of native curcumin and its low oral bioavailability. We demonstrated that a highly dispersible and bioavailable curcumin formulation (HC; 4.5 mg native curcumin/kg), but not the same dose of native curcumin, induces the formation of beige adipocytes in inguinal white adipose tissue (iWAT) in mice. We also examined two other approaches to enhance curcumin-mediated beige adipocyte formation and reduce the required functional dose.

1) Combination of HC and another food factor

We demonstrated that the co-administration of a lower dose of HC and artepillin C (a characteristic constituent of Brazilian propolis) significantly induced the development of beige adipocytes in iWAT in mice. Artepillin C enhances the generation of local norepinephrine from accumulated alternatively activated macrophages in iWAT mediated by HC.

2) Combination of exercise and HC Exercise provides various benefits for overall metabolic health. Exercise combined with food-derived factors may have significant or synergistic effects on increasing energy expenditure and suppressing body fat accumulation. Interestingly, the combination of exercise and administration of HC synergistically induced beige adipocyte formation, although exercise or HC alone did not. These unique findings suggest that curcumin can be used as a dietary supplement during exercise to enhance exercise-mediated health benefits.

Our studies are good examples of a curcumin formulation, or co-administration of curcumin formulation and other food-derived factors, enabling an effect that native curcumin cannot otherwise achieve.

Keywords: anthocyanins, curcumin

SY(T7)3-02

Cellular uptake and absorption of yellow curcumin and other compounds

Kiyotaka Nakagawa[1]

1. Tohoku University (Japan)

Lipids in our body can oxidize for various reasons, resulting in the formation of lipid peroxides which are believed to cause certain diseases. Therefore, it is important to reveal the type of oxidation reactions (radical oxidation, singlet oxygen oxidation, etc.) that take place in the body. In our laboratory, we have been aiming to clarify such types of oxidation reactions by analyzing the detail structures of lipid peroxides in vivo using mass spectrometric techniques1-3). We have hypothesized that we can effectively inhibit in vivo oxidation by selecting appropriate antioxidants according to the type of oxidative reaction; thus, we are conducting various experiments to prove this.

Curcuminoids, on the other hand, are yellow fat-soluble polyphenols found in turmeric. Among the oxidation reactions mentioned above, curcumin is known to be effective towards radical oxidation and has been reported to possess beneficial effects such as anti-tumor effects. However, the bioavailability of curcumin in humans is not high, thus, the true effects of curcumin may not be fully realized. Recently, we discovered that the affinity of curcumin to albumin is an important factor that affects the cellular uptake of curcumin4). Hence, an accelerated cellular uptake and physiological activity of curcumin may be achieved by focusing on this affinity5).

Currently, various antioxidant polyphenols are marketed for the purpose of disease prevention. Further advancement of the above two studies (lipid peroxides and curcumin) should enable identification of the oxidative reactions that proceed in the body, leading to the development of new functional foods that can act effectively with a clear in vivo mechanism of action. In terms of curcumin, an increased bioavailability and a more effective inhibition of radical oxidation in vivo should be achieved. In this

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

symposium, I will present such efforts including examples of lipid peroxides, curcumin, and other antioxidant polyphenols.

Anthocyanins: diet, metabolism, and physiological effects

Colin D. Kay[1]

1. North Carolina State University (USA)

Anthocyanins have traditionally been studied for their colorant properties (i.e., used as dyes), while their use in nutrition is much more recent. Anthocyanins are primarily found in the diet in blue- and purple-colored berries and in natural food colorants. To a lesser extent, anthocyanins are consumed in wine, purple corn and carrots, black rice and hibiscus. It's calculated we consume on average between 10 and 20 mg/day from our usual diets, but these values can vary considerably, with high consumers reported to ingest 70-100mg/day, while those taking dietary supplements can consume much higher levels. Anthocyanins undergo many chemical reactions once ingested, including pH dependent chemical degradation, microbial catabolism, and human phase II metabolism, with most anthocyanin metabolites reported as microbial metabolites. Anthocyanin publications have experienced exponential growth since the 1990s, and while initial health research focused on antioxidant activity, modern therapeutic targets include: cardiometabolic disease, cancer, bone health, inflammatory conditions and cognitive function, to list a few. Activity has been reported on membrane transport, enzyme activity, microbial and tumor cell growth, endothelium-dependent and -independent vasodilation, energy expenditure and body weight. Despite 30 years of concerted research, the direct mechanisms of action of anthocyanins remain elusive, possibly as the field has focused primarily on the precursor anthocyanins, over their known microbial metabolites. In an attempt to pinpoint the possible mechanisms of action of anthocyanins, we have created **an MS^n** quantitative metabolomics database and analytical workflow to characterize the contribution dietary anthocyanins make to the human metabolome, with focus on microbial metabolites of anthocyanins. As online food compositional databases lack comprehensive metabolome details, our data-capture workflow utilized an evidence mapping protocol using PubMed, Web of Knowledge and SCOPUS. Here we aimed to capture compositional data relative to the "berry metabolome". Next, we developed a database of berry phytochemicals, with curation of compound synonyms matched to InChI key, physical and chemical properties (mass, formula) and database identifiers (i.e., PubChem ID, HMDB ID, PhytoHub, KEGG ID, CAS InChiKey, SMILES). The database allows interrogation of berry phytochemicals and their possible interactions with biochemical and disease pathways, utilizing data visualization techniques including self-organizing maps, node-link diagrams, sankey diagrams and other visual analytics techniques. Information curated and organized in the knowledge database facilitates the prediction of the bioactivity of anthocyanin-rich food consumption. Here we found anthocyanin metabolites (hydroxybenzoic acids, hippuric acids, hydroxyphenylacetic acids) mapped to metabolic and transport pathways and neuronal systems, linking to numerous disease pathways, including cardiovascular disease, cancer, nervous system and digestive systems diseases, mental disorders, metabolic and immune system diseases. These findings backup nutrition intervention and biomarker study findings, and suggest anthocyanins perturb common metabolic pathways which have downstream effects on disease pathways.

Colorful Carotenoids: Molecular Mechanisms and Implications for Chronic Disease Prevention

Xiang-Dong Wang[1]

1. Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, MA (USA)

Carotenoids are yellow, orange and red lipophilic pigments and occur widely in nature, and carry out a variety of important biological functions. Despite the earlier unexpected findings of the human intervention trials that were conducted to determine the protective effect of beta-carotene on the incidences of lung cancer found no protective effects, supporting evidence that indicates a protective role of fruits and vegetables rich in carotenoids in prevention of chronic diseases continues to be reported in human epidemiological studies and in mechanistic studies using cell culture and animal models. It is important to understand the roles of carotenoids and their derivatives in the process of chronic diseases, with special attention to their metabolism and biological actions, molecular targets, dose effects, and organ-specific effects. We have recently provided strong evidence-based scientific verification of two major carotenoids, lycopene and beta-cryptoxanthin, has anti-inflammatory and anti-carcinogenic properties in lungs and

livers. Additionally, differential mechanisms of carotenoid actions including endogenous cleavage by carotenoid cleavage enzymes and influenced by gut microbiome that may also have protective effects against obesity/cigarette smoking/excessive alcohol consumption-related complications. My presentation will provide an overview of carotenoid metabolism, and the molecular pathways involved in the anti-inflammation/tumorigenesis properties of carotenoids on human health and cancer development.

Food in pace: how to cultivate and eat crops on the moon?

Eiji Goto[1]

1. Chiba University (Japan)

JAXA (Japan Aerospace Exploration Agency) Space Exploration Innovation Hub Center (hereinafter "Exploration Hub") has been working in study of the realization of the concept of "Lunar farming" on the moon since 2017

The Lunar Farming Concept Study Working Group of Exploration Hub carried out studies on crop cultivation technology, unmanned technology, recycling, and overall system. Crop production and resource recycling in a lunar-base farm is a key component for a food supply system to support long-term stay of human beings on the Moon. We use an artificial light-type plant factory (vertical farm) equipped with a hydroponic cultivation system instead of soil and control temperature, humidity, light, CO_2 gas, O_2 gas which are above-ground environmental factors necessary for plant growth. The main food crops that can be cultivated there are cereals, legumes, potatoes, nuts and seeds, leafy vegetables, fruit vegetables, and root vegetables.

Based on the Dietary Intake Standards, an index (estimated energy requirement) was determined for energy to avoid excess or a deficiency of energy intake. There were three types of indicators regarding nutrients to avoid insufficient intake (estimated average requirement, recommended dietary allowance, and adequate intake). There were also indicators to avoid health problems because of overdose (tolerable upper intake level) and indicators to prevent lifestyle-related diseases (tentative dietary goal for preventing lifestyle-related diseases), for a total of six indicators.

Based on these background, we selected 8 crop species and calculated the cultivation area needed to meet the energy and nutrient requirements. The crops are rice, soybean, potato, sweet potatoes, tomato, strawberry, cucumber and leafy vegetable such as lettuce. We also proposed examples of recipes for meals that can be created using these 8 crop species.

In this presentation, I will report the concept study and introduce how to cultivate these crops in a plant factory on the moon.

Keywords: Dietary Intake Standards, food crop, plant factory, space farming, vertical farm

EDEN ISS: Analogue Testing of Plant Cultivation for Space

Daniel Schubert[1]

1. German Aerospace Center (Germany)

EDEN ISS: Analogue T Sustained human presence in space requires the development of new technologies to maintain environmental control, to manage wastes, to provide water, oxygen, food and to keep future astronauts healthy and psychologically fit. The cultivation of higher plants in dedicated greenhouse modules is advantageous from this regard due to their ability to be used for food production, carbon dioxide reduction, oxygen production, water recycling and waste management. Furthermore, fresh crops are not only beneficial for human physiological health, but also have a positive impact on crew psychological well-being.

Under the lead of DLR (Institute of Space Systems), the EDEN ISS project team focused on advancing bio-regenerative life support systems, in particular plant cultivation technologies and procedures for space and planetary habitats. Over the last four years, essential Controlled Environment Agriculture technologies were designed, developed and integrated within the Mobile Test Facility, consisting of two interconnected 20 ft shipping containers. During a dedicated analogue test mission at the German Neumayer III research station in Antarctica, the greenhouse system provided a variety of fresh pick-and-eat crops for the overwintering crew of 10 members. This was of particular importance during their 8 months long isolation phase, when no plane or ship resupply of the station occurred.

The presentation will give a general overview the project and focuses on the deployment- and isolation phase of the EDEN ISS research platform in Antarctica.

Material recycling plant production system for life support in space

Yoshiaki Kitaya[1]

1. Osaka Metropolitan University (Japan)

Plant culture in space has recently been of more significant concern as the possibility of realizing human-crewed space flights over a long duration and even human habitation on other planets is increasing. The feasibility of achieving long-duration human-crewed space missions will be highly dependent on the controlled ecological life support systems (CELSSs) centered upon crop production in space farming. Plants will play essential roles in food production, CO_2 conversion, and water purification. Space farming will require establishing appropriate plant culture facilities with scheduled crop production and high yields with a rapid turnover rate. Here I will outline topics on fundamental knowledge about expected plant functions in the CELSS and the development of closed plant production facilities in space, including problems for growing healthy plants over a complete ontogenetic cycle in space farming. I summarize the possible effects of low gravity on plant growth and reproduction because of heat and gas exchanges between plants and the atmosphere. The challenges regarding environmental control under low gravity conditions in space are also considered. Sweetpotato is one of the candidate crops in space farming. Sweetpotato culture has many advantages over the culture of other crops because sweetpotato grows rapidly with less requirement of fertilizer and water for culture compared with other candidate crops. Sweetpotato has a high yield of edible biomass with high nutritional values allowing a little inedible part as waste because it can be utilized for the leafy vegetable as an antioxidative functional diet as well as the root crop as a high energy diet. The concept of CELSS can be developed into urban ecosystems incorporated with agriculture and the effective utilization of biomass. Assuming that the amount of input material from outside the system and input energy other than solar energy can be minimized, we get closer to a material recycling society with a less environmental load. The Earth is an almost entirely closed environment where plants, humans, and other heterotrophs coexist. Therefore, CELSS can be considered as a miniaturization of the material recycling system on Earth.

Crickets as the food of the future

Sumihare Noji[1]

1. Tokushima University (Japan)

It has been reported that by 2050, the population of the earth may exceed 10 billion. As a result, food shortages are expected to occur. Especially, the demand for protein will exceed our ability to procure it. On the other hand, increased protein production dependent on conventional livestock using cattle and pigs is known to accelerate global warming and induce climate change. To overcome this situation, insect diets are currently attracting attention. Crickets, in particular, are expected to be the food of the future, because they are omnivorous and can be farmed at high densities in an environmentally friendly manner. We have been studying crickets for more than 25 years and have used our knowledge to research ways to make crickets an efficient food source. In particular, we are developing methods to effectively raise crickets by using food residues and other materials that humans have not been able to eat or left uneaten. In addition, we are also conducting research on the domestication of crickets using genome editing technology to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

optimize their use as a food source. We are also studying the use of cricket excrement as fertilizer for plants. If crickets can be used as a virtuous eco-cycle food source, it may be possible to produce food not only on Earth, but also in extreme environments such as outer space. We will present the results of our research and the current status of cricket food in Japan. This study was conducted in collaboration with Drs. Takahito Watanabe, Taro Mito, and Katsuyuki Miyawaki.

Anti-muscle atrophy effects of polyphenols

Chantal Simon[1, 3, 4], Stephane Blanc[2]

1. University of Lyon (France), 2. CNRS IPHC UMR 7178 University of Strasbourg, (France), 3. CarMen Laboratory, INSERM (France), 4. Human Nutrition Research Centre of Rhône-Alpes (France)

Loss of skeletal muscle mass is the consequence of various conditions including disuse, aging and disease. An elevated oxidative stress related to mitochondrial dysfunction is considered as one major contributor of muscle atrophy, though the underlying molecular mechanisms are not fully understood. Polyphenols, plant-based compounds with antioxidant and anti-inflammatory properties, have thus a potential as complementary therapies to prevent the loss skeletal muscle mass and function in various muscle disorders. During the 2 last decades, basic-research studies confirmed significant effects of polyphenols in counteracting muscle damages in several in-vitro and in-vivo muscle atrophy models. In these studies, polyphenol compounds appear to mainly act by reversing mitochondrial dysfunction. Interventional studies in humans are however sparse. A few studies led to encouraging beneficial effects in different physiological and pathological states such as aging, sedentary behavior and disuse, metabolic diseases, and malnutrition. More comprehensive research and additional controlled clinical trials are still needed to better clarify the place of specific polyphenols compounds in preserving skeletal muscle in human and identify the molecular and cellular underlying mechanisms.

Circular Food Production System Using Algae & Animal Cell Culture

Tatsuya Shimizu[1]

1. Tokyo Women's Medical University (Japan)

As future sustainable food production in outer space and in a lunar base, we propose circular cell culture of algae/animal cells and three-dimensional tissue fabrication using those cells. Currently, grain cultivation and livestock breeding with grain are carried out for producing foods. It exploits vast land surfaces on the earth, and only edible parts of these organisms are used as food. Additionally, the non-edible part has a large environmental impact. Such a food production system is not suitable in confined space like outer space and lunar base. Therefore, we have challenged novel food production system based on culturing cells which are the basic units of all living organisms that provide food. Our basic idea is that grain is replaced with algae and livestock is replaced with animal cells. Algae can be cultured and expand with photosynthesis. Then animal cells are cultured and expand with culture medium including basic nutrients (glucose, amino acids and vitamins) extracted from algae. Furthermore, animal cell culture wastes including ammonia are re-used for algae culture. These circular cell culture might lead to minimization of the space for food production. We have already demonstrated the expansion of both algae (chlorococcum littorale) and animal cells (C2C12 myoblasts) in the circular cell culture. By improvement of medium recycling efficiency, we are now trying to develop a totally circular cell culture system. Regarding 3-D muscle-like tissue fabrication, there are several tissue engineering technologies. The most popular approach is tissue engineering using 3-D scaffold. However, in most cases, the scaffold is problematic in the point of view SDGs. In some cases, natural polymers including collagen and gelatin are used as scaffolds, which are obtained from animals. In other cases, synthetic polymers are used, which needs complex synthetic process. On the other hand, we have developed original tissue engineering technology which layers 2-D cell sheets without any scaffolds. Three-D muscle-like tissues (cultured meat) have been engineered by layering bovine muscle cell sheets. In the future, additional developments should lead to a sustainable cultured food production system using the circular cell cultures and tissue engineering in limited and confined spaces. The technology will be also applicable to sustainable food production on the earth.

Bioinformatics and Computational Biology-in the Discovery of Dietary Peptides with Angiotensin Converting Enzyme-I Inhibitory Activity

Kaustav Majumder[1]

1. University of Nebraska-Lincoln (USA)

Present research on dietary bioactive peptides suggests that these peptides can contribute to the prevention of developing non-communicable disease pathogenesis ranging from cardiovascular disease to cancer. Hypertension or high blood pressure is one of the primary causes of morbidity and mortality worldwide. Renin-angiotensin-aldosterone system (RAAS) is one of the significant pathways of blood pressure regulation, and Angiotensin-converting enzyme-I (ACE-I) is a critical component of the RAAS pathway. Inhibition of ACE-I is a well-known method of regulating blood pressure. Food-derived peptides with ACE-I inhibitory activities are receiving significant research attention due to the global prevalence of hypertension. However, identifying, and characterizing ACE-I inhibitory peptides from different food proteins is labor-intensive and time-consuming. This study developed bioinformatics and a dynamic molecular docking-based web server to quickly predict the ACE-I inhibitory peptides from other food proteins. This independent web server can take input in FASTA format or UniProt ID to perform the in silico gastrointestinal digestion and then screen the resulting peptides for ACE-I inhibitory activity. The web server also provides the structural features of the active peptides and their interaction with ACE-I through the dynamic molecular docking method. Therefore, this web server can instantly identify and characterize novel ACE-I inhibitory peptides produced after the gastrointestinal digestion of different food proteins. Furthermore, we have applied the approach of machine learning to predict novel ACE-I inhibitory peptides from the concerned food proteins. This enables us to develop an advanced platform for generating and predicting food-protein-based ACE-I inhibitory peptides with antihypertensive activity.

Visualization of flavor perception

Takeshi Imai[1]

1. Kyushu University (Japan)

Foods contain a variety of volatile chemicals that create unique flavors. Olfaction is essential for the recognition of flavors, representing nutrients and their conditions in foods. Mammals detect odorants with odorant receptors expressed by olfactory sensory neurons in the nasal cavity. Each olfactory sensory neuron expresses only one type of odorant receptor out of a repertoire of ~1,000 in mice and ~400 in humans. Olfactory sensory neurons expressing the same type of odorant receptor converge their axons to the same location within the olfactory bulb, the first relay station in the brain, allowing for parallel processing of different inputs. We study odor perception in the mouse olfactory system using in vivo calcium imaging. In this talk, I will present an emerging new logic for how naturalistic odors are detected and processed in the peripheral olfactory system.

Keywords: Olfaction, Odorant receptor, Olfactory sensory neurons, In vivo imaging

SY(T7)5-03

Visualization of taste

Keisuke Sanematsu[1]

1. Kyushu University (Japan)

Tastes play an essential role as sensors for the uptake of nutrients to maintain homeostasis and for the avoidance of toxic substances. However, it is not easy to objectively evaluate human taste sensitivity in psychophysiological study due to subjectivity. Visualization of taste is one of the powerful tools to elucidate how taste receptors interact with taste substances. Here, we used functional assay and molecular dynamics simulaition to visualize the function of the G-protein-coupled sweet receptor, TAS1R2/TAS1R3. Calcium imaging for HEK 293 cells heterologously expressing TAS1R2/TAS1R3 clarified the molecular mechanisms of the interactions between the sweet taste receptors and taste modifiers. In addition, molecular dynamics simulations predicted dynamic allostery for the transmembrane domain of TAS1R3. Our simulations reproduced species-specific sensitivity of the sweet taste receptor to allosteric modulators. Upon receptor activation, the allostery induced by positive allosteric modulator agonist destabilized the intracellular part of the TAS1R3, an interface of the Gα subunit, along with ionic lock opening. Our predictions were supported by the functional assays of a common human variant of the TAS1R3. This study provides important insights not only for the visualization of taste receptor function but also for predicting dynamic activation for other G-protein-coupled receptors.

Keywords: Sweet taste receptor, Allostery, Molecular dynamics, Calcium imaging

Visualization of food polyphenols by matrix assisted laser desorption/ionization mass spectrometry imaging technique

Huu-Nghi Nguyen[1], Mitsuru Tanaka[2], Toshiro Matsui[2]

1. Institute for Research and Development of Organic Products (Viet Nam), 2. Kyushu University (Japan)

Food polyphenols, which found in tea, coffee, and a variety of fruits and vegetables, have been recognized as an important sources of nutraceuticals owing to their antioxidant, anticancer, antidiabetic, and anti-cardiovascular properties. In order to evaluate bioavailability of polyphenols, analytical tools such as liquid chromatography-mass spectrometry (LC-MS) techniques have been developed and applied Matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI) is a promising *in situ* analytical tool allowing for simultaneous visualization of drugs or food compounds in the organs. However, poor MALDI-MS detection of polyphenols in some common matrices requires more appropriate matrix for MALDI-MS of polyphenols. Thus, our primarily objective was to develop a new matrix for negative MALDI-MS of polyphenols. According to the photobase generator property of nifedipine under ultraviolet (UV)-irradiation, our results demonstrated for the first time that nifedipine successfully achieved the higher and selective MS detection of a model bioactive polyphenol, epigallocatechin-3-*O*-gallate (EGCG) in negative MALDI-MS. Of the dihydropyridines investigated, only nifedipine with *ortho*-positioned nitro group facilitated the detection of EGCG, suggesting that the nitrosophenyl pyridine photobase derived from nifedipine by UV-dehydration reaction under laser irradiation at 355 nm was a key player in deprotonation of polyphenols in negative MALDI-MS. Our further study was performed to establish an *in situ* MALDI-MSI visualization technique for investigating intestinal absorption and metabolism of polyphenols. In this research, two representative bioactive polyphenols, i.e. a *non*-absorbable theaflavin-3'-*O*-gallate (TF3'G) and an absorbable epicatechin-3*O*-gallate (ECG), were selected for MALDI-MSI after their intestinal transport experiments. The results showed that the nifedipine/phytic acid-aided MALDI-MSI technique provided the first *in situ* evidence on local distribution of these polyphenols in small intestine. Interestingly, visualized localization of TF3'G in rat intestine illustrated non-absorbable polyphenol could incorporate into intestinal tissue followed by efflux out to apical compartment. Combination of the present MALDI-MSI with inhibitor-aided intestinal transport experiment of polyphenols was found to be useful for elucidating intestinal absorption routes of TF3'G and ECG. The visualized results demonstrated that TF3'G was stable against phase II metabolism, while the non-targeting visualization by MALDI-MSI revealed the rapid phase II metabolism of ECG to form methylation, sulfation, and their combination conjugates in the small intestine. In conclusion, the present nifedipine/phytic acid-aided MALDI-MSI technique must be a powerful and novel *in situ* analytical tool for investigating intestinal absorption and metabolism of polyphenols without any labelling or extraction preparation steps.

Keywords: MALDI-MSI, Polyphenols, Visualization

Application of foodomics for evaluation of food quality

Yoko Iijima[1]

1. Kogakuin University (Japan)

Foods are composed of various ingredients, the composition of which controls the characteristics of each food. Their composition depends on many steps during food production, such as food material, cooking/processing conditions, and fermentation conditions, etc. Therefore, quality of each food cannot be evaluated by only specific limited ingredients, but comprehensive analysis is required for food. Recently, foodomics approach, which is based on metabolomics by comprehensive metabolite analysis, has been arisen as effective to elucidate food quality. Especially, odor or aroma as flavor in food directly affects our appetite and preferences for it. Therefore, here, evaluation of food focusing on comprehensive flavor profiles and its application are introduced based on our research. Application of foodomics on various foods such as herbs, vegetables and processed food enabled to differentiation of samples and identification of key ingredients involved in it. Furthermore, biosynthesis of these characteristic ingredients, factors for their generating conditions, their relationship with sensory evaluation were leaded, indicating that foodomics is a useful approach to elucidate qualitative difference of foods.

Keywords: foodomics, metabolomics, flavor

Antioxidant compounds in the mushroom *Boletopsis leucomelas* (PERS.) FAYOD and how they change via cooking

Kazutoshi Shindo[1]

1. Japan Women's University (Japan)

Reactive oxygen species (ROS) are produced via several endogenous and exogenous processes and damage important biomolecules, such as lipids, proteins, and DNA. The accumulation of oxidative damage is one of the primary determinants of aging and occurrence of diseases such as autoimmune diseases, neurodegenerative disorders, multiple types of cancer, diabetes mellitus-related complications, stroke, heart attacks, pain and inflammation. Because intake of antioxidants may help prevent cellular damage and diseases mediated by free radicals, several studies have been conducted to investigate the therapeutic effects of antioxidants.

Because antioxidant activity of compounds can be easily evaluated via lipid peroxidation-inhibiting activity, which reflect

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

an accumulated effect of ROS and the deterioration of biological systems, we searched for new natural antioxidants in foods using this assay, and found that the mushroom, *Boletopsis leucomelas* (PERS.) FAYOD, possesses potent lipid peroxidation-inhibiting activity. Mushroom *Boletopsis leucomelas* (PERS.) FAYOD (Japanese name: kurokawa) has a bittersweet taste and is widely consumed worldwide, including Eastern Asia and Europe.

Antioxidant compounds in the mushroom *Boletopsis leucomelas* (PERS.) FAYOD were isolated using chromatographic methods, and their structures were determined via detailed analyses using high-resolution atmospheric pressure chemical ionization mass spectrometry and nuclear magnetic resonance. We identified five known *p*-terphenyl compounds (Bl-I, Bl-II, Bl-III, cycloleucomelon-leukopentaacetat, and Bl-IV) and one *p*-terphenyl new compound (Bl-VI); we determined the complete structure of cycloleucomelon-leukopentaacetat in this study. All these compounds possess potent lipid peroxidation-inhibiting activities. We further investigated changes in their chemical structures and antioxidant activities by applying heat (grilling, boiling, and microwave heating), and proved the production of two known *p*-terphenyl compounds (BI-V and boletopsin A) and one new *p*-terphenyl compound (BI-VII) via deacetylation of the original *p*-terphenyl compounds for the first time. We also found that DPPH radical scavenging activity was enhanced upon moderate heat cooking (boiling and microwave heating) due to changes in *p*-terphenyl compounds.

Keywords: Boletopsis leucomelas (PERS.) FAYOD, antioxidant activity, p-terphenyl compounds, heating

Visualization of food function using LC-MS

Haruya Takahashi[1]

1. Kyoto University (Japan)

Recently, the “double burden of malnutrition”, that is the coexistence of overnutrition (obesity and overweight) alongside undernutrition (stunting and wasting) became a serious problem all over the world. In particular, obesity has become a serious problem in advanced societies. Dyslipidemia and glucose metabolism disorder, which result from obesity, are recognized risk factors for serious disorders including arteriosclerosis, hepatic steatosis, insulin resistance, diabetes, and cardiovascular disease. Therefore, the avoidance of dyslipidemia and glucose metabolism disorder is important for the prevention and treatment of these diseases.

Lifestyle plays an important role in the avoidance of obesity. The appropriate dietary habits as well as exercise and nutritional status reduces the risk of serious diseases induced by obesity. Accordingly, studies on food function contribute to health-related quality of life.

Food is a complex containing not only nutrients but also bioactive compounds. Our study focuses on the effect of the bioactive compounds on health. For example, we analyzed the compounds contained in Koji using LC-MS. Koji is made from grains (e.g. rice, wheat, and soybeans) fermented with *Aspergillus oryzae* and essential for the production of many Japanese traditional foods including miso, soy sauce, and sake. We identified hydroxy-octadecadienoic acids contained in Koji as peroxisome proliferator-activated receptor (PPAR) α activators. PPARα is expressed at high levels in the liver, where it promotes β-oxidation via enhancement of the expression of its target genes. Therefore, PPARα activation is important for the improvement of diseases related to lipid metabolism dysfunction. We also demonstrated that both the PPARα activator and Koji induce the mRNA expression of peroxisome PPARα target genes and reduce triglyceride accumulation in murine hepatocytes. These effects were not observed in PPARα-KO hepatocytes. We therefore conclude that Koji contains valuable food-derived compounds which are capable of improving dyslipidemia.

For several decades, studies on food function have revealed the presence of many bioactive compounds capable of avoiding dyslipidemia and glucose metabolism disorder. However, the effect of food on health remains poorly understood. This is because food contains too many micro-compounds, making it difficult to identify. One of problem-solving approach is the assembly of new comprehensive assessment of food function using metabolome analysis. Metabolome analysis based on liquid chromatography coupled with ultra-accurate mass spectrometry is essential for an overview of food compounds (foodomics), and has been applied to the investigation of animals, plants, and humans. This enables the determination of molecular formulae, from precise mass data, and subsequent identification is provided by a metabolite database. This is an effective approach to analyze bioactive compounds and animal metabolites. The application of metabolome analysis to the assessment of food function using *in vitro and in vivo* contributes to comprehensive understanding of the effect of food on health near future.

Molecular interaction of functional food ingredients with biological components

Tsutomu Nakayama[1]

1. Tokyo University of Agriculture (Japan)

Food ingredients show various biological activities, which are functional, toxic, or both. These activities are typically triggered by specific molecular interactions, such as substrate-enzyme, ligand-receptor, lectin-sugar or antigen-antibody, although hydrophobic molecular interactions with phospholipid membranes are also sometimes important. Ingredients in tea infusions, such as caffeine, theanine, catechins and theaflavins show specific interactions. Caffeine inhibits phosphodiesterase after binding with the adenosine receptor, causing an increase in cyclic AMP and subsequent release of adrenaline. This leads to stimulation of the central nervous system and many other ensuing effects. Theanine is the ethylamide derivative of glutamic acid and provides an umami taste after specific interaction with the umami receptor in taste buds. Epigallocatechin gallate (EGCg), a tea catechin, interacts with the 67-kDa laminin receptor to cause various effects. The covalent binding of catechins and theaflavins with amino acid residues or proteins has been also reported. Recently, hydrophobic interactions between tea polyphenols and phospholipid membranes have attracted much attention. As an example, the antibacterial activity of EGCg is ascribed to interactions with cell membranes. Similarly, antioxidant activity towards low density lipoprotein, the growth inhibition of cancer cells, antiviral activity towards influenza virus, the induction of apoptosis in cancer cells, and astringency caused by tea polyphenols, have all been ascribed to hydrophobic interactions with phospholipid membranes. Biophysical parameters, such as partition coefficients, binding constants, inter-molecular and inter-atomic distances, and microscopic images, should be analyzed to elucidate the mechanisms of these hydrophobic interactions. We are investigating the molecular interactions of black tea polyphenols with phospholipid vesicles to elucidate the mechanisms underlying astringency, the inhibition of cholesterol absorption, and the inactivation of viruses. We have developed an improved method to analyze the turbidity of small volumes of vesicle solutions and use the results as an indicator of molecular interactions with phospholipid membranes. The use of a portable visible spectrophotometer with an LED detection system allows rapid turbidity analysis, such as our analysis of the dose-dependencies of respective catechins and theaflavins on the turbidity of phospholipid vesicle solutions. We found that theaflavins generally cause aggregation of the vesicles at much lower concentrations than do catechins, reflecting the higher hydrophobicity of theaflavins compared to catechins. Theaflavin-3-*O*-gallate (TF2A) and theaflavin-3,3'-di-*O*-gallate (TF3) caused the aggregation of phospholipid vesicles with higher turbidities than did theaflavin-3'-*O*-gallate (TF2B) at the respective concentrations. An NMR study providing chemical shifts, nuclear Overhauser effect, and relaxation times revealed that the galloyl moiety of TF2A interacts with the choline moieties of phospholipid head groups more closely than that of TF2B. These results indicate that the presence of a galloyl moiety at a specific location in the molecule is important for the interactions. The polyphenols in black tea infusions may synergistically interact with phospholipid vesicles, and the compounds other than the known polyphenols may also be due to such molecular interactions.

67-kDa laminin receptor mediates the beneficial effects of a green tea polyphenol EGCG

Hirofumi Tachibana[1]

1. Kyushu University (Japan)

Green tea is one of the most consumed beverages in the world. Several clinical and animal studies have shown the beneficial effects of green tea. (−)-Epigallocatechin-3-*O*-gallate (EGCG) is one of the major compounds in green tea, and several studies emphasize its central role in the beneficial effects of green tea. EGCG is known to exhibit various biological and pharmacological properties. 67-kDa laminin receptor (67LR) has been identified as a cell-surface EGCG receptor that confers EGCG responsiveness to cancer cells at physiological concentrations. 67LR has been shown to mediate the beneficial activities of this phytochemical, such as anti-atherosclerosis, insulin sensing modulation, anti-allergic, and anti-inflammatory activities. MYPT1, eEF1A, protein phosphatase 2A, Akt, endothelial nitric oxide synthase, soluble guanylate cyclase, protein kinase Cd, acid sphingomyelinase, sphingosine kinase 1 and cGMP are EGCG-sensing relating molecules that are vital, via 67LR, for EGCG activities *in vivo*. Some drugs and food factors potentiate bioactivities of EGCG by modulating the EGCG-sensing pathways. My presentation focuses on highlighting the current understanding of EGCG sensing mechanisms through 67LR by which EGCG exerts biological properties.

Keywords: EGCG, sensing, cGMP, 67LR

Bioavailability and biotransformation of tea polyphenols: how the biotransformation affects our understanding of the beneficial health effects of tea polyphenols

Shengmin Sang[1]

1. North Carolina A&T State University (USA)

Background and objectives: Tea is one of the most popular beverages in the world. Consumption of tea has been associated with many health benefits including the prevention of cardiovascular disease, cancer, and obesity. These effects are attributed to the polyphenol compounds in tea with catechins being the major components in green tea and theaflavins (TFs) and thearubigins (TRs) as the unique compounds in black tea. In general, tea polyphenols are extensively metabolized in vivo and have poor systematic bioavailable. It is puzzling how tea polyphenols generate in vivo efficacy if they are poorly bioavailable. We hypothesized that tea polyphenol metabolites retain their bioactivities. The objective of our studies is to dissect the metabolic profiles of tea polyphenols using knowledge-based targeted and untargeted metabolomic approaches.

Methods: Using LC/MS based targeted and untargeted metabolomic approaches, we systematically studied the biotransformation of epigallocatechin 3-gallate (EGCG), TFs, and TRs in mice and humans.

Results: We identified several new metabolic pathways of EGCG including cysteine conjugation, glucosidation, oxidation, conjugation with reactive carbonyl species, and amination. Some of the new metabolites, such as cysteine conjugated EGCG and the aminated EGCG retain the bioactivities of EGCG. Furthermore, we studied the metabolism of TFs and TRs especially their microbial metabolites. For TFs, we identified the oxidized and aminated metabolites as well as the microbial degradation products. For TRs, we found that tea catechin dimers, such as TFs, and theasinensins, are also the building blocks of TRs.

Conclusions: Several new metabolic pathways of tea polyphenols were identified, suggesting the bioavailability of tea polyphenols was underestimated in the past. Microbiota has the potential to metabolize tea polyphenols to small molecular bioavailable metabolites.

Food bioactives on gut and brain health

Chin-Kun Wang[1]

1. Chung Shan Medical University (Taiwan)

This study was aimed to compare the beneficial effect of catechin-enriched green tea and Oolong tea on mildly hypercholesterolemic and mild cognitive impairment (CDR=0.5; clinical dementia rating score) subjects. Sixty subjects (180-220 mg/dL) were enrolled and divided into three groups as catechin-enriched green tea (CEGT), catechin-enriched oolong tea (CEOT) or placebo. Subjects were instructed to drink (2 x 300 mL) of CEGT (780.6 mg of catechin), CEOT (640.4 mg of catechin) or placebo beverage for 12 weeks. Drinking CEGT and CEOT significantly decreased ($p < 0.05$) the body weight, fat, and BMI, lipid peroxidation as well as lipid profile (TC, LDL-c, HDL-c, and TG). Also, intervention with CEGT and CEOT significantly improved ($p < 0.05$) the oxidative indices (TEAC, GSH) and antioxidant enzymes (SOD, CAT, GPx, GR). Moreover, ultrasound examination endorsed the hepatoprotective activity of CEGT and CEOT by reverting mild fatty liver to the normal hepatic condition because of antioxidant and hypolipidemic activities. The feces amounts and the time to pass through intestine for both groups were all improved. For the dementia evaluation, all the subjects' CASIC2.0 score were also greatly reduced. To summarize, both CEGT and CEOT showed similar antioxidant and hepatoprotective activities. However, CEOT displayed superior lipid-lowering activity than CEGT or placebo, and also promote brain health, hence it could be urged to amend the wellness condition of mildly hypercholesterolemic and mild cognitive impairment subjects.

Keywords: green tea, oolong tea, hypercholesterolemic, mild cognitive impairment, CDR

Development of functional green tea and the use of functional food labeling system in Japan

Mari Maeda-Yamamoto[1]

1. National Agriculture and Food Research Organization (Japan)

In 2015, Consumer Affairs Agency of Japan (CAA) launched a new food labeling system known as “Foods with Function Claims (FFC).” The system is characterized by the fact that in addition to general processed foods and supplements, fresh foods are also subject to labeling; businesses themselves, not the government, are responsible for safety and functionality; this is a notification system, and reported information is disclosed on the CAA's website before it is sold; and functionality includes "expression

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of a specific part of the body" and "evaluation by subjective indicators" can be used. As of June 21, 2022, 5576 FFCs have been launched, including 149 fresh foods such as Satsuma mandarin, tomato, spinach, soybean sprout, kale, eggplant, pumpkin, perilla leave, garlic, broccoli, green pepper, mushroom, apple, grape, pineapple, banana, bilberry, lemon, melon, barley, chicken, pork, egg, and fish. Tea (*Camellia sinensis L.*) has been found to exhibit various bioregulatory activities, such as being anti-oxidative, body fat reductive, anti-hypertensive, anti-hypercholesterolemic, anti-cognitive, anti-bacterial, and having immune regulatory effects. We have found the anti-allergic effect of epigallocatechin-3-*O*-(3-*O*-methyl) gallate (EGCG3″Me) and epigallocatechin-3-*O*-(4-*O*-methyl) gallate (EGCG4″Me) isolated from Japanese or Taiwanese tea leaves. EGCG3″Me strongly inhibit mast cell activation and histamine release after Fc epsilon RI cross-linking through the suppression of tyrosine phosphorylation (Lyn) of cellular protein kinase and the suppression of myosin light chain phosphorylation and high-affinity IgE receptor expression via binding to the 67 kDa laminin receptor. 'Benifuuki' was a tea cultivar to contain most EGCG3″Me. The human clinical studies showed that the nasal or eye symptoms of cedar pollinosis or perennial rhinitis were significantly relieved in 'Benifuuki' green tea containing 34mg/day of EGCG3″Me compared with placebo 'Yabukita' green tea that did not contain EGCG3″Me without affecting any normal immune response. One consecutive month of ingestion of 'Benifuuki' green tea was useful for the reduction of some symptoms caused by Japanese cedar pollinosis. Furthermore, the addition of ginger extract increased the anti-allergic effect. From these results, "Benifuuki green teabag", and "Memehanacha (ready to drink)" were released as the first anti-allergic FFC in 2015. The health claim of 'Benifuuki' green teabag was "it alleviates eye or nose discomfort caused by exposure to house dust or cedar pollens". Currently, 32 FFCs (tea bags, powdered tea, tea extract, etc.) containing *O*-methylated catechin as a functional ingredient were launched. As related studies, we found that the reducing effect of serum lectin-like oxidized LDL receptor-1 containing apolipoprotein B (LAB) level and the lowering effect of serum 1,5-anhydroglucitol level by long-term intake of 'Benifuuki' green tea, and developed a tea infuser "Rich plus" for rapidly extracting EGCG3″Me. FFCs, which were developed using other tea ingredients, has the following functional claims; Function to reduce body fat (tea catechins (recommended daily intake: 400-540 mg), gallate type catechins (150-340 mg), epigallocatechin gallate (EGCG, 300 mg), suppression of postprandial blood glucose increase (EGCG (140.2 mg), cognitive function to maintain cognitive function (theanine (200mg), theanine (50.3mg) plus EGCG (131mg)), support healthy sleep at night and reduce fatigue and drowsiness upon waking (theanine (200mg)).

Keywords: Foods with Function Claims, Benifuuki green tea, anti-allergic action

The creation of SHOKU-gaku (Transdisciplinary Science of Eating, Food, and Nutrition for Health and Wellbeing) and its goals: with an example of food function enhancement by the oral microbiome

Nobuhiro Takahashi[1], Jumpei washio[1]

1. Tohoku University Graduate School of Dentistry (Japan)

"Shoku-gaku" is a newly coined Japanese word, meaning "Transdisciplinary Science of Eating, Food, and Nutrition for Health and Wellbeing (TEFoN)". This is the world's first new transdisciplinary science that integrates oral science with the existing disciplines of food science and nutrition science. In 2020, Tohoku University Graduate School of Dentistry, in collaboration with Tohoku University Graduate School of Agricultural Science and Miyagi University School of Food Industrial Sciences, launched the concept of Shoku-gaku (TEFoN) and establish the Innovative Research and Education Center as a base for conducting this new science (iREC-TEFoN). The goal is to realize lifelong health and wellbeing by right eating and right food.

The topics covered in Shoku-gaku (TEFoN) are: 1. Oral function science: sensing of eating (chewing, swallowing, etc.) and tasting (taste, smell, texture, etc.), 2. Food science: functional foods and disaster foods, 3. Nutrition science: new functional food molecules and personalized nutrition, 4. Microbiome science: food-induced modification of oral/intestinal microbiome and food components modification and new functions by oral/intestinal microbiome, 5. Data science of eating, health and wellbeing. Based on these transdisciplinary activities, we will develop new functional foods that bring about health and wellbeing, and create "eating programs" for lifelong health and wellbeing. To utilize these results in society, social co-creation, including industry-academia collaboration, social demonstration, and social implementation, is essential.

In the past 20 years, the role of dentistry has been expanding from the prevention and treatment of oral diseases to the promotion of oral and systemic health. Since eating is the most important factor for the promotion of health and wellbeing, dentistry has the responsibility to conduct Shoku-gaku (TEFoN), as a discipline of the oral cavity, the gateway to food. From these perspectives, Shoku-gaku (TEFoN) will be one of the redefinitions and a new mission of dentistry in the future, which aims to promote oral and systemic health and wellbeing. At the same time, it will also be a great opportunity to finally include food science and nutrition science, which have not been included in dentistry and medicine in Japan, into the curricula of dentistry and medicine. Shoku-gaku (TEFoN) will shift medical and dental care to more proactive prevention, pre-disease control, and health promotion, enabling the revitalization of the super-aging society that humanity will soon face around the world.

In this presentation, we will discuss the concept of Shoku-gaku (TEFoN), its background and current activities. Furthermore, using nitrate as an example of one of the food components, we will explain how the oral microbiome may enhance food function and contribute to oral and systemic health.

Lipopolysaccharide Neutralizing protein in Miso, Japanese Fermented Soybean Paste

Makoto Kanauchi[1], Naoki Syoji[1]

1. Miyagi University (Japan)

Intestinal flora typically amount to 100 trillion cells comprising 400 bacteria species. Gram negative bacteria of one kind in the flora have lipopolysaccharides (LPS), which stimulate intestinal activity. Fatality rates from severe diseases caused by LPS are 30–50%. According to recent probiotic theories of health, vigorous lactic acid bacteria in yogurt are eaten by many people to improve their intestinal environment. Moreover, some lactic acid bacteria reportedly have activity for neutralizing LPS from *Escherichia coli*. Actually, since ancient times, miso has been regarded as able to alleviate intestinal failure. Miso, a fermented paste made from soybeans, is used traditionally for seasoning of food. Since ancient times, it has been a dietary source of protein and nitrogen in Japan because of its high nutritional value and important health functions such as the estrogen-like activity of isoflavones, anti-oxidation, and angiotensin-converting-enzyme inhibition activity. Anti-inflammation effects of miso clearing mechanisms constitute a new healthy function. Today, similarly to yogurt, miso is regarded by many as a healthy food After some miso samples were analyzed, their LPS neutralization substrates were researched. First, their LPS neutralization activity was assayed. Consequently, only one miso sample has 85% elimination activity, 4 samples had 50–80% LPS neutralization activity, and 10 samples had 19–50% activity. The others failed to show activity. The one miso sample with the most neutralization activity among the samples also had the greatest amount of soluble nitrogen at 0.48%. Correlation analysis was conducted to assess LPS neutralization activity and other compounds in miso. The LPS neutralization activity was found to be related strongly with soluble nitrogen in miso; its coefficient *R* was 0.8329. A relation was found with fluorescent dye using ANS in miso. Therefore, LPS neutralization activity was found to have a relation with hydrophobic peptides in miso. Results indicate that miso neutralized LPS that might cause intestinal tract inflammation. After fractioning of miso, the LPS neutralization activity fractionations (proteins) were isolated from miso extract using Blue native polyacrylamide gel electrophoresis (PAGE). A protein found at 10–30 kDa on the polyacrylamide gel was identified using nano LC-MS/MS as 2S albumin in soybean (*Glycine max*). The protein had two LPS binding motifs: SKWQHQ (22 amino acid residues) and EKQKKKMEKE (131 amino acid residues). The protein in miso was found to have LPS neutralization activity, as assayed by prostaglandin D2 (PGD2) production from macrophage cells. Results show that LPS-neutralizing protein (LNP) from miso inhibited PGD2 production by macrophage cells. Particularly, 50 mg/mL of LNP solution and LPS (10 mg/mL) inhibited cell production of PGD2. Data were inferred as significantly different ($P < 0.05$) from results of statistical analyses by ANOVA testing and Tukey tests. The 2S albumin in soybean is LNP, an LPS-neutralizing protein produced in miso.

Keywords: lipopolysaccharides (LPS), Anti-inflammation, Miso, Japanese Fermented Soybean Paste

Recent discoveries on the effects of vitamin K on endocrine.

Yusuke Ohsaki[1], Hsin-Jung Ho[1], Yoshihiko Minegishi[1], Asagi Ito[1], Michio Komai[1], Hitoshi Shirakawa[1]

1. Tohoku University (Japan)

Vitamin K is one of the fat-soluble vitamins and is mainly composed of vitamin K1 contained in plants and vitamin K2 (menaquinone) derived mainly from microorganisms. It has been shown that some of the ingested vitamin K is specifically converted in animal tissues to menaquinone-4 (MK-4), a type of vitamin K2. This MK-4 is known to have certain effects not found in other vitamin Ks.

Vitamin K acts as a cofactor for γ-glutamylcarboxylase and is an essential cofactor involved in post-translational modification (activation) of vitamin K-dependent proteins. Since vitamin K-dependent proteins include blood coagulation factors and bone matrix proteins, vitamin K plays an important role in blood coagulation and maintenance of bone homeostasis. On the other hand, vitamin K is also present in high concentrations in several tissues other than the liver and bones. Tissues such as testis and pancreas, where the action of vitamin K is not fully understood, contains relatively higher concentration of MK-4 in the regardless of the type of vitamin K ingested, suggesting that vitamin K, especially MK-4, could possess unknown functions.

We attempted to elucidate the novel function of vitamin K by analyzing the gene expression level of rat testis by the DNA microarray method. The expression level of a series of genes involved in the synthesis pathway of isoprenoid, cholesterol, and testosterone, including Cyp11a, a rate-determining enzyme to produce testosterone, were altered depending on the degree of vitamin K sufficiency. In addition, plasma and testicular testosterone levels were also significantly increased in the group with vitamin K supplemented diet compared to vitamin K deficient diet group, indicating that vitamin K could involve in androgen hormone production. In addition, an experimental system using testis Leydig cell lines also confirmed testosterone production dependent on the addition of vitamin K, suggesting that the cAMP-PKA-CREB-mediated pathway is involved in this mechanism.

We also conducted a study using the islets of Langerhans cell in the mouse pancreas to elucidate the function of vitamin K in the pancreas. We have shown that vitamin K enhances glucose-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

stimulated insulin secretion and may be involved in glycemic homeostasis. Furthermore, in a study using β-cell lines, it was also shown that vitamin K enhances glucose-stimulated insulin secretion in a concentration-dependent manner. As part of the mechanism, we have shown that it may be mediated by the exchange protein directly activated by cAMP 2 (Epac 2) pathway following the increase in intracellular cAMP concentration.

These results indicate that vitamin K may be involved in testicular androgen hormone production, and maintenance of blood glucose levels through pancreatic insulin secretion.

Natural polyphenols as therapeutic and preventive agents for Alzheimer's disease

Masahito Yamada[1, 2, 3]

1. Kudanzaka Hospital (Japan), 2. Kanazawa University (Japan), 3. Tokyo Medical and Dental University (Japan)

Epidemiological studies. Epidemiological studies have suggested that diets rich in polyphenols or phenolic compounds are associated with a reduced risk of dementia or Alzheimer's disease (AD). In our population-based cohort in Nakajima, Ishikawa, Japan, we have analyzed how lifestyle-related factors (diets/exercise and laboratory data) at baseline of normal cognition are related to future cognitive decline in a prospective, longitudinal study. We found that consumption of green tea, but not coffee or black tea, was associated with reduction of risk of cognitive impairment approximately 5 years after the baseline of normal cognition, after controlling confounding factors such as age, gender, lifestyle-related diseases, lifestyle-related factors, and apolipoprotein E E4. AD accounted for 67% of all causes of dementia in this cohort. As green tea is rich in polyphenols, we considered that natural polyphenols may have preventive effects on AD.

Effects of natural polyphenols in AD models. Polyphenols/phenolic compounds have anti-oxidant and anti-inflammatory properties. Furthermore, various polyphenols/phenolic compounds have been reported to have specific actions in AD models: modulation of amyloid precursor protein (APP) processing, inhibition of amyloid β-protein (Aβ) aggregation, destabilization of Aβ aggregates, promotion of Aβ clearance, alleviation of Aβ-induced oxidative stress/toxicity/synaptic dysfunction, and inhibition of tau phosphorylation and aggregation. Our studies with *in vitro* AD models revealed that some polyphenols, such as rosmarinic acid (RA) and myricetin, efficiently inhibit oligomerization as well as fibril formation of Aβ through differential binding, whilst reducing Ab oligomer-induced synaptic and neuronal toxicity. A transgenic mouse model fed orally with such compounds showed significant reduction of soluble Aβ oligomers as well as of insoluble Aβ deposition in the brain.

Clinical trials with natural polyphenols for AD. Several polyphenols or phenolic compounds, including curcumin, resveratrol, and (-)-epigallocatechin-3-galate (EGCG), have been investigated in clinical trials, although their efficacy in prevention or treatment for AD has not been established as yet. Based on the results of our studies with AD models, we proceeded to clinical trials with RA for prevention and treatment of AD/dementia. For clinical trials, we prepared capsules of *Melissa officinalis* (lemon balm) leaf extract rich in RA. A randomized-controlled trial (RCT) in healthy individuals confirmed safety, tolerability, and pharmacokinetics of the *M. Officinalis* extract (UMIN-CTR: UMIN000004997). Then, we performed an RCT with the RA-rich *M. officinalis* extract in patients with mild AD dementia, and found that the extract was safe and well-tolerated, and that Neuropsychiatric Inventory Questionnaire (NPI-Q) score significantly improved in the *M. officinalis* group compared with worsening in the placebo (P = 0.012), suggesting that the *M. officinalis* extract may improve neuropsychiatric symptoms (UMIN000007734). Currently, an RCT to elucidate the effect of the *M. officinalis* extract for dementia prevention in non-demented subjects is ongoing (UMIN000021596).

Conclusions. Beneficial properties of natural polyphenols/phenolic compounds for prevention and treatment of AD have been suggested in epidemiological and experimental studies. For clinical use, several compounds have been investigated by clinical trials, however, preventive or therapeutic effects on AD have not been proved so far, requiring further clinical trials to establish their efficacy.

Microbiota metabolites modulate the T helper 17 to regulatory T cell (Th17/ Treg) imbalance promoting resilience to stress-induced anxiety- and depressive- like behaviors

Giulio Maria Pasinetti[1]

1. Icahn School of Medicine at Mount Sinai (USA)

Chronic stress disrupts immune homeostasis while gut microbiota-derived metabolites attenuate inflammation, thus promoting resilience to stress-induced immune and behavioral abnormalities. There are both peripheral and brain region-specific maladaptations of the immune response to chronic stress that produce interrelated mechanistic considerations required for the design of novel therapeutic strategies for prevention of stress-induced psychological impairment. This study shows that a combination of probiotics and polyphenol-rich prebiotics, a synbiotic, attenuates the chronic-stress induced

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

inflammatory responses in the ileum and the prefrontal cortex promoting resilience to the consequent depressive- and anxiety-like behaviors in male mice. Pharmacokinetic studies revealed that this effect may be attributed to specific synbiotic-produced metabolites including 4- hydroxyphenylpropionic, 4-hydroxyphenylacetic acid and caffeic acid. Using a model of chronic unpredictable stress, behavioral abnormalities were associated to strong immune cell activation and recruitment in the ileum while inflammasome pathways were implicated in the prefrontal cortex and hippocampus. Chronic stress also upregulated the ratio of activated proinflammatory T helper 17 (Th17) to regulatory T cells (Treg) in the liver and ileum and it was predicted with ingenuity pathway analysis that the aryl hydrocarbon receptor (AHR) could be driving the synbiotic's effect on the ileum's inflammatory response to stress. Synbiotic treatment indiscriminately attenuated the stress-induced immune and behavioral aberrations in both the ileum and the brain while in a gut-immune co-culture model, the synbiotic-specific metabolites promoted anti-inflammatory activity through the AHR. Overall, this study characterizes a novel synbiotic treatment for chronic-stress induced behavioral impairments while defining a putative mechanism of gut-microbiota host interaction for modulating the peripheral and brain immune systems.

The evidences of sulforaphane from animal and cell studies to prevent or treat Alzheimer's disease

Jiyoung Kim[1]

1. Seoul National University (Korea)

Sulforaphane, an organosulfur compound present in cruciferous vegetables, is known as one of the most powerful activator of transcription factor nuclear erythroid 2-related factor-2 (Nrf2). It has been shown to exert neuroprotective effects in experimental in vitro and in vivo models of neurodegeneration. The studies have further extended to several neurological diseases, including Alzheimer's disease (AD), Parkinson's disease, Huntington's disease, amyotrophic lateral sclerosis, multiple sclerosis, autism spectrum disorder, and schizophrenia. The potential effects of sulforaphane on cognitive function and the cholinergic system were investigated by evaluating learning and memory retention in C57BL/6 mice using the Morris water maze test and assessing cholinergic markers acetylcholine, acetylcholinesterase, and cholineacetyltransferase in C57BL/6 and primary cortical neurons exposed to scopolamine. The effect of sulforaphane on neuronal brain-derived neurotrophic factor (BDNF) expression and its tyrosine kinase receptor B (TrkB) synaptic signaling pathways were also investigated. Whether sulforaphane modulates the production of amyloid-β (Aβ) and tau, the two main pathological factors in AD, is also investigated using triple transgenic Alzheimer's disease mouse model (3XTg-AD). Finally, sulforaphane ameliorated memory deficits in 3 × Tg-AD mice as revealed by novel object/location recognition tests and contextual fear conditioning tests. On the other hand, biological indicators to predict sulforaphane's responders were reviewed under the concept of personalized nutrition. This work is supported by the Korea Research Foundation Grant given to Jiyoung Kim #NRF-2012R1A1A3011954, #NRF-2015R1A1A3A04000963 and #NRF-2020R1I1A1A01054684.

Rosmarinic acid suppresses tau phosphorylation and cognitive decline by downregulating the JNK signaling pathway

Shoko Kobayashi[1], So Yamamoto[1], Moeko Noguchi-Shinohara[2],Tsuyoshi Hmaguchi[2], Masahito Yamada[2], Keiko Abe[1, 3]

1. Seoul National University (Korea)

The number of patients with Alzheimer's disease (AD) is increasing rapidly worldwide; however, its definite treatment is not yet established. Therefore, food-based prophylaxis of AD is desired. Several epidemiological studies have indicated that a polyphenol-rich diet reduces the risk of AD. We found that rosmarinic acid (RA), a food-derived polyphenol, is a prophylactic candidate for AD. Our group has analyzed the mechanism of *in vitro* inhibition of Aβ aggregation, which is the main pathological hallmark of AD. However, the mechanism of RA activity *in vivo* remains unclear; therefore, we examined the effect of RA in AD model mice and investigated the underlying mechanism. First, we investigated the effect of RA on cognitive function in 3×Tg-AD mice using behavioral tests. In Y-maze and novel object recognition tests, 10-month 3×Tg-AD mice from the RA group exhibited improved behavioral performance for spatial cognition and object memory. Immunohistochemistry was performed to evaluate the expressions of Aβ and p-tau, which are key molecules of AD progression. The accumulation of Aβ was suppressed in the RA group. According to the proportion of p-tau-positive cells to the total number of cells in the hippocampus, there was a significant decrease in the CA1 region of the RA group relative to the control group. Then, we performed DNA microarray analysis of the hippocampus to elucidate the mechanisms of RA activity. KEGG analysis showed that inflammation-related pathways, such as MAPK/JNK signaling, were suppressed in the RA group. Furthermore, DNA microarray analysis showed that JnK3 was the most markedly downregulated tau kinase and RT-qPCR revealed decreased *JnK3* expression in the hippocampus. Immunohistochemical analysis showed lower expression levels of p-JNK and p-c-Jun in the CA1 region in the RA group relative to those in the control group, indicating attenuated JNK signaling in this region. Further, we

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

investigated the gene expression levels of the central and peripheral inflammatory mediators as potential factors that alter the activity of stress-associated JNK. In addition to the representative inflammatory mediators, such as *interleukin-1β* and *tumor necrosis factor-α*, reduced levels of chemokines and damage-associated molecular patterns were observed in the RA group at both the central and peripheral sites. Although inflammation was suppressed in both the periphery and brain, the order in which this suppression occurred is unclear. Recent studies have suggested that neuroinflammation significantly contributes to AD pathogenesis. Numerous preclinical and clinical studies have demonstrated that peripheral inflammation is communicated to the brain. Therefore, AD prevention should aim at suppressing the inflammation in both the periphery and brain. In our study, RA intake suppressed hippocampal inflammation and led to the downregulation of the JNK signaling pathway that induces tau phosphorylation. Supplementation with RA exerted an anti-inflammatory effect not only in the central nervous system but also in the peripheral organs. Downregulation of the JNK signaling pathway in the hippocampus may be a potential mechanism underlying the inhibition of the progression of AD pathology and cognitive deficit due to RA intake.

A Perspective on Omega-3 Fatty Acids and Cardiovascular Disease from 40 Years of Research

William S. Harris[1]

1. Fatty Acid Research Institute (USA)

Omega-3 fatty acids burst into the scientific and medical world in 1971 with the first publication from Dyerberg and Bang about the Greenland Innuits. Their research was the first to link high blood omega-3 levels of EPA and DHA with reduced risk for cardiovascular disease (CVD). I was first introduced to EPA and DHA in the late 1970s when I studied their effects on human lipid metabolism. Twenty years later my interests began to migrate towards discovering the extent to which blood levels of omega-3 fatty acids can be viewed as risk factors for disease, much like cholesterol and blood pressure are risk factors for CVD, a low omega-3 level is too. With the invention of the Omega-3 Index (RBC EPA+DHA) in 2004 we began to publish studies link a low Omega-3 Index to not only increased CVD risk but also risk for dementia, for diabetes, for depression, and ultimately for premature death. As a nutritionally-modifiable risk factor, the Omega-3 Index should be incorporated into clinical practice to guide medical care so as to reduce risk for many chronic diseases. This talk will review the effects of omega-3 fatty acids on human lipid metabolism (primarily triglyceride lowering) and on risk for CVD events from randomized trials, and it will also cover the associations between a low Omega-3 Index and risk for multiple human diseases.

Conflict of Interest Disclosure: WSH holds an interest in OmegaQuant Analytics, LLC a clinical laboratory that offers blood fatty acid testing to researchers, health care providers and consumers.

Hypertrglyceridemia and low LDL cholesterol

Ki Hoon Han[1]

1. University of Ulsan (Korea)

Under the condition of serum low LDLc with high triglyceride levels:

•Little single genetic background supports low LDLc and high TG, suggesting multiple genetic/non-genetic factors may play roles simultaneously.

•LDLc becomes less powerful predictive value for CVD risk under low LDLc / high TG levels.

•Calculated LDLc levels underestimate LDL particle burden when TG level becomes higher.

•High TG and low LDLc implies TRL-dominant condition and non-HDLc level is largely affected by TG (TRL-associated cholesterol), not LDLc.

•Same nonHDLc level, but with higher TG suggests more burden of atherogenic lipid particles. •Under the condition of low LDL/high TG, LDL particle may become heterogenous dominant with small dense LDL.

•Calculating nonHDLc and measuring apoB may be more informative for the ASCVD prevention.

•LDLc is mostly determined by LDLR-mediated clearance while TG level is determined by multiple metabolic steps from synthesis, lysis and clearance. The prolonged residual time of TRL particles may cause atherosclerotic change of arteries.

Postprandial hypertriglyceridemia as a risk factor of atherosclerosis

Yoshio Fujioka[1]

1. Kobe Gakuin University (Japan)

Accumulating clinical studies revealed that postprandial hypertriglyceridemia is associated with atherosclerosis, and several clinical guidelines determine the diagnostic criteria for both fating and non-fasting hypertriglyceridemia. The nature of these is elevated levels of triglyceride-rich lipoproteins, especially remnants. This session will discuss the characteristics of remnants and the mechanism of their atherogenesis, and therapy for postprandial hypertriglyceridemia.

Keywords: Postprandial hypertriglyceridemia, atherosclerosis, remnants

HDL functionalities and life-style modification

Masatsune Ogura[1, 2]

1. Chiba University Graduate School of Medicine (Japan), 2. Eastern Chiba Medical Center (Japan)

Regarding the prevention of atherosclerotic cardiovascular diseases (ASCVD), epidemiological and observational studies have shown that the lower the blood level of low-density lipoprotein cholesterol (LDL-C), the better. Intervention studies have also shown that this is also true for the LDL-C level. Since low high-density lipoprotein cholesterol (HDL-C) levels have been reported to be a risk for ASCVD, it has been considered logical to increase HDL-C levels with the goal of counteracting residual risk after LDL-C lowering therapy. However, higher blood levels of HDL-C are not necessarily better, and in patients already receiving LDL-C-lowering therapy, increasing HDL-C levels by treatment did not have a preventive effect against ASCVD. Therefore, HDL research has undergone a paradigm shift from "quantity to quality“. With respect to HDL quality, cholesterol efflux capacity has been noted as one of the measurable HDL functionalities. Many investigators, including ourselves, have reported that cholesterol efflux capacity is a more useful surrogate marker of atherosclerosis than HDL-C levels. From the above perspective, it is interesting to study the effects of lifestyle on HDL-C levels and HDL function. This symposium lecture will review studies on the relationship between lifestyle and HDL function that have been reported to date. In addition, I will present our recent report on the effects of genetic polymorphisms of aldehyde dehydrogenase and drinking habits on HDL-C levels and HDL function. I would also like to discuss issues facing HDL function measurement research and the direction of HDL research.

Conflict of Interest Disclosure: Dr. Ogura has received lecture honoraria from Kowa and Amgen.

The hormetic dose-response mechanism in Nrf2 vitagene system activation and acquired Resilience: Designing new Pharmacotherapeutic Frontiers

Vittorio Calabrese[1], *Marialaura Ontario*[1], *Angela Trovato*[1], *Luigi Maiolino*[1]

1.University of Catania (Italy)

Human life develops and expands not only in time and space, but also in the retrograde permanent recollection and interweaving of memories. Therefore, individual human identity depends fully on a proper access to the autobiographical memory. Such access is hindered or lost under pathological conditions such as Alzheimer's disease (AD), including recently associated oxidant pathologies, such as Parkinson's disease (PD) or neurosensorial degeneration occurring in Menière's disease. Oxidative stress and altered antioxidant systems play a role in the aetiology of major neurodegenerative disorders, and altered expression of genes sensing oxidative stress, as well as decreased cellular stress response mechanisms could synergistically contribute to the course of these oxidant disorders. Mushrooms have been used in traditional medicine for thousands of years [1-2]. In our recent study we evaluated the effects of *Hericium erinaceus*, a nutritional mushroom with important antioxidant effects, in a rat model of AD. *Hericium erinaceus* administration reduced behavioral changes and hippocampal neuronal degeneration. Additionally, it reduced phosphorylated-Tau levels and aberrant APP overexpression and β-amyloid accumulation. Moreover, *Hericium erinaceus* decreased the prooxidative and pro-inflammatory hippocampal alterations induced by AD. In particular, it reduced the activation of the NLRP3 inflammasome components, usually activated by increased oxidative stress during the AD. Collectively, our results showed that *Hericium erinaceus* has protective effects on the behavioral alteration and histological modification associated with the AD acting by the modulation of the oxidative and inflammatory pathways, as well as regulating brain cellular stress. Herein, we discuss cellular mechanisms underlying AD neuroinflammatory pathogenesis that are contributory to Alzheimer's disease. We describe endogenous cellular defence mechanism modulation and neurohormesis as a potentially innovative approach to therapeutics for AD and other neurodegenerative conditions that are associated with mitochondrial dysfunction and neuroinflammation, including Meniere disease patients as a measurable model of

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

neurodegenerative neuro-cochleosensory system. Particularly, we consider the emerging role of Vitagenes as an important component of the neuroprotective network, as well as the importance of *Coriolus* and *Hericium* nutritional mushrooms in redox stress responsive mechanisms and neuroprotection [2]. In addition, we have explored the development of PD-related pathology in the context of an experimental model of Traumatic brain injury (TBI) and the potential ability of *Coriolus versicolor* and *Hericium erinaceus* to prevent neuro-degenerative processes. A growing number of studies have demonstrated that dietary interventions regulate mitochondrial ROS production, detoxification and oxidative damage repair. Many (but not all) of these nutritional interventions are related with extension of lifespan, or protection against diseases related with age, in mammals. Emerging nutraceuticals are today showing promise as modulators of mitochondrial redox metabolism capable of eliciting beneficial outcomes. Mushrooms, known for their strong antioxidant properties, have attracted interest due to their potential in neuroprotection, antioxidant, and anti-inflammatory effects, as well as in proteome and mitochondrial homeostasis restoration as a basic mechanism to withstand mitochondrial dysfunction-associated neuroinflammatory disorders [1-3].

Nutritional hormetins, functional foods and hormesis for healthy ageing and longevity

Suresh Rattan[1]

1. Aarhus University (Denmark)

A detailed understanding of the biological basis of ageing rules out the existence of any specific gerontogenes as the cause of ageing. Genes determine our ability to live and maintain health for a limited period, known as the essential lifespan (ELS), required by nature for the continuation of the species. We are surely able to live much longer than our species' ELS, but our natural survival abilities then need a helping hand for living longer, for maintaining health and for protecting ourselves from diseases in old age. A promising and holistic approach for achieving this is the phenomenon of mild stress-induced hormesis. Physical, nutritional and mental hormetins, which induce hormesis, lead to the stimulation and strengthening of the maintenance and repair systems in cells and tissues. Exercise, heat and irradiation are examples of physical hormetins, which activate heat shock-, DNA repair- and anti-oxidative-stress responses. Several non-nutritional chemical components in functional foods, including flavonoids and polyphenols present in spices, herbs and other sources, are examples of nutritional hormetins, which induce anti-oxidative and anti-inflammatory stress responses. Calorie restriction and intermittent fasting are also hormetins, which activate the autophagic and sirtuin-mediated stress responses. Intense brain activity and focussed attention comprise mental hormetins, which also induce various stress responses. A combination of different hormetins can therefore be the drugs for maintaining, improving and recovering health during ageing.

SY(T7)11-3
Novel mechanisms underlying bioactivities of phytochemicals *via* hormesis

Akira Murakami[1], *Shiho Kawaguchi*[1], *Nao Fujiwara*[1], *Akari Ishisaka*[1]

1. University of Hyogo (Japan)

Plants biosynthesize phytochemicals as the secondary metabolites for adaptation to environmental stressors, including intense sunlight and invading organisms. Some of these compounds are biologically dormant and stored in the form of inactive glycosides, and then when insect or microbe exposure occurs, those defensive phytochemicals become activated by β-glucosidases, derived from plants or microbes, to produce bioactive metabolites. These phytochemicals exhibit biological effects to protect against environmental stresses *via* specific mechanisms of action that function to counteract them. Thus, a reasonable fundamental question is why and how phytochemicals have beneficial effects on humans. In fact, the mechanisms of action underlying beneficial functions of phytochemicals remain to be fully elucidated. Most of, if not all, phytochemicals are recognized as xenobiotics in animals are known to induce adaptive responses. Essential related mechanisms include expressions of antioxidative and xenobiotic-metabolizing enzymes, and heat shock proteins (HSPs). Thus, hormesis has been recognized to be an adaptive mechanism by which mild stressors can potentiate the protective capacity of the host, while those at excessive levels are harmful or lethal. We have previously reported that zerumbone, a sesquiterpene in *Zingiber zerumbet* Smith, exhibits anti-inflammatory activity through its non-specific binding to biological proteins by targeting their cysteine residues (1,2). This phytochemical was found to induce protein stress and thereby activated heat shock factor1, which is the key transcription factor for up-regulating anti-inflammatory proteins, including HSPs. On the other hand, the hormesis-related early events in lipolysis induced by polyphenols have recently been identified (3,4). Both curcumin and (-)-epigallocatechin-3-gallate were found to markedly decrease the amounts of triglycerides in differentiated Huh7 mouse hepatoma cells. Interestingly, oxidative and protein stresses

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

induced by those polyphenols were also demonstrated to significantly contribute to their lipolysis effects. Moreover, the key response to lipolysis was identified as a marked decrease in intracellular ATP levels. Meanwhile, pretreatments of RGM1 gastric mucosal epithelial cells with allyl isothiocyanate (AITC), the pungent taste of 'Wasabi', at lower concentrations resulted in a marked increase in resistance to cytotoxicity induced by AITC at a higher one. This phenomenon may resemble the acquisition of tolerance toward spicy foods by daily consumption of such foods, which can be described as 'chemical training' (5). In addition, our preliminary experiments have shown that quercetin, the major flavonoid in onions, and its metabolites were detected for the first time in the breast milk of quercetin-fed mother mice. Interestingly, they were also found in the blood and urine of newborn mice, suggesting that breast milk-derived quercetin may exert 'chemical training' effects in newborn mice. Taken together, phytochemicals may partially exhibit their bioactivities through hormesis-related mechanisms, and this hypothesis may be supported by the fact that they often show side-effects when given at high doses. SY(T7)11-4
Hormetic response to B-type procyanidin Ingestion may involve stress-related neuromodulation via the gut–brain axis: preclinical and clinical observations.

Naomi Osakabe[1]

1. Shibaura Institute of Technology (Japan)

B-type procyanidins, a series of catechin oligomers, are among the most ingested polyphenols in the human diet. Results of a recent large-scale intervention study have suggested that intake of B-type procyanidins reduces cardiovascular disease risk. Another novel focus has been on the effects of B-type procyanidins on central nervous system (CNS) function. Although long-term B-type procyanidin ingestion is linked to health benefits, a single oral intake has been reported to cause physiological alterations in circulation, metabolism, and the CNS. Comprehensive analyses of previous reports indicate an optimal mid-range dose for the hemodynamic effects of B-type procyanidins, with null responses at lower or higher doses, suggesting hormesis. Findings also indicate that other physiological responses to oral administration of B-type procyanidin follow a hormetic pattern. Indeed, polyphenols, including B-type procyanidins, elicit hormetic responses in vitro, but animal and clinical studies are limited. Hormesis of hemodynamic and metabolic responses to B-type procyanidins was recently confirmed in animal studies, however, and our work has linked these effects to the CNS. Here, we evaluate the hormetic response elicited by B-type procyanidins, recontextualizing the results of intervention trials. In addition, we discuss the possibility that this hormetic response to B-type procyanidins arises via CNS neurotransmitter receptors. We will verify the direction of future research for B-type procyanidins in this lecture.

SY(T8)1-1
Urban allotment gardening and its impact on human health and wellbeing

Masashi Soga[1]

1. The University of Tokyo (Japan)

The promotion of healthy lifestyles in urban areas is a major challenge for the domain of public health. Urban allotment gardens can offer immense potential as an inexpensive intervention that can help address numerous health-related difficulties confronting metropolitan areas. However, quantitative evidence remains scarce. This paper will present the results of the two studies conducted recently by the author's research group. The first study involved the administration of a questionnaire survey to 332 people in Tokyo to quantify the effects of participation in allotment gardening on their physical, psychological, and social health. The results of the questionnaire survey were utilized to compare five health outcomes self-reported by allotment gardeners (respondents who used allotments) and non-gardener controls (participants who did not use allotments). These five consequences were perceived general health, subjective health complaints, body mass index (BMI), mental health, and social cohesion. Accounting for socio-demographic and lifestyle variables, the regression models revealed that allotment gardeners reported significantly superior perceived general health, lesser subjective health complaints, better mental health, and more social cohesion than non-gardeners. No significant difference was found in the average BMI of gardeners and non-gardeners. These results suggest that regular gardening in urban allotment sites improves the physical, psychological, and social health of city residents. The second study accomplished by the author's group attempted to confirm the generality of the findings of the first study. To this end, it executed a systematic review and meta-analysis of research assessing the effects of gardening, including urban allotment cultivation, on human health and wellbeing. An extensive literature search was performed to accumulate empirical studies comparing health outcomes in a control cohort (non-gardeners or pre-gardening experience reporting) and a treatment group (gardeners or post-gardening experience reporting). The mean difference of health outcomes between the two groups was calculated for each study, and the weighted

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

effect size was then determined for both investigations across samples and for the sets of subgroup studies. The systematic review identified 22 case studies (76 comparisons between the control and treatment groups) relevant for the meta-analysis. The case studies demonstrated a wide range of health outcomes including the alleviation of depression, reduction of BMI, and the enhancement of life satisfaction, quality of life, and social cohesion. Meta-analytic estimates demonstrated significant positive effects of gardening on the health outcomes for the full participant group as well as the sets of subgroup studies but the effect sizes differed for eight subgroups. These results robustly evidence the beneficial effects of gardening on health and support the findings of the first study. Chronic and non-communicable diseases are becoming more prevalent at an unprecedented pace worldwide. The results presented here are of great consequence for healthcare policy in such a context. They suggest that participation in allotment gardening in urban areas can potentially ensure improved and healthy lifestyles and can help prevent or alleviate health-related risk factors. It is thus recommended that policy-makers and health practitioners should recognize allotment gardening as an important health promotion tool and should encourage people to participate in it.

The Japanese preference for collaborations between citizen's farms and food-support organizations

Kiyo Kurisu[1]

1. The University of Tokyo (Japan)

The proportion of low-income households has increased in recent years, in tandem with a rise in social disparities. The relative poverty rate in Japan was worse than the OECD average. Food banks collecting items that are still edible and offering them to low-income households can help resolve the problems of both food-waste and poverty. However, it has been indicated that the supply of vegetables remains insufficient because dry foods are primarily offered to households. This study contemplated a future system of offering vegetables from citizens' farms to low-income households through food-support organizations such as food banks and children's cafeterias.

Three aspects were investigated to evaluate the possibility of the system: 1) the food-support organization's intention to receive vegetables from citizen's farms, 2) the preferences of people to use the land as citizen's farms in collaboration with food-support organizations, and 3) intentions of using citizen's farms in collaboration with food-support organizations.

The first point was addressed via a questionnaire survey conducted in December 2019 for food banks and children's cafeterias throughout Japan. Responses were received from 38 food-bank groups and 94 children's cafeterias. Nearly 90% of children's cafeterias responded positively to collaborations with citizens' farms; however, food banks without any experience in handling vegetables were reluctant to cooperate. The issue of past experience exerted a significant effect on the intention and possibility of food banks receiving vegetables from citizens' farms. Concerns about when the vegetables would be served and the quality and types of vegetables had a significant influence on the perceived ability of food banks to receive vegetables.

Conjoint analysis was performed using four types of land use to investigate preferences apropos different land-use patterns: a) citizens' farms without collaborations with food-support organizations, b) citizens' farms with such collaborations, c) parks, and d) open spaces for disaster prevention. An online survey was conducted throughout Japan in August 2021, and gained 11,520 respondents. The results revealed the highest preference for open spaces for disaster prevention. People who knew about citizens' farms, who had experienced vegetable gardening, and who had a higher emotional affinity toward nature showed a stronger preference for citizens' farms with collaborations with food-support organizations.

Evaluation of the actual intention to use farms was probed through an online questionnaire survey with respondents who had shown positive preferences for citizens' farms with or without collaborations with food-support organizations in the previous survey. Respondents living in four prefectures (Tokyo, Saitama, Kanagawa, and Chiba) in the Kanto area were targeted (n = 4,720) and the survey was conducted in December 2021. The results elucidated that around 30% of the respondents would like to use citizens' farms with or without collaborations with food-support organizations. However, only one-third of this 30% were willing to pay a usage fee. The fee of 2,510 JPY/month (21.8 US$/month) was asserted as acceptable and this value remained the same for citizens' farms with or without collaborations with food-support organizations.

Keywords: Citizen's preference, urban allotment, conjoint analysis, food-support organization.

Linkages between dietary diversity of farmers and agriculture in West Java, Indonesia

Kazuaki Tsuchiya[1]*, Takuya Furukawa*[2]*, Shinya Ikeda*[3]*, Makiko Sekiyama*[1]*, Koji Harashina*[4]*, Susanti Withaningsih*[5]*, Parikesit Parikesit*[5]

1.National Institute for Environmental Studies (Japan), 2. Forestry and Forest Products Research Institute (Japan), 3. Ibaraki University (Japan), 4. Iwate University (Japan), 5. Padjadjaran University (Indonesia)

Dietary diversity is a key concept for balanced nutritional intake and this theory has attracted attention as a complementary indicator vis-à-vis individual energy and nutrient (protein, vitamins, etc.) intake. Dietary diversity can be measured more easily than individual nutrient intake using formatted questionnaires. This is expected to contribute to the development of nutrition improvement programs, especially in

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

developing countries. It is important to understand the socio-economic drivers that increase dietary diversity to utilize dietary diversity in nutrition improvement programs. However, the number of existing studies is adequately substantive for the comprehension of distinctions in diverse food and agriculture systems around the world. In particular, knowledge is lacking apropos the drivers of dietary diversity in areas where commercial agriculture has developed. Previous studies have indicated two main factors influencing dietary diversity: production variety and market access. Production variety refers to the multiplicity of crops produced by a household or individual in a given period. Several studies have demonstrated that higher production variety is associated with higher dietary diversity, but numerous other studies have not confirmed this relationship. The connection between production and dietary diversity may be explained by the significance of subsistence agriculture and the effects of production diversity on the economic stability of households. Market access is often described by distance to food markets as a proxy variable, but the relationship between dietary diversity and the varied non-farming roles of farm households has not been fully explored. Both production variety and market access could strongly influence dietary diversity in areas dominated by commercial agriculture. A dietary and agricultural survey was conducted in 2019 in a village in Bandung, West Java, in Indonesia. Environmental and health concerns have resulted in the introduction of coffee agroforestry, a new type of commercial agriculture in this region that offers an alternative livelihood in comparison to traditional commercial agriculture of intensive vegetable production. The survey results evidenced associations between dietary diversity, production variety, and market access observed in the study area. The nutritional implications of these relationships in a commercial agricultural area are also discussed in the study. This presentation will also deliberate on the potential development of measurement methods of these key indicators of links between food and agriculture.

Keywords: dietary diversity, production variety, market access, agroforestry.

Nutrient deficiency in children in the deforested front of Cambodia in relation to different food sources

Takuya Furukawa[1], Saiko Shikanai[2], Makiko Sekiyama[3], Makoto Ehara[1], Sivleng Voeun[4], Koung ry Ly[4], Naven Hon[5], Jackson Frechette[5], Norint Net[6]

1. Forestry and Forest Products Research Institute (Japan), 2. Aomori University of Health and Welfare (Japan), 3. National Institute for Environmental Studies (Japan), 4. ANFRC (Cambodia), 5. CI Cambodia (Cambodia), 6. Cambodia MoE (Cambodia)

Deforestation is a driver of biodiversity loss and climate change. Macroscopic analyses have suggested that it could also cause vital consequences for human nutrition, including the nourishment of children. A study was initiated in Cambodia by the author's group. The forests in this region are disappearing at the fastest rate in Southeast Asia. The study examined the nutritional status of the children living in forested areas and probed the roles discharged by discrete food sources: edible items that were purchased, self-produced, wild, and shared by neighbors. The weights and heights of 161 children aged 5–10 years and residing within and around the Prey Lang Wildlife Sanctuary in Stung Treng Province of Cambodia were measured in February 2020. Their food intake (24-hour recall) and the source of each food item were also surveyed. Stunting (HAZ ≦ -2), underweight (WAZ ≦ -2), and acute malnutrition (BMI-Z ≦ -2) were observed in one-fourth, one-fourth, and one-tenth of the children, respectively. Intake was insufficient for many nutrients, except for sodium and vitamin C. Serious deficiencies were observed for zinc, copper, potassium, calcium, vitamin A, and vitamin B1 (thiamin). More than half of the children did not even reach 50 % of the Recommended Dietary Allowance for these nutrients (RDA). The sufficiency of nutrients ingested by each child (NT) was also assessed by counting the number of nutrients (maximum 14) for which the RDA of the corresponding age and sex was satisfied. The observed minimum, maximum, and mean NT of the children were 0, 13, and 3.66, respectively. When the purchased food was removed from the calculation, the mean NT dropped to 0.56, and most children could not meet the RDA for all nutrients, except for vitamin C, which could be acquired from locally grown fruits. The impact of removing self-produced food was not as substantial as the elimination of purchased food, but there was also a moderate drop in mean NT = 2.62 and RDA sufficiency in energy, protein, dietary fiber, phosphorus, iron, and vitamin C. There was little change in mean NT and the overall pattern of nutrient sufficiency (3.53 and 3.43, respectively) when wild food (those from forest, fallow, stream, etc.) and shared provisions were eliminated. The preliminary results evinced that purchased food was the most important food source and that it supplied numerous nutrients to the children, followed by self-produced food. The contribution of wild and shared food items was very small in terms of satisfying RDA levels. However, the study results also implied that food supplied from these sources was insufficient to meet the nutrient requirements of many children for most nutrients, except for sodium and vitamin C. Better access to food markets and enhanced provision of nutritious and diverse foods from the local agricultural system would be crucial aspects of consideration in planning livelihood support programs in the region. Attention must also be paid to the potential structural shortcomings of the local food system in which some vitamins and minerals (especially zinc, copper, and potassium) and vitamins appear difficult to access.

SY(T8)2-1
Small-scale fisheries and aquaculture that contribute to the local needs on human nutrition in developing countries

Nobuyuki Yagi[1]

1. The University of Tokyo (Japan)

Fish and fishery products play a vital role for food and nutrition security by providing food and income. Fish is an 'irreplaceable' animal-source food (ASF) in many Asian and African countries where large numbers of people are undernourished and poor. Fish and other aquatic animals are rich sources of a wide range of micronutrients, essential fatty acids and animal protein that are crucial for human brain development and cognition. Fish is the most commonly and frequently eaten, cheapest ASF in many low-income food deficit countries where the diet is mainly dominated by starchy staples and plant-source foods. Adding small amounts of fish to the plant-based diet can significantly improve diet quality.

At the same time, fish has always been treated as a commodity. It generates monetary income for family fisher-folks, as well as foreign money for the developing countries. According to the data by Food and Agriculture Organization of the United Nations (FAO), approximately 37.6% of fish are exported. This percentage is higher if compared with other agricultural products. As for rice, only 9.1% are exported. This suggests that rice is produced mostly for the purpose of domestic consumptions, whereas fish are farmed or caught targeting at export markets.

Pros and cons for the export operations need to be assessed carefully. Demand for fish has increased in recent years, both in developed and developing countries with the growing global population. New rich sectors in cities increase their consumption of animal protein. On the other hand, in some rural areas few fishers and fish farmers can consume the commodity they catch or grow; instead, they sell the majority of their catch to earn money to meet other necessities. In the same local areas, commercial fish buyers have market powers and lend money to artisanal fishers. In return, the buyers obtain fish at lower price from the money borrowers. A shift of fisheries from subsistence to export oriented ones could result in inequity and malnutrition. Maintaining equitable society as well as well healthy ecosystems that allow sustainable supplies and consumption of fish and fisheries products are crucial for the health and wellbeing of people.

JICA's support for the fisheries and aquaculture sector and its contributions to food and nutrition security in developing countries

Shunji Sugiyama[1]

1.Japan International Cooperation Agency (Japan)

JICA has been working with developing countries for the development of fisheries and aquaculture sector in a various context. Although our activities are not always designed to directly address the nutrition issues, it is observed that there is a certain effect on food and nutrition security since our strength is to reach out to the rural areas where economically vulnerable people reside and malnutrition is prevalent. The contributions of JICA's efforts in fisheries and aquaculture development in addressing nutrition issues can be found in the following aspects. 1) Ensuring sustainable supply of aquatic foods: fisheries resources are often under threat of over-exploitation and aquatic food supply could be seriously diminished if due efforts are not made for resource management, 2) Increasing localized production of aquatic food; fish farming has the potential to feed the people in need in rural areas, 3) Increasing complementarity with agricultural production; in drought prone areas, subsistence production of famed fish play a role in supplying nutritious food in food deficit dry periods, 4) Reducing vulnerability to acute food insecurity; when local communities are devastated by natural disasters such as drought or cyclones, locally managed water areas can serve as the food bank for the people. In this connection, some reports from field activities in Eritrea, Ethiopia, Mozambique, Benin, Guinea, and Vanuatu are introduced. Our challenge remains, however, with how to ensure nutrition sensitive approach in such development efforts. The above-mentioned activities are aimed at other objectives such as resource management and promotion of aquaculture, and hence there is a limitation in increasing the positive effect on nutrition improvement of target population. New opportunities exist with the Initiative for Food and Nutrition in Africa (IFNA), which is a joint initiative led by African Union Development Agency New Partnership for Africa's Development and JCA. The IFNA sees the importance of non-staple food production such as fish and it is envisaged that nutrition sensitive approach in JICA's projects will be strengthened in the framework of IFNA.

Transforming food systems with aquatic foods for healthier people and planet

Shakuntala Haraksingh Thilsted[1]

1.WorldFish (Malaysia)

In just the last few years, there have been a number of global initiatives in which aquatic food systems have been integrated. These include the UN Food Systems Summit 2021, termed the people's summit, and COP 26. The Scientific Group for the UN Food Systems Summit 2021 provided seven priorities for transforming food systems to end hunger and protect our planet; one being: “sustain aquatic foods”. At COP 26, following on the UN Food Systems Summit 2021, calls for transformation of food, land and water systems for nourishing people as well as our planet were made. Aquatic food systems were recognized and acknowledged for their importance in enabling climate mitigation measures. Aquatic foods, in particular, seaweed and low trophic animals featured prominently in discussions on nature-based solutions for addressing the challenges of climate crises. At the same time, aquatic foods; the diverse and very many animals, plants and microorganisms found in marine and inland waters are considered superfoods; bountiful in multiple nutrients; including minerals, vitamins, and essential fatty acids. These nutrients are crucial for cognition, development and growth in young children as well as nutrition and health in adults. As aquatic foods are consumed by over three billion people and provide livelihood opportunities for over 800 million people, globally, it is imperative that we advocate for food and nutrition policies, investments and interventions that include aquatic foods for nourishing nations.

Contribution of fish to the diets of low-income households

Anna Lartey[1]*, Aaron Christian*[1]*, Grace Marquis*[2]*, Esi Colecraft*[1]

1. University of Ghana (Ghana), 2. McGill University (Canada)

The State of Food Security and Nutrition in the World 2021 report estimated that 3 billion people were not able to afford a healthy diet. Poor diet remains a major cause of disease and severely impacts economic development. Animal source food (ASF) accounts for 36% of the total cost of healthy diets. In many Sub-Saharan African countries, fish represents an affordable source of animal protein that is culturally acceptable. Under the auspices of the *Enhancing Nutrition through Animal Source Food Management* (*ENAM*) project, we undertook a study to improve Ghanaian children's ASF intake. We assessed the contribution of fish to household diets in three agro-ecological regions. Using food frequency data, we analyzed the frequency of consumption of different types of ASF by household food insecurity status. Consumption of poultry, eggs, dairy, and red meat in the past week was significantly more frequent among feed secure/mildly food insecure households compared moderate/severe food insecure households However, there was no difference in the frequency of fish consumption by household insecurity status. Almost all households (>98%) reported fish consumption in the past week. In all, 15 different species of fish were identified from household diets. We conclude that fish is the most accessible ASF for low-income households in this study population. With its high accessibility, there is need to assure that it is reaching all vulnerable members of households in adequate amounts.

Fishing for Complements: How Aquaculture Helps Improve Diet Quality among the Poor

Patrick Webb[1]

1. Tufts University (USA)

Interest in 'blue food' systems has grown in recent years. A focus on aquatic foods (fish, shellfish, algae, etc.) is underpinned by recognition that diets around the world would be enhanced by inclusion of water-based production, and that blue food systems can be nature-positive complements to terrestrial farming. This paper focuses on the contributions to, and benefits from, aquatic foods to livelihoods and diets of poor households in resource constrained settings.

Dimensions of the Food Environment to consider when promoting fish and other aquatic foods in low- and middle-income countries

Gina Kennedy1, Lora Iannotti[2], Molly Ahern[3], Shakuntala Haraksingh Thilsted[4]

1. Global Alliance for Improved Nutrition (USA), 2. Washington University in Saint Louis (USA), 3. Food and Agriculture Organization of the United Nations (Italy), 4. WorldFish (Malaysia)

Introduction: Fish and other aquatic foods are nutritious and healthy food choices that can also be sustainable. The nutrient density of fish and aquatic foods (especially seaweed, small fish and bivalves), surpass that of staple grains and tubers, fruits and vegetables. Small fish species, in particular, are rich in calcium, iron, zinc, vitamin A and vitamin B12. Several dimensions of the food environment, or the space where consumers procure food, influence consumer choice and are important to consider when promoting fish and other aquatic foods.

Methods: We use a food environment lens to review availability, affordability, desirability, convenience and sustainability of aquatic foods and consider opportunities and barriers to promote fish and other aquatic foods for sustainable, healthy diets.

Results and Discussion: *Availability*: Over 3,000 species of fish, crustaceans, molluscs, aquatic plants and aquatic animals are used for food. The global per capita consumption of fish has been steadily increasing over the past three decades, in large part due to increasing contribution of aquaculture. However, there is a concerning downward trend in consumption predicted in sub-Saharan Africa. Reducing loss and waste, estimated at approximately 35% is urgently needed. There are positive examples of improvements gained in LMICs through simple and low-cost investments in technologies such as raised rack drying, reducing contact with insects and improvements in sanitation and hygiene practices at retail level. *Affordability*: To respond to malnutrition in all its forms, affordability must include nutrient density and not only price per quantity. Recent studies on the affordability of fish and other aquatic foods compared to other major food groups, are mixed. In grouping fish and other aquatic foods from marine waters all together, the price per unit quantity relative to other foods, especially cereals and oils is high. However, when foods are ranked by cost/nutrient density, the affordability of fresh fish was ranked next to that of eggs and milk in Asia. Additionally, the price of small fish species is lower than that of large species. *Desirability and Convenience*: Food safety is a concern among consumers and fish are very susceptible to spoilage and contamination. Innovations that make nutrient-dense fish and aquatic products ready to use and safe are important to consumers. In the USAID NOURISH project in Cambodia; small fish species were processed into a ready-to-use fish powder that was widely accepted and created employment for women-owned businesses. *Sustainability*: The USAID Fish Innovation Lab project *Samaki Salama* in coastal Kenya tested an integrated intervention in small fisher households through sustainable fisheries production to increase availability and access and social marketing to encourage families to give fish to young children.

Conclusions: A vast array of aquatic foods can ensure nutrition security and offer consumers healthy, sustainable dietary choices. Adopting low-cost, proven strategies to reduce loss and improve food safety, and employing innovations in sustainable fisheries, food processing and social marketing can help to increase the nutritional benefits of fish and other aquatic foods towards the transformation of food systems to nourish people.

Household engagement with aquaculture-horticulture is associated with better diet quality

Rumana Akter[1], Yagi Nobuyuki[2], Sugino Hiroaki[2], Shakuntala Haraksingh Thilsted[3], Shibani Ghosh[4], Sabi Gurung[4], Katherine Heneveld[4], Robin Shrestha[4], Patrick Webb[4]

1. Save the Children (Bangladesh), 2. The University of Tokyo (Japan), 3. WorldFish (Malaysia), 4. Tufts University (USA)

Background: Multiple micronutrient deficiencies are highly prevalent among in Bangladesh. Common micronutrient deficiencies reported in Bangladesh are vitamin A, iron, calcium, folic acid, zinc, vitamin B12, and iodine.

Objectives

The study assessed diet quality of households by their types of engagement with homestead aquaculture and/or horticulture production or none. Socio-demographic determinants of diet quality were also studied.

Methods: Data for this paper were sourced from the "Bangladesh Aquaculture-Horticulture for Nutrition Research" study conducted by the Feed the Future Innovation Lab for Nutrition, collected between January and April 2016. Diet quality was assessed using a nutrient adequacy ratio (NAR), based on the preceding 7 days' dietary recall of the household. Adult male equivalent units (AMEs) were calculated for age- and sex-specific intra-household distribution of household intakes. Mean adequacy ratios (MAR) were computed as an overall measure of diet quality, using NAR. In addition to energy, the study assessed dietary intake of total eleven micronutrients: iron, calcium, zinc, vitamin A, thiamine, riboflavin, niacin, vitamin B6, folate, vitamin B12, and vitamin C.

Results: Better diet quality (mean±SD) was associated with households engaged in both homestead aquaculture and horticulture (0.43±0.23; p <0.001) compared to only one type of agriculture (0.38±0.20) or none (0.36 ±0.20). Tukey's post-hoc test confirmed significant differences in diet quality between both and either engagement (0.05±0.01, p < 0.001), both and no engagement (0.07±0.01, p < 0.001), and either and no engagement households (0.02±0.01, p <0.001). Recommended

dietary micronutrients and energy intake were significantly and positively associated ($p < 0.01$) with households engaged in both types compared to either or no type of engagement, except for vitamin B6 and vitamin C ($p < 0.05$). Quantity of fish and seafoods, vegetables, fruits, legumes/nuts/seeds, and staple food intakes were significantly higher (278.8 g/person/d; 88.9 g/person/d; 69.0 g/person/d; 14.7 g/person/d; and 395.4 g/person/d respectively; $p < 0.001$) in households engaged in both aquaculture and horticulture compared to either or none. Sources of fish and seafood and vegetables consumed by the households in both/either engagement were mostly from households' own production. Generalized estimating equations showed that diet quality was influenced by the higher educational level and occupation of adult household members, higher daily per capita food expenditure, sex, family size and region.

Conclusion: Household engagement in both homestead aquaculture and horticulture have the potential to improve diet quality of households.

Keywords: diet quality, aquaculture, horticulture, dietary micronutrients

SY(T8)3-1
1-Deoxysphingolipids and their analogs in foods: the occurrence and potential impact on human health

Jingjing Duan[1], Zhenying Hu[1], Junliang Wan[1]

1.Nanchang University (China)

Typical sphingolipids are comprised of sphingoid bases, such as sphinganine and sphingosine, these are produced via the condensation of L-serine with a fatty acyl-CoA by serine palmitoyltransferase. Many organisms, including mammals, produce “atypical” sphingolipids that are synthesized *de novo* with alanine as 1-deoxysphingoid bases, that can be synthesized as 1-deoxyceramides by *N*-acylation. The biological functions of 1-deoxysphingolipids are still not well understood but are noticeable in neuropathies, diabetes, non-alcoholic steatohepatitis, and other metabolic diseases[1]. Considerable variability in the amounts and molecular subspecies of atypical sphingoid bases and their *N*-acyl metabolites have been found in meats and seafoods, espically in squid and octopus[2]. More than this, we recently discovered a group of “1-deoxyceramide mimic” metabolites of a 1-deoxysphingaine analog: fusarium toxin 2-amino-14,16-dimethyloctadecan-3-ol (2-AOD-3-ol) from *Fusarium avenaceum*-infected crops and fruits. 2-AOD-3-ol was predominantly present as a C16:1 fatty acid-assembled form rather than as the free amine. Although 2-AOD-3-ol and its fatty acyl derivatives were barely detected in fresh samples, the contents of these fusarium toxins accumulated with the extension of food storage up to approximately 32-50 mg/kg dry weight in naturally stored rice, grapes, apples, and oranges[3]. The amounts of the 1-deoxysphingolipids are lower than typical sphingolipids in foods analyzed thus far, but their relative efficacy might be comparable or even greater because 1-deoxysphingoid bases can be readily absorbed but not can be phosphorylated and degraded in intestinal cells[4]. A broader assessment of the dietary sphingolipids is needed because food materials might contain sufficient amounts of atypical sphingolipids that could have beneficial or possibly deleterious effects on human health.

Structure and function of fucosylated chondroitin sulfate from sea cucumber

Shiguo Chen1

1. Zhejiang University (China)

Sea cucumber polysaccharide is a highly sulfated marine polysaccharide, and its titer is much higher than that of plant polysaccharide. However, sea cucumber polysaccharide has low mass spectrum and nuclear magnetic response, difficult structure identification, and the sulfuric acid structure is easy to be destroyed during degradation, which leads to the unclear structure-activity mechanism of sea cucumber polysaccharide and limits its deep development. Therefore, it is urgent to analyze the structure of sea cucumber polysaccharide and develop accurate structure-activity products.

In our study, online hydrophilic interaction chromatography–Fourier transform mass spectrometry (FTMS) was applied to analyze the fucosylated chondroitin sulfates (FCS) oligosaccharides. These depolymerized FCS fragments were quantified and compared using the glycomics software package, GlycReSoft. The quantified fragments mainly had trisaccharide-repeating compositions and showed significant differences in fucosylation (including its sulfation) among different species of sea cucumbers. Detailed analysis of FTMS ion peaks and top-down nuclear magnetic resonance spectroscopy of native FCS polysaccharides verified the accuracy of this method. This bottom-up approach provides rich detailed structural analysis and provides quantitative information with high accuracy and reproducibility and should be suitable for the quality control in FCSs as well as their oligosaccharides. We then prepared highly purified FCS trisaccharide repeating units from hexasaccharide (6-mer) to octadecasaccharide (18-mer), including those with 2,4-disulfated and 3,4-disulfated Fuc branches. In vitro anticoagulant activities and surface plasmon resonance binding tests indicated those of larger molecular sizes and 2,4-disulfated Fuc branches showed stronger anticoagulant effects with respect to anti-FXase activity, as well as stronger binding to FIXa among various clotting proteins. All FCS 9–18 oligomers also resulted in no bleeding, hypotension, or platelet aggregation risk during blood circulation. Thus, FCS 9–18 oligomers with 2,4-disulfated or 3,4-disulfated Fuc branches exhibit potent and safe antithrombotic activity needed for clinical applications.

Dietary fish protein improves skeletal muscle weight

Taro Kishida[1,10], Kenji Uchida[2,10], Mina Fujitani[1,10], Takafumi Mizushige[3,10], Fuminori Kawabata[4,10], Kohsuke Hayamizu[5,10], Shinji Okada[6,10], Naoko Goto-Inoue[7,10], Kohei Watanabe[8,10], Hiroyasu Mori[9,10]

1. Ehime University (Japan), 2. Nippon Suisan Kaisha Ltd. (Japan), 3. Utsunomiya University (Japan), 4. Hirosaki University (Japan), 5. Yokohama University of Pharmacy (Japan), 6. The University of Tokyo (Japan), 7. Nihon University (Japan), 8. Chukyo University (Japan), 9. Tokushima University (Japan), 10. APP research society (Japan)

Epidemiological studies have long reported that fish consumption contributes to health, however, there is little knowledge about the function of fish protein. We have focused on Alaska pollack protein (APP), which is widely used such as Kamaboko and fish sausage, and have searched for health-promoting function. In these studies, we found that dietary APP increases skeletal muscle mass in rats compared to a casein diet feeding, even though there was no exercise load. Although we have first found the increasing effect of dietary APP on skeletal muscle in high-fat diet feeding for 4 to 8 weeks, in subsequent studies, we found that dietary APP increases skeletal muscle mass both male and female, even in a very short period of 2 to 7 days, regardless of whether in a high-fat or a normal diet feeding. We also found that dietary APP increased rat skeletal muscle weight in the recovery period after immobilization. In these experiments, the administration of APP is performed by feeding AIN-93 diets in which all the protein sources are substituted casein with APP. As a result of the dose response study, the skeletal muscle weights in the rats fed diets in which more than one-third protein source were substituted APP for casein were significantly increased. The amino acids mixture powder similar to the amino acids composition of APP did not affect skeletal muscle mass. The characteristics of the amino acid composition might not contribute to the mechanism. Dietary APP increased the cross-sectional area of the gastrocnemius skeletal muscle and collagen-rich connective tissue. In order to investigate the mechanism of action, we measured the gene expression of factors involved in skeletal muscle formation and muscle protein synthesis and degradation. Dietary APP decreased gene expression of muscle-specific ubiquitin ligase (atrogen-1, MuRF1) and myostatin, suggesting that the synthesis of muscle protein was promoted and the decomposition was suppressed by dietary APP. A comparative and chronological analysis using cDNA microarrays revealed that dietary APP leads to a similar series of changes in gene expression to those for inhibition of muscle protein degradation and subsequent muscle regeneration after exercise-induced muscle injury. Furthermore, comprehensive proteomic analyses were conducted and the pathway analyses indicated that the activity of the growth factor signaling pathway was significantly impacted by dietary APP. Moreover, APP could promote protein synthesis by activating the protein kinase B/mechanistic target of the rapamycin signaling pathway, which is also promoted by exercise. Several clinical trials have already been conducted to examine the effect of increasing muscle mass by ingesting APP. In a study investigating the effect of APP ingestion on training-induced neural and muscular adaptations in older adults, significant increases in lower extremity muscle mass and muscle strength from 0 to 8 weeks were demonstrated only for APP. And in a study investigating the effect of APP ingestion on no training-induced neural and muscular adaptations in older adult women, daily APP intake can increase skeletal muscle mass and lower-extremity muscle strength in healthy older women from 12-24 weeks more than whey protein intake.

Keywords: Fish protein, Alaska pollack, skeletal muscle.

Nutraceutical potential of siphonaxanthin, a green algal carotenoid

Tatsuya Sugawara[1], Yuki Manabe[1]

1. Kyoto University (Japan)

Marine algae are a potential renewable resource in the marine environment and an excellent source of nutritional and bioactive compounds such as carotenoids, dietary fiber, amino acids, essential fatty acids, vitamins, and minerals, which contribute to several beneficial effects in human health. Algal carotenoids are of particular interest because they are structurally and functionally different from those found in land plants. We have focused on the utilization of functional food components in unutilized biological resources and food processing residues, and have found that siphonaxanthin has various biological activities such as anti-angiogenic, anti-obesity, and anti-inflammatory effects more potent than other carotenoids. Siphonaxanthin is a specific keto-carotenoid of siphonaceous green algae, which helps in absorbing available green and blue green light under water. In edible green algae such as *Codium fragile*, *Caulerpa lentillifera*, and *Umbraulva japonica*, siphonaxanthin content is approximately 0.03%–0.1% of the dry weight.

We have previously demonstrated that siphonaxanthin potently suppresses the viability of human leukemia HL-60 cells via induction of apoptosis (*Biochim. Biophys. Acta* 1810: 497-503, 2011) and possesses significant anti-angiogenic activity via down-regulation of signal transduction by fibroblast growth

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

factor receptor-1 in vascular endothelial cells (*Phytomed*. 17: 1140-1144, 2010; *Mol. Cell. Biochem*. 380: 1-9, 2013). On the other hand, dietary siphonaxanthin shows the anti-obesity and protective effects against lipotoxicity (*J. Nutr*. 145: 490-498, 2015; *Lipids* 53: 41-52, 2018; *Nutr*. *Res.*77: 29-42, 2020). Siphonaxanthin also exhibits the unique anti-inflammatory properties (*J. Oleo Sci.* 63: 291-294, 2014; *J.Nat . Med*. 74: 127-134, 2020; *Nutrients* 13: 3699, 2021). Interestingly, siphonaxanthin supplementation can prevent skin photoaging such as wrinkling and skin barrier disruption in UVA-irradiated mice. In this case, detectable amounts of siphonaxanthin and its metabolites were accumulated in the dermis and epidermis. We also have evaluated the mechanism of intestinal absorption and metabolic fate of dietary siphonaxanthin (*Lipids*.54: 707-714, 2019; *Mar*. *Drugs* 18: 291, 2020.).

Our results indicate that siphonaxanthin has strong potential as a nutraceutical candidate among marine carotenoids. Our novel findings open up new avenues for future research on the advanced utilization of siphonaxanthin as a bioactive substance.

Metabolomics as a generic tool to help us understand food quality

Robert David Hall[1]

1. Wageningen University & Research (Netherlands)

Consumers continue to demand to be able to buy food materials with enhanced product quality and which are obtained from more sustainable production systems. Most crops are effectively used as chemical factories with the food crops producing our nutrients and vitamins. But in addition to these basic nutritional requirements, the role of molecules associated with food flavour and fragrance as well as appearance (e.g. colour) should never be underestimated. These are usually the drivers of consumer choice and re-purchasing behaviour. Plant-based foods comprise ca 80% of all food consumed globally. Plants are incredibly successful biochemists with each species producing tens of thousands of metabolites, the synthesis of which is strongly controlled both spatially and temporally. Furthermore, the chemical components in our food are dependent on the influence of both genetic and environmental factors. A final determinant is of course how food materials are processed before reaching the supermarket shelf. Plant metabolomics approaches have been developed and widely applied over the last 15 – 20 years in untargeted strategies to allow us to mine and chart the plant metabolome and determine how both internal and external factors influence the final chemical profile. These technologies now help us gain deeper insights into the extent of the complexity of plant metabolism and reveal the nature of its dynamism. In this talk I shall use a number of examples involving a range of crop species where we have exploited LC-MS and / or GC-MS – based technologies to gain a deeper understanding of how biochemical profiles are linked to aspects of crop phenotype and how these, in turn, relate to final product quality for both fresh and heavily processed foods. Diverse crops have been studied to demonstrate the truly generic nature of the methodology and the potential value of such approaches in an applied context. By exploiting metabolomics data we have become able to design new strategies to improve the biochemical composition of crop materials and how these are best converted into our food products in order to meet better future demands for quality and sustainability.

Metabolomics approach for durian orchards towards innovative products

Supaart Sirikantaramas[1]

1.Chulalongkorn University (Thailand)

Durian (*Durio zibethinus* L.) is one of the important economic fruits for many Southeast Asian countries including Thailand. We used metabolomics to dissect chemical compositions in both early immature durian fruit, an agricultural waste from durian orchards, and pulps during postharvest ripening. LC-MS approach leads to identification of polyphenols in the immature fruit that can be exploited as a novel source in many products. Multi-platform metabolomics in durian pulps provided data on metabolic changes during fruit ripening and metabolic variation in different cultivars. These data help us to understand compounds contributed to the flavour of durian and will be useful for breeding program. In addition, we identified several bioactive compounds such as gamma-glutamylcysteine and GABA that can be used as a bioactive marker in dietary supplement products. Therefore, we believed metabolomics is a powerful strategy towards developing innovative products.

Mass spectrometry based metabolomics for quality improvement of high value food products

Sastia Prama Putri[1]

1. Osaka University (Japan)

Metabolomics is the study of global quantitative assessment of metabolites in a biological system. Metabolites are the result of the interaction of the system's genome with its environment and are not merely the end product of gene expression but also form part of the regulatory system in an integrated manner. The exhaustive profiling of metabolites is an advantageous feature for analysis of various kinds of organisms including microbes and plants compared to the conventional analysis that only targets specific compounds. Metabolites, target in metabolomics technology, can be directly connected with phenotype that is sensitively affected by any type of perturbation or stress. The capacity of metabolomics to measure metabolites as well as to identify food components favor its usefulness for detection of adulterated crops or food products as well as for food quality improvement. Our group has pioneered the application of metabolomics for quality assessment of various important tropical food and crops. Here, several examples of metabolomics application for discrimination and classification of important food products will be provided. In addition, metabolite profiling for quality improvement of high value food products such as mango, mangosteen, pineapple, banana, shrimp, coffee, cacao, fermented foods will be discussed in this talk.

Comprehensive analysis of aroma components and metabolites in alcoholic beverages

Katsura Sekiguchi[1]*, Kuniyo Sugitate*[1]*, Chika Nogami*[1]*, Sadao Nakamura*[1]

1.Agilent Technologies (Japan)

Foods and beverages contain numerous organic compounds with various functions and effects. Some have nutritious value, some contribute to the taste and flavor, some maintain its quality, and some are known to promote healthy conditions of those that acquire it. The wide range of physiochemical properties of the components require different analytical techniques to identify and quantify but advances in analytical technology now enables various types of automation, from sample preparation, chromatographic analysis, to sample analysis, providing us with an even higher level of reliable results. This automation eases the use of multivariate analysis for finding trace levels of differences in sample types.

In this study, three types of analysis using different chromatographic instrumentation was done on the 6 different red wine samples. Flavor compounds were analyzed with extraction by SPME (solid phase micro extraction), analysis and simultaneous detection by GC-MS (gas chromatography – mass spectrometry) and GC-SCD (gas chromatography- sulfur chemiluminescence detector) using a capillary splitter. Samples were derivatized and analyzed by GC-MS for metabolite analysis. Water dilutions of samples were analyzed by CE-MS (Capillary Electrophoresis – Mass Spectrometry). A retention time locked metabolomics library was used to identify the metabolomic compounds.

After comparison of 4 different types of SPME fibers for the extraction of flavor compounds, the fiber with the combination of Carboxen and PDMS (polydimethylsiloxane) showed the most sulfur peaks from the SCD results. The largest 14 peaks from the SCD were identified using spectral and RI (retention indices) information. Comparison of total sulfur amount and sulfur compound constitution resulted in a 4-fold difference at most between the wine with the least and most amount of sulfur detected. Mercaptans, sulfides, sulfur dioxide, carbon disulfide, sulfur dioxide, and thio-alcohols were the main sulfur compounds detected. The GC-MS and CE-MS results were taken to multivariate analysis. After filtering the entities by parameters like frequency and variability, PCA (principal component analysis) and clustering showed differences of compounds like furans, esters, acids and their amounts contained. Sensory evaluation results did match with the metabolomic compounds and their difference by wine sample, showing that this procedure can be an efficient was to evaluate samples and their differences.

Such analysis methods handling multiple compounds within multiple samples using multivariate analyses has proven to be a useful tool for finding differences and their factors between samples.

Profile of Human Milk Oligosaccharides and Changes over 52 weeks in Healthy Taiwanese Mothers

Ting-Jang Lu[1], Chih-Chieh Lin[1], Ya-Chen Lu[1], Pei-Yin Lin[1], Yao-Jong Yang[2], Chieh-Chang Chen[3], Hsin-Yu Lin[3], Wei-Kai Wu[3], Chien-Nan Lee[3], Ming-Shiang Wu[3]

1. National Taiwan University (Taiwan), 2. National Cheng Kung University Hospital (Taiwan), 3. National Taiwan University Hospital (Taiwan)

Background and objectives: Human milk oligosaccharides (HMO) promote the growth of probiotics. The HMO profiles in milk vary among individuals with genetic backgrounds and maternal diet. The HMO profile data are still limited, especial from Taiwanese mothers. The objective of this study is to investigate the HMO profile changes in Taiwanese mothers over 52 weeks of lactation.

Method: We quantified 17 major HMO and semi-quantified 4 HMO in samples from 89 Taiwanese mothers (n = 39, 24, 44, 24, 37, 41, 23, 5 at week 1, 2.5, 4, 5, 8, 16, 24, 52 postpartum) using porous graphitic carbon liquid chromatography-Orbitrap mass spectrometry.

Results:2'-FL, 3-FL, LNFP II, LNT, and LNFP I accounted for most HMO (>65%). The total HMO concentration significantly decreased (p < 0.05) from 10.87 to 7.09 g/L over 24 weeks postpartum. The concentration of 3-FL increased dramatically from 0.60 to 1.90 g/L (316%), while LNT and LNFP I significantly decreased from 1.31 to 0.51 (39%) and 1.23 to 0.28 g/L (23%), respectively. 2'-FL significantly reduced from 2.48 to 1.22 g/L (49%) over 16 weeks postpartum. HMO with Le^x antigen epitope significantly increased from 15.9 to 38.0% in relative abundance over 24 weeks postpartum. In contrast, the H1 antigen and non-epitope group significantly decreased from 10.3 to 2.8% and 28.3 to 10.1% over 52 weeks postpartum. Furthermore, we observed that the HMO profile changed in those mothers who supplemented with folic acid during pregnancy.

Conclusions: The concentration of total HMO, 2'-FL, LNT, and LNFP I significantly decreased during the lactation period, while 3-FL significantly increased. Folic acid supplements during pregnancy may affect HMO profiles. It is necessary to study further the effects of maternal dietary patterns on HMO profiles.

SY(T8)5-2
Determination of triacylglycerol oxidation mechanisms using liquid chromatography-tandem mass spectrometry

Shunji Kato[1]

1.Tohoku University (Japan)

Triacylglycerol (TG), the main component of edible oil, is oxidized by thermal- (radical) or photo-(singlet oxygen ($^1O_2$) oxidation to form TG hydroperoxide (TGOOH) as the primary oxidation product. Since TGOOH and its subsequent oxidation products cause not only the deterioration of oil quality but also various toxicities, preventing the excessive oxidation of edible oils is essential. Thereby understanding oxidation mechanisms that cause the formation of TGOOH is necessary (e.g. radical oxidation is effectively suppressed by tocopherol). Isomeric information of TGOOH provides insights about oil oxidation mechanisms (i.e., radical- and $^1O_2$-oxidation). We recently observed the hydroperoxide-position specific fragmentations based on cation-π interaction on mass spectrometry (1). Using this phenomenon, highly selective analytical method for TGOOH isomers was developed. This method clearly distinguished the mechanisms that contributes to edible oils oxidation (e.g. canola oil (2) and rice bran oil (3)).

Importantly, these isomeric structures provide the insights about not only oxidation mechanisms but also the structure of secondary oxidation products. Recently, we constructed the generation pathways of certain secondary oxidation products based on some factors such as the structure of lipid hydroperoxide isomers, radical delocalization, and the stability of resulted compounds (4). These pathways precisely predicted the resulted secondary oxidation products such as acrolein.

Therefore, these methods and insights would be valuable in the understanding of oil and food oxidation mechanisms, and may be applied to the development of preventive methods against food deterioration. In this symposium, I will introduce these analytical methods and obtained results.

Visualization of functional food factors by matrix-assisted laser desorption/ionization imaging mass spectrometry

Nobuhiro Zaima[1,2]

1. Kindai University (Japan), 2. Agricultural Technology and Innovation Research Institute (Japan)

Food contains various functional food factors that have an impact on biological activities. Many technologies have been reported to analyze molecules of interest in foods. High-performance liquid chromatography-mass spectrometry or gas chromatography-mass spectrometry is solid approach to detect molecules of interest with high sensitivity. However, these technologies are not available for the analysis of the spatial distribution of molecules of interest. Matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI) is considered as an ideal complementary approach to visualize distribution of molecules in foods. MALDI-MSI is a two-dimensional MALDI-MS technology that can detect compounds in a tissue section without purification, separation, or labeling. MALDI-MSI can be used to visualize the spatial distribution of chemical compounds or biomolecules in foods. Although the methodology of MALDI-MSI in food science is not yet fully established, the versatility of MALDI-MSI is expected to open a new frontier in food science. Here, I would like to introduce the applications of MALDI-MSI and discuss the future in the field of food science.

Molecular species analysis of sphingolipids from marine invertebrates

Jie Xu[1]*, Xincen Wang*[1]*, Peixu Cong*[1]*, Changhu Xue*[1]

1. Ocean University of China (China)

Marine invertebrates are a paraphyletic group that comprises more than 90% of all marine animal species, including mollusks, crustaceans, echinoderms, etc. Sphingolipids (SLs) are ubiquitous structural components of cell membranes and are essential for cell functions under physiological conditions or during disease progression. We propose that dietary SLs represent a “functional” constituent as emerging strategies for improving human health. However, the profiles of SL molecular species from marine invertebrates remain to be known very limited. According to our study, the species and contents of SLs in marine invertebrates are relatively abundant, including ceramides (Cer), sphingomyelins (SM), cerebrosides (HexCer), gangliosides (GLS), and some novel SLs such as ceramides 2-aminoethylphosphonate (CAEP) and deoxy-ceramides (DeoxyCer).

An RPLC-MS method was utilized and revealed that the percentage of SLs (Cer, HexCer, and SM) in shellfishes is considerable (18.8–38.6%). The characterization of their special long-chain base (LCB) structure (mainly d19:3) and N-acyl group (mainly 16:0) was realized. Furthermore, the d14:1 and d16:1 were the main LCB in Cer, HexCer, and SM of shrimp species with low content. In particular reference to sea cucumber, the LCB of HexCer mainly contains d17:1. We identified three GluCer subclasses from sea cucumber *Cucumaria frondose* and the most dominant molecular species were d17:1/24:1, d18:2/24:1, d18:2/24:1h, and t17:0/24:1h. The HexCer contents of sea cucumbers were 0.42-4.44 mg/g dry weight, among which *Bohadschia marmorata* was the highest.

A HILIC-MS analysis method was established to comprehensively investigate GLS, an acidic complex SL containing sialic acid (Sia). Invertebrate GLS have unique structures, containing N-acetylneuraminic acid (Neu5Ac), N-glycolyl-neuraminic acid (Neu5Gc), sulfated Neu5Gc and 3-deoxy-D-glycero-D-galacto-nonulosonic acid (KDN). We identified 17 special GLS subclasses in echinoderms. The polymerization degree of Sia in echinoderm GLS can be up to 4, and the linkage among Sias was mostly determined to be 2–8 or 2–11. Neu5Gc, sulfated and fucosylated Neu5Gc prevalently existed in echinoderm GLS. A new type of GLS with a phosphoinositidyled Sia was first characterized in sea cucumber *Bohadschia marmorata*. GM_4 was detected as a basic GLS structure of sea urchins and sea cucumbers, with different ceramide structures (t18:0/22:1h and d18:1/23:1h, respectively). Semi-quantitative analysis showed that the contents of GLS in echinoderms were 0.2–7.3 mg/g dry weight, with the highest GLS content in sea urchin *Glyptocidaris crenularis*.

Additionally, we established an NPLC-MS method for comprehensively identifying and semi-quantifying of complicated CAEP species from different marine invertebrates. Our study found that squid *Loligo chinensis* had the highest CAEP content (4.9±0.4 mg/g dry weight) and the most complex composition of molecular species, whereas starfish *Asterias amurenis* had the lowest CAEP content (1.9±0.6 mg/g dry weight), among five marine invertebrates (squid, mussel, oyster, neptunea, and starfish). Several DeoxyCer with low abundance (0.06–0.33 mg/g dry weight) were also detected in shellfish species.

These bioactive SLs have potential roles in revealing the nutritional value of marine invertebrates and serving as biomarkers for distinguishing different marine invertebrates. Moreover, our massive SLs data could facilitate the geographical origin traceability of aquatic products.

Poly (D, L-lactide-co-glycolide)-phospholipid nanocarrier for efficient delivery of carotenoids

Baskaran Vllikannan[1], Arunkumar Ranganathan[2], Yuki Manabe[3], Tatsuya Sugwara[3], Takashi Hirata[4], Ravi Hindupur[5], Veeresh Toragall[1]

1. CSIR-Central Food Technological Research Institute (India), 2. John. A. Moran Eye Center, University of Utah (USA), 3. Graduate School of Agriculture, Kyoto University (Japan), 4. Shijonawategakuen University (Japan), 5. Children's National Medical Centre (Washington, DC) (USA)

Carotenoids (lutein, zeaxanthin, fucoxanthin, astaxanthin etc.) exhibit various biological activities. Their application in food and pharmaceutical industries are very much restricted due to meagre aqueous solubility, photo-, and thermal stability, and biological availability. The stability and bioavailability of carotenoids can be enhanced by nano encapsulation with a suitable polymer matrix and specific lipid carrier. To maximize bio-availability and bio-efficacy of carotenoids, we have developed lutein-poly (lactic-co-glycolic acid) (PLGA)-phospholipid (PL) nano carrier, chitosan (CS) - sodium tripolyphosphate (TPP) - glycolipid (GL) multifaceted nano system (CS-NGs) and chitosan-oleic acid-sodium alginate-based nano-carrier system (LNCs). These nano carriers were characterized for their physical and chemical properties and bioavailability of loaded carotenoids *in vitro* and *in vivo*. Nano carriers were found safe for application with no toxicity. The cellular uptake of lutein and fucoxanthin from nano system were higher than from mixed micelles. LNCs and CS-NGs displayed 1000-fold higher aqueous solubility. The mean size and zeta potential value of lutein-PLGA NCs (+PL) and CS-NGs were 100 to 140 nm and - 44 ± 5 mV and PDI of 0.174 ± 0.02. The amorphous nature of lutein in PLGA NCs (+PL) and CS-NGs was confirmed by XRD and DSC. *In vitro* lutein and fucoxanthin release kinetics showed an initial burst followed by sustainable release up to 85 to 90 %. *In vitro* bioavailability showed 62 to 70% higher lutein and fucoxanthin bio accessibility than form mixed micelles. The AUC of lutein and fucoxanthin after an oral dose of lutein-PLGA NCs (+PL) and CS-NGs revealed 3.91-fold (plasma), 2.89-fold (liver), and 3.12-fold (eyes) higher absorption than the control (mixed micelles) in rat model. A dose-dependent increase in plasma (135.20, 165.30 nmol/mL) and eyes (1.51 & 3.98 µg/g) was observed upon oral gavage of LNCs (10 and 100 mg/kg BW). The IC_{50} of lutein-PLGA NCs (+PL) in Hep G2 cells at 72 h was 4.5 µM as opposed to 23.4 µM for lutein in free form. Thus, results reveal that PL and oleic acid added to PLGA NCs and CS-NGs help in enhancing the solubility, stability of carotenoids which in turn resulted in higher bioavailability and bioefficacy and hence nano carrier system could be an efficient therapeutic tool to conquer macular degeneration, retinopathy and obesity complications owing to health benefits of lutein and fucoxanthin.

Characteristics of fine lipid particles enhancing absorption of dietary lipophilic compounds

Kaeko Murota[1]

1. Shimane University (Japan)

Nutrients and other dietary functional components exhibit a wide range of chemical and physical properties, and thus the optimal intake of such beneficial food factors from natural and complex foodstuffs is often difficult. Intestinal absorption of lipophilic compounds depends on their solubility in the intestinal fluid to be delivered to the absorptive epithelium. It is well known that coexistence of lipids is essential for the absorption of lipophilic vitamins such as carotenoids and retinoids. There are a variety of nanotechnologies applying to drug delivery as well as dietary products to enhance the bioavailability of various functional components. In our study, vitamin E (α-tocopherol, VE) absorption was evaluated using fine lipid particle. VE solubilized with plant oil and processed to two types of water-soluble particles with emulsifiers were evaluated in our study. Water solubility was greatly enhanced with the fine-particle processing using food additive emulsifier with less than 100 nm as diameter, compared with soluble powder with approximately 1000 nm as diameter. When these samples were administered intraduodenally to the thoracic-lymph cannulated rats, the lymphatic transport of VE was higher with the Φ100-nm particle than with the Φ1000-nm particle. Absorbability of VE from the f100-nm particle was comparable to the post-prandial mimic solution. However, in the Caco-2 cell culture system, the Φ100-nm particle and the Φ1000-nm particle gave similar absorbability. The cellular uptake and the basolateral transport of VE were lower than when VE was administrated as the post-prandial mimic solution, indicating that the higher water solubility and nano-level diameter were not the critical features to accelerate the cellular uptake in the enterocyte. Interestingly, the absorbability of VE from the Φ100-nm particle in rats was reduced when Orlistat, a pancreatic lipase inhibitor, was co-administrated. The suppressive effect by Orlistat on VE absorption was not observed with the Φ1000-nm particle, suggesting that the inhibition of pancreatic lipase partly reduced the VE absorption from fine lipid particle. In conclusion, it is indicated that the fine lipid particle processing enhanced the absorption of VE *in vivo* via increasing the water solubility to enhance the accessibility to the intestinal mucosa. Also, the enlargement of the surface area of smaller particles may facilitate the lipid digestion within the particle following the micelle formation including VE.

SY(T8)6-3
Colloidal aspects underpinning the digestion of lipid delivery systems

Pete Wilde[1]

1.Quadram Institute Bioscience (UK)

Many bioactive food ingredients and drugs are poorly soluble in water and require lipid-based carriers to improve delivery and bioavailability. Understanding the colloidal behaviour and digestibility of lipids is essential for the design and formulate more effective lipid-based delivery systems. As lipids are immiscible with the water-phase, lipid digestion is a process which primarily occurs at the interface between the lipid and water phases. Hence the enzymes (lipases) which are water soluble must adsorb to the lipid surface for lipid hydrolysis (lipolysis) to take place. The interface is usually occupied and stabilised by adsorbed layer of surface active molecules such as emulsifiers, polar lipids, proteins etc. This layer can influence the colloidal stability and accessibility of the lipases to the lipid phase. Lipid digestion begins in the stomach, where the interfacial properties of the lipid phase can control coalescence, flocculation and creaming of the lipid phase, which can all affect lipid hydrolysis, but can also control the kinetics of lipid delivery to the small intestine. We demonstrated this by comparing the *in vitro* digestion of solid and liquid fats in a food matrix, which successfully reproduced the kinetics of plasma lipid appearance in a parallel human study. In the small intestine, lipolysis is further facilitated by bile salts which are emulsifiers and play multiple roles during duodenal lipid digestion, solubilisation of lipophilic bioactives and absorption. Understanding how bile salts interact with lipids, lipases and other food components will help us understand how these processes can be controlled to influence the rate and extent of lipid digestion. I will present some of the key factors which influence the colloidal behaviour and hence digestibility of lipid-based systems, supported by recent research which can be used to inform the design and development of more effective lipid delivery systems

Keywords: Lipid, Digestion, Delivery, Colloid, Interface.

Structure and functions of Lipid Droplets/Oleosomes

Costas Nikiforidis[1]

*1.*Wageningen University and Research (Netherlands)

Oleosomes, also known in biology as Lipid Droplets are storage organelles, found in all eukaryotic organisms. They have a unique architecture consisting of a hydrophobic core of neutral lipids, which is enclosed by a phospholipid monolayer that is decorated by a specific set of proteins. Oleosomes is the mechanism that organisms developed to safely store energy and use it when necessary. For this, the oleosome membrane is evolved to a metastable material, which is designed to withstand physical and chemical stresses but releases the neutral lipids upon specific stimuli. However, the structure-function relationship of the molecular components in the oleosome membrane is still not well understood and requires more attention to take complete advantage of their potential functions. Currently, we are investigating the molecular combinations at the oleosome membrane and their properties in different molecular soups. We aim towards understanding their physicochemical role in biological mechanisms and exploiting their properties in advanced and broad applications, from trafficking molecules to bio-catalysis.

Keywords: Oleosomes, lipid droplets, emulsions, carriers.

Microchannel Emulsification Technology for Dilute and Concentrated Oil-in-Water Emulsions

Mitsutoshi Nakajima[1]*, Khawenn Seah*[1]*, Marcos A Neves*[1]*, Isao Kobayashi*[2]

1. University of Tsukuba (Japan), 2. Food Research Institute, NARO (Japan)

Emulsions prepared by mechanical homogenizers are mostly polydisperse and rather unstable. More stable emulsions are needed for bioactives encapsulation. We have investigated the use fabricated microchannel for preparing monodisperse emulsions. Relatively efficient emulsification was achieved using asymmetrically structured microchannels with slit and microholes. The slit structure caused large distortion of the oil-water interface, and the interfacial tension induced spontaneous droplet formation. Laboratory-scale MC emulsification (MCE) equipment was already industrialized and used for various applications in food and chemical industries. Monodisperse emulsions in dilute condition up to 10% oil volume fraction was possible to formulate by microchannel emulsification. Highly concentrated emulsion is an emulsion system with high oil volume fraction, in which the droplets are closely packed together with advantages of its tunable textural properties, low water activity, large surface area features and high bioactives encapsulation. However, highly concentrated emulsions with higher internal fraction are often concerned about their coalescence stability due to the high droplet concentration. In this presentation, microchannel emulsification was used to prepare monodisperse oil-in-water highly concentrated emulsions and their stability were investigated, and compared with conventional mechanical homogenization in order to explore its potential to be applied in the food and nutraceuticals. Refined soybean oil was used as a dispersed phase whereas emulsifiers such as whey protein isolate and polyoxyethylene sorbitan monolaurate and sodium dodecyl sulfate. Highly concentrated emulsions prepared were characterized and evaluated based on their physical and chemical stability.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Monodisperse highly concentrated emulsions were successfully prepared with different emulsifiers with concentration as low as 0.5 wt%. The monodispersity of emulsion droplets showed good stability despite having relatively larger droplet size, which might be due to slight difference of Laplace pressure between droplets. Monodisperse highly concentrated emulsions prepared showed comparable or better physical and chemical stability than polydisperse ones. Highly concentrated emulsions prepared by microchannel also showed excellent chemical stability in preserving bioactive compounds. Hence, it could be potentially applied to food and nutraceutical products that carry high-value bioactive compounds.

Chemoprevention by vitamin A and its derivatives

Xian-Yang QIN[1]

1. RIKEN (Japan)

Hepatocellular carcinoma (HCC) is a deathly cancer with increasing global deaths in the past 20 years. Progressive loss of total hepatic retinoid storage has been associated with the development of hepatic diseases including HCC. Acyclic retinoid (ACR) is an orally administrated vitamin A derivative that binds to cellular retinoic acid-binding protein with an affinity equal to that of all-*trans* retinoic acid, selectively inducing retinoic acid receptor-β-dependent signaling. ACR is the first agent to show promising efficacy and safety in phase 2/3 trials for the prevention of HCC recurrence in patients who underwent surgical removal of the primary tumors. However, a recent phase 3 trial with a specific focus on patients classified as Child-Pugh A reported no statistical superiority of ACR over placebo in inhibiting the recurrence of HCV-positive HCC (NCT01640808). Further studies identifying predictive biomarkers that indicate the response to ACR are essential for improving the treatment and prognosis of HCC.

Here, we performed a genome-wide transcriptome screen and identified that ACR suppressed the expression of a proto-oncogene MYCN selectively expressed in HCC cells but not in normal hepatic cells. Data mining of clinical datasets showed that MYCN expression in HCC was correlated positively with both cancer stem cell (CSC) and Wnt/β-catenin signaling markers, whereas negatively with mature hepatocyte markers. Immunofluorescence and flow cytometric analyses showed MYCN expression marked an EpCAM+ CSC-like subpopulation, which was selectively targeted by ACR. Proteome and metabolome analyses showed the expression of fatty acid desaturases and the content of unsaturated fatty acids were increased in MYCN high expression EpCAM+ CSC-like HCC cells. Inhibition of lipid desaturation using either the chemical inhibitor or siRNA/shRNA against stearoyl-CoA desaturase-1 (SCD1) suppressed cell proliferation as well as MYCN gene expression in HCC cells, grown as both monolayer and spheres. Mechanistic study using RNA-seq based transcriptome analysis revealed that endoplasmic reticulum (ER) stress related signaling networks such as endocannabinoid cancer inhibition pathway were under the control of SCD1 in HCC cells. The chemical inducer of ER stress inhibited MYCN gene expression, while the chemical inhibitor of ER stress partially rescued the suppression of MYCN gene expression by ACR in HCC cells. In the cohort studies in Japan, Taiwan and Europe, MYCN gene expression was expressed at higher levels in HCC tumor than in non-tumor tissues. There was a significant positive correlation between MYCN expression and recurrence of HCC with single tumor but not with multiple tumors. In a retrospective analysis of phase 3 trial of ACR, serum MYCN was identified as the risk factor mostly associated with HCC recurrence. HCC patients with a lower serum MYCN levels after a 4-week treatment period had a significantly lower risk of recurrence in ACR group, but not in placebo group.

In summary, MYCN holds promise for the biomarker-based precise medicine in the prevention of HCC with ACR.

Toxicity prediction of natural compounds

Kohsuke Hayamizu[1]

1. Yokohama University of Pharmacy (Japan)

Kampo medicine are composed of several crude drugs, a part of which are used as food. Each crude drug contains huge of natural organic chemicals, resulting in a complex multi-component system. On the other hand, there is no comprehensive report that investigates the information of crude drugs or the information of the ingredients contained and the safety information such as the results of toxicity tests. We comprehensively investigated the chemical structures of the substances contained in crude drug and predicted the potential toxicity in *Kampo* medicine preparations using computational toxicology techniques based on the structural formula information. The predicted items include cardiotoxicity, hepatotoxicity, and genotoxicity. The results of the calculations were compiled into a database, and to date, 40 formulations with the highest annual use and 1110 compounds contained in these formulations have been included in the in-house database. Next, we examined in detail the prediction of the inhibition of the hERG K^+ channel, which is the target for the evaluation of cardiotoxicity. We used the QSAR model of a commercially available program created by artificial neural networks, using experimental assay results of about 1000 compounds as training and test data. As a result, 52 compounds were estimated to be positive for inhibition. In addition, we constructed an ensemble model using a data set of about 14,000 compounds to improve the accuracy. In order to understand the interaction with hERG in more detail, we have started to study it by docking simulation. In this symposium, we will present these results.

StemPanTox: a fast and wide-target drug assessment system using ES and iPS cells.

Wataru Fujibuchi[1]

1. Kyoto University (Currently, Nippon Shinyaku Co., Ltd. and The University of Tokyo) (Japan)

The assessment of chemical effects on animals has limited consistency to humans. Adding consideration for animal protection, effective alternatives are desired. Previously, we developed a method that predicts developmental toxicity based on undifferentiated human embryonic stem (ES) cells using gene networks, achieving an extremely high performance (AUC = 0.93–1.00) for neurotoxins, genotoxic carcinogens, and non-genotoxic carcinogens. Here, we advanced this method to predict *adult* toxicities of 24 chemicals in six categories (neurotoxins, cardiotoxins, hepatotoxins, two types of nephrotoxins, and non-genotoxic carcinogens) and achieved high prediction predictability (AUC = 0.90–1.00) in all categories. Moreover, to develop a system with fewer ethical issues, we screened for an induced pluripotent stem (iPS) cell line to predict the toxicities based on the gene networks of iPS cells using transfer learning of the ES cell gene networks. We successfully predicted toxicities in four categories (neurotoxins, hepatotoxins, glomerular nephrotoxins, and non-genotoxic carcinogens) with high performance (AUC = 0.82–0.99). This system, called "StemPanTox", is applicable to a wide range of chemical toxicity assessments using iPS cells once a gene expression database has been developed from a standard stem cell line. This method holds promise for tailor-made safety evaluations using personalized iPS cells.

Food ingredients controlling cell differentiation and histone modifications

Yoichi Nakao[1], Satoshi Otsuka[1], Midori Kawamura[1], Shutaro Fujino[1], Fumiaki Nakamura[1], Daisuke Arai[1], Nobuhiro Fusetani[1]

1. Waseda University (Japan)

In Japan, one of the world's leading super-aged societies, the number of patients with neurodegenerative diseases such as dementia and Parkinson's disease is growing, and therefore counterplans are urgently needed. If there are functional ingredients that can prevent or treat neurological diseases in the foods we can consume daily, this could be one of the effective countermeasures. However, many food components do not show strong biological activity (highly active components may show toxicity), and many of them are thought to be effective when consumed daily over a long period. Therefore, it is essential to use a "highly sensitive assay system" to detect functional components in foods.

Neural stem cells (NSCs) are self-renewing pluripotent stem cells that can differentiate into neurons, astrocytes, oligodendrocytes, etc. NSCs are present not only during development but also in all adult mammals, including humans, and are known to continue providing differentiated neural cells throughout life. Recently, it has become clear that aging and mental stress reduce the differentiation potential of NSCs, suggesting a link to neurodegenerative diseases such as Alzheimer's disease and Parkinson's disease. Therefore, compounds that regulate the differentiation of NSCs are expected as the prevention and treatment of these diseases.

We have developed an in vitro neural differentiation assay system using mouse embryonic stem cell (mESC)-derived neural stem cells (NSCs) and applied it to the search for functional food ingredients. This assay system can detect active substances affecting neural differentiation with high sensitivity. In addition, because this is an in vitro system, rapid analysis the mechanism of action is also possible.

On the other hand, histone modification, like DNA methylation, is one of the major mechanisms of epigenetic regulation of gene expression and is involved in various biological phenomena including cell differentiation during development. Histone modifications (acetylation, methylation, phosphorylation, etc.) occur at multiple sites on each histone molecule that makes up the nucleosome, and the modification patterns are complex. Therefore, the search for food components that change histone modifications requires an assay system that can detect them simultaneously and with high sensitivity. We have developed an assay system that monitors multiple histone modifications in parallel using more than 20 monoclonal antibodies specific for each histone modification.

Combining the above histone modification assay system with the in vitro cell differentiation model using mouse ES cells has enabled us to conduct not only search for functional food ingredients, but also earch for novel epigenetic drug materials and evaluation of the effects of environmental factors such as endocrine disruptors on gene expression.

In this presentation, we will introduce our recent results of the search for functional food ingredients with astrocyte

FRESH: A Global Fruit and Vegetable Research Initiative

Deanna K Olney[1]

1.International Food Policy Research Institute (USA)

Fruit and vegetable intake is below recommended levels in nearly every country across the globe contributing to poor quality diets. Improving diets, including increasing intake of fruit and vegetables, could save one in five lives annually. In low- and middle-income countries (LMICs), the extent and nature of this nutrition challenge is poorly understood, due, in part, to insufficient dietary data. To increase fruit and vegetable intake issues related to availability, accessibility, affordability, and desirability need to be addressed. This will require using evidence-based approaches that address these issues throughout the value chain – from production to transportation and processing, to food environments to consumption.

In this Symposium, we will discuss a new research initiative developed in close partnership between CGIAR, the World Vegetable Center, and other partners, in which researchers will work with innovation, implementation, and scaling partners to address low fruit and vegetable consumption in LMICs. We aim to take an innovative, holistic end-to-end approach that begins with consumers, to better understand their dietary patterns and the barriers to increased fruit and vegetable consumption they face such as insufficient year-round availability of diverse fruits and vegetables (availability and cost); inadequate access to safe, diverse fruits and vegetables (accessibility); low income coupled with high prices of fruits and vegetables (affordability); and lastly, desirability where even when fruits and vegetables are available and affordable, intakes are still below recommended levels which requires a closer look at context and population-specific considerations preventing people from making healthy diet choices and identifying and testing innovative programs and policies to support healthy diets.

The subsequent presentations in this symposium will examine each of the issues listed above and provide insights as to how the FRESH Research Initiative will address these, and in some cases, will highlight some early findings.

The use of fruit and vegetables to generate Income, improve diets and mitigate climate risks: a review of the evidence

Pepijn Schreinemachers[1], *Jody Harris*[1], *Rosaine Nerice Yegbemey*[3], *Sandhya S. Kumar*[2], *Mercy Mwambi*[1], *Christelle Marie Komlan*[3]

1. World Vegetable Center (Thailand), 2. World Vegetable Center (India), 3. World Vegetable Center (Benin)

Fruit and vegetables are an essential and irreplaceable part of a healthy diet. Global consumption of these foods falls well below recommended levels. A survey of people in 28 low- and middle-income countries found that 80% of individuals consume less fruit and vegetables than the World Health Organization recommends for good health. Low consumption of these foods is not just a key risk factor for human health, but also for planetary health as the mean carbon footprint of fruit and vegetables is much lower than animal-sourced food while providing key nutrients. Furthermore, the production and trade of fruit and vegetables generates profit and income that is often far greater than what farmers can earn from staple food grains.

Despite these purported benefits, fruit and vegetables have been relatively neglected in agricultural and food security policies due to a preoccupation with staple grains. Correcting this imbalance requires a sound understanding of how fruit and vegetables contribute to income, diets and climate change mitigation. Focusing on impact evaluation research undertaken by the World Vegetable Center and partners over ten years, we present a review of studies across the food system, from improved vegetable seed and agronomic practices adopted by farmers to the promotion of home and school gardens in rural areas, to awareness raising campaigns among consumers.

The review recognizes that pathways to impact can be long or short. An example of a long impact pathway is investments into vegetable breeding: new traits are incorporated into vegetable varieties that are sold to farmers who use it to produce a better crop, which they sell to consumers who desire these crops, and use the money earned to buy food. The time period from initial investment to ultimate impact can stretch for a decade or more in such impact pathway, and has many confounding factors that make it challenging to show numerically the exact pathways by which investments in vegetable breeding contribute to healthier diets. Consequently, the impact evidence is much stronger for shorter pathways. An example is the large body of literature on the impact of home gardens, which typically couple nutrition education with training in gardening and the supply of vegetable seed (sometimes also including small livestock or fish). Here the evidence is strong that home garden interventions can contribute to improved nutrition outcomes within a short period of time, although the success of home gardens depends much on the quality of intervention designs and local context.

In general, we observe a lack of high-quality studies on the impact of policies and interventions in the fruit and vegetable sector, particularly for low- and middle-income countries and for the longer impact pathways. Evidence is especially limited for the impact on greenhouse gas emissions. This review of studies

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

undertaken by the World Vegetable Center is feeding into a larger systematic review of interventions and impacts, and this session seeks feedback to further shape that review and identify gaps and opportunities.

SY(T8)8-3
Sustainable intensification for safe food production

Ravi Gopal Singh[1]

1. International Maize and Wheat Improvement Center (CIMMYT) (Mexico)

Soils can beneficially or adversely affect human health, and likewise human activity can impact soil health. Modern agricultural practices have affected soil health. Farmers are now using more fertilizer nutrients to produce optimum yield. Fertilizer consumption in developing world has increased significantly in last few decades. For example, in India, total NPK (N, P_2O_5 and K_2O) consumption increased nine-folds (from 2 million to 18 million tons) between 1970 and 2000. Per-hectare NPK consumption increased from 11 to 95 kg in the same period. Inappropriate fertilizer uses in intensive cropping led to several soil related problems including micronutrient deficiencies, salinization, acidification, and erosion. Research shows that intensive use of inputs creates a vicious cycle from which it is difficult to get out. For example, indiscriminate insecticide uses leads to a loss of natural predators and parasites and pest resurgence consequently, creating greater need for pest control. The changing climate affects the pathosystem including those that are already difficult to control are spreading to new areas, and the rapid emergence and spread of new or previously unimportant pests and diseases. Likewise, in commercial agricultural areas, repeated tillage can degrade organic matter, reduce hydraulic conductivity, and not only affect groundwater recharge but also reduce water storability of the soils, which makes soil vulnerable for erosion and paucity of soil water for crops. Under this context, our experience with conservation agriculture (CA) based crop management showed that optimal use of inputs and the systems functionality can make food production, economical, resilient, diverse, and sustainable. To restore soil function to optimum levels, crop diversity is essential. We found that sustainable intensification and diversification not only improved crop yields, enriching diet diversity but also reduced input use and risks. The sustainable intensification options helped in managing weeds, pests and diseases, efficient water use, enriched agrobiodiversity, less pesticide use resulting safer food production at lesser costs. The sustainable intensification and diversification with good agronomic practices and ecosystem service approaches can built system resilience to biotic, abiotic, and economic stresses.

Low cost interventions in value chains can reduce postharvest waste of fruits and vegetables

Emma Ruth Bayogan[2], *Jennifer Ekman*[1], *Angelina T Lacap*[2], *Leizel B Sectretaria*[2]

1. Applied Horticultural Research (Australia), 2. University of the Philippines Mindanao (Philippines)

People know that fruit and vegetables are good for them. Despite this, most people usually eat far less than the recommended five servings per day. The reasons for this may be cultural, price based, or simply that quality produce is not available. In many cases, high prices are a major barrier. This is frequently due not to lack of production, but to difficulties in getting fruit and vegetables from paddock to plate. In southeast Asia, it is estimated that 30 to 60% of fruit and vegetables grown are wasted. Long and complex value chains, lack of refrigeration and poor handling practices all increase losses. However, relatively simple interventions can have significant benefits. Here we present three case studies based on work in the Philippines, focussed on bitter melon, eggplant and mangoes. Interventions included modification of production practices (growing under a protective shelter), harvesting and packing method (avoiding bruising) and ripening technique (reduced time and/or gas concentration). All tested interventions increased saleable life. It is concluded that low-cost interventions can increase both availability and quality of fruit and vegetables, thereby facilitating increased consumption.

SY(T8)8-5
Creating food environments to support fruit and vegetable-rich diets

Neha Kumar[1], Quinn Marshall[1]

1. International Food Policy Research Institute (USA)

The food environment is where the production and supply end of the food system meets the consumption and food intake end, sometimes but not always through markets. Core elements of the food environment include availability and access to foods; vendor and product characteristics, price and affordability of foods; and marketing and regulation that structure the environments within which people access foods that form a healthy diet, including the policy, programmatic and economic drivers of these. The food environment covers aspects outside of immediate consumer preferences that structure and shape food choice, both towards healthy diets and under-and over-nutrition outcomes. Food environment descriptions and diagnoses are limited, and largely undertaken in high-income countries, though these are beginning to be done in some LMIC contexts. Interventions into food environments (again largely in high-income contexts) focus on wider questions of accessibility (including school or other institutional meals including local procurement, and bringing healthy foods such as fruits and vegetables closer to consumers; affordability (including consumer-end fruit and vegetable subsidies, and more general social protection92); and how the wider product, retail and regulatory environment shape food environments (including labelling and advertising of foods and zoning law). Policy choices and policy processes underpinning these areas has started to be assessed as a route to sustainable intervention. The strongest evidence favors multi-component interventions in the food environment for fruits and vegetables. Our research questions and outputs are focused on 1) diagnosing and understanding fruit and vegetable food environments and 2) applying and innovating new fruit and vegetable focused interventions. To do so we follow a mixed methods approach including household and retail surveys; qualitative assessments of the lived experience of food environments; affordability studies geospatial analysis, policy and equity process and case study approaches and impact evaluations. In understanding fruit and vegetable food environments, we examine the following key research questions: 1) What are the characteristics of food environments in relation to fruit and vegetables? 2)How do these vary by time and context and for different populations? 3) What evidence exists on food environment interventions? 4) What are the political economy and equity dimensions enabling and disabling such options? We will present initial findings on understanding of fruit and vegetable food environments in Sri Lanka and Benin.

Intake of fruit and vegetables among men and women in rural Sri Lanka

Deanna K Olney[1], Bess Caswell[2], Renuka Silva[3], Malika Fernando[4]

1. International Food Policy Research Institute (USA), 2. US Department of Agriculture Agricultural Research Service (USA), 3. Wayamba University of Sri Lanka (Sri Lanka), 4. World Food Programme (Sri Lanka)

Background and objectives: Worldwide poor-quality diets are the leading cause disease and a primary cause of all forms of malnutrition. Improving diets, including increasing intake of fruit and vegetables, could save one in five lives annually. In this study we assessed dietary intake among men and women in rural Sri Lanka as part of an evaluation of the effectiveness of a nutrition-sensitive resilience building program implemented by the World Food Programme and their partners within the Government of Sri Lanka and with the Foundation for Health Promotion. Our primary objective was to assess the dietary patterns of the survey participants (program participants and a control group) and to assess program impact on dietary intake. Here our primary objective is to examine intake of fruits and vegetables among men and women in rural Sri Lanka.

Methods: All dietary data across three time points were collected through 24-hour recall interviews, conducted over the phone by trained enumerators from Wayamba University of Sri Lanka. Here we report the findings from the endline survey conducted with 1080 participants. Dietary intake data was categorized following the food group definitions recommended by the FAO for use among women of reproductive age. Data was further disaggregated for men and women.

Results: Intake of fruits and vegetables was common, with over 90% of respondents consuming at least one fruit or vegetable in the prior 24 hours. However, only about one-third of survey respondents ate dark green leafy vegetables and about one-quarter ate vitamin A-rich fruit and vegetables in the 24 h prior to the survey. No meaningful differences between men's and women's intake of fruits and vegetables were detectable at endline.

Conclusions: Although intake of fruit and vegetables is common among adults in rural Sri Lanka, intake of dark green leafy vegetables and other vitamin A-rich fruits and vegetables is less common. Future analyses will assess whether a nutrition-sensitive resilience building program was successful in improving diets among men and women in rural Sri Lanka, including their intake of fruit and vegetables.

Risk management for microbial hazards in foods

Yoshimasa Sasaki1

1. National Institute of Health Sciences (Japan)

Foodborne diseases caused by microbial hazards constitute significant public health concerns worldwide. Human beings have fought against microbial foodborne diseases since before the recorded history. Microbial hazards include bacteria, viruses, fungi and parasites. Toxins and other harmful metabolites are chemical hazards but produced by microorganisms. If food-producing animals are infected with microorganisms, in most cases, the animals do not have visible symptoms. As we got over some microbial hazards, new hazards, such as Shiga toxin–producing Escherichia coli, antimicrobial resistant bacteria and prions, appeared and spread. In human eating habits and diets, many changes have occurred over the last few decades. For example, in Japan, low-salt foods, uncooked or lightly cooked foods are widely available now. Imported foods are also common. These foods are available not only from the market but also from the Internet. The government promotes the consumption of game meats. Therefore, when dealing with microbial hazards, these complex and changing situations should be considered and a science-based approach is essential. For this, risk analysis serves as a good and useful tool in evaluating and controlling microbial hazards to protect the health of consumers and ensure fair practices in food trade. The Codex Alimentarius Commission adopted the 'Principles and guidelines for the conduct of microbiological risk management (MRM)' in 2007. The eight general principles for MRM are: (1) Protection of human health is the primary objective in MRM; (2) MRM should take into account the whole food chain; (3) MRM should follow a structured approach; (4) MRM process should be transparent, consistent and fully documented; (5) Risk managers should ensure effective consultations with relevant interested parties; (6) Risk managers should ensure effective interaction with risk assessors; (7) Risk managers should take account of risks resulting from regional differences in hazards in the food chain and regional differences in available risk management options; and (8) MRM decisions should be subject to monitoring and review and, if necessary, revision. This presentation focuses on the second general principle for MRM; and introduces the prevalence of non-typhoidal Salmonella spp. and measures for controlling Salmonella infection/contamination in chickens and chicken eggs in the whole chain of chicken egg production/distribution in Japan. Since late 1980's, the annual number of food-poisoning outbreaks caused by Salmonella spp. has sharply increased. While risk analysis was not introduced yet in Japan for microbiological food safety until early 2000's, the Government of Japan implemented many control measures based on scientific data in the whole food chain. As the results of these control measures, the number of the outbreaks have decreased since 2000. Even at the present time, Salmonella is still main cause of bacterial outbreaks, the current main source food of the outbreaks is chicken meat rather than chicken eggs in the past. To further decrease the outbreaks, the reduction in Salmonella contamination of chicken meat is necessary. This example of chicken eggs helps understand the importance of the application of "food chain approach".

SY(T8)9-3
Precision food safety -using whole genome data to inform risk assessment in food safety

Seamus Fanning[1]

1. University College Dublin (Ireland)

Foodborne disease surveillance is now at a critical juncture. Whilst remaining firmly embedded in the principles of risk analysis; including assessment; management and communication, technological developments have opened up new opportunities for food safety, in its pursuit of the protection of public health. Microbiological food safety has traditionally been monitored using culture-based protocols designed to detect; characterise and identify the target foodborne pathogen. Bacterial pathogens have been mainly studied at the species level without any consideration being given to the microbiological context, from which the bacterium was originally recovered. Technological advances in high-throughput DNA sequencing in the early 2000's have made available accurate

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

sub-typing protocols that can be deployed to track foodborne pathogens across the food chain whilst describing the associated microbial communities, from which they have arisen. These advances have rapidly changed the approach to foodborne disease surveillance and the assessment of risk to human health. This paradigm shift hearlds the era of ***precision food safety***. In this presentation, examples demonstrating the application of DNA sequencing in the context of microbiological food safety will be presented. These will describe strategies used to accurately identify bacteria and genotypes of importance to food safety whilst considering challenges to food microbiological risk assessment of the future.

U.S. Food and Drug Administration Activities to Address Chemical Contaminants in Food

Paul South[1]

1. U.S. Food and Drug Administration (USA)

The U.S. Food and Drug Administration (FDA) enforces the Federal Food, Drug, and Cosmetic Act, a law intended among other things, to ensure that the U.S. food supply is safe for human consumption particularly when it may contain poisonous or deleterious substances. FDA conducts a broad range of activities to address food-borne natural and anthropogenic chemical contaminants. FDA activities include the development of analytical methods for testing food as well as targeted and non-targeted monitoring of food for contaminants. FDA also uses science-based risk analysis including risk assessment to determine if contaminants may pose a health risk, and risk management and risk communication to protect the public health.

Keywords: USFDA, chemical contaminants

SY(T8)9-5
Excess intake of micronutrients: evaluating the risks for human health

Agnes de Sesmaisons Lecarre[1]*, Laura Ciccolallo*[1]*, Leng Heng*[1]*, Laura Martino*[1] *Silvia Valtuena Martinez*[1]

1. European Food Safety Authority (Italy)

Less than one century ago, thiamine was the first vitamin isolated. An era of active research had kicked off and most essential vitamins and minerals were identified by the mid-20th century. In the wake of the discovery of their role in 'deficiency diseases', the chemical synthesis of micronutrients led to the development of treatment and prevention strategies based on single nutrient substance, consumed in the form of food supplements or fortified foods. Policies of fortification of staple foods were introduced in the 1930s and developed around the world during the whole century. These approaches were effective at reducing the prevalence of many common deficiency diseases, such as pellagra (niacin), goitre (iodine), and microcytic anaemia (iron).

However, like other chemicals, micronutrients can lead to adverse health effects if consumed in excess. As research raised concerns about too much of a nutrient, policymakers and regulatory authorities sought scientific advice to characterise and manage associated risks. The nutrition community introduced the concept of "tolerable upper intake level" (UL) in the 1990s, defined as the maximum daily intake above which a nutrient may cause adverse effects. Nutrient risk assessment adapted approaches developed for other food chemicals consisting in 4 steps: hazard identification, hazard characterisation, exposure assessment and risk characterisation. Yet, distinctive characteristics of micronutrients were recognised: there is a (lower) level of intake below which risk of deficiency or sub-optimal functioning arises, and most nutrients are subject to homeostatic regulation of body content, which provides protection against exposures above usual intakes. Early risk assessments focussed on characterising the toxicity profile of the nutrient and intake levels up to which "no adverse effect" was observed (equivalent to a 'NOAEL' for chemicals). The evidence was often limited to animal experiments, case reports or incidental findings from human trials which had aimed at exploring the potential benefits of "high dose" micronutrient intake.

Over the past two decades, the knowledge and understanding of potential adverse effects related to excess intake of micronutrients has evolved, with growing concerns that they may contribute to the risk of chronic diseases. This raises new scientific questions and challenges the traditional conceptual framework of ULs. Reflections regarding the types of effects that could inform the derivation of an UL ('biologically based model') also progressed, paving the way for novel assessment strategies. Also, scientific authorities throughout the world have strengthened their risk assessment processes through the development of systematic and transparent methodologies. Meta-analysis, dose-response modelling and structured approaches to evidence integration are increasingly used to support evidence-based conclusions.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Moving into the 21st century, the market of food supplements and fortified (‘functional') foods continues to grow, led by emerging trends: attention to physical and mental well-being, slowing down of the aging process, cure of metabolic disorders. This makes current consideration of upper levels for micronutrients highly relevant for public health. This presentation discusses the principles applied in recent nutrient risk assessments of the European Food Safety Authority, and the methodological progresses that occurred in the field.

Conflict of Interest Disclosure: None

Overview: The “Nutrient-Repositioning” -Unexpected Amino Acid Functions -

Yasuyuki Kitaura[1], Kohsuke Hayamizu[2]

1. Graduate School of Bioagricultural Sciences, Nagoya University (Japan), 2. Yokohama University of Pharmacy (Japan)

“Repositioning” is usually used to indicate drug repositioning, or the finding of new disease applications for existing, approved drugs. Nutrients such as proteins, fats and carbohydrates are substances that organisms need to live and grow. Proteins are made of amino acids which are organic compounds with amino and carboxy group. Amino acids are also degraded for gluconeogenesis as well as biogenesis of nucleic acids, phospholipids, aminosugars, hormones and neurotransmitters. Moreover, they themselves have physiological functions through their binding proteins such as leucine and arginine, activators for mammalian target of rapamycin complex 1 (mTORC1), a highly conserved serine/threonine protein kinase, promoting protein synthesis (translation) and inhibiting protein degradation by suppressing autophagy. So far, the individual amino acids have been revealed to have new physiological functions and indicated the possibilities applying them as functional food factors (also called “neutraceuticals”) for promoting human health in addition to traditional nutrients. In the pharmaceutical field, finding new efficacies of existing drugs and repurposing them for other diseases is called as drug repositioning (also known as redirecting, repurposing and reprofiling) which helps reducing the cost and risk for developing new drugs in pharmaceutical companies. As above, nutrients including amino acids have multiple functions and act as pharmaceuticals, so that we propose the discovery of effects different from the existing effects of nutrients as "nutrient-repositioning”.

The new findings of disordered BCAA catabolism for metabolic disease

Eri Wada[1,2], Takayoshi Suganami[1], Tadahiro Kitamura[2]

1.Nagoya University (Japan), 2. Gunma University (Japan)

Dysregulation of glucagon is associated with the pathophysiology of type 2 diabetes. In fact, glucagon receptor antagonists have been shown to decrease blood glucose levels in type 2 diabetes. We previously reported that postprandial hyperglucagonemia is more obvious than fasting hyperglucagonemia in type 2 diabetes patients. However, which nutrient stimulates glucagon secretion in the diabetic state and the underlying mechanism after nutrient intake are unclear.

To answer these questions, we measured plasma glucagon levels in diabetic mice after oral administration of various nutrients. We found that protein, but not carbohydrate or lipid, increased plasma glucagon levels in diabetic mice. Among amino acids, BCAAs, but not the other essential or nonessential amino acids, increased plasma glucagon levels. To clarify the molecular mechanism, we also assessed the effects of nutrients on glucagon secretion by using islets isolated from diabetic mice. In addition, we analyzed the expression levels of branched chain amino acid (BCAA) catabolism-related enzymes and their metabolites in diabetic islets. We found that the expression levels of BCAA catabolism-related enzymes and their metabolite contents were altered in diabetic islets compared to control islets, indicating disordered BCAA catabolism in diabetic islets. Furthermore, BCKDK inhibitor BT2 suppressed BCAA-induced hypersecretion of glucagon in diabetic islet. Taken together, postprandial hypersecretion of glucagon in the diabetic state is attributable to disordered BCAA catabolism in pancreatic islet cells. Considering that disorders of BCAA catabolism have been reported in the heart, liver, and brown adipose tissue in various metabolic diseases, disordered BCAA catabolism may be a common cause of various metabolic diseases, including type 2 diabetes.

We also propose that this study not only clarifies important pathophysiological aspects of diabetes but also provides potential applications for dietary therapy.

Assessment of histidine-associated pathophysiology in leukemia patients and mouse models

Boryana Petrova[1,2], Naama Kanarek[1,2,3], Alan Wong[1,2], Peter Cole[4]

1. Boston Children's Hospital, Boston (USA), 2. Harvard Medical School, Boston (USA), 3. Broad Institute, Boston (USA), 4. Rutgers Cancer Institute of New Jersey (USA)

Histidine is an essential amino acid that has several functions beyond protein synthesis; Histidine is a precursor for carnosine and histamine - anti-inflammatory and immune-modulatory molecules, as well as for trans-urocanate - a natural sunscreen molecule. Excess histidine is degraded in cells through the histidine degradation pathway. Histidine catabolism requires the coenzyme folate (tetrahydrofolate, THF), that is also required for nucleotide synthesis and other metabolic processes. This requirement associates histidine degradation with metabolic pathways that are essential for fast proliferating cells such as cancer and activated immune cells. Further, because folate is a target for anti-cancer and autoimmune diseases therapy, the histidine degradation pathway becomes relevant for these therapies, as a consumer of folate. Indeed, we have previously shown that histidine supplementation in mice, that boosts histidine degradation, sensitizes leukemia cells to the anti-folate methotrexate (MTX) through increased consumption of THF by the histidine degradation pathway. This resulted in inhibition of *de novo* nucleotide synthesis, restricted tumor progression, and improved survival of leukemia-bearing mice. These findings present an opportunity to enhance efficacy of anti-folate therapy by supplementation of histidine, and this can allow lower doses of the anti-folate drugs that are notorious for their side effects, especially in the brain. In order to advance these findings to clinical applications, we are addressing the feasibility of histidine supplementation for enhanced anti-folate treatment in the primary and secondary sites of pediatric acute lymphoblastic leukemia (ALL) - the blood and the brain, in ALL mouse models. Further, in humans, excess histidine was detected in the plasma following histidine supplementation, but currently no such data exist for the brain, and for the site of leukemia brain lesions – the cerebrospinal fluid (CSF). Therefore, we study the levels of histidine with disease progression and following anti-folate therapy in the brains of pediatric ALL patients with and without central nervous system (CNS)-involvement of the leukemia. These studies will guide further investigation in ALL mouse models, where we can identify feasibility and optimal timing and duration of histidine supplementation for enhanced anti-cancer therapy. Further, our work will inform clinical studies in patients treated with anti-folate therapy. The potential to develop modern treatments that incorporate metabolic drugs or dietary therapy enhancement is transformative for health equity: we are proposing to incorporate a cost-effective therapy or nutritional modifications, which can be financially accessible to all, in the standard-of-care regime and offer more hope to patients from underserved communities.

Effects of food ingredients on back pain and knee pain

Kenji Nagao[1]

1. Ajinomoto Co., Inc. (Japan)

Multisite pain, including low-back and knee pain, is a major health issue that greatly decreases quality of life. This study demonstrated the effects of l-serine, which provides necessary components for nerve function, and eicosapentaenoic acid (EPA), which exerts anti-inflammatory properties, on pain scores of adults with pain in the low back and/or knee for at least 3 mo. The participants were randomly allocated to either the active group (daily ingestion of 594 mg l-serine and 149 mg EPA) or placebo group. The Japan Low Back Pain Evaluation Questionnaire (JLEQ) scores at week 8 were lower in the active group. The Japanese Knee Osteoarthritis Measure (JKOM) scores at week 4, week 8, and week 12 were lower in the active group. Additionally, the active group had 11-27% better scores compared with the placebo group for the Brief Pain Inventory. No adverse events were observed. l-Serine and EPA were effective for pain relief in adults with low-back and knee pain.

Keywords: Amino Acid, Omega-3 Fatty Acid, low-back and knee pain, multiple site pain, neuropathic pain.

Dietary intervention studies and new aspects of gene – diet interactions

Maria Lankinen1, Ursula Schwab[1,2], Markku Laakso[1,2]

1. University of Eastern Finland (Finland), 2. Kuopio University Hospital (Finland)

We have a strong history of successful prevention strategies and studies for preventing lifestyle related diseases in Finland. The extremely high cardiovascular mortality in an eastern province North Karelia in Finland caused great concern in 1970s, when North Karelia project was launched. Due to this successful project, coronary mortality was reduced in middle age population by 84% from 1972 to 2014. Another good example is the Finnish Diabetes Prevention Study (DPS) which was one of the first controlled, randomized intervention studies to show that type 2 diabetes (T2D) is preventable with lifestyle intervention. The risk of diabetes was reduced by 58% in the intensive lifestyle intervention group compared with the control group. Nowadays it is known that many lifestyle related diseases

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

are multi-factorial and arise from the interaction of gene variants, lifestyle and environmental factors. This is a new important aspect to study. Understanding of complex relationship between genes, nutrition and metabolism is a way to more personalized nutrition. The most powerful study design to investigate gene-lifestyle interactions are intervention studies including individuals selected based on their genotypes. These kind of studies are scarce, since they can be done only based on large genotyped population. We have been privileged to be able to invite people with specific genotype from the Metabolic Syndrome in Men (METSIM) study including over 10 000 men with detailed phenotype and genotype data. We have recently conducted three genotype based intervention studies. The largest one compares the effects of lifestyle intervention on the prevention of T2D in people with high genetic risk for T2D compared with people with low genetic risk for T2D based on the genetic risk score including 76 risk genes. Two other interventions use a candidate gene approach with focus on *PNPLA3*, which is associated with hepatic lipid accumulation and chronic liver diseases including non-alcoholic fatty liver disease (NAFLD), and *FADS1*, which strongly regulates responses to dietary intake of polyunsaturated fatty acids. These interventions included modification of dietary fat intake. These projects aim to reveal whether the genetic screening and individualized intervention programs are needed to effectively prevent and optimize the treatment of these multifactorial, lipid metabolism related diseases T2D and NAFLD.

SY(T9)1-2
Nordic foods and diet– what can we learn about them applying metabolomics approach?

Kati Hanhineva[1,2]

1. University of Turku (Finland), 2. University of Eastern Finland (Finland)

Nordic countries are well known for their clean nature and its products. The concept of a Nordic diet has gained great research interest recently. Traditional Nordic foods such as whole grain rye, barley and oat, various Nordic berries and fruits, cabbage, roots and tubers, native fish and wild land-based animals as well as rapeseed oil have been the target of many nutritional studies, especially in the Nordic countries. Thus, the knowledge and understanding on these foods and more recently on the whole healthy Nordic dietary pattern has been increasing, and proving evidence that it may be as healthy as the traditional Mediterranean diet when composed of healthy Nordic counterparts, *i.e.* local Nordic foods. Metabolomics technology offers a possibility to study both foods and human metabolic responses on them facilitating understanding on deep interactions between food, gut microbiota, and physiological responses. Indeed, following recent advances over the last years, metabolomics has become a fundamental tool to study changes in molecular phenotype caused by molecules inherent to different exposures, including diet, and their interaction with host wellbeing, risk of disease or other outcomes. The same development has been going on in food science to investigate the effect of technological processes on the food biochemical composition that is relevant in terms of their potential health benefits. In addition, metabolomics can provide new and unexpected biomarkers of foods that are associated with disease development and prevention. In this presentation I will provide demonstration on various studies related to the Nordic foods and diet assessed with non-targeted metabolite profiling approach. I will show how metabolomics can be utilized to profile the rich biochemical content of foods, how it aids in understanding the metabolic conversions gut microbiota has on the dietary compounds, and eventually how we can utilize the technique to assess the impact diet and gut have on our endogenous metabolism and health thereafter.

Keywords: metabolomics, microbiota, food, biochemicals, metabolites

SY(T9)1-3
Successful vitamin D policy in Finland – a model for other countries?

Suvi T. Itkonen[1]

1. University of Helsinki (Finland)

Finland is an example of successful vitamin D food fortification policy that has contributed markedly to the country's improved vitamin D status in the population. This presentation gives insights into the reasons, decisions, implementation and effects of vitamin D food fortification in Finland.

In the beginning on 2000's, low vitamin D status was demonstrated as a potential public health problem in healthy adults in Finland as a consequence of a lack of dermal synthesis of vitamin D3 during the wintertime because of limited UVB irradiation and low dietary vitamin D intake. Vitamin D fortification of widely consumed staple foods, fluid milk products, as well as fat spreads started in 2002. The fortification levels were based on scenarios and the effects of implementation on the adult population's vitamin D status were strictly followed up. As the observed effects on the population's vitamin D status were not strong enough, the recommended fortification levels were doubled in 2010, the recommended fortification amounts being for fluid milk (except for organic ones) 1 microgram per 100 g and for fat spreads (not butter) 20 micrograms per 100 g. As a consequence, in 2011, the majority of the adult population had adequate vitamin D status (serum 25-hydroxyvitamin D $\geqq$50 nmol/l). Even though the fortification policy is voluntary, almost all domestic manufacturers follow the current fortification recommendations. The success story has

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

been strongly based on the willingness of the food industry to implement the recommendations. Increased vitamin D supplement use has also contributed to the improved vitamin D status. The National Nutrition Council has given instructions on vitamin D supplementation to ensure adequate vitamin D intake in the most vulnerable population groups.

Keywords: vitamin D, food fortification, 25-hydroxyvitamin D, food policy, Finland

The International Impact of Tadasu Saiki and the Imperial Institute of Nutrition (Tokyo, 1916-1945)

Josep L. Barona[1,2]

1. Universidad de Valencia (Spain), 2. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

This paper analyses the international impact of Tadasu Saiki and the Imperial State Institute of Nutrition during the interwar years (1916-1945). Is starts by presenting the figure of Dr Tadasu Saiki, his origins, his instruction as a university student in Japan, his doctoral and postdoctoral research at the United States, and the initiative to create a predecessor of Institute of Nutrition. This initiative took place at a time of very critical context, during the Great War, under very hard sanitary and dietary conditions. My paper explains the dietary condition of the population and Saiki's nutritional ideology, in order to improve the physical and physiological condition of the Japanese population. Supported by the Japanese Government, Saiki explained his experience to the authorities at the League of Nations, and his lectures and reported caused strong impact among European and American experts. As a result, the prestige and international impact of Japanese research and social policies around nutrition grew and the exchanges with international experts were frequent and fruitful.

The National Health and Nutrition Survey in Japan: a history of 75 years

Hidemi Takimoto[1], Emiko Okada[1], Mai Matsumoto[1], Ryoko Tajima[1], Tomoko Aoyama[1], Xiaoxi Yuan[1]

1. National Institute of Biomedical Innovation, Health and Nutrition (Japan)

Objectives: The National Health and Nutrition Survey, Japan (NHNS; formerly the National Nutrition Survey) has been conducted every year in Japan from 1945- 2019. From its start and to the present, it has evolved in order to focus on current public health issues, which is its unique characteristic. We aim to summarize the history and origins of this unique national survey and describe its present situation. Methods: Officially published national reports were investigated to obtain information on the aims, survey areas, subjects, and survey items of the NHNS. Results: The National Nutrition Survey in Japan was initiated with the aim of obtaining information about food supplies due to post World War 2 food shortages. After the problem of food shortage was resolved, the survey objective of the NHNS has changed, to monitor the health status of the population so that the government could comprehensively promote health in accordance with enacted laws. The survey was designed to provide national representation through randomized selection and was initially planned to assess dietary intake, anthropometric measurements, and physical symptoms among the Japanese. At present, it is conducted in three parts that collect nutrition, physical, and lifestyle data. Consequently, the purpose and content of the NHNS have expanded over time. Throughout its 75-year history, the NHNS has continued to monitor Japanese dietary intake and health status, further contributing to various national policies on health, food systems, and nutrition. However, the 2020 and 2021 surveys were not conducted due to the COVID-19 pandemic. Conclusion: The current state of health in Japan may be largely due to the contributions of the NHNS to public health through public health policy based on survey results. We hope that the NHNS continues to develop in the future, to continuously monitor the health status of the population even in times of pandemic.

AI nutrition: Application of AI technology in nutrition field

Michihiro Araki[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

The AI nutrition project started in April 2020 at the National Institute of Biomedical Innovation, Health and Nutrition. Through collaboration with the Artificial Intelligence Center for Health and Biomedical Research (ArCHER) and various researchers, we are advancing data science using artificial intelligence (AI), machine learning, and numerical analysis technology while accumulating evidence related to health and nutritional metabolism such as various cohort data, measurement data, and open data. At the same time, we are also developing AI/data analysis technology for handling multi-scale data from the molecular level to the individual/population level.

In the development of AI analysis platform, we are promoting the development of algorithms and systems that will be the basis for various high-dimensional data analysis. Specifically, in addition to developing multiple types of dimension compression/visualization technology and machine learning technology, we are also developing AI/data analysis technology that matches various data including numerical and information analysis. Using these technologies, we are developing indicators for defining health and nutrition such as frailty syndrome and estimation of total energy consumption, food classification, and so on.

As a molecular-level approach, we are building a metabolism model to accumulate metabolism-related evidence such as food and intestinal bacteria. In metabolic model development, we mainly use deep learning technology to estimate the metabolic network from genome/amino acid sequence information, that is, to develop technology for searching and designing unknown metabolic reactions. In the metabolism model analysis, we are conducting a metabolism simulation of the intestinal flora and an analysis of health food/drug interactions.

It is expected that these efforts will lead to new evidence and findings in digital health and nutrition fields, and intervention proposals for improving individual healthier lifestyles and self-care. As health issues in individual lifestyles have begun to attract attention, we aim to formulate advanced health measures in detail according to the individual's health condition through AI nutrition research.

Frontiers in Disaster Nutrition - Establishment of a special section of disaster nutrition.

Nobuyo Tsuboyama-Kasaoka[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

The Global Disaster Nutrition section was established at the National Institute of Biomedical Innovation, Health, and Nutrition in 2018. This is the first section dedicated to dealing with nutrition after disaster in Japan. The slogan of us is “evidence to action.” The mission of our section is to reduce health and nutrition problems associated with natural disasters and pandemics.

To achieve this mission, there are three main tasks: 1) Research for reducing food and nutrition problems after natural disasters, 2) development of nutritional assistance systems after disasters, and 3) provision of information and support tools.

Specifically, our section works during natural disasters to collect information about food and water using the Ministry of Health, Labour, and Welfare online Emergency Medical Information System (EMIS), in addition to other information systems in disaster areas, and to share it with the local governments and institutes responsible for providing and controlling food and water. In addition, this section provides information leaflets on disasters for nutrition and diet, hygiene control, baby and mother, and elderly and non-communicable diseases in English, Spanish, Tagalog, Hangul, Vietnamese, and Chinese on their website.

Keywords: disaster, health, nutrition, pandemics

Cost and affordability of a healthy diet: Global analyses of food prices for nutrition

William A. Masters[1]

1. Tufts University (USA)

This presentation will summarize results of global and national studies using new metrics for each population's access to a healthy diet, using retail prices of the least expensive locally available items needed to achieve nutrient adequacy and meet food-based dietary guidelines. These new metrics of diet cost and affordability were developed since 2016 at Tufts University, in partnership with the FAO and the World Bank as well as IFPRI and numerous collaborators in Africa, Asia and Latin America through a project now known as Food Prices for Nutrition. The metrics match price observations with food composition data to compute the least-cost combination of locally available items to meet nutritional needs, thereby tracking the ability of agriculture and food systems to supply healthy diets at time and place. Globally we find that about 3 billion people cannot afford even the least-cost foods needed to meet national dietary guidelines, with significant spatial and seasonal variation within countries. Least-cost diets provide an operational definition of food access, distinguishing among possible causes of inadequate diets to guide policy and program interventions. At times and places where even the least-cost items are relatively expensive, improvements in agricultural production and food distribution would be needed to reduce price. Where it is not possible to reduce diet costs, lack of affordability could be addressed through transfer programs, safety nets and social protection. For over 60% of the world's population, however, we find that retail items for a healthy diet are already affordable but may not be consumed for other reasons, including the time costs of meal preparation and preferences for attractive but less healthy items. Using least-cost diets to track affordability of healthy foods provides a useful complement to other metrics, providing internationally comparable measures for the cost and affordability of healthy diets. Methods and data have been updated by UN agencies in each annual SOFI report (FAO, IFAD, UNICEF, WFP and WHO 2020, 2021 and 2022) and also used in a variety of other settings as shown at https://sites.tufts.edu/foodpricesfornutrition. Global and subnational findings discussed in this presentation have specific relevance to closing gap in micronutrient intake, guiding food policy towards improved diets and lifelong health around the world.

Keywords: Food environments, Food systems, Diet costs, Diet quality

Conflict of Interest Disclosure: None

Further Collaborators: The Food Prices for Nutrition project is led by William Masters at Tufts University, with Anna Herforth (co-director) and numerous collaborators including partnerships with the World Bank (led by Nada Hamadeh and Marko Risannen), IFPRI (led by Derek Headey) and FAO (led by Cindy Holleman) as well as Yan Bai (World Bank and Zhejiang University).

SY(T9)4-2
Understanding expenditure patterns and choices in low-income households

Daryl Collins[1]

1. Decodis (USA)

Background and objectives. Low-income households not only earn little money but this money often comes into their households into their households in irregular streams, making it a challenge to meet daily needs as well as those across longer times periods such as a week or month, as well as expected seasonal needs and unexpected emergencies. The financial management choices of low-income households are geared not only to sustaining themselves in the present but planning for the longer-term in the context of irregular and unknown income flows.

Methods. Financial Diaries are a social research methodology which track the income, expenditure and financial management flows on a day-to-day basis for a year. This paper will draw from Financial Diaries from South Africa, Kenya, India, Pakistan, Mozambique, Tanzania and Mexico.

Results. Because many low-income households rely on irregular income flows from small business and farming, their financial management practices necessarily aim to be restrictive on a day-to-day basis in favor of ensuring money is available at a future time. Although nutritional intake is a daily imperative, low-income households also know that money must be set aside for other needs at other times. The type and amount of food is consumed therefore is not consistent day-to-day but can change dramatically depending on households' income patterns and how sure they are of income coming at a specific time in the future. Therefore, households can deliberately choose to spend

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

less than they could on food in favor of saving for emergencies, an opportunity or an important event in the future.

Conclusions. Dramatic differences in the amount and types of food that low-income people eat from day-to-day and week-to-week need to be taken into account when considering how best to understand and improve nutritional deficiencies within low-income households.

Keywords: financial diaries, food expenditure, income variability

SY(T9)4-3
Applying tools for estimating lowest-cost nutrient-adequate and healthy diets for the design of food assistance and social protection transfers

Saskia de Pee[1], Mysbah Balagamwala[1], Zuzanna Turowska[1], Lindsey Wise[1], Chris Coffey[1], Geraldine Honton[1], Jo Jacobsen[1]

1. World Food Programme (Italy)

Background and objectives. Cash, food and other income-type transfers are used for social assistance as well as food assistance to enable families to better meet their essential needs, including for food. The transfers may be packaged together with other goods and services aiming to achieve specific purposes such as women's empowerment, preventive health care coverage, prevention of malnutrition, school enrolment etc. We will share recent experiences of how the cost and affordability of nutrient-adequate diets were used to inform design of transfer packages, including setting transfer value as well as inclusion of complementary services, in different situations, to increase potential of these programmes to prevent malnutrition.

Methods. Data on availability and prices of foods from different food groups in local markets as well as food expenditure data were used to estimate the lowest possible cost and affordability of nutrient-adequate diets in Nigeria, Somalia and Kenya, and used to propose transfer packages for nutrition-sensitive food assistance for families in North East Nigeria, young children and pregnant and breastfeeding women at-risk of undernutrition in Somalia, and a nutrition-sensitive universal child benefits grant in Kenya.

Results. The lowest possible costs of nutrient-adequate diets were substantially higher than target population's food expenditure in all three countries, and it was not possible to close the entire affordability gap with cash/food assistance alone as the transfer value would have had to be much higher than what the programs could afford. However, based on the programs' goals, the information on local food availability and prices as well as other service delivery platforms that could reach the intended participants through their respective modalities, options to improve transfer design were proposed and scenario estimations for impact on cost and affordability performed.

Conclusions. Estimation of cost and affordability of healthy, nutritious diets for families as well as for specific target groups, coupled with information on what foods are available in their food environment, at what cost and on how they are spending their resources including on which foods, should be used to inform the design of nutrition-sensitive transfers for food assistance, prevention of malnutrition packages as well as social assistance.

Conflict of Interest Disclosure: The authors have no conflict of interest to report.

SY(T9)4-4
Promoting Healthier Diets: A Practical Fiscal Policy Framework

Stella Nordhagen[3], Daniel Maceira[1], Alen Jimenez[2], Valeria Iñarra[2]

1. University of Buenos Aires (Argentine), 2. Center for the Study of State and Society (Argentine), 3. GAIN (Switzerland)

Motivation: The quality of the diet and the prevention of associated risk factors are topics of growing interest among actors interacting in health systems. Nutritional habits and lifestyles are closely related to health status and future exposure to certain types of non-communicable diseases. Improving health outcomes demands a shift to diets that comply with higher nutritional standards. Fiscal policies are tools widely used to encourage or discourage specific habits in the population, but not necessarily effective for all foods.

Objective: to present a comprehensive analytical tool for the design of an informed fiscal policy, in order to promote better alimentary decisions.

Methodology: The document defines each product based on three characteristics, which interact with each other: a nutritional quality measure; its estimated demand price elasticity; and the gap between actual and desired consumption. Measures of food quality are based on international definitions (GAPA: to promote, to limit and to discourage; and NOVA: fresh, processed, ultra-processed), applied to each food product present in the Argentine National Consumption Survey (ENGHo) produced by the National Statistical Institute, and own demand price elasticities were calculated (based on AIDS and Heckman approaches) to key food products. Moreover, consumption gaps provide information regarding the percentage deviation between the optimal and current diet followed by the population. Overall, the document introduces a three-dimension cube to analyze policy interventions.

Results: For Argentine households, we find that, by and large, the more unhealthy a food family, the more price elastic and, hence, targetable with taxes. Healthier food groups also reveal some degree of price sensitivity in their demand, which suggests that there may be some room for the introduction of subsidies to their price. At the same time, a third dimensional

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

analysis identifies under and over consumption of certain products.

Policy implications: While taxes may reduce the consumption of low quality products, alternative interventions may be adequate for other parts of the food product space. In addition, the gap between current and ideal consumption serves as a reference for the intensity of the intervention.

SY(T9)5-1
Improving the quality of child malnutrition data for SDG monitoring: mapping the unfinished research agenda

Sorrel ML Namaste[1], On Behalf of the Anthropometry Working Group

1. The Demographic and Health Surveys (DHS) Program, ICF (USA)

Accurate data on child malnutrition is a key input for national governments and partners to develop and implement appropriate policies and programmes to address the nature and scale of malnutrition in their unique contexts. Height/length and weight are the most common anthropometric measurements used to define malnutrition. While seemingly simple, it has proven difficult to obtain accurate and precise measurements in population-based surveys and there have been concerns over the quality of these data. This precipitated the WHO and UNICEF to develop recommendations on the collection of anthropometric data in representative surveys. Using evidence-based information and expert experience, criteria and standards for collecting, analysing, and reporting malnutrition estimates were developed. The result has been remarkable progress in strengthening existing anthropometric measurement procedures and the adoption of new procedures in large-scale surveys, which has been shown to improve the quality of anthropometric estimates. Yet, there are many questions still to be answered. To advance this effort, the WHO-UNICEF Technical Expert Advisory Group on Nutrition Monitoring (TEAM) formed an Anthropometry Working Group to set a global research agenda. Based on a collaborative, iterative consensus-development process the group identified nine research topics: 1) definition and use of biologically and statistically derived anthropometric z-score flag values, 2) thresholds for anthropometric data quality indicators, 3) making the standardization process easier to administer during training, 4) identification and disentanglement of random and systematic error, 5) accuracy of collecting a single versus multiple height/length measurements, 6) minimizing the impact of hair and clothing obstruction in height/length and weight measurements, 7) best practices and value of conducting re-measurement during field work, 8) effective collection of age data to generate anthropometric z-scores, and 9) innovations in measurement equipment.

The release of briefs for each topic are planned on the research questions, type of research, primary and secondary outcomes, and data source with the intent of serving as a catalyst for addressing research in these areas. This talk will cover key research questions on anthropometric data collection in a survey context and offer insights on approaches to answer these questions. For anthropometric data to be beneficial to decision making, it is essential to increase engagement and investment in research on the 'how to' of collecting high-quality anthropometric data.

Meeting the measurement needs of the changing face of children's diets around the world

Vrinda Mehra[1], Julia krasevec[1], Chika Hayashi[1], Laurence Grummer-Strawn[2], Kuntal Kumar Saha[2], Trevor Croft[3], Mary Arimond[3]

1. UNICEF Data & Analytics Section (USA), 2. WHO (Switzerland), 3. The Demographic and Health Surveys Program, ICF (USA)

Background and objectives: Indicators for assessing infant and young child feeding practices (IYCF) were published in 2008 with an accompanying operational manual released in 2010. In the years following their introduction, these indicators have been used to assess the status of and monitor progress in child feeding practices using data gathered mainly through large-scale surveys such as the Demographic and Health Surveys and the Multiple Indicator Cluster Survey. Following a decade of experience using the 2008 edition of the IYCF indicators, UNICEF and WHO organized technical consultations to revisit, refine and expand the set of recommended child feeding indicators, and released updated global guidance in 2021.

Results: Experience using the recommended IYCF indicators has raised some challenges related to definitions and operationalization. The updated global guidance addresses the issues highlighted during the technical consultations by revising the definitions for five out of the 15 previously existing indicators, excluding four indicators published in the 2008 guide from the 2021 edition due to challenges related to their interpretation, communication and operationalization and adding seven indicators that better measure the changing face of children's diets. For example: a major issue was that the minimum dietary diversity indicator, as defined in 2008, did not count breast milk as part of the diet diversity food groups while counting formula and milk, which led to breastfed children showing up as having less diverse diets than their non-breastfed peers in many contexts. Despite specific instruction against

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

comparing breastfed and non-breastfed children in the previous guidance, experience showed that such comparisons were often made, which made assessment between breastfed and non-breastfed children unfair and inconsistent. To address this problem, minimum dietary diversity was revised to include breast milk as an additional food group. Another key issue was the lack of recommended standard indicators related to unhealthy feeding practices, which evidence suggested was a growing problem in many countries.

Conclusion: In total, the 2021 guidance has 17 recommended indicators, including the first ever global standard indicators to measure unhealthy eating practices. These indicators are key for supporting programmatic action and monitoring progress on IYCF at national and global levels.

Keywords: nutrition, infant and young child feeding practices, diets.

Advancing methods, metrics, collection, and use of data on nutrition intervention coverage at household level

Rebecca Heidkamp[1,2]

1. Johns Hopkins Bloomberg School of Public Health (USA), 2. WHO-UNICEF Technical Expert Advisory Group on Nutrition Monitoring (TEAM) (Switzerland)

Coverage is generally defined as the proportion of the population who should receive a program, intervention or service that actually do receive it. It is a more proximal indicator of policy implementation than more distal outcomes including diet quality as well as micronutrient and anthropometric status. Many governments, implementing partners, donors, and advocates rely on periodic large-scale household surveys such as Demographic Health Survey (DHS) to monitor whether priority populations are equitably covered by nutrition policy actions. Administrative data also play a roll. Recent efforts to map the availability of coverage data for interventions included in national multisector nutrition plans across South Asia and West Africa identified multiple data gaps. This presentation highlights the progress that WHO-UNICEF TEAM and other initiatives are making to improve nutrition intervention coverage measurement across low and middle income countries (LMIC), while summarizing key research gaps and operational challenges that remain.

TEAM has supported multi-stakeholder efforts to develop new coverage indicators and advocate for their collection. The 2017 Global Nutrition Monitoring Framework highlighted gaps in infant and young child feeding (IYCF) counseling coverage. In 2018, new IYCF counseling coverage indicators were endorsed by TEAM and adopted in the global DHS-8 questionnaire which is used in more than 90 countries. Ongoing indicator development work aims to fill data gaps or improve validity of metrics for coverage of maternal nutrition interventions during pregnancy including the gradual transition from iron folic acid to multiple micronutrient supplements as well as for nutrition-sensitive social protection and other nutrition interventions outside of the health sector. Recent investments in administrative data, including release of a core nutrition module for DHIS-2, also help fill information gaps on who is being reached with IYCF counseling, growth monitoring and promotion and acute malnutrition treatment.

TEAM and others are also working to improve collection and use of coverage data in countries. Recent National Nutrition Information Systems guidance emphasizes the importance of defining common core indicators and developing national and sub-national data strategies with explicit budgets and financing plans to ensure data are available to meet decisionmakers' needs. Nigeria and India are two examples of countries that feature intervention coverage data on scorecards, dashboards and sub-national profiles for nutrition audiences. Finally ongoing work to develop flexible methods for assessing co-coverage and composite coverage across multiple nutrition interventions will further support the use of data for planning and implementation of multisectoral nutrition strategies in LMIC.

Looking ahead, more research and collaborative effort is needed to define indicators of implementation quality and effective coverage of nutrition interventions within and beyond the health sector. There is also need to address cost challenges of regular population-based data collection, working on innovations in mobile surveys and other innovative sources of information about who is being reached.

The Healthy Diets Monitoring Initiative: toward the development of healthy diet metrics for national and global monitoring

Jennifer Coates[1], Edward A. Frongillo[2], Francesco Branca3, Lynnette Neufeld[4], Victor Aguayo[5], Shelly Sundberg[6], Sara Farley[7], Kuntal Saha[3], Chika Hayashi[5], Elaine Borghi[3]

Unhealthy diets and the associated burden of disease are a concern worldwide, with many countries grappling with nutrition and health issues caused by co- existing undernutrition and overweight and obesity. Healthy diets are critical for achieving several Sustainable Development Goals and the World Health Assembly global nutrition targets. Yet, no dietary intake indicators have been adopted for tracking progress toward these

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

global targets in populations over 2 years old, and few countries routinely monitor their population's dietary intake to inform their own policies and programs. The limited availability and use of dietary data are due, in part, to the lack of consensus on which measures and indicators should be used to capture important components of healthy diets with validity across settings and populations. This lack of consensus dissuades countries and donors from investing in data collection and use, hampering the tracking of their progress towards improved diets.

In collective recognition of this challenge and the need for action, WHO and UNICEF, through their Technical Expert Advisory Group on Nutrition Monitoring (TEAM), have joined forces with FAO to resolve these issues and chart a way forward through the Healthy Diets Monitoring Initiative. The Initiative is guided by a Strategic Planning Group that includes the Nutrition Division Directors from the three UN agencies, as well as TEAM Co-chairs and Secretariat, the TEAM diet quality technical working group, and key donors. The presentation will summarize: 1) the goals and objectives of the Healthy Diets Monitoring Initiative, 2) components of a healthy diet to prioritize for global and national monitoring, 3) an overview of the relative strengths and weaknesses of a range of diet quality metrics and tools, 4) plans for future research and potential next steps for achieving consensus and engagement with the broad community of stakeholders who are concerned with the assessment and monitoring of healthy diets.

What “Japan Nutrition” has achieved and how can it contribute globally

Teiji Nakamura[1]

1. Kanagawa University of Human Services (Japan)

Before the Meiji Restoration, during the modernization of Japan, the diet of most Japanese people was simple and suffered from many nutritional deficiencies. 150 years ago, Japan modernized its nation and introduced nutrition science to improve its undernutrition diet due to its traditional staple food bias. It also controls obesity and non-communicable diseases caused by westernization of the diet after high economic development, and maintains a healthy and long-lived country. The reason is that the government, universities, industry, and professional associations have collaborated to improve nutrition as a national policy.

After the war II, our country suffered from severe hunger and imported food from the USA. At that time, we purchased vehicles and used these vehicles to provide nutritional education in every corner of the country. The improvement of nutrition in Japan took place through both food distribution and nutrition education. The nutrition educational vehicles were not food trucks that distributed food, but a vehicle that was used for education and to promote nutrition. Nutrition education does not relieve hunger or provides good taste, but it was the seed for a lifetime of health and happiness. In the end, Japan nutritional improvement have changed the food policy of USA into a nutrition policy.

We have trained many nutritionists and dietitians who are nutritional professionals, and placed them in every place of society according to the nutritional polices. For example, dietitians have provided school lunches and nutrition education in schools, managed clinical nutrition and dietary therapy for the sick in hospitals and welfare facilities and promoted for workers through company cafeterias, restaurant, and catering industries. Today, the program of school lunch has become a place for comprehensive learning about agriculture, fisheries, labor, nutrition, cooking, health, manners, spirit, human relations, food hygiene, environment, and culture.

This Japan's century-long history of nutritional improvement has created a social environment where currently people can access healthy food and receive nutritional education, no matter where they eat. We created a healthy Japanese-style diet by appropriately mixing a traditional low-nutrition diet with a high-nutrition Western diet.

“Green recovery" has been called out as a post-corona reconstruction plan, and diets with low greenhouse gas emissions are being considered. The amount of greenhouse gases emitted by the Japanese from livestock is less than half of the global average by FAO. The reason why we were able to create a healthy diet with less environmental impact is that Japan has introduced and practiced nutrition while inheriting the traditional food culture that respects nature.

We call this unique Japanese approach to nutritional improvement “Japan Nutrition”, and we want to share it with the world and contribute to the solution of malnutrition.

What has been done and should be pursued for Vietnamese nutrition system?

Nguyen Do Huy[1], Shigeru Yamamoto[2], Tuyen Danh Le[1], Teiji Nakamura[3], Yasuhiro Kido[7], Nobuko Murayama[8], Tri Ta[4], Kenji Shinkai[6], Eriko Kondo[6], Ngoc Duc Dang[5]

1. National Institute of Nutrition (Viet Nam), 2. Jumonji University (Japan), 3. Kanagawa University of Human Services (Japan), 4. Vietnam Ministry of Education and Training (Viet Nam), 5. E hospital (Viet Nam), 6. The Ajinomoto Foundation (Japan), 7. Konan Women's University (Japan), 8. University of Niigata Prefecture (Viet Nam)

In 2011, the National Institute of Nutrition, Hanoi Medical University and Ajinomoto group launched the Vietnam Nutrition System Establishment Project (VINEP) with the aim of developing, training and utilizing “messengers” who can deliver knowledge of accurate nutritional information and awareness of nutrition-related issues among Vietnamese citizens. The group set three steps of activities to achieve the purpose of VINEP that are: Step1) Establishment support of dietitian training course/education system, Step2) Establishment support of national nutrition-related laws/code and Step and 3) National wide expansion support of established nutritional systems. The results of VINEP that are: 1) The country's first dietician training course was established by ministry of education and training (MOET) at Hanoi Medical University (HMU) in 2013, and in 2022, there are 12 universities conducting dietitian training courses, 2) The sub-Vietnamese Dietetic Association (Sub-VDA) as a precursor of VDA was established by the Vietnam Nutrition Society in 2014, stimulating to establish VDA in 2019, 3) VINEP has also worked alongside the governments to provide regular nutrition-related workshops/symposium to determining the first legal occupational status of dieticians (job code, 28/2015/TTLT-BYT-BNV) by ministry of health (MOH) in 2015, 4) HMU produced the country's first qualified 43 dieticians in August 2017, with the advocacy activities of VINEP, 5) The regulation of one dietitian pers 100 beds in hospital was approved by government (Circular 18/2020/TT-BYT stipulating nutritional activities in hospitals issued by the Ministry of Health) and VINEP continuously drives to establish more advanced nutritional systems for “nutrition standard” to help dietician actual activity. Through the improvement of infrastructure to convey accurate nutritional information through the enhancement of a nutritional system, VINEP contributes to raise and disseminate accurate nutritional knowledge to the whole country. Through such efforts, dieticians who have acquired proper knowledge of nutrition will help Vietnamese citizens improve their nutrition on their own initiative. Future plan of VINEP: 1) Establishing more advanced nutritional systems for “nutrition standard”, 2) Strengthening existing VDA, 3) Cooperation with multisectoral, public and private partners to develop and implement of school nutrition project that combines school lunch and nutrition education at elementary schools in Vietnam.

Meaning of VINEP in global nutrition contexts

Yasuhiro Kido[1]

1. Konan Women's University (Japan)

In 2011, Ajinomoto Co., Inc. launched “Vietnam Nutrition System Establishment Project (VINEP) ”with the National Institute of Nutrition of Viet Nam, and four years dietitian training course was started at Hanoi Medical University in 2013. The Japan Dietetic Association, Jumonji University, Kanagawa University of Human Service, and others cooperated in the projects, and the first 43 dietitians were fostered in Viet Nam in 2017. In 2022, there are 12 universities conducting dietitian training courses in Viet Nam. Furthermore, the Ajinomoto Foundation has been continuing this project since 2017, and supporting the creation of a sustainable education system that will enable dietitians to play an active role. The results of VINEP that are: 1) the dietitian training course has been established. 2) the job code has been established. 3) the Vietnamese Dietetic Association (VDA) has been established. 4) the regulation of one dietitian pers 100 beds in hospital was approved by government. In order for the newly fostered dietitians to play an active role in improving the health of people in Viet Nam, the nutrition education system still needs to be improved. In countries where nutrition education systems have not been established, establishing a nutrition education system and taking on the roles of maintaining and promoting the health, preventing and treating diseases, and preventing nursing care of the people will greatly contribute to improving in global nutrition contexts.

Trial of school nutrition program in Vietnam

Nobuko Murayama[1]

1.University of Niigata Prefecture (Japan)

The double burden of malnutrition is emerging as a health and nutrition challenge in Vietnam. Obesity, energy and micronutrient deficiencies have been reported in school-aged children. Childhood obesity needs to be corrected as it leads to later obesity, both physiologically and behaviorally. In addition, energy, protein, and micronutrient deficiencies during childhood may lead to stunting of growth and development and need to be corrected. Nutritional interventions for school-aged children include school lunches. School lunches are being introduced around the world because of their strong points of direct provision of food, which ensures the effectiveness of nutritional interventions, motivates parents to send their children to school to receive an education, and activates local agriculture. On the other hand, the nutritional benefits of school lunches have been considered to address energy and nutrient deficiencies. However, it has not been considered as a solution to the problem of obesity. Japan's school nutrition programs are unique in that they integrate school lunch and nutrition education. This may contribute not only to nutritional deficiencies, but also to improving children's knowledge, attitudes, and skills, and to improving obesity through behavior change. Therefore, with the aim of improving the double burden of malnutrition, the Vietnamese-Japanese team has initiated a trial of a Japanese-style school nutrition program in Vietnam in 2020, which will include the development of nutrition education programs and teaching materials, along with a review of school lunch menus. Online training was provided to Vietnamese dietitians. The menu pattern for school lunch is a combination of a staple meal, a side dish of meat, fish or egg, and a side dish of vegetables. A Vietnamese healthy plate was created to show the appropriate amount. The KAP model was used for the nutrition education intervention, and instructional plans and materials were developed for nine topics, including quality and quantity of a meal, quality and quantity of snacks, importance of breakfast, exercise and hand washing. Methods for monitoring leftover food surveys, survey design for effectiveness testing, and survey instruments were developed. The program has since been suspended due to the spread of the COVID-19 infection, but is scheduled to resume in 2022.

Childhood nutrition practices may have a positive impact on nutrition behavior in adulthood. School nutrition programs, coexistence of school lunch and nutrition education, are effective for behavior change and nutritional status. The research will be carried out in September 2022, in order to apply the Japanese school nutrition model in Vietnam, include school lunch and nutrition education. The specific objectives of this study examine effects of school lunch and nutrition education on the knowledge, attitude, behavior (KAP) and nutritional status of school children, and on KAP of parents. This study will investigate the benefits of the school nutrition program and then spread to other parts of Vietnam. The study will be carried out in 02 primary schools, in urban and rural areas. School meal interventions and nutrition education communication will be part of the research. Nutrition education will be conducted for 2 months and include 8 lessons based on the Japanese Nutrition Education Programs. The following are the contents of the eight lessons: 1. A healthy meal 2. Grains group 3. Vegetables group 4. Main dish 5. Breakfast 6. Snacks 7. Exercise 8. Hand washing The study was able to assess the impact of nutrition education and school lunch on both parents' and children' KAP as well as their nutritional status. As a result, it is possible to introduce changes that are relevant to Vietnam and intervene in a broader manner.

Vietnam is updating primary school curricula and textbooks in order to help students develop physically and mentally; traits and capacities; self-awareness, family, and community values; study and living habits. For primary school students, health care

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

knowledge and skills are integrated in all subjects, especially Physical Education is the first goal. The focus is on equipping students' health care knowledge and skills. Knowing and implementing some basic requirements of integrated nutrition at the beginning of physical education lessons is one of the competencies required in elementary school students. 5th grade students need to have knowledge of " Exercise Nutrition ". However, the teaching of nutrition for primary school students currently faces many difficulties. PE teacher and general teachers have had knowledge of nutrition, but do not have a curriculum suitable for primary school students. After participating in the study on the application of 8 nutrition lessons for students based on the Japanese school nutrition program at 02 schools in 02 provinces in Vietnam. We recognize that this approach, if implemented in Vietnamese primary schools, will be an effective solution to help Vietnamese primary children gain health-care knowledge and skills. In the near future, we hope to carry out this research model in 5 provinces (with 2-3 districts each) representing the Regions in Vietnam. The next phase is to develop the model, submit it to the national scientific council for approval, provide a recommendation to the Ministry of Education and Training (MOET), organize training for teachers and guide the application of the results of this study. The output of this partnership is Vietnam's school nutrition program.

Building capacity to scale-up improved inpatient treatment of severe malnutrition: experiences of South Africa

Shuaib Kauchali[1], Ann Ashworth[2]

1.National Department of Health (South Africa), 2. London School of Hygiene and Tropical Medicine (UK)

Background and objectives: As a middle-income country, South Africa reported that 27% of children under 5 years are stunted and 15% are underweight. Ten-percent of under-5 inpatient admissions were severely malnourished (SAM), contributing at least two-thirds to in-hospital death rates. South Africa embarked on a national program to scale up the WHO 10-Steps Guidelines (WTS) using quality improvement approach from 2008 when inpatient case fatality rates (CFR) were as high as 20%. We describe the approach we took to half the national CFR between 2008 and 2021.

Methods: We reviewed the routinely reported inpatient admissions and deaths data from 2008, and evaluated the impact of multidisciplinary healthcare worker training, building systems and changing care processes at all levels of care, with a focus on improving quality of inpatient care. We applied a 'whole system' accountability approach and developed 'ways of governing' and supporting facilities to overcome implementation challenges. We also developed standard treatment guidelines, job aids and monitoring and evaluation tools for facilities to use and report against.

Results: In 2008/9, there were 12,028 admissions and 2,311 deaths (CFR of 19.2%) to inpatient units reported across the country. Between 2008 to 2012, training on the WTS were conducted, followed by intensive continuous provincial and district level technical assistance, frequent data reviews and focus on ensuring high levels of clinical and systems reliability in care of SAM inpatients between 2012 and 2017. Facility improvement teams also reported their monthly performance at organised district management teams review meetings. Currently, all inpatient facilities admitting SAM cases were implementing the WTS. There has been a steady decline in the CFR from 2009 (19.2%) to 7% in 2021, with both numbers of

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

admissions (8,093) and deaths (568) decreasing during observation period.

Conclusions: The traditional approach to reducing CFR by changing clinical practices through training and "pushing" principles of adherence to WTS is a necessary step but not sufficient to achieve sustained improvements we have observed. Adding a layer of accountability ("ways of governing") and continuously reviewing the performance at facility level ensures a supportive environment to institutionalise the recommended care practices.

Building capacity to scale up improved inpatient treatment of severe acute malnutrition in Bolivia

Ana Maria Aguilar Liendo[1]

1. Universidad Mayor de San Andres (Bolivia)

Background and objectives: Severe acute malnutrition (SAM) remains a current issue in many parts of the world, undermining young children's well-being and survival. Bolivia has adopted an integrated management approach for SAM recommended by UN organizations; this includes early identification and treatment in primary health facilities. However, inpatient care is needed for severely ill children with life-threatening complications. Bolivia was an early implementer of the World Health Organization (WHO) guidelines for inpatient management of SAM. Implementation started as a pilot, and the immediate reduction in mortality helped the guidelines to become established within the health system, and be scaled-up nationwide. The presentation will describe the steps used in Bolivia to build capacity for implementing and scaling-up the WHO guidelines across the country, factors that contributed, and limitations encountered in the process. **Methods**: Qualitative and quantitative data of case management in health facilities were reviewed, along with staff reports, findings from workshops, supervisions, and published papers related to implementation. The review was complemented with structured interviews with key actors working in primary care and hospital settings to fill gaps. **Results**: The WHO inpatient guidelines for SAM were implemented successfully in Bolivia's National Health System after an initial application which demonstrated reductions in case fatality rates from around 25% initially to 5-7%. Building capacity and scaling up was possible through political commitment and a support network of policy makers, academic institutions, and scientific societies. Data analysis showed: i) adoption of the guidelines by designated hospitals, ii) availability of appropriate supplies to manage SAM, iii) reduction of SAM cases, and iv) continuation of low case fatality rates.

Conclusions: Capacity to implement and sustain WHO inpatient SAM guidelines in the entire health system involved many steps, complex logistics, and the support of policy makers, academia, and scientific societies; the logistics needed for sustainable management must be embedded in the health system's structure and budget.

Building capacity to Scale up improved inpatient treatment of severe malnutrition: experiences of Malawi

Sylvester Kathumba Kathumba[1]

1. Ministry of Health, Malawi (Malawi)

Community-based management of Acute Malnutrition has been successfully implemented in Malawi since 2002. However, the bottleneck to the efficient programme delivery has been poor quality of care for children with severe acute malnutrition admitted in the inpatient care units. Ministry of Health with support from partners has been addressing malnutrition challenges through integration of CMAM into routine health services, multi-sectoral approach to dealing with the challenges and quality improvement in the inpatient care unit for severely malnourished children. The Malawi experiences details actions taken by the Ministry to improve quality of care through training and supportive measures. To improve quality of care the Ministry with support from partners implemented a cascade of activities. After the review of CMAM Guidelines in 2016, the Ministry set up a team of Master Trainers in Inpatient Care who were trained by Region WHO Trainers for Inpatients Care. These master trainers were responsible for training and setting up National Trainers. So the National Trainers have been providing capacity building support to 104 inpatient care units in the country. Each of the 104 Inpatient care Unit has facility-based mentor who provides technical support when required. The Ministry also introduced Quality Improvement (QI) approach. Each district identified factors associated with high mortality and set up strategies to improve quality of care and Programme outcomes. The QI Approach the inpatient care facilities were able to systematically identify problems and causes of the high death rate and develop priority solutions to improve case management. During the period of the intervention, the Ministry observed improvement in 5 aspects of children with severe acute malnutrition management especially in 7 health facilities which had case fatality rate of over 10%. These aspects include; assessment of medical and nutrition complications which was at 94.6% after 17 months of implementation from a baseline of 23%. Prevention of dehydration was at 95.8% from 20.6%. treatment of dehydration was at 92.9% from 14.1%. Cautious

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

feeding was at 94.7% from 26.7% and finally death audits within 72 hours of death from 0% to 50% in the 17th month of quality improvement approach. Through the training of Health Service Providers, the Ministry was able to build confidence in service deliver and controlled the death rate to less than 10%. Other underlying causes of high death rates in the inpatient care such as late presentation, mismanagement of emergency cases in the outpatient section and inadequate availability of essential supplies and equipment need to be resolved.

Building capacity to scale-up improved inpatient treatment of severe malnutrition: experiences in Ghana

Reginald Annan[1], Linda Nana Esi Aduku[1], Samuel Kyei-Boateng[1], Alan A. Jackson[2], Ann Ashworth[3], Sunhea Choi[2]

1. Kwame Nkrumah University of Science and Technology (Ghana), 2. University of Southampton (UK), 3. London School of Hygiene and Tropical Medicine (UK)

Background: Scaling up management of severe acute malnutrition (SAM) using the WHO guidelines has a very great potential to reduce child mortality, but it requires improved operational capacity in LMICs. The malnutrition eLearning developed by University of Southampton and the IMTF provided an opportunity for SAM management scale-up, and support for its integration into curricula was seen as an added opportunity for continual utilization of the course.

Objective: We describe the identification and training of educators/trainers of pre-service institutions and the impact on course utilization and integration.

Methods: A survey was conducted of 11 pre-service health institutions to assess prior teaching on malnutrition and utilization of eLearning in teaching, and 22 trainers/educators were invited to a two-day workshop. Pre-workshop questionnaire assessed current teaching and opportunities for eLearning integration. During the workshop, actions plans for course integration were developed by each institution. Follow-up for 12 months was used to evaluate the utilization of the course and its integration into the curriculum at the institutions.

Results: Pre-workshop, only 2 of the 11 academic institutions used eLearning for teaching, and teaching on malnutrition was superficial. Workshop participants described what health professionals should know and be able to do regarding SAM; their roles as educators in achieving this; gaps in current teaching on SAM; challenges of face-to-face training of existing and future health professionals, and how the malnutrition eLearning could help address these gaps. Educators were equipped with skills and techniques for integrating the course, which included taking the malnutrition eLearning course themselves, creating awareness of the malnutrition eLearning course, engaging with institutional managers on course integration, reviewing existing curricula, and integrating the course into teaching/training. All 11 institutions developed action plans for integration. At the 12-month follow-up, 6 institutions had integrated the malnutrition eLearning into their existing courses, 1 reported that curriculum integration was in progress and 1 institution was using aspects of the course for teaching. Currently, all 11 institutions use the course.
Conclusion: The workshop created awareness for eLearning in teaching, and equipped educators on integrating malnutrition eLearning into teaching and curricula, and improving course utilization.

Redefining concepts and methods for nutrition sciences. What sets it apart from medical sciences?

Hinke Haisma[1], Marjukka Kolehmainen[2], Isabel Slurink[3], Stefania Noerman[4], Anna Danielewicz[5], Jakub Morze[5]

1. University of Groningen (Netherlands), 2. University of Eastern Finland (Finland), 3. Tilburg University (Netherlands), 4. Chalmers University of Technology (Sweden), 5. University of Warmia and Mazury in Olsztyn (Poland)

Background and objectives: The Federation of European Nutrition Societies (FENS) has established three working groups on the topic of improving the standards of nutrition. Working group 1, which is composed of 28 nutrition scientists across Europe, focuses on concepts and methods and takes as a starting point that nutrition science is about the *maintenance of health*, and not just about the prevention of disease. This raises challenges in issues of: cause and effect; hierarchy of evidence; the use of biomarkers, and participatory approaches. The objective is to contribute to the debate about why and how concepts and methods for nutritional sciences are different from concepts and methods used in medical sciences.

Methods: We chose five exemplary topics to illustrate what sets nutrition sciences apart from medical sciences by doing scoping reviews based on Web of Science, Scopus and Pubmed assuring a wide range of perspectives from both the natural and social sciences.

Results: The five examples are: (1) Sugar and quality of life; (2) Vitamin D and cardiovascular diseases; (3) Vitamin D and COVID-19; (4) Failure to adhere to dietary interventions; (5) Overweight prevention in low SES populations. Examples 1 and 2 provide an in-depth exploration of both clinical and community-based epidemiological studies to provide guidance for the design of

future similar studies. Example 3 concerns the ranking of papers based on their statistical approach and the construction of a statistical model followed by both internal and external validation. Example 4 focuses on observational studies and will contribute to our understanding of why we may miss effects of an intervention because of poor compliance. Example 5 specifically explores the added value of participatory approaches as a bottom-up approach that gives voice to those who have not been heard, and is thus well suited for marginalised individuals or population groups.

Conclusions: At the conference a synthesis of the above-mentioned examples will be presented as well as a recommendation for concepts and methods in nutrition science tailored to better address the current complexities in nutrition challenges in clinical and societal applications.

Keywords: concepts, maintenance of health, cause and effect, hierarchy of evidence, participatory approaches

Conflict of Interest Disclosure: The authors declare no conflict of interest.

SY(T9)9-2
How can the credibility of nutrition science be improved? An update of FENS-WG2

Federico J.A. Perez-Cueto[1], Alessandra Bordoni[2], Jutta Dierkes[3], Kirsi Laitinen[4], Jan de Vries[6], Theo Ockhuizen[7], Philip Calder[5]

1. Umeå University (Sweden), 2. Università di Bologna (Italy), 3. University of Bergen (Norway), 4. University of Turku (Finland), 5. University of Southhampton (UK), 6. De Vries Nutrition Solutions (Netherlands), 7. Nutricom (Netherlands)

Background and objectives: The Federation of European Nutrition Societies (FENS) has organised three working groups to improve the standards of the Nutrition field. Working Group 2 (WG2) deals with organisation, capabilities and funding. The field of nutrition has faced issues of credibility due to contradictory messages often resulting from financial conflicts of interest. WG2 require an in-depth evaluation of how funding affects nutrition education and as result, how the field is currently organised, often in complex relation other disciplines. Hence, it addresses how nutrition science is communicated within the scientific world; and, how it can better recognize and deal with conflicts of interest resulting of interactions with different stakeholders, including industry.

Objective: To report on the progress of WG2, with focus on how nutrition educations in EU and the funding opportunities interplay in shaping nutrition research and science, and how both can contribute to improving the credibility of the discipline.

Methods: Qualitative approach in two phases a) Inventorying of educations and funding landscape for nutrition in EU and beyond through desk research in 2021; and b) Refining education and funding through questionnaires sent to FENS members. **Results**: WG2 developed a framework of definitions for nutrition science, research, education and promotion. Nutrition is an integrative science that bridges disciplines and actors through the food chain. The focus and methodologies of nutrition education varies between and within EU countries, as it is integrated in disciplines from medicine to agriculture. Public funding is not always clearly addressed to nutrition, as it is part of larger disciplinary calls. Industrial funding is frequently from very large companies, while SMEs appear not to have the funds for nutritional research. Funding influences the orientation of research-based nutrition education. Positive interactions with industry are facilitated when third parties are involved e.g. EU funded projects.

Conclusions: Nutrition education is offered within disciplines e.g. medicine, food technology, dietetics, sociology or agriculture, and has a different meaning for each. Common definitions for nutrition science, research, education and promotion will facilitate communication within the scientific community. Funding strengthens the researchers who benefit from it shaping their teaching, research output and societal impact. Public funding should catalyse healthy academia-industry interactions to overcome the risk of financial conflicts of interest and improve the credibility of nutrition science.

San Diego State University, California (USA)

Background

The third working group of FENS, which is composed of twenty nutrition scientists across Europe, has been charged with establishing a series of guidelines and recommendations for European wide implementation to assure and promote public trust in nutrition science.

Objectives

A clear issue with the credibility of nutrition science has been identified with public confusion and distrust generated by a lack of clarity and transparency when publishing nutrition science research. There is an urgent requirement to review the current communication process for nutrition research to clearly and accurately summarise the findings and highlight their impact, in the context of current public health nutrition guidance, to ensure this research is credible and relevant to a public audience.

Initiatives This working group has focused on two main initiatives. Firstly, an evaluation of the CONSORT statement as it relates to nutrition trials. The Statement details the minimum requirements for reporting RCTs, however, there is currently no nutrition-specific guidance, and it remains unclear whether such guidance is warranted to improve reporting in nutrition. We have assembled an international and geographically diverse committee of experts across a range of nutrition trial domains. Sixteen of the 25 CONSORT items have thus far been identified to potentially require additional guidance when reporting nutrition RCTs. Secondly, the working group has focused on the production of a detailed series of guidelines for writing and reviewing press releases. Research has identified that many of the inaccuracies in mainstream reporting stem from the original press release and these guidelines aim to address these concerns.

Conclusion

For the first initiative, the work will be peer-reviewed and results mapped and presented in an opinion piece for publication in the scientific press. The guidelines for reviewing and writing press releases will be presented together with recommendations for other potential initiatives to support and promote public trust in nutrition science

Writing Your Research Paper and Selecting the Right Journal to Submit Your Work

Teresa Davis[1], Katherine Tucker[2], Christopher Duggan[3], Jack Odle[4]

1.Baylor College of Medicine (USA), 2. University of Massachusetts Lowell (USA), 3. Boston Children's Hospital (USA), 4. North Carolina State University (USA)

Research needs to be disseminated to broaden scientific knowledge and improve health. Scholarly publishing also advances a scientist's career, boosts future funding, and fosters transparency in the research process.

In this session, the American Society for Nutrition's Editors will share insights on getting research published in leading journals. Findings need to be published in the most appropriate journal to reach the target audience. Other factors to consider include journal impact factor, speed of publication and costs. Authors are encouraged to choose influential journals in the field, so that they get the most rigorous peer-review as this process always strengthens a manuscript and builds trust in science. Being aware of predatory journals is imperative as these journals continue to proliferate. Common tactics of predatory journals include use of deceiving titles similar to established journals; exploitation of the open access model for profit; and omission of common services such as peer review, editing and content indexing.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Types of scientific writing include systematic reviews and meta-analysis; original research articles including clinical studies (e.g., randomized controlled trials, cohort studies) and animal studies; case series/reports; and perspectives.

Resources are available to assist authors with manuscript preparation. The International Committee of Medical Journal Editors (ICMJE) guides authors on ethical considerations and preparation of manuscripts and uniform requirements. The ICMJE's well-established criteria help ensure an efficient peer review process. Other resources include the CONSORT Guidelines for reporting clinical trials; PRISMA for systematic reviews and meta-analysis; ARRIVE guidelines for animal studies; and STROBE that aids reporting of observational studies.

Finally, all authors benefit by fully understanding the peer review process. Quality, stringent peer review is the cornerstone of scholarly publishing. After a preliminary assessment to ensure that the work fits within a journal's scope, a manuscript is assigned to an associate/academic editor who selects peer reviewers and oversees the review. This individual will evaluate revisions, if needed, and make recommendations on acceptance or rejection. Within ASN journals, peer review is anonymous, and a statistical board review is available to consult on methods and analysis.

Authors should follow the reviewers' advice and respond graciously and respectfully. Respond to all reviewers' comments and clearly identify revisions made. If a manuscript is not accepted, don't despair. Take the feedback gained and revise the manuscript for another journal. Within the ASN journal portfolio, it is not uncommon for manuscripts to be transferred to another journal that may be a better fit or provide another opportunity for consideration after revision.

Innovative Financing for Nutrition: Is there a business Case?

Meera Shekar[1], Kenji Shibuya[2], Dariush Mozaffarian[7], Simon Bishop[4], Elina Knudsen[6], Meghan O'Hearn[7], Christopher Warburton[5], Helene van Berchem[6], Kyoko Shibata[1], Anne Mullen[3]

1. Global Lead, Nutrition, World Bank Group (USA), 2. Tokyo Foundation for Policy Research (Japan), 3. Nature Food (UK), 4. The Power of Nutrition (UK), 5. Lion's Head Global Partners (UK), 6. Reference Capital (UK), 7. Tufts University (USA)

Malnutrition in all its forms, including undernutrition, obesity and other dietary risks, is the leading cause of poor health, lost productivity and lost human capital. Malnutrition is not only a major component of health, human development, and human security, but is further compounded by climate change through sustainable food systems. There is general consensus to create a focus on common systemic drivers that need common actions, and sustainable and health-promoting business models. However, only the climate change agenda has gotten traction and financing at scale from the global community. Nutrition remains a relative orphan with modest global traction from the public sector (primarily for the undernutrition agenda), and almost no traction from the private sector, for either undernutrition or obesity. Though recent events such as the "Nutrition-for-Growth" (N4G) summit hosted by the government of Japan in December 2021 have led to a commitment of nearly $30 billion for nutrition and food security, it is still unclear how many of these commitments will translate in to action on the ground. This symposium will focus on the recent efforts which aim to maximize available resources for nutrition through innovative financing, in tandem with maximizing the impact of available financing: "More Money for nutrition, More nutrition for the Money" across the globe.

Introduction of Cochrane systematic reviews in nutrition

Katharina da Silva Lopese[1], Norio Watanabe[2]

1. St. Luke's International University (Japan), 2. Soseikai General Hospital (Japan)

To promote health and well-being not only in clinical practice but also in society, the development of reliable and validate evidence is essential. Cochrane was established in the early 1990s and delivers high-quality information to guide the decision-making process on health-related matters. Cochrane primarily provides evidence from Cochrane Systematic Reviews. These reviews systematically summarize the results from existing studies and assess the certainty in the evidence following the Cochrane guidelines. The Cochrane Library currently contains over 7,500 systematic reviews, which are used in various medical fields. Cochrane has also played a central role in developing new methods of evidence synthesis. The presenter is an active Cochrane member, author and instructor, and will introduce the methodology for producing Cochrane systematic reviews and overview reviews using nutrition-related examples.

Food Environmental Intervention: A Systematic Review

Kimi Sawada[1]

1. Tokiwa University (Japan)

The prevalence of non-communicable diseases is a global issue, and many studies are being conducted in the field of public health nutrition to formulate strategies for health management and the prevention of non-communicable diseases. A shortage of vegetables and fruits and excessive consumption of fats and sugar can lead to chronic diseases. A few countries, such as Mexico and the United Kingdom, have implemented national policies that impose a tax on foods with excessive amounts of sugar (sugar tax). These countries recommend a reduction in the purchase of these foods and encourage the consumption of healthy foods. Incentives (i.e., price reductions for healthy foods and introduction of point systems in supermarkets and cafeterias) have been promoted, in addition to national policies. We conducted a systematic review using the Cochrane method to identify the impact of such pricing strategy incentives as food environment interventions on consumer eating behaviors and health outcomes. In this symposium, we will introduce the promotion process and features of the systematic review, as well as difficulties in conducting a systematic review using the Cochrane method.

Economical analysis of fruit and vegetable intake in Japan

Ruoyan Gai[1]

1. National Institute of Social Security and Population Research (Japan)

This study aimed to project the reduction in the CVD burden under different scenarios of increased fruit and vegetable intake in Japan by 2060. Based on Monte Carlo simulations projecting disease burden attributable to different scenarios of fruit and vegetable intake patterns by sex and age, the study suggested that a relevantly large percentage of the CVD burden can be alleviated by promoting even modest increases in fruit and vegetable consumption in Japan. As the results, across all age groups, men had a higher daily vegetable intake than women but a lower daily fruit intake. Comparing with recommended intake level, the total CVD burden was estimated to be 302,055 DALYs attributable to inadequate fruit consumption in 2015, which accounted for 12.6% of the total CVD burden. In 2060, the percentage of the CVD burden due to insufficient intake of fruit is estimated to decrease to 7.9% under the moderate increase scenario and to decrease to 4.5% under the high increase scenario. The study provided an example of projected health and economic impacts of nutritional interventions.

SY(T9)13-1
A global overview of the state of food composition, with a focus on challenges for dietary surveys

Bridget Anna Holmes[1], Doris Rittenschober[1], Fernanda Grande[1], Yuko Nanjo[1], Victoria Padula de Quadros[1], Agnieszka Balcerzak[1], Rita Ferreira de Sousa[1], Teresa Bevere[1], Pauline Allemand[1], Jacqueline Tereza da Silva[1]

1. Food and Agricultural Organization of the United Nations (FAO) (Italy)

Dietary assessment involves the collection of information on the quantity, and usually frequency, of foods and drinks consumed over a specified time. The calculation of energy and nutrient content of foods and drinks consumed in dietary surveys is performed using food composition tables (FCTs). The availability and use of good quality and up-to-date relevant country- or regional FCTs to convert food consumption into nutrient intake is critical. It is essential that FCTs are updated regularly to be representative of the foods available in a country, include new foods and drinks introduced on the market, and to update the nutritional value of foods and drinks that may have changed in composition over time e.g. as a result of changes in manufacturing processes or reformulations due to government health initiatives.

Many countries have their own national FCTs, although they are of varying levels of quality and completeness. According to recent evaluations made by FAO, more than 100 countries have already published at least one FCT, however many countries, including many low- and middle- income countries, still have no published food composition data. Published FCTs vary a lot in terms of quality, coverage, documentation, accessibility and frequency of updates. Around half of available FCTs were last updated more than 10 years ago.

By combining dietary survey data and food composition data it is possible to determine whether or not the diet is nutritionally adequate. Many conditions need to be met to link dietary survey data with food composition data effectively and correctly. The FCT must be selected carefully, considering quality and relevance (year, country, language), method and quality of data analysed or collated, but also availability and access. The completeness and relevance of the food list must be considered, together with reliability (e.g. percentage of items with missing values) and the list of nutrients that can be reported. Interviewers must be very familiar with both the local diet and the FCT to be used, in order to probe subjects effectively and obtain adequate detail for subsequent coding and transformation of data into estimated nutrient intakes. The matching of food items to the appropriate code or codes in a food composition table is challenging and time consuming. The use of poor quality FCTs may introduce error into the estimates of energy and nutrient intake which may impact on prevalence of nutrient inadequacies.

This presentation will highlight the global coverage and gaps of FCTs, highlight associated challenges in the linking of this data to dietary surveys, and provide updates on FAO's recent work in food composition.

Unlocking Food's Comprehensive Biochemical Composition for Human and Planetary Health

Selena Ahmed[1], Steven M Watkins[2,5], Tracy Shafizadeh[2,5], John de la Parra[3,5], Jessica Prenni[4,5]

1. American Heart Association (USA), 2. Verso Biosciences (USA), 3. The Rockefeller Foundation (USA), 4. Colorado State University (USA), 5. Periodic Table of Food Initiative (USA)

Globally, we are failing to meet multiple nutritional, health, and environmental targets linked to food. Characterizing food in its full biochemical and quantitative diversity is central to data-driven decision making for supporting human and planetary health. This presentation features efforts of the Periodic Table of Food Initiative, a participatory effort to create a globally shared data resource on food's comprehensive biochemical profiles to complement existing food composition efforts. We performed a baseline experiment to assess variability of analytical approaches across laboratories in order to understand challenges and opportunities of evaluating food biochemical profiles. Twelve standard reference food samples were provided to three established metabolomics laboratories representing a range of food types (apple, banana, tomato, lettuce, carrot, onion, spinach, potato, soybean, beef, cow's milk, and chicken egg). Each lab analyzed provided samples using their established analytical approaches based on high-resolution LC-Mass Spectrometry and submitted: (i) results of detected and annotated compounds; (ii) normalized quantitative values and; (iii) details of their analytical methods. Results revealed that data were highly reproducible within laboratories while quantitative results were not comparable between laboratories due to low overlap of analyte identification. For example, a total of 927 named biochemicals were returned from the analysis of the standard reference apple sample with only 14 biochemicals reported by all three laboratories. Findings demonstrate that despite highly developed analytical technology, the data pipeline, annotation tools, and reagents are fragmented between laboratories, making cross-laboratory comparison difficult. This baseline study supports the need for the development of standardized methods, reagents, and a common data pipeline to populate a democratized global data resource for food biochemical profiling. We conclude with a snapshot of preliminary results from analyzing 100 foods using standardized methods, reagents, and a common data pipeline developed by the Periodic Table of Food Initiative.

Food Nutrition Cloud: concepts and developments in food data, tools and services for food labelling and reformulation in nutrition research

Paul Michael Finglas[1], Igor Pravst[2], Karl Presser[4], Daniela Segovia-Lizano[1], Sian Astley[3], Susanne Westenbrink[5], Barbara Korousic-Seljak[6], Kurt Gedrich[7]

1. Quadram Institute Bioscience (UK), 2. Nutrition Institute (Slovenia), 3. EuroFIR AISBL (Belgium), 4. Premotec GmbH (Switzerland), 5. National Institute for Public Health and the environment (RIVM) (Netherlands), 6. Jozef Stefan Institute (Slovenia), 7. Technical University of Munich (Germany)

Background and objectives: Existing food nutrition security (FNS) data, knowledge, and tools for agri-food sciences are fragmented, lack critical mass, and access is unevenly distributed. This means FNS data are not readily found, accessible, interoperable, or reusable (FAIR), and existing services focus on clinical and biological sciences. FNS-Cloud is developing the first-generation 'food cloud' by federating existing and emerging datasets and developing and integrating services to support re-use through the European Open Science Cloud (EOSC). This talk will introduce FNS-Cloud and explore some of the first outputs, FNS Data Map and Catalogue and focusing on existing (use cases) and emerging (field trials) data. Methods: Based on existing food datasets, two use cases will be presented. Firstly, we will explore between-country comparison of branded food data for research, nutrition surveillance and policy. The goal is to investigate differences in the nutritional quality of the food supply in four European countries (NL, SI, DE and CH) across selected food categories (non-alcoholic beverages, yoghurts, breakfast cereals). Comparison testing will include assessment of energy, sugar and fats, which are commonly targets for food reformulation, as well as overall food quality scoring, using nutrient profiling. Secondly, food labelling data has been also used to compare different tools to investigate different approaches for estimating contents of nutrients in processed foods. The goal is to estimate the wider micronutrient data that is missing on the food label. Results: Work is ongoing on identifying processes used, defining required outputs. Harmonised datasets have been prepared for selected branded foods and test results will be produced and improved in a stepwise manner. Procedures to evaluate performance, quality requirements and nutritional results from the tools are under construction. Conclusions: The use of harmonised food datasets combined with advanced ICT tools and services will facilitate better research and exploitation of knowledge as well as delivering training and support to boost confidence and build capacity amongst user communities to improve the sustainability of European food systems and further enhance existing strengths in FNS research. Acknowledgements: Food Nutrition Security Cloud (FNS-Cloud) has received funding from the European Union's Horizon 2020 Research and Innovation programme (H2020-EU.3.2.2.3. – A sustainable and competitive agri-food industry) under Grant Agreement No. 863059 – www.fns-cloud.eu.

Overcoming challenges in food matching

Fernanda Grande[1], Yurika Ueda[1], Sitilitha Masangwi[1], Ana Moltedo[1], Rachele Brivio[1], Aydan Selek[1], Agnieszka Balcerzak[1], Stefania Vannuccini[1], Salar Tayyib[1], Bridget Holmes[1]

1. Food and Agriculture Organization of the United Nations (FAO) (Italy)

Background: Food matching refers to the activity of linking food consumption or supply data with food composition data to calculate nutrient intake or availability. Food matching should aim for the highest quality match possible by identifying the most appropriate food in the most appropriate source of compositional data. This matching a critical and challenging step to obtain high quality estimations, considering that data from food consumption/availability and food composition tables (FCTs) describe and classify foods using distinct criteria and descriptors.

Objectives: To establish a systematic approach to match foods from the FAO Supply Utilization Accounts (SUAs) and food composition data from different FCTs and document the challenges.

Methods: To assist with the selection of the FCTs for use during the food matching, eight screening questions from the new FAO/INFOODS Evaluation Framework were used to assess the quality of the potential FCTs. Documentation from the selected FCTs was carefully checked to identify the components, units, denominators and number of missing values for each component. The FAO/INFOODS component identifiers (also called tagnames) were assigned for a more precise component identification. The main criteria applied during the food matching was performed according to the FAO/INFOODS Guidelines for Food Matching.

Results: A total of 29 FCTs were assessed but only 13 were considered eligible in terms of quality for the food matching. After the component evaluation, 20 components were considered for the first phase of the food matching including energy, edible portion, six minerals and four vitamins. Food matching included about 550 food items from the SUAs list, considering crops, livestock and fisheries. A quality criteria was assigned to each matching according to the FAO/INFOODS guidelines. Many challenges and limitations were identified, both in the list of SUAs items and in the foods listed in the FCTs, such as limited food description, lack of standardization for calculated components, food fortification, biodiversity, food processing, etc. Specific matching criteria was established on a food group or food basis and assumptions and limitations documented in detail. Some key examples will be presented and discussed.

Conclusions: Multiple challenges were overcome during the food matching, thus setting a systematic approach was critical, especially where tasks involved several professionals. The systematic approach matching foods from the SUAs to food composition data facilitated the development of a single global food composition table to access food availability data.

SY(T9)13-5
Nutrient data needs and emerging issues of food composition databases

T Longvah[1]

1. National Institute of Nutrition (India)

The food composition database (FCD) is central to most areas of food, nutrition and health activities. Nevertheless, many countries do not even have their own FCD, and most of the existing ones were constructed using borrowed data from other countries and sources. There is also an acute lack of analytical data in most country FCDs due to the high cost and complexities involved in generating it. FCD is being used in many areas not well anticipated years back, and the demand for high-quality analytical data is increasing daily. The realization that nutrients can vary a hundredfold within the same food species has spurred the need for high-quality analytical nutrient data at variety, cultivar and breed levels for food crops. Such data is crucial for implementing nutrition-sensitive agriculture to promote the consumption of varieties or cultivars with higher nutrients or for crop biofortification to alleviate micronutrient malnutrition. Beyond nutrient diversity, the nutritional importance of dietary diversity is now widely recognized in addressing all forms of malnutrition. The potential of indigenous food crops, including wild foods, to improve dietary diversity remains largely unknown and underexploited. However, available evidence calls for systematic investigation as many potential indigenous foods can be the impetus for change and the starting point to mainstream it into the global food system. Attention to non-nutrient biologically active compounds in foods that may provide a health benefit beyond the traditional nutrients is growing. With newer and more sensitive analytical techniques evolving continuously, the science of human nutrition has enlarged to recognize the role of minute quantities of bioactive components in foods that modulate metabolic processes and reduce disease risk. Though only in minute quantities, the variety and content of biomolecules in foods are almost unexplored. The demand for high-quality analytical data on foods globally is urgent; investing in this area is crucial in terms of the potential to protect and improve public health nutrition over the following decades.

Adolescent girls' and boys' micronutrient and anthropometric status in Nepal, Bangladesh, Ghana, Burkina Faso, Guatemala, and the USA

Yaw Addo[1], Maku E Demuyakor[1,2], Mica J Jenkins[1], Maria Elena D Jefferds[1]

1. US Centers for Disease Control and Prevention (USA), 2. Mcking Consulting Corporation - Atlanta (USA)

Background: Despite recognition of adolescents aged 10-19 years as a population at-risk for malnutrition, there has been minimal population-based assessment of nutritional status of adolescents worldwide. Using data collected in the last decade, this presentation provides information on micronutrient and anthropometric status of adolescent boys and girls ages 10-19y from multiple geographic locations.

Methods: We analyzed data from national or sub-national micronutrient surveys and nutrition and health surveillance systems. Data were collected between 2012-2019 in Ecuador (2012), Ghana (2019), Guatemala (2017/2018), Great Britain (2014), Malawi (2015-2016), Mexico (2012), Nepal (2016), and the United States (2015-2018). We calculated prevalence of anemia based on hemoglobin (Hb) adjusted for altitude and/or smoking (Hb < 115 g/L for adolescents < 12years, <120 g/L for 12–14y and girls 15y+, and <130 g/L for boys 15y +), inflammation-adjusted iron deficiency (ID, Ferritin <15 µg/L), iron deficiency anemia (IDA), and when available, vitamin A deficiency (VAD), zinc, vitamin B12 and folate deficiencies. Prevalence of stunting (Height for Age Z-score <-2), thinness (BMI-for-age Z, BMIZ<-2), and obesity (BMIZ < 2) were examined across countries and sex.

Results: Data from 12,996 adolescents found that prevalence of micronutrient deficiencies (MND) varied by sex and location. Anemia ranged from 0.4% in Guatemala to 23.8% in Malawi among boys, and 2.7% in Guatemala to 21.5% in Ghana among girls. Among boys, ID was 1.4% in Malawi and 14.1% in Mexico whereas IDA was generally low among boys, from 0.0% in Great Britain to 2.1% in Mexico. Among girls, ID was highest in Great Britain at 27.5% and lowest in Malawi at 12.3%, while IDA was 1.1 % in Ghana and highest in the US at 7.2%. Vitamin A data was available in 4 countries. Among boys, VAD ranged from 0.0 % in Malawi to 8.5% in Ecuador, while among girls, VAD ranged from 0.6% in Great Britain to 8.8% in Malawi. Zinc deficiency (3 countries) was 2.4% in Great Britain and highest in Malawi for both boys and girls at 58.6% and 56.3%, respectively, with the lowest for girls at 3.1% (Great Britain). Vitamin B12 deficiency (4 countries) among girls ranged from a low of 0.4% in Mexico to a high of 11.3 % in Malawi. Serum folate deficiency (3 countries) was low (<0.4%) among boys Mexico and Ecuador, but among girls, it was lowest at 1.0% in Ecuador and highest at 18.8% in Malawi. Like MND, the prevalence of stunting, thinness, and obesity varied widely across countries, sex, and the extremes of the distribution. For example, whereas thinness in girls was 0.0% in Great Britain, it was 14.0% in Nepal, conversely obesity was 10.2% in Great Britain and 0.7% in Nepal.

Conclusion: The wide variation in prevalence of multiple burdens of malnutrition among adolescents observed across geographic regions highlights the importance of continued surveillance to provide up-to-date data in this population group. Consistent monitoring of nutrition metrics is critical to the design of impactful interventions and to inform national policy.

Systems integration and partnerships to effectively deliver weekly iron and folic acid supplementation programs to adolescents in low-income and middle-income countries

Mandana Arabi[1], Marion Roche[1], Laura Rowe[1]

1. Nutrition International (Canada)

Adolescence is a time of rapid growth and development and increasing nutritional needs, especially in the case of iron for adolescent girls with a third estimated to be anaemic in low- and middle- income countries. Until recently adolescents have not been the focus of health and nutrition programs and they are among the least likely to access the health system for preventative services. Systems thinking goes beyond multisectoral delivery of programs and considers the multiple cross-cutting and interrelated determinants of malnutrition, identifying levers for positive change to increase impact, and fostering enhanced sustainability by working across systems and delivery platforms.

Methods: By applying a systems-based approach to improving adolescent nutrition, with a focus on expanding reach and impact of weekly iron folic acid supplementation (WIFAS) programs, we identify opportunities for increasing equitable reach of WIFAS in select countries in Asia and Africa. In addition to considering the health, education and social protection sectors that are engaged to deliver WIFAS, the current enabling environment within the country needs to be considered in order to inform programming decisions and outcomes such as program relevance, feasibility, design, and anticipated impact. This analysis includes the current context around policy and governance, infrastructure and markets, inputs and services, information and communication, financing, household resources, and the sociocultural environment. **Results:** Most WIFAS programs supported through the Right Start initiative in Africa and Asia initiated with school-based delivery, where the largest number of girls could be reached through a collaboration with the health and education sector. In some cases these programs were complemented by smaller scale resource-intensive facilities or community-based delivery with attempts to reach out-of-school girls. India, with the longest standing WIFAS programs operating at national and state level, is a country reaching millions of girls through a multisectoral WIFAS

program delivered through social protection, school platforms and collaboration and delivery, financing and reporting aligned with the health system. Vulnerable girls seem to be the hardest to reach through all channels, yet a systems approach offers more potential, especially adapting when vulnerability changes. This was especially relevant in COVID as all girls become out of school for varying lengths of time.

Conclusions: Adolescents have been among the most marginalized from the health system, making a systems-based approach strategic for addressing the complex issues and determinants of adolescent anaemia and weekly iron folic acid supplementation programs; yet strengthening the youth-responsiveness of health systems is also much needed as part of sustainable impact.

Clinical Nutrition in COVID-19 – strategies for prevention, management and recovery

Shane McAuliffe[1,2]

1. NNEdPro Global Centre for Nutrition & Health (UK), 2. The Walton Centre NHS Foundation Trust (UK)

Given the sustained global impact of the COVID-19 pandemic, many areas of health and lifestyle have been called into question and examined in this context. Malnutrition exists on a spectrum, with people at both extremes at greater risk of morbidity and mortality from infection. To this end, observational research into COVID-19 outcomes has shown that people with nutrition-related non-communicable conditions such as the metabolic syndrome, obesity and diabetes mellitus are at greater risk of morbidity and mortality from infection (1,2), while undernutrition in the clinical setting has also been predictive of poor outcomes (3). Accordingly, much has been written about the importance of nutrition in COVID-19 prevention and clinical management.

Specific attention has been given to the role of nutrition in immune health in the context of COVID-19, in particular the relationship between dietary micronutrients and infectious disease (4,5). In other respiratory infections, correction of micronutrient deficiencies has been effective in promoting improved immune responsiveness, granted the key observation of effect in these cases has been in those with deficient status (6). This emphasises the importance of robust systems for testing and treating nutritional insufficiencies and deficiencies, in cases of COVID-19 infection and more widely.

Through rapid changes in food environments and living conditions, a global nutrition transition is generating a new double burden of malnutrition (DBM) in which undernutrition and overweight co-exist within populations, and often within individuals. Both of these states have the potential to impair adequate functioning of the immune system (4). A bidirectional relationship exists between nutrition and infection, whereby poor nutritional status predisposes one to infection and the body's immune response against infection can be weakened by a poor nutritional status.

Mortality from COVID-19 has been highest among older people and those with comorbidities, who are also often most at risk of malnutrition in society. Malnutrition in these groups is often community acquired and associated with poor clinical outcomes in secondary care (7). To complicate this further, due to unprecedented service pressures during the COVID-19 pandemic, standard procedure and practice has been difficult to maintain and nutrition screening and assessment will have been impacted. Accordingly, people discharged from hospital are likely to be at high risk of malnutrition due to several factors including the effects of acute illness and additional barriers to nutrition support during hospital admission (8,9). This has likely resulted in a high prevalence of malnutrition in our communities, meaning increased vulnerability to future illness and infection.

The COVID-19 pandemic will be remembered for many reasons and will leave a lasting legacy on healthcare systems. However, one positive which could result from this impact is an increased acknowledgement of the important role of nutrition in this setting, with the recognition of nutritional status can be considered a modifiable risk factor in the prevention and treatment of COVID-19. This too provides a platform for the promotion of healthy diet and lifestyle choices to the population at large. Additional emphasis on public health messaging can be used as an opportunity to facilitate discussions around nutrition related behaviour change at a population level (10). Similarly, lessons learned during the pandemic can provide a catalyst for all healthcare professionals to embed nutritional care into routine practice.

SY(T9)15-2
Global Nutrition, COVID-19 recovery and Long COVID

Sumantra Ray[1], Shane McAuliffe[1], Dominic Crocombe[1]

1. NNEdPro Global Centre for Nutrition & Health (UK)

This session outlines the current evidence base and active research for nutrition in COVID-19 recovery and in the management of Long COVID. Malnutrition, in particular undernutrition and sarcopenia, is associated with prolonged recovery from COVID-19. Severe COVID-19, especially in patients requiring inpatient or intensive care, is a profoundly hypermetabolic condition that can lead to depletion of energy stores and lean muscle mass. Therefore, the recovery phase can be lengthy (months to years), disease severity can partly predict length of recovery, and patients with pre-existing malnutrition

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

are most at risk of infection-related weight loss and malnutrition. Chronic symptoms affecting taste, olfaction, swallow and the gastrointestinal tract can have obvious implications for nutritional intake. Currently, the core principles of optimal nutrition in recovery from COVID-19 are akin to recovery from other infectious diseases, namely meeting adequate protein, macronutrient and micronutrient requirements, taking into account deficits in these dependent on age, baseline nutrition status, biometrics, disease course and complications.

Long COVID (also termed post COVID-19 condition) is a heterogenous syndrome characterized by persistent symptoms (commonly fatigue plus cardiorespiratory, neurological, gastrointestinal, or other symptoms) occurring beyond 12 weeks following initial infection. It can limit physical and cognitive function, independence and quality of life. In most countries, healthcare services for patients with Long COVID are variable, with clinicians of many different specialties running clinics that vary by region and healthcare system. There are several clinical research trials exploring the natural history and management of Long COVID; most of these assume value from a multi-disciplinary approach to Long COVID management, yet data on nutritional factors appear to be included in very few active trials. Our group advocates for nutrition assessment and individualised management to be actively included in Long COVID clinical services and research. We are collaborating with researchers to better understand the role of nutrition in Long COVID.

Tailoring science communications including nutrition and health advice to different regions, at different times during the COVID-19 pandemic to date

James Bradfield[1,2]

1. NNEdPro Global Centre for Nutrition & Health (UK), 2. Department of Nutrition & Dietetics, King's College Hospital NHS Foundation Trust, London, UK (UK)

The COVID-19 pandemic presented unprecented challenges in almost all areas of public, private and professional life. The ever-evolving nature of the COVID-19 pandemic was unlike almost any phenomena encountered by those in the field of science, research or clinical practice. While this presented some very predictable hurdles, it also created difficulties for those communicating the emerging evidence around the virus, treatments and vaccines. The NNEdPro Global Centre attempted to contribute to the growing need for accurate, reliable and region specific resources through the establishment of our COVID-19 Taskforce and its own dedicated microsite[1]. With its far-reaching regional networks, NNEdPro was in a prime position to host a repository of generic and region specific public health resources to highlight upto-date policy and practice across the globe. The primary aims of this Taskforce was to improve health during the COVID-19 pandemic, by focusing on nutrition research, clinical practice and public health.

The first step was to establish our Taskforce, with membership made up of clinicians, public health nutritionists and social scientists to name but a few. Meeting online to discuss the developments in the pandemic and the response from the scientific world, the Taskforce set about addressing some of the early nutrition issues plagued by inaccuracies and embelishment. One of the early nutrition claims during the pandemic was regarding foods that could 'boost' your immune system. In many cases, those sharing these ideas meant well, however the concern arose in the Taskforce that this may cause people to disregard other advice such as to stay at home, wash their hands and adhere to social distancing. As a result, a pair of articles were written in a local newspaper attempting to dispell the myths that had arisen in early spring 2020[2,3]. In addition, a simple 10-point plan with associated pictures was created to show how people could support a healthy immune system through diet[4]. Drawing on our global networks, this guide was later translated into a dozen international languages[4] and has since been viewed more than 13,000 times.

NNEdPro's flagship journal, BMJ Nutrition Prevention and Health, soon established a special collection on Nutrition Interactions with COVID-19. Among the first articles published were a report on the potential role of vitamin D in COVID-19[5], a comprehensive review of the role of nutrients in immunity[6] and an appraisal of the evidence for dietary micronutrients in COVID-19 specifically[7]. Importantly, all articles were open access and were therefore open to all.

The Taskforce felt that one of the most important factors in our work, was promoting and sharing reliable information. This required constant surveillance by team members around the emerging literature and public health interventions, communication with leaders in our global networks and collation of information in one online repository. Perhaps as importantly, we continued to produce educational material in real time in the shape of webinars, podcasts and our International Summit. Our aim throughout was to help combat some of the misinformation that arose over the course of the pandemic and we can reflect now on some of the lessons learned along the way in this symposium.

Nutritional preparedness for future waves of the SARS-CoV-2 and similar respiratory viruses

Martin Kohlmeier[1], Bryndis Eva Birgisdottir[2]

1. University of North Carolina (USA), 2. University of Iceland (Iceland)

Since the initial infections in 2019, the SARS-CoV-2 pandemic has proceeded in several waves. There have been strong indications that nutritional circumstances, particularly vitamin D deficiency, importantly contribute to the build-up of epidemic waves, during the dark season in high-latitude regions (Kohlmeier 2020, Ilie et al., 2020, Rhodes et al., 2020). Large segments of the populations countries at high latitude are known to be vitamin D deficient in winter and spring (Hanssen et al., 2018, Lanham-New et al., 2020). We are reporting here our previous experience with planning a community-based intervention to reduce virus transmission while mitigating disease outcome. This randomized intervention design is to be implemented in areas with high infection rates, targeting adults, who just received a negative antigen test and are thus not yet infected or are at a very early stage of infection. When they agree to participate, they will be randomized to moderately high oral vitamin D or placebo and asked to immediately start with their assigned regimen. Use of the supplements is to continue until the local infection rates return again to low risk levels. The primary outcomes of interest are self-reported morbidity as well as hospitalization and death rates. The main barrier to obtaining the requisite support for a sufficiently powered intervention trial was the low confidence in a substantive role of seasonal vitamin D deficiency in respiratory tract virus infections. Several trials with vitamin D at the time had reported failure to achieve the intended disease mitigation. However, all of them started supplementation many days or even weeks after the viral infection was already established. At least three different Mendelian randomization studies all reached the conclusion that vitamin D is unlikely to mitigate infection, but there are questions whether the genetic instruments are adequate proxies for vitamin D status during winter (Kohlmeier, Baah, 2021). A few other studies estimating vitamin D intake before infection and following infection risk and disease outcomes observed lower transmission and milder outcomes. The generally favorable results of these studies only become available after efforts had failed to get an intervention trial off the ground. The current state is that we still do not know with enough confidence that avoiding vitamin D deficiency will reduce SARS-CoV-2 transmission. Trials of the kind described above are just as urgently needed as before, not least in light of potentially different effectiveness with newer virus variants.

Reflections from 2.5 years of NNEdPro Nutrition and COVID-19 taskforce activity

Bryndís Eva Birgisdóttir[1], Sumantra Ray[2,6,7], Dominic Crocombe[2,3], James Bradfield[2,4], Shane McAuliffe[2,5], Martin Kohlmeier[2]

1. University of Iceland (Iceland), 2. NNEdPro Global Centre for Nutrition and Health, St John's Innovation Centre, Cambridge (UK), 3. Royal Free London NHS Foundation Trust, London (UK), 4. King's College Hospital NHS Foundation Trust (UK), 5. The Walton Centre NHS Foundation Trust (UK), 6. Ulster University (UK), 7. University of Cambridge (UK)

Background and objectives: The NNEdPro Global Centre for Nutrition and Health established its Nutrition and COVID-19 taskforce in March 2020 to aid the pivoting of operations and provide a focal point in the public health, healthcare and health research landscape for nutritional issues relating to COVID-19.

Methods: Critical and constructive reflections at 24 months (March 2020-March 2022) using an implementation science framework by key taskforce representatives.

Results: Successes to date include: (1) transitioned to online operations whilst maintaining research and educational activities; (2) contributed significantly to the research evidence base on nutrition and COVID-19 risk prevention, clinical management, and food security; (3) established an up-to-date and dynamic library of resources for professionals and the public; (4) multisector collaborations, including with key academic and industry partners, frontline healthcare providers, and medical publishing (joint special collection with BMJ Nutrition, Prevention and Health with over 25 papers); (5) provided a platform for early-career researchers; (6) disseminated region-specific information through established networks and social media platforms; (7) provided scientific content for novel nutrition science communications forum, IKANN-25; (8) advocated at national and international levels for inclusion of nutrition in COVID-19 policy. Challenges faced include: (1) navigating transitions through pandemic phases and shifting clinical and research priorities, with variable timelines across global regions; (2) the widespread lack of sustained grant funding available for nutrition research in COVID-19, especially for interventional trials in high risk populations; (3) limited acknowledgement in official policy that certain forms of malnutrition are modifiable factors in COVID-19 prevention and

mitigation, compared to other public health measures, e.g. face masks and vaccinations; (4) remaining true to the evidence-base and maintaining scientific rigour when discussing nutrition during the pandemic, which is particularly challenging in social media discourse. Future priorities include nutrition in COVID-19 recovery and long COVID, the pandemic's impact on nutrition and food security, and nutrition in future pandemic planning and resilience.

Conclusions: This taskforce has championed the role of nutritional factors in COVID-19 research, education, clinical practice, and policy through wide-ranging and collaborative activities with the emergence of a forward looking programme led by implementation thinking.

SY(T9)16-1
Impacts of the COVID-19 pandemic on diets, nutrition practices and nutrition services in UNICEF's Eastern and Southern Africa region: Evidence from remote surveys in Botswana, Eswatini, Lesotho, Kenya, Malawi, Uganda

Chloe Angood[1]

1. UNICEF's Eastern and Sothern Africa Regional Office (Kenya)

UNICEF's Eastern and Southern Africa Regional Office (ESARO) undertook research to understand the impacts of the COVID-19 pandemic on diets, nutrition practices and nutrition services in the region. Remote data collection took place remotely in six countries (Botswana, Eswatini, Lesotho, Kenya, Malawi, Uganda) between May and August 2021 using telephone and internet surveys. Overall, 57,589 respondents took part in the survey.

Results show that 59% of caregivers reported reduced consumption of one or more healthy food groups for children aged 6-23 months (average 3 out of 11 healthy food groups) due to COVID-19, with the biggest reduction reported in animal source foods and unhealthy foods. 20% of caregivers of children under two years reported that their infant was breastfed less often due to COVID-19. 82% of caregivers of children aged 2-18 years and self-reporting adolescents aged 15-18 years reported reduced consumption of one or more healthy food groups due to COVID-19 (average 5.7 out of 13 food groups) and 73% of caregivers of children who responded via internet surveys reported that their child consumed reduced variety of foods since COVID-19. Animal source foods and unhealthy drinks and snacks were the food groups most frequently reported to be consumed less among children aged 2-18 years. 84% of pregnant and lactating women (PLW) reported reduced consumption of one or more healthy food groups due to COVID-19 (5.5 out of 13 food groups), with the biggest reductions reported in animal source foods and unhealthy drinks and snacks.

Severe household food insecurity according to the Food Insecurity Experience Scale (FIES) was reported by 39% of caregivers of children under two years, 33% of caregivers of children aged 2- 18 years, and 34% of PLW. Severe or moderate household food insecurity was reported by 76% of caregivers of children under two years, 74% of caregivers of children aged 2-18 years, and 72% of PLW. PLW reported that, while food continued to be available on markets, food access fell due to reduced purchasing power, either because of lack of money (61% of respondents) or higher food prices (33% of respondents). COVID-19 disrupted nutrition services in ESA with the largest negative impact reported by both service users and service providers on maternal health and nutrition services, Iron and Folic Acid supplementation for adolescent girls, and nutrition counselling.

Results indicate that the COVID-19 pandemic had a negative impact on infant and young child feeding practices in terms of reduced frequency of breastfeeding and a negative impact on child, adolescent and mothers' diets in terms of reduced variety of foods consumed, and reduced consumption of animal source foods rich in protein and micronutrients. Results also suggest some positive impacts on diets in terms of reduced consumption of unhealthy drinks and snacks and increased consumption of micronutrient-rich vegetables. Resources are urgently needed to re-expand and prioritize efforts to prevent stunting and micronutrient deficiencies in ESA. Use of remote survey methods enabled the collection of nutrition data during COVID-19 related movement restrictions, but remote methods have important limitations and more research and guidance is needed on their use.

Keyword: COVID-19, diets, infant and young child feeding, food insecurity

How COVID-19 affected maternal and infant nutrition practices, health service delivery and food systems in Kenya: Key Findings and Program Implications

Justine A. Kavle[1], Laura Kiige[2], Brenda Ahoya[3], Constance Gathi[3], Betty Samburu[2], Lucy Maina[4], Lacey Ramirez [1], Rose Wambu[4], Patrick Codjia[2]

1. Kavle Consulting, LLC (USA), 2. UNICEF Kenya, Division of Nutrition (Kenya), 3. Kavle Consulting LLC (Kenya), 4. Ministry of Health Kenya, Division of Nutrition and Dietetics (Kenya)

Background: This implementation science study, is one of the first, to comprehensively understand the effects of COVID-19 on maternal health service delivery and the concurrent impacts on breastfeeding practices in Nairobi and Uasin Gishu Counties, Kenya. **Methods**: The study triangulated in-depth interviews (IDIs) with 31 lactating women (including COVID-19 positive), 10 health workers, 10 community health volunteers, 15 IDIs and 4 focus group discussions with government stakeholders and implementing partners from urban (Nairobi County) and rural areas (Uasin Gishu County) of Kenya. Secondary analyses of trends in Kenyan Health Information System (KHIS) facility and breastfeeding indicators was also conducted. **Results**: Attendance of maternal and child health services declined and was attributed to fear of COVID-19 infection, transportation issues and COVID-19 imposed restrictions. Facility and community health providers described confusion surrounding provision of guidance around breastfeeding for women who were at-risk or COVID-19 positive. Fear of COVID-19 infection early in the pandemic disrupted early and exclusive breastfeeding practices, which was subsequently addressed by the health workforce, as women relayed exclusively breastfeeding due to stay-at-home orders. Importantly, the COVID-19 pandemic negatively affected the diets of both pregnant and lactating women and provision of psychosocial support during the pandemic was limited. Reductions in overall food choice and consumption for women and their households were driven by high food insecurity, pandemic-fueled unemployment, and higher prices of most food items. In addition, access to markets and availability of perishable foods was compromised during the pandemic. **Conclusion**: Efforts to "build back better" for COVID-19 should include addressing gaps pertaining to maternal, infant and young child nutrition counseling and health education at facility and community level to prevent disruptions in maternal and infant health services and related nutrition practices due to pandemic-related misperceptions and taboos. This should include strengthening provision of practical, culturally responsive nutrition and psychosocial support for women and their families.

An exploration of the effect of COVID-19 on adolescent nutrition in Kenya: Key Findings and Program Implications

Laura Kiige[1], Justine A. Kavle[2], Patrick Codjia[1], Constance Gathi[3], Brenda Ahoya[3], Lacey Ramirez[2], Stacey Katua[1], Florence Mugo[4]

1. UNICEF Kenya (Kenya), 2. Kavle Consulting, LLC (USA), 3. Kavle Consulting LLC (Kenya), 4. Ministry of Health Kenya, Division of Nutrition and Dietetics (Kenya)

Background: This implementation science study sought to gain a better understanding of the effects of COVID-19 on adolescent food choice, dietary intake, and related behaviors in Nairobi and Uasin Gishu Counties, Kenya. **Methods**: The study triangulated eight focus group discussions (FGDs) conducted with adolescents 10-19 years of age, in-depth interviews with ten health facility providers, and a combination of FGDs and key informant interviews with government stakeholders and implementing partners (n=13) from urban (Nairobi County) and rural areas (Uasin Gishu County) of Kenya. **Results**: During the COVID-19 pandemic, adolescents tended to avoid commonly consumed junk foods, in favor of immune-boosting "protective" foods. Widespread unemployment rendered some food items unaffordable for families of adolescents. Adolescents relayed experiences of reductions in dietary intake and used various strategies to support families financially, in response to rising food insecurity. School closures mandated during the pandemic likely contributed to declines in overall physical activity and a greater tendency among adolescents to engage in risky behaviors, which were disruptive to adolescent health.

Conclusion: To improve the diets of adolescents and build back better from COVID-19, country programs should build on the healthy mindset brought on by the pandemic while providing additional targeted nutrition-sensitive measures (i.e. social protection, agriculture initiatives) to cushion adolescents and their families from rising food insecurity, as an effect of COVID-19.

How have poor urban populations' food security and food purchasing habits been impacted by COVID-19? Insights from three city slums in Asia

Sophie Goudet[1,2], Jessica Blankenship[2], Elizabeth Drummond[2], Britta Shumacher[3], Anusara Shinghkumarwong[3], Carolyn Auma[1], Heather Ohly[1], Rini Astrianif[1], Jeline Marie Corpuz[1], Rebecca Pradeilles[1]

1. Dikoda LTD (UK), 2. UNICEF, nutrition East Asia and Pacific Office (Thailand), 3. WFP nutrition Asia and Pacific (Thailand)

The COVID-19 pandemic has threatened the nutrition status of people around the world, particularly the youngest, the poorest and the most vulnerable. The pandemic, and the extraordinary measures needed to contain it, have constrained access to nutritious and affordable foods, disrupted health and nutrition services and overburdened social protection systems in many contexts. In Asia, the pandemic's impact on food chains and the economic impact on households are now well documented. During the pandemic, many vulnerable households – including those in poor, urban areas – remain at risk of food insecurity, with potential increases in malnutrition especially for young children and women. A cross-sectional survey was implemented in 2020-2021 to assess the impact of COVID-19 on food security, diet quality and access to essential services among poor urban communities in three South East Asian cities (Jakarta in Indonesia, Quezon city in the Philippines and Yangon in Myanmar). Data were collected on household food insecurity (FAO Food Insecurity Experience Scale) and nutrition indicators using Computer Assisted Telephone Interviewing (sample size of 730 households in Jakarta, 2700 in Quezon city and 3077 in Yangon) and compared with pre-COVID-19 baseline data when available. A COVID-19 impact index composite of category of shock severity and livelihood based coping strategy was developed and used to assess the level of exposure to COVID-19. Measurement of qualitative impact of COVID-19 was based on respondents' perceptions towards changes in their food provisioning, consumption and feeding patterns during the pandemic. COVID-19 has exacerbated poverty in vulnerable populations. Households in extreme poverty were most severely impacted by COVID-19 compared to all other income groups. Concerns about food in the last month was seen in many households in Jakarta (66%), Quezon City (87%) and Yangon (74%) and it was highest among households that were most severely impacted by COVID-19 in 2 cities (using the COVID-19 impact index). There was an interplay between food affordability and physical access. Households dramatically altered the way they purchased food, to cope with financial in-access and physical access challenges, either by reducing purchases of nutrient-dense foods or substituting. Given that the COVID-19 crisis pushed vulnerable urban populations further into poverty, it is crucial that authorities and stakeholders responsible for governance and oversight of food systems in urban areas coordinate, to ensure innovative and sustainable monitoring system of the nutrition and livelihoods situation among the urban poor. It is also important to design social protection interventions to support households in coping with shocks and disruptions to the urban food system. Specific actions for food security, social protection, nutrition and monitoring are recommended.

Urban food systems in Asia: COVID-19, food security and resilience. An analysis and characterization of 8 urban food systems in selected cities in Asia

Anusara Singhkumarwong[1], Heather Ohly[2], Martyn Clark[2], Sonja Read[2], Severine Frison[2], Nicolas Bidault[1], Britta Schumacher[1], Sophie Goudet[2]

1. World Food Program Asia and Pacific (Thailand), 2. Dikoda (UK)

Background and objectives: The COVID-19 crisis has significantly disrupted food systems, particularly, those that support urban populations. However, insufficient evidence existed on the impact on availability, access, and use of foods for vulnerable urban populations. The gaps in evidence of urban food system weaknesses during the COVID-19 crisis and the likely consequences on food security and nutrition in poor urban population indicated a need to better understand urban food system dynamics and identify areas of interventions for the World Food Programme and other partners.

Methods: This research study conducted in early 2021, assessed the level of resilience of urban food systems in the face of the COVID-19 crisis in eight selected cities in Asia. A range of methods and data sources were used to characterize urban food systems and explored external drivers, food supply chains, food environments, individual factors, consumer behaviour and diet outcomes. In addition to analysis of secondary data and geospatial data, primary data were collected from private sector, local government actors, UN agencies, NGOs and community-based organizations using both quantitative and qualitative data collection methods. collection methods.

Results: COVID-19 has increased levels of vulnerability and food insecurity in cities through three main mechanisms, which varied geographically between cities and temporally throughout the pandemic. These include 1) disruptions to food supply chains; 2) Increased food prices; and 3) Loss of income. The combination of increased food prices and loss of income affected food affordability for the urban poor. Food prices increased during the pandemic in all eight cities, with considerable variations between cities and between food groups. The analysis suggests that food systems in the eight cities did not show high levels of resilience to respond effectively to the pandemic.

Conclusions: There is a need for governments and development actors to consider innovative response to COVID-19 and to strengthen the resilience of urban food systems against inevitable future shocks. Positive opportunities for transformation of urban food systems exist. Innovative

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

transformations represent an area that could be strengthened on the supply side to increase the resilience of the economy and the livelihoods of those working in the food system by protecting income and the access of vulnerable individuals to the food system.

SY(T9)17-1
Total dietary fat intake, fat quality and health outcomes: scoping reviews of systematic reviews of prospective studies and current guidelines

Lukas Schwingshackl[1], Berthold Koletzko[1]

1. University of Freiburg (Germany)

Introduction: We conducted a scoping review of systematic reviews (SRs) on dietary fat intake and health outcomes in human adults, and a scoping review of dietary guidelines with the intent of developing a position paper by the "IUNS Task force on Dietary Fat Quality" tasked to summarize the available evidence and provide the basis for dietary recommendations. **Methods**: We systematically searched several databases for relevant SRs of randomized controlled trials (RCTs) and/or prospective cohort studies published between 2015-2019 assessing the association between dietary fat and health outcomes. We systematically searched several databases and websites for relevant guidelines published between 2015-2019. **Results**: Fifty-nine SRs and twenty guidelines were included. The findings from SRs of prospective cohort studies, which frequently compare the highest vs. lowest intake categories, found mainly no association of total fat, monounsaturated fat (MUFA), polyunsaturated fat (PUFA), and saturated fat (SFA) with risk of chronic diseases. SRs of RCTs applying substitution analyses indicate that SFA replacement with PUFA and/or MUFA improves blood lipids and glycemic control, with the effect of PUFA being more pronounced. A higher intake of total trans-fat, but not ruminant trans-fat, was probably associated with an increased risk of mortality and cardiovascular disease based on existing SRs. Findings form current guidelines indicated quantitative range intake recommendations for daily total fat intake included boundaries from 20-35% of total energy intake (TEI), for monounsaturated-fat (MUFA) 10-25%, for polyunsaturated-fat (PUFA) 6-11%, for saturated-fat (SFA) =<11-=<7%, for industrial trans-fat (TFA) =&<2-0%, and <300-200 mg/d for dietary cholesterol. The methodological approaches to grade the strength of recommendations were heterogeneous, and varied highly between the included guidelines. Only the WHO draft guideline applied the GRADE approach and graded the following recommendation as "strong": to reduce SFA to below 10%, and TFA to below 1% and replace both with PUFA if SFA intake is greater than 10% of TEI. **Conclusion**: Overall, the available published evidence deems it reasonable to recommend replacement of SFA with MUFA and PUFA and avoidance of consumption of industrial trans-fat.

SY(T9)17-2
Changes in dietary fat intake over time

Shoichiro Tsugane[1], Ryoko Katagiri[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Current situations and trends in dietary fat intake from national representative survey were investigated in Japan (National Health and Nutrition Survey (NHNS), since 1946), Korea (Korean National Health and Nutrition Examination Survey (KHANES), since 1998), US (National Health and Nutrition Examination Survey (NHANES), since 1999 annually), and UK (National Diet and Nutrition Survey (NDNS), since 2008).

Current situations of dietary fat intake (% total energy (TE)) were estimated to be 23% in Korea 2018, 29% in Japan 2019, 33% in US 2016 and 34% in UK 2016-18. In Japan, it was only 6% in 1948 and sharply increased to 10% in 1958 and over 20% in 1973. Thereafter it was gradually increased and over 25% in 1988 and 29% in 2019. The increased trend was also observed in Korean men, 19% in 2008 to 23% in 2018, and women, 18% to 22%. In US, it was gradually increased from 32% in 1999 to 36% in 2018 and almost stable, 33% in 2008-9 and 34% in 2016-8 in UK.

Regarding quality of dietary fat, saturated fatty acid (SFA) intake(%TE) was less than 10%; 8.7% in Japan and 7.0% in Korea, however it showed the increasing trend. In US and UK, the trends were almost stable, but the values exceed 10%, approximately 12%. Monounsaturated fatty acid (MUFA) intake (%TE) was currently 11% in Japan, 7% in Korea, 12% in US and 13% in UK. The trends were parallel with SFA. In contrast, US adults experienced a significant increase in %TE from polyunsaturated fatty acid (PUFA). Current PUFA intake was 6.1% in Japan, 5.5% in Korea, 8.4% in US and 6% in UK. Global consumption and changes in fat intake from Global Dietary Database (https://www.globaldietarydatabase.org/) are also investigated. This database contains diet exposure data drawn from national health surveys and nutrition databases, compiled by researchers of the Global Dietary Database Consortium, part of the Global Burden of Disease Nutrition and Chronic Disease Expert Group (NutriCoDE). Daily intake (g/day) of meats, milk and seafood, major source of dietary fat, are 51, 150 and 75 in Japan, 55, 85 and 59 in Korea, 76, 199 and 18 in US and 61, 260 and 30 in UK. These data support higher saturated fatty acid intake and lower marine n-3 PUFA intake in US and UK. GDD also provides dietary trans fatty acid (TFA) intake and %TE was estimated to be 0.9-1.0% in Japan and Korea and 1.4-2.7% in UK and US.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Global trends of dietary fat were also investigated by systematic analysis including 266 country-specific nutrition survey as a part of NutriCoDE. In general, while SFA and TFA were stable, the intakes of n-3 and n-6 PUFA were gradually increased between 1990 and 2010.

Keywords: Dietary fat, Current situation, Trend, saturated fatty acid, polyunsaturated fatty acid

SY(T9)17-3
Recommendations of the IUNS Task Force on Dietary Fat Quality

Berthold Koletzko[1]

1. Munich University (Germany)

The IUNS created a Task Force to prepare evidence based position paper and recommendations on the Advisable Quality of Dietary Fat. This report is supposed to be shared with the national nutrition societies and the scientific community, as well as practitioners in the health and nutrition fields, public health and regulatory bodies, and food producers. Key messages shall also to be shared with the public. A group of twelve experts in the field from around the field agreed to contribute to the work, comprising both eminent experts and early career scientists. While we had originally intended to hold one or more face to face meetings of the expert group, due to the Covid-19 pandemic we reverted to online discussions. The task was discussed and the key questions to be addressed were agreed upon. Two scoping reviews of systematic reviews relating to recommendations in the adult population were performed to serve as the basis of the work (1, 2). Based on these recommendations on dietary fat intake and dietary fat quality for the adult population were agreed upon in consensus. The group decided to expand the work and also perform systematic reviews on the evidence for pregnant and lactation women, and for infants and children, which are ongoing at the time of writing this abstract. The outcomes and conclusions will be presented.

Evidence-based guideline on protein intake and disease prevention

Bernhard Watzl[1], *Anna M. Amini*[2], *Julia Haardt*[2], *Nicole Kalotai*[2], *Andreas Lehmann*[2], *Annemarie Schmidt*[2], *Anette Buyken*[3], *Anja Kroke*[4], *Lukas Schwingshackl*[5]

1. Max Rubner-Institut (Germany), 2. German Nutrition Society (Germany), 3. University of Paderborn (Germany), 4. Fulda University (Germany), 5. University of Freiburg (Germany)

The German Nutrition Society is currently developing an evidence-based guideline on protein intake which focuses on the role of dietary protein intake for the primary prevention and risk modification of various non-communicable diseases. The aim of this guideline is to investigate whether dietary protein intake with regard to quantitative (higher vs. lower dietary protein intake) and qualitative considerations (total, plant-based or animal-based protein intake) affect the development of selected health-related outcomes in the general adult population. The following outcomes are investigated: blood pressure, body weight and body weight-related outcomes, bone health, cancer, cardiovascular diseases, kidney health, muscle health and type 2 diabetes mellitus. To assess the overall certainty of evidence for each health-related outcome, umbrella reviews of systematic reviews with or without meta-analyses of prospective studies are conducted. Systematic literature searches are performed in the three databases PubMed, Embase and Cochrane Database of Systematic Reviews. The methodological quality and outcome-specific certainty of evidence is evaluated using a modified version of “A Measurement Tool to Assess Systematic Reviews 2” (AMSTAR 2) and the NutriGrade scoring system, respectively. The overall certainty of evidence is assessed for each relevant exposure-outcome link based on the consistency of results, the methodological quality, the outcome-specific certainty of evidence and the biological plausibility. Finally, results from all health-related outcomes will be brought together and overall recommendations regarding dietary protein intake will be derived based on an Evidence to Decision framework. This will consider the overall certainty of evidence derived from the outcome-specific umbrella reviews, but also other aspects such as ecological sustainability, dietary intake levels of protein and dietary preferences.

Update on extra-skeletal health effects of vitamin D - implications for recommendations

Jakob Linseisen[1]

1. University of Augsburg (Germany)

There is accumulating evidence that vitamin D may beneficially affect several extra-skeletal diseases, including respiratory tract, autoimmune, neurodegenerative, and mental diseases. We identified systematic reviews (SRs) of cohort studies and randomized controlled trials (RCTs) as well as single Mendelian randomization studies and summarized the results in an umbrella review. Observational data on primary prevention suggest an inverse association between vitamin D status and the risk for acute respiratory tract infections (ARI) and depression, whereas data for asthma, multiple sclerosis (MS), and type-1 diabetes mellitus (T1DM) are still scarce. SRs of RCTs support the observational findings in the case of ARI. Further, SRs of RCTs indicate beneficial therapeutic vitamin D effects in patients with asthma and COPD. In addition, we also reviewed the literature on the specific association between vitamin D status and COVID-19 disease risk and severity of the disease. The implications for recommendations to the general public or for specific high-risk groups are being discussed.

Food-based dietary guidelines in Germany

Anne Carolin Schäfer[1,2]*, Kiran Virmani*[1]*, Johanna Conrad*[1]*, Heiner Boeing*[3]*, Bernhard Watz*[4]

1. German Nutrition Society (Germany), 2. University of Bonn (Germany), 3. German Institute of Human Nutrition Potsdam-Rehbrücke (Germany), 4. Max Rubner-Institut (Germany)

Background and objectives

The current food-based dietary guidelines (FBDG) in Germany already prove to be environment-friendly and health-promoting. In their derivation, predominantly the coverage of nutrient needs was considered among diet-health relations and dietary habits. In view of the pressing challenge of the environmental burden of diets, mathematical optimisation techniques are suitable tools to simultaneously account for the interrelated and conflicting properties of foods. For the new generation of FBDG for Germany, the objective is to develop an evidence-based, transparent methodology to identify dietary changes accounting for the sustainability dimensions health, environment, and social issues. The methodology shall also enable the integration of further dimensions and associated indicators.

Methods The derivation process and selection of dimensions was guided by the definitions and frameworks for FBDG derivation of official international institutions and by common optimisation practices. Two workshops, organised by the Federation of European Nutrition Societies, gave guidance as well. The indicators of the dimensions were operationalised according to the goals of the FBDG and also mathematical conditions. As the underlying food categorisation system, FoodEx2 by the European Food Safety Authority was selected.

Results Three parameters define the optimisation algorithm: 1) The decision variables, which are observed food intakes; 2) acceptability constraints, and 3) the linear objective function. The latter consists of three components that are weighted against each other and minimizes environmental impact (dimension environment; included indicators: greenhouse-gas emissions and land use), diet-related health burden (dimension health; included indicator: disability adjusted life years), and relative deviation from the observed dietary intake (dimension social issues; included indicator: dietary habits).

Conclusions

Our innovative approach enables the integration of multidimensional requirements in FBDGs and is flexible regarding the importance given to each indicator. It will support the derivation of healthy and sustainable FBDG for Germany.

SY(T9)18-4
How to shape and assess dietary behavior using mobile devices

Britta Renner[1]*, Harald Thomas Schupp*[1]

1. University of Konstanz (Germany)

Technological development in the field of mobile technologies is proceeding at a rapid pace increasingly immersing everyday life. The regular use of smartphones and other mobile technologies also opens up new avenues for dietary surveys and behavioral change. The technical features of smartphones, such as GPS and cameras, enable users to document and track their eating habits in daily life. In addition, it is also possible to record complex data about eating behavior at the moment of experience in specific everyday situations. New technologies thus offer not only **more** data, but also qualitatively **different** data. For example, they show us time

signatures, when and for how long food is eaten, and also the circumstances, e.g., where and with whom food is eaten.

Furthermore, mobile technologies can also be used to tailor behavior change interventions more specifically to individual user needs and specific eating situations. These potentials of mobile technologies for dietary monitoring and intervention are illustrated by recent results from a systematic review and meta-analysis comprising 6348 participants and 373 outcomes with sample sizes ranging from 10 to 833, including 27 randomized controlled trials (RCTs). Here a beneficial effect of app-based mobile interventions was identified for improving nutrition behaviors (g= 0.19; CI 0.06-0.32, P = .004) and nutrition-related health outcomes (g = 0.23; CI 0.11-0.35, P = .001). Research conducted within the BMBF project SMARTACT show first promising results in terms of improving dietary behavior and various health parameters. Taken together, the potentials of mobile technologies for changing eating behavior are discussed with respect to higher-level perspectives such as Food as Health and Food as Well-being.

SY(T9)19-2
Measuring sustainable diets: nutrition and ecosystem metrics

Jennie I Macdiarmid[1]

1. University of Aberdeen (UK)

Sustainable diets are described as diets with a low environmental impact that are nutritionally adequate, safe and healthy, as well as socially and culturally acceptable, affordable and accessible. This FAO definition is a widely accepted and used, but the multidimensional and complex nature of sustainable diets presents a significant challenge in measuring them. A clearly defined metrics is necessary to assess progress towards diet-related goals and targets (including many of the Sustainable Development Goals), to formulate dietary guidelines, inform policy development and to help consumers make food choices. To date, there is no commonly agreed metrics for measuring sustainable diets. The objective of this presentation is to review of the development and use of metrics for measuring sustainable diets. Sustainable diets can be divided into three general components, health and nutrition, environment, and social and economics. Within each component there are multiple attributes and potential measurements, for example, nutrient requirements, diet diversity, nutrient density and consumed of specific foods can be used to measure aspects of nutrition and dietary quality. The metric chosen is often based on the availability of data. Reviews have shown that the majority of published papers comparing dietary patterns used greenhouse gas emissions as a surrogate for environmental impacts because of the existence and accessibility of data. However, greenhouse gas emissions data are often a global average figure that can be too general as it masks the variation in production methods that is particularly important when comparing low- and middle-income countries with high-income countries. An advantage of using metrics is that it can highlight potential unintended consequences that would not be foreseen if a single attribute was used. For example, nuts are included in many food-based dietary guideline and while they tend to be associated with relatively low greenhouse gas emissions, they are water intense and commercially grown in water scare areas of the world. Similarly, sustainable diets are often associated with plant-based diets, which are assumed to be healthy and have a low environmental impact, but this is not necessarily the case, especially today with increasing availability of highly processed plant-based foods in many countries.

SY(T9)19-3
The Ecological Nutrition Framework for Informing Nutrition Activities (ENFINA): Guiding fit-for-purpose decision-making to promote sustainable diets

Mark Lawrence[1]

1. Deakin University (Australia)

The rapid transition in food systems around the world and the emergence of novel dietary patterns dominated by ultra-processed foods, increasing animal-/plant-sourced food ratios and rising food waste has no ecological or evolutionary precedent. Sustainable diets are being threatened. Nutrition policymakers have an unparalleled amount of evidence available to inform the development of dietary guidelines and policy actions to promote sustainable diets. However, decision-making processes are fraught with scientific and political challenges when developing evidence-informed nutrition activities. This presentation reports on the development and strategic application of 'ENFINA', the Ecological Nutrition Framework for Informing Nutrition Activities, as a novel tool to guide decision-making for nutrition activities to promote sustainable diets.

Nutrition science is complex and has a history of developing well-intended but ineffective nutrition activities, often with adverse unintended consequences. The field of Ecological Nutrition provides a theoretically grounded scientific basis for guiding 'fit-for-purpose' nutrition activities. In this study Ecological Nutrition was defined as, 'an interdisciplinary body of knowledge, methods, and tools which encompass nutrition-mediated interactions between human physiology and food environments based in ecological and evolutionary theory'.

How can fit-for-purpose decision-making be operationalised in practice? Core concepts from ecological and evolution theories were synthesised to underpin the design of ENFINA. The

framework proposes reforms to the conventional nutrition evidence synthesis and translation methods from their current mostly 'one-size-fits-all' and nutrient-centric (reductionist) orientations to an orientation that is fit-for-purpose for nutrition activities intending to promote sustainable diets.

The framework is applied to integrate a sustainability dimension into food based dietary guidelines as well as nutrition actions such as front-of-pack labelling. The application of the framework's fit-for-purpose orientation to how evidence is synthesised and translated for nutrition decision-making increases the likelihood that the resulting nutrition activities will be effective and less prone to adverse unintended consequences in promoting sustainable diets.

Highlights from the High Level Panel of Experts of the Committee on World Food Security

Barbara Burlingame[1]

1. Massey University (New Zealand)

Background and objectives: The High Level Panel of Experts on Food Security and Nutrition (HLPE) is the United Nations body for assessing the science related to world food security and nutrition. It is the science-policy interface of the Committee on World Food Security (CFS) and provides independent, comprehensive and evidence-based analysis and advice through a scientific, transparent and inclusive process, grounded the principle of food/nutrition as a human right.

Methods: Policy recommendations concerning sustainable diets, extracted from the 18 reports of the HLPE, are presented, with emphasis on nutrition and food systems, agroecology, climate, the role of livestock, food losses and waste, data and analysis tools, critical and emerging issues in food security and nutrition, and the global narrative.

Results: Focussing on human nutrition and environmental/ecosystem sustainability, a range of specific policy recommendations are presented, covering global to local levels, to achieve the vast number of goals and targets related to food security and nutrition. Two new dimensions to the formal definition of food security were proposed to be widely applied, consistent with the concept and definition of sustainable diets: 'sustainability' and 'agency'. Sustainability is the fundamental, indispensable element that requires immediate actions in the present to safeguard the future of food security and nutrition. Agency is the element that enables/facilitates individuals and communities to use their own power to effect change, even when top-down political will is ineffectual.

Conclusions: In every case, regardless of the thematic emphasis within the broad subject of food security and nutrition, and sustainable diets, urgency of action is the common, but heretofore neglected, call. The Covid-19 epidemic, and the recent glimpses of a global conflict, have sharpened the focus on the imperative of urgency related to food security and nutrition.

Panel Discussions

PD1-1
COVID-19, Food and Nutrition in the United States of America

Rachel Novotny[1], Jean Butel[1]

1. University of Hawaii at Manoa (USA)

In the United States of America (USA) government response to the COVID-19 pandemic included Legislation (Families First Coronavirus Response Act, FFCRA, in 2020 and the American Rescue Plan of 2021). Even prior to COVID-19, poor diet was the leading underlying cause of death in the USA, though disparities exist. This paper reviews literature describing the COVID-19 food- and nutrition-related response in the USA. Electronic literature searches on PubMed and Web of Science search engines identified information related to the USA food- and nutrition-related response to COVID-19 pandemic, until March 2022. Search terms were food, nutrition, COVID, and the United States of America. Papers were reviewed, qualitatively. Key USA food assistance programs leveraged were the Supplemental Nutrition Assistance Program (SNAP), the Supplemental Feeding Program for Women, Infants, and Children, the National School Lunch Program and the Commodity Supplemental Food Program. SNAP increased its benefit and added online application and pandemic electronic benefit transfer options for families. School lunch became free for children. WIC participation increased and WIC innovated for children, though not for women or infants. The Commodity Supplemental Food Program provided food for seniors. Local responses included expanded community food resources and home gardening. Food banks increased food distribution, community and senior centers increased meal distribution. Challenges included panic food buying, food distribution disruptions, a lag in food and unemployment benefits for new applicants, and varying access to nearby healthy food retailers. Disparity in access to benefits was found. School meal participation decreased during the pandemic. Young children experienced increased BMI. There was an increase in consumption high-sodium foods, home-prepared foods, consumption of sweets, red and processed meats, and refined grains and decreased consumption of whole fruits, vegetables, and lean proteins. Households with young children and seniors experienced greater food insecurity, as did households located in areas with low food access. Obesity and obesity-related chronic diseases were associated with severe outcomes from COVID-19. Households experiencing food insecurity had higher rates of COVID-19 infections compared to food secure households. Misinformation led to use of unproven methods to prevent and treat COVID. Successes related to developing “grab and go” school meal options, and adaptability of community food distributions, and online acceptance of SNAP benefits. In the USA, COVID food- and nutrition-related response focused on food assistance, income assistance and housing assistance. Improved resiliency is needed- in coordination and addressing vulnerabilities in global food supply chains, access to local foods, and surveillance systems, for both emerging infections and food systems.

COVID, Food and Nutrition in Indonesia

Rimbawan Rimbawan[1], Khaerul Fadly[1]

1. IPB University (Bogor Agricultural University) (Indonesia)

While struggling to address long-standing food security and nutrition challenges, Indonesia is facing an unprecedented crisis triggered by the COVID-19 pandemic. Actions are required on many dimensions of food security and nutrition to address the impact of the pandemic on food security and nutrition. This report is based on the latest secondary data available, updates on relevant policies and programs related to food security and nutrition, and new challenges, especially the rise of the triple burden of malnutrition. To control the pandemic, Indonesia implemented an activity restriction policy in 2020 called the large-scale social restriction (PSBB), and in 2021 the emergency public activity restriction (PPKM), involving multi stakeholders' collaboration. Some regencies and districts applied PPKM, based on the severity of Covid-19 cases. Thirty-four ministries and agencies served on a task force team to accelerate the COVID-19 response. All 34 provinces and 496 out of 514 districts-municipalities developed regional task forces. Several private organizations contributed by managing volunteer recruitment for medical services, financial donations, water sanitation and hygiene (WASH) logistics, and coordination support. Non-governmental organizations, United Nations agencies, and universities collaborated to control the pandemic. Seven priority areas identified were health, risk communication, community engagement, logistics, food security, mitigating the socioeconomic impact of the crisis, critical multi-sectoral services, and protection of vulnerable groups. In 2020, the Ministry of Health reported that only 19.2% of Public Health Centers continued to run the Government Integrated Health Post program. Furthermore, the latest available data from the National Nutritional Status Survey showed that there were increasing cases of underweight in children under five, from 16.3% in 2019 to 17.0% in 2021. According to the study of status and determinants of food insecurity and undernutrition in urban

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

poor areas of Jakarta (SDFU, 2020), households experienced reduced income during the pandemic, moderate or severe food insecurity, used some form of coping strategy (using savings, relying on informal debt, selling household assets and goods). Households with children under five dramatically altered how they purchased food due to COVID-19. Food affordability was cited as a greater concern for households than food access and mode of purchase or delivery. Household food insecurity during COVID-19 exacerbated the poor quality of women's diets. Also, children ate fewer nutritious foods and unhealthy foods due to limited household purchasing power. Besides healthy food and diet promotion, the government published guidance on the use of herbal and multi-vitamin-mineral supplements to maintain and improve immunity. Additionally, the government took action to mitigate the impact of the pandemic on food security with food production, that is with home gardening and micro-credit programs to boost micro and small enterprise businesses. Several social assistance programs were established, such as cash transfer, basic foods, village-level direct cash assistance, and electricity subsidy. These programs resulted in positive impacts in easing the burden of the pandemic. The social safety net programs should be extended, and efforts to maintain a good health system, food supply, and price stabilization should be continued.

PD1-3
COVID-19, Food and Nutrition in Thailand

Patcharanee Pavadhgul[1]

1. Mahidol University (Thailand)

Thailand has successfully contained the first wave of COVID-19. A national strategy for responding to COVID-19 was implemented with surveillance at three levels. The surveillance included points of entry into the country, hospitals and healthcare facilities and active case finding in the community by village health volunteers and related agencies from both the public and private sectors. Risk communication preparedness involved continually assessing risks and monitoring people's behaviors to develop appropriate communication strategies and messages for all populations, age groups, sexes and both Thais and non-Thais. Social media played a crucial role in raising awareness of the general public regarding the dangers of COVID-19. Using information technology in tracing COVID-19 was developed to record population movement data for the benefit of contact tracing among risk groups and bringing them into the disease surveillance and investigation process.

The COVID-19 outbreak and the control measures affected risk behaviors and future non-communicable disease among Thai people. An online survey in 2020 was performed to assess 7,711 people from 77 provinces. People had more stress and gained weight (31.7%). The factors resulting in weight gain were eating more food including instant noodle, dessert, sugar sweetened beverage, fruit and less physical exercise. However, they were increased focus on herbs and local remedies. The government of Thailand approved green chiretta (*Andrographis paniculata*) and fingerroot (*Boesenbergia rotunda*) to treat early symptoms and reduce the severity of COVID-19.

United Nations expect COVID-19 had an impact on food and nutrition security in the short and long term. The long-term impact will likely be most pronounced in children who were in the first 1,000 days of their lives during the pandemic. The supply-side shocks, the availability and prices of food, have been a concern in the short term. On the demand side, a decrease in purchasing power is likely to affect the quality of diets and access to nutrition services. The closure of schools put a further strain on households where children depend on school meals for lunch. These changes in dietary quality can reduce nutrient intake, which can lead to micronutrient deficiencies in women and children, and worsening of wasting among children who are at or near the cut-off for wasting, and stunting in children under five. These impacts will be felt most by the urban poor and informal sector workers and migrant labor households who are most vulnerable to the economic shocks associated with COVID-19. At the same time, consumption of foods that are rich in fat and sugar has risen among households in urban areas. These dietary changes, combined with a reduction in physical activity could increase the risk of obesity and developing NCDs, an existing public health concern in Thailand across age groups. Food security strategies among communities during the pandemic were (1) food banks (the growth and consumption of organic vegetables, the paddy rice fund), (2) food exchanges (exchanging rice and fish), and (3) food pantries (food donation). Policy choices should address food and nutrition security, and center on the health system, the food system, and food and nutrition surveillance.

COVID-19, food, and nutrition in Japan

Asami Ota[1]

1. University of Niigata prefecture (Japan)

Japan`s outbreak of the COVID-19 epidemic started in April 2020 (first wave), and in January 2022, the epidemic of Omicron strains (sixth wave) occurred. As a result of the later start to the epidemic, the number of infections and deaths are likely to be lower than other countries. However, the epidemic has deepened health disparities. Early in the epidemic (2020 April and May), office workers worked from home and most of the schools closed. According to the Household Survey (Ministry of Internal Affairs and Communication), household consumption of rice, pasta, and frozen foods temporarily increased during this time. Relatedly, the restaurant industry showed a severe sales decline during this time. Studies in Japan showed that, during the pandemic, groups working at home were more likely to have a higher income and education, a temporary deterioration in physical activity, and increased bodyweight. In another study, participants whose income decreased showed a higher

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

frequency of using takeout food. Most studies were online surveys, which very low-income groups might not have responded to. Regional level study showed that high unemployment rates, or high restaurant industry workers per prefecture rate, was related to higher mortality rates. Service industry workers have a higher risk of infection and low-income groups tend to have a higher risk of chronic diseases that affects mortality from COVID-19 infections. Children`s studies showed increase in screen time, both increase or decrease of body weight and decrease of physical strength. A food survey of elementary school children found that a "well balanced dietary intake" - the intake of dairy products, meat, fish, eggs, vegetables, and fruit – was low in all income groups (quartiles) and was the lowest in the lowest- income group. In Japan, there are various support funds for people in need and a child rearing allowance for single parents, though there is no funding directly protecting food security. Single parent surveys showed that many are limiting the amount of food or frequency of feeding. And though they have many problems, they are feeling difficulty asking others for help. In the long term, measure, encouraging food literacy from young age, through school meal programs and nutrition education might narrow the disparity. All children could experience healthy food, have knowledge of nutrition and practice basic cooking skills. In the short term, packing school lunch to take out like the “grab and go" program in the U.S, in school closure or in long vacations, are affordable ways to provide food to children. For adults, collaboration between public and private sectors may be needed in order to have contact with people in need, as there is no specific place to contact them in a way that protects personal information. Food supplies can be through volunteer groups, local children's cafeterias or food banks. In addition to providing food, teaching cooking, may be a way to develop food literacy for the adult group. Japan experienced worsened health and food disparities. A food system which can reach all, leaving no one behind, is needed.

Omega-3 Fatty Acids for Depression: Recent Finding

David Mischoulon[1], Boadie W Dunlop[3], Becky Kinkead[2,3], Pamela J Schettler[2,3], Stefania Lamon-Fava[4], Jisun So[4], Krishna Rao Maddipati[5], Jennifer C Felger[3], Maurizio Fava[1], Mark Hyman Rapaport[2,3]

1. Massachusetts General Hospital (USA), 2. University of Utah (USA), 3. Emory University (USA), 4. Tufts University (USA), 5. Wayne State University (USA)

Background: Omega-3 fatty acids have demonstrated promising efficacy for treating depressive disorders, but there is still limited consensus on optimal formulations, doses, and target populations. Given the anti-inflammatory properties of omega-3s, they may be well suited for individuals with depression and high inflammation states, including being overweight or obese.

Methods: We compared clinical efficacy and biological effects of three eicosapentaenoic acid (EPA) doses versus placebo on inflammatory biomarkers, depressive symptoms, and EPA metabolites and resolvins (Rv) E1-3. We randomized 61 unmedicated adults (75% female; 45.5 +/- 13.8 years) with DSM-5 major depressive disorder (MDD), body mass index (BMI) >25 kg/m2, and plasma high-sensitivity C-Reactive Protein (hs-CRP) >=3.0 mg/L to EPA 1 g/day, 2 g/day, 4 g/day or placebo for 12 weeks. We hypothesized an EPA-related effect size (ES) >= 0.40 for decrease in plasma interleukin (IL)-6, peripheral blood mononuclear cell (PBMC) cytokines, and lipopolysaccharide (LPS)-stimulated tumor necrosis factor (TNF) production. Response was defined as a >=50% decrease of Inventory of Depressive Symptomatology, Clinician-Rated version (IDS-C30) scores. We also hypothesized an EPA-related ES >= 0.35 at weeks 8 and 12 for decrease in IDS-C30 scores or a sustained effect on IDS-C30 response rates at weeks 8 and 12, and that changes in hs-CRP, IL-6 and LPS-stimulated PBMC TNF production would be associated with depressive improvement.

Results: In 45 completers, only median PBMC TNF decreased at 2 g/day EPA. No EPA dose produced a >= 0.35 ES reduction in plasma IL-6 or mitogen-stimulated TNF. Response rates were 64% for EPA 4 g/day and 40% for placebo (odds ratio [OR]= 2.63; Cohen d = 0.53), 38% for EPA 1 g/day and 36% for EPA 2 g/day (P>0.05 for all comparisons). EPA 4 g/day showed a significant correlation between percent decrease in plasma hs-CRP and IDS-C30 symptom reduction at 12 weeks (Spearman rho=0.691, p=0.019). In 42 patients with available EPA and resolvin data, plasma EPA and EPA-derived metabolite concentrations remained unchanged in the placebo group. Plasma EPA and metabolites, including 18-hydroxyeicosapentaenoic acid (18-HEPE), which is the precursor of resolvins RvE1-3, increased significantly and dose-dependently in all EPA supplementation arms. RvE1 was undetected in all treatment groups, while RvE2 and RvE3 increased dose-dependently. Arachidonic acid-derived lipoxin B4 (LXB4) also increased in the 4 g/day arm.

Conclusions: EPA 4 g/day demonstrated a medium effect size for response rates compared to placebo and may alleviate MDD in overweight adults with high inflammation; hs-CRP may be associated with clinical response. EPA 4 g/day also produced a robust increase in plasma EPA and 18-HEPE, which may promote conversion to RvE2 and RvE3, and LXB4. Their associations with reduced inflammation and clinical improvement remain to be clarified.

Conflict of Interest Disclosure: Dr Mischoulon has received research support from Nordic Naturals and heckel medizintechnik GmbH. He has received honoraria for speaking from the Massachusetts General Hospital Psychiatry Academy. He also works with the MGH Clinical Trials Network and Institute (CTNI), which has received research funding from multiple pharmaceutical companies and NIMH.

PD2-3
Role of Omega-3 Polyunsaturated Fatty Acids in Perinatal Depression

Kei Hamazaki[1]

1. Gunma University (Japan)

Omega-3 polyunsaturated fatty acids (hereafter, omega-3) such as DHA are important constituents of the brain and nerves, and they are required in large amounts, especially during pregnancy and lactation. However, omega-3 cannot be synthesized in the body, so it must be obtained from food. According to a postmortem brain study of fetuses, the daily requirement was estimated to be 67 mg in the third trimester of pregnancy (Clandinin MT, et al 1981). A cohort study in Germany showed a negative correlation between weeks of gestation and months of lactation and omega-3 in blood (Gellert S, et al 2016). When there is inadequate intake of omega-3, animal experiments have shown that mother rats supply omega-3 to their fetuses even at the expense of their own brain (Levant B, et al 2006). MRI studies have shown that the cerebral volume of healthy mothers during a singleton pregnancy does in fact decrease by about 4%-6% by the time of delivery, before returning to its original volume after delivery (Oatridge A, et al 2002). One possible reason for the volume reduction is the supply of n-3 polyunsaturated fatty acids to the fetus. Thus, if insufficient omega-3 is consumed during pregnancy, neuropsychiatric disturbances may affect both mother and child. Analysis of a large dataset obtained in an ongoing birth cohort study conducted by the Ministry of the Environment in Japan— the Japan Environment and Children's Study (JECS) involving around 100,000 representative pregnant women— revealed lower odds ratios for depression in mid-late pregnancy and after delivery in women who had higher intakes of fish and omega-3 during pregnancy (Hamazaki K, et al 2018, 2020). Different fish contain different amounts of methylmercury, which can have adverse neurodevelopmental effects. Large fish bioaccumulate larger amounts, whereas smaller fish do not have levels for concern, such as yellowfin tuna, salmon, sardines, yellowtail, albacore, horse mackerel, Pacific saury, bonito, Pacific bluefin tuna, mackerel, and sea bream (Ministry of Health, Labour and Welfare). According to the National Health and Nutrition Survey, fish consumption is consistently declining in Japan. This is occurring alongside decreasing amounts of omega-3 in Japanese mother's breastmilk over the last three decades (Yoshida S, et al 2019). Fish is rich in minerals, vitamins, high-quality protein, and omega-3, and therefore in this symposium we will discuss the importance of fish consumption in pregnancy.

PD2-4
The Interplay of Stress, Inflammation, and Omega-3 PUFAs in Depression

Kuan-Pin Su[1,2]

1. China Medical University, Taichung (Taiwan), 2. An-Nan Hospital, Tainan (Taiwan)

The increasing global burden calls for the development of novel approaches to tackle unmet needs in prevention and treatment of depression underlying biological, psychological and social dysregulations. Depressed patients with chronic low-grade inflammation might be classified as a subgroup of major depressive disorder (MDD); therefore, looking for antidepressant therapies from anti-inflammatory pathways could improve treatment effectiveness for this subgroup of patients. Omega-3 (or n-3) polyunsaturated fatty acids (PUFAs) are anti-inflammatory both in peripheral organs and central nervous systems and have clinically applied in the treatment and prevention of depression, cardiovascular diseases, dyslipidaemia, diabetes and arthritis. Anthropological studies suggest that human beings evolved to a modern diet with less than one-tenth of omega-3 to omega-6 PUFAs intake ratio, which leads to a constitutional bias toward chronic systemic inflammatory status to explain dramatically increasing of depression and chronic medical illnesses in modern world. The presentation is to provide our recent clinical and pre-clinical studies and an overview about the role of inflammation in “mind-body” comorbidity and present anti-inflammatory mechanisms by which n-3 PUFAs may orchestrate the molecular and cellular functions and facilitate the therapeutic pathways in chronic medical illnesses and depression.

Fish oil may ease anxiety

Yutaka Matsuoka[1]

1. Former Division Chief of National Cancer Center (Japan)

Systematic review and meta-analysis (JAMA Netw Open, 2018) have revealed that omega-3 fatty acids can help relieve symptoms in patients with anxiety disorder. Omega-3 fatty acids didn't help people who did not have specific clinical conditions. Patients who benefited most were those who took 2,000 mg per day or more. Although omega-3 fatty acids is not a first-line treatment for anxiety, for patients who are not responsive to psychotherapies, eating fatty fish might be a promising alternative.

Keywords: anxiety, posttraumatic stress disorder, fish oil, omega-3 fatty acids

International Agency for Research on Cancer, World HPublic Health Department, AviceInternational Agency for Research on Cancer, World Health Organizationnne Hospital, AP-HPealth Organization (France)

Background and objectives: Artificial sweeteners are widely used today by the food industry as an alternative to sugar, providing sweet taste and nearly no calorie. Potential adverse effects of these food additives on cardiovascular disease (CVD) risk have been suggested in experimental studies, but data from studies involving humans remain very limited. Previous cohorts have focused solely on artificially sweetened beverages. Our objective was to study the associations between artificial sweeteners from all dietary sources (beverages but also table-top sweeteners, dairy products, etc.), overall and by molecule (aspartame, acesulfame-potassium and sucralose), and risk of CVDs (overall, coronary heart and cerebrovascular).

Methods: The study included 103,388 participants of the web-based NutriNet-Santé cohort (2009-2021, mean age=42.2±14.4, 79.8% female, 904,205 person-years). Artificial sweetener intake as well as detailed dietary data were assessed thanks to repeated 24h dietary records, including names and brands of industrial products consumed. Multi-adjusted Cox proportional hazard models were performed. Exposure to artificial sweeteners were coded as three category variables: non-consumers, lower consumers (artificial sweetener intake below the sex-specific median) and higher consumers (above the sex-specific median).

Results: Compared to non-consumers, higher consumers of total artificial sweeteners had increased risk for CVD (n=1502 incident cases, HR=1.17 (1.01-1.35), P-trend=0.04) and more specifically cerebrovascular diseases (n=777, HR=1.34 (1.10-1.62), P-trend=0.004). Higher consumption of aspartame was associated with increased cerebrovascular diseases (HR=1.29 (1.03-1.60), P-trend=0.01). Higher consumption of acesulfame-K was associated with a higher risk of CVD (HR=1.24 (1.04-1.47), P-trend=0.02) and cerebrovascular diseases (HR=1.29 (1.02-1.64), P-trend=0.1). No association was detected for coronary heart diseases (n=730 incident cases).

Conclusions: Findings from this large-scale prospective cohort suggest a direct association between higher artificial sweetener consumption and increased CVD risk, in particular cerebrovascular. These results provide key novel information in a context where artificial sweeteners, present in thousands of food and beverage brands worldwide, are currently undergoing a re-evaluation by the European Food Safety Authority and other health agencies.

Further Collaborators: Researchers from public institutions can submit a collaboration request including information on the institution and a brief description of the project to collaboration@etude-nutrinet-sante.fr. All requests will be reviewed by the steering committee of the NutriNet-Santé study. If the collaboration is accepted, a data access agreement will be necessary and appropriate authorizations from the competent administrative authorities may be needed. In accordance with existing regulations, no personal data will be accessible.

OAB(T1)1-2
Fortified milk intake reduces iron, vitamin A, vitamin C, calcium, and B-vitamins inadequacies in Pakistan school-aged children: a diet modeling study

Myriam Afeiche[1], Diane Zimmermann[1], Laurence Donato-Capel[2], Tsz Ning Mak[1]

1. Nestle Research Lausanne (Switzerland), 2. Société des Produits Nestlé S.A. (Switzerland)

Background and objectives: While 89% of Pakistani 5-9y old consume dairy products, only 8% comply with Pakistan's recommended dairy intake of 2-3 servings-day (s-d). More than 80% have inadequate intakes of calcium, iron, zinc, and vitamin A. Other main nutrient inadequacies include vitamin C (60%), B-vitamins (around 25%, except for folate 75%). The objective of this study was to evaluate the theoretical impact of adhering to 2s-d dairy recommendations on nutrient adequacy in Pakistani school-aged children.

Methods: Adherence to dairy recommendation was calculated using dietary data collected in 5370 children via a 24–hour diet recall in the School–age Children Health & Nutrition Survey in Sindh and Punjab, Pakistan (SCANS) in 2019–2020. Two modelling scenarios were applied to test the impact on nutrient intakes of a) substituting current milk intake (volume by volume) with a fortified milk beverage and b) adding a fortified milk

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

beverage to current intake to meet dairy intake recommendations. Mean nutrient intakes and percentages of children with inadequate intakes (compared with dietary reference intakes) were estimated before and after applying modelling scenarios.

Results: Among 4452 children consuming milk, the hypothetical substitution of current milk intake with fortified milk lowered nutrient inadequacies for vitamin C (by 89%), riboflavin (by 59%), vitamin A (by 55%), iron (by 31%), thiamin (by 30%), and calcium (by 28%), compared to baseline. Among 4358 children consuming less than 2 dairy s-d, a high percentage of nutrient inadequacies were observed: all children had calcium and zinc inadequacy, 98% iron, 90% vitamin A, and 59% vitamin C. The theoretical addition of fortified milk to current consumption of dairy products nearly eliminated vitamins C and A inadequacies, reduced calcium inadequacy by 7% and iron by 12%.

Conclusions: Substituting usual milk intake with fortified milk can bring additional nutrients that are not typically found in usual (unfortified) milks and help close nutrient gaps such as iron, vitamin A, vitamin C, and B-vitamins inadequacies. In children not adhering to dairy recommendations, increasing dairy with a fortified milk contributes to eliminating nutrients gaps for vitamins C and A and reduce nutrient inadequacies for calcium and iron.

Keywords: diet modelling, nutrient inadequacy, dairy, milk, school-aged children

OAB(T1)1-3
Irregularity in energy and nutrient intake and its association with BMI and Waist Circumference in adults from the UK National Diet and Nutrition Survey (2008-17) Rolling Programme

Luigi Palla[1], Rawan Gadi[4], Gerda Pot[3], Graham Horgan[2], Annarita Vestri[1]

1. University of Rome La Sapienza (Italy), 2. University of Aberdeen (UK), 3. Louis Bolk Institute (Netherlands), 4. London School of Hygiene and Tropical Medicine (UK)

Background and Objectives: Recent evidence suggested that individuals with a more irregular intake of energy, especially during breakfast and between meals, appeared to have an increased cardiometabolic risk. This project aims at finding irregularity eating patterns of energy, free sugars and saturated fats, and investigating their potential associations with measures of obesity.

Methods: Diet diary data repeated over 4 days for 6802 adults aged 19 or older from the UK Nutritional Diet and Nutrition Survey (2008-17) was utilised. Irregularity score of energy, free sugars and saturated fats were calculated for each time slot using mean absolute deviation around the mean (MAD). Principal component analysis (PCA) on the correlation matrix was applied to derive irregularity eating patterns (IEP) of energy, free sugars and saturated fats intake. Multivariable regression models accounting for the complex survey design were used to assess the association between the derived IEP and body mass index (BMI) as well as waist circumference (WC).

Results: Three orthogonal IEP were identified for each of type of nutrient and for each the first principal component (IEP1) was defined as an average level of irregularity across the day for that specific intake. The other principal components for energy were interpretable as (ii) a linear contrast between irregularity at main meal and irregularity at snack-time and (iii) irregularity in the day vs irregularity in the night. After adjustment for confounders, every 1 unit increase in IEP1 of energy intake was significantly associated with 0.38 kg/m2 and 0.86 cm increase in BMI and WC, respectively. Increase in overall IEP of free sugars and saturated fats were significantly associated with an increased level of BMI. In women only, a unit increase in overall irregularity score for saturated fat was associated with a 1.07 cm higher WC.

Conclusions: Adults who tended to have a higher irregularity in energy intake, free sugars and saturated fats had higher average BMI and WC. Women who had an overall irregular intake of saturated fats tended to have a higher WC. Further research should seek to identify the determinants of IEP establishing the causal relations with obesity via prospective study designs.

Dietary acid load, cardiometabolic syndrome and bone resorption among postmenopausal Malaysian Chinese women

Sook Yee Lim[1], Yoke Mun Chan[2], Yit Siew Chin[2], Zalilah Mohd Shariff[2], Vasudevan Ramachandran[3], Manohar Arumugam[2]

1. UCSI University (Malaysia), 2. Universiti Putra Malaysia (Malaysia), 3. Bharath Institute of Higher Education and Research (India)

Background and objectives: Studies showed that acidic diet dominated by animal sources and low in vegetables and fruits, can lead to chronic metabolic acidosis and thus cause calcium loss from bone. Despite acid-base balance theory hypothesized habitual consumption of high dietary acid load (DAL) is associated with a higher risk of osteoporosis, the scientific evidence has been inconsistent. Thus, this study aimed to explore the effects of DAL and cardiometabolic syndrome (CMS) and their potential interactions on bone resorption rate.

Methods: This cross-sectional study recruited 211 postmenopausal women in community settings. DAL was estimated using potential renal acid load from food frequency

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

questionnaire. Sleep quality was assessed using Pittsburgh Sleep Quality Index (PSQI). Serum levels of 25(OH) vitamin D was determined by using the ADVIA Centaur VitD assay and serum collagen type 1 cross-linked C-telopeptide (CTX1) was used as a surrogate bone marker to assess bone resorption. Cardiometabolic syndrome was determined according to Harmonized criteria.

Results: Results showed that age (β = -0.145, t = -2.002, p <0.05) was negatively associated while DAL (β = 0.142, t = 2.096, p<0.05) while sleep quality (β = 0.147, t = 2.162, p<0.05) and height (r = 0.136, p<0.05) were positively associated with CTX1. On the other hand, other variables (CMS traits, CMS, serum of 25(OH), years of menopause, years of education and physical activity) were not significantly associated with CTX1. There was no significant interaction effect between DAL and CMS on bone resorption.

Conclusions: Current findings proposing high DAL, but not CMS, is a potential risk factor for bone resorption. This study does not support the interaction effect of DAL and CMS on bone resorption but provides scientific insight on how acidic diet may influence bone resorption rate. Appropriate planning for preventing or delaying the onset of osteoporosis among postmenopausal women is highly warranted.

Keywords: Dietary acid load, cardiometabolic syndrome, bone resorption, postmenopausal women

OAB(T1)1-5
Discovery of metabolite biomarkers of meat consumption and their association with incident type 2 diabetes in a Swedish population-based cohort

Stefania Noerman[1], Anna Johansson[1], Lin Shi[1,2], Kati Hanhineva[3,4], Carl Brunius[1,5], Rikard Landberg[1]

1. Chalmers University of Technology, Gothenburg (Sweden), 2. School of Food Engineering and Nutritional Science, Shaanxi Normal University, Xi'an (China), 3. Institute of Public Health and Clinical Nutrition, University of Eastern Finland, Kuopio (Finland), 4. Department of Life Technologies, Food Chemistry and Food Development Unit, University of Turku, Turku (Finland), 5. Chalmers Mass Spectrometry Infrastructure, Chalmers University of Technology, Gothenburg (Sweden)

Background and objectives: Biomarkers of different meat intakes, complemented with self-reported intake, could clarify their yet inconsistent associations with incident type 2 diabetes (T2D). We aim to discover potential plasma metabolite biomarkers for intake of various meat food groups, and to investigate their associations with the risk of developing T2D. **Methods**: Self-reported meat intake, covariates, and fasting plasma samples were from a case-control study nested within the prospective Västerbotten Intervention Program (VIP), including 403 randomly selected participants who developed T2D (median 7 years to diagnosis) and matching controls. We used random forest on untargeted LCMS metabolomics data (24758 features) to discover biomarker candidates to reflect the intakes of total-, processed-, and unprocessed meat, as well as poultry. Selected features were adjusted for age, sex, and total energy intake using partial Spearman correlation with meat intake. These selected features were further associated to T2D risk using conditional logistic regression, adjusting for age, sex, physical activity, smoking, total energy and alcohol intake. **Results**: Features associated with total- (n=18), processed- (n=67), unprocessed meat (n=29), and poultry (n=53) were identified. Processed meat intake was associated with octenoylcarnitine (r = 0.32, FDR = 1.28 x 10^{-8}), decatrienoylcarnitine (r = 0.24, FDR = 3.40 x 10^{-5}), and inversely with methylproline (r = -0,18, FDR = 0.002). Poultry intake was associated with hydroxyvaleric acid (r = 0.16, FDR = 5.70 x 10^{-3}) and inversely with LPC (17:1) (r = -0.20, FDR = 1.93 x 10^{-3}) and PC(15:0/18:2) (r = 0.18, FDR = 4.09 x 10^{-3}). Interestingly, they were also associated with T2D risk. Octenoylcarnitine (OR 1.41, 95% CI 1.21-1.65, FDR = 1.05 x 10^{4}), decatrienoylcarnitine (OR 1.37, 95% CI 1.17-1.61, FDR = 4.86 x 10^{-4}), and hydroxyvaleric acid (OR 1.60, 95% CI 1.34-1.92, FDR = 3.45 x 10^{-6}) were associated with higher T2D risk, whereas methylproline (OR 0.77, 95% CI 0.66-0.90, FDR = 4.21 x 10^{-3}), LPC(17:1) (OR 0.71, 95% CI 0.61-0.83, FDR = 1.47 x 10^{-4}), and PC(15:0/18:2) (OR 0.73, 95% CI 0.62-0.85, FDR = 4.86 x 10^{-4}) with lower risk. These associations disappeared after adjustments, except for hydroxyvaleric acid (OR 1.47, 95% CI 1.19-1.82, FDR = 0.015). **Conclusion**: We discovered several biomarker candidates of meat intake which were also associated with T2D risk.

OAB(T1)1-6
Revision of dietary reference intake of iodine for Chinese

Wanqi Zhang[1], Wenxing Guo[1], Wen Chen[1]

1. Tianjin Medical University (China)

Background: The dietary reference intake (DRIs) of iodine is significant in guiding the public scientific iodine supplementation. The 2000 version of the Chinese iodine DRIs standard was derived based on foreign research data. The data on Chinese dietary reference intake of iodine are incomplete and need to be supplemented.

Methods: Summarizing the latest progress of iodine intake in domestic and foreign research to provide evidence for the revision of iodine DRIs.

Results: The adult's iodine tolerable upper intake levels (UL) of 600μg/d in the 2013 version of the iodine DRIs standard is based on the Chinese double-blind iodine intervention experiment. The iodine DRIs data of other populations were derived from foreign studies. Subsequently, Zhang et al.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

conducted a large-scale epidemiological survey on children in areas naturally exposed to different concentrations of water iodine, and found that when iodine intake was greater than 250μg/d and 300μg/d, respectively, the goiter rate in children aged 7-10 and 11-14 was greater than 5%. It is suggested that the iodine intake of children aged 7-10 and 11-14 should not exceed 250μg/d and 300μg/d. Besides, several studies have reported a significant increase in the incidence of subclinical hypothyroidism in pregnant women with urinary iodine concentrations above 250 μg/L. The Iodine balance study in pregnant women suggested that urinary iodine excretion is 1.8 L/d. About 90% of daily dietary iodine intake is excreted in the urine. It is assumed that the upper limit of daily iodine intake for pregnant women is about 500 μg/d.

Conclusions: The 2013 version of the adult's iodine UL was revised based on a randomized double-blind trial of iodine supplementation. New research evidence suggests that children aged 7-10 and 11-14 years old and pregnant women can tolerate upper intake levels of iodine of 250μg/d, 300μg/d and 500μg/d, respectively.

Conflict of Interest Disclosure: The authors declare that they have no potential conflicts of interest.

Keywords: iodine, dietary reference intakes, tolerable upper intake levels

Dietary factors and risk of SARS-CoV-2 infection: prospective analyses from the Moli-sani Study Cohort

Marialaura Bonaccio[1], Augusto Di Castelnuovo[2], Simona Costanzo[1], Mariarosaria Persichillo[1], Amalia De Curtis[1], Francesco Gianfagna[3], Chiara Cerletti[1], Maria Benedetta Donati[1], Giovanni de Gaetano[1], Licia Iacoviello[4]

1. IRCCS Neuromed (Italy), 2. Mediterranea Cardiocentro (Italy), 3. Università dell'Insubria and Mediterranea Cardiocentro (Italy), 4. IRCCS Neuromed and Università dell'Insubria (Italy)

Background and Objectives: A healthy and balanced diet plays a major role in supporting the immune system which is critical to protect the host from pathogenic organisms. To date, evidence on the relationship between dietary habits and the risk of SARS-CoV-2 infection is still scarce. **Methods**: Analyses included 1,096 participants from the Moli-sani Study (2005-2010) who were re-examined in 2017-2020, and in January-September 2021. Food intake was assessed in 2017-2020 using a semi quantitative 188-item food frequency questionnaire. Adherence to the Mediterranean diet was evaluated using the Mediterranean Diet Score (MDS) ranging from 0 to 9. Multivariable logistic regression models were used to estimate odds ratios (OR) and 95% confidence intervals (95%CI) for incident SARS-CoV-2 infection in association with the MDS, its individual components and nutritional factors. **Results**: Out of 1,096 participants, 90 either reported to have tested positive for COVID-19 or were positive for anti-SARS-CoV-2 antibodies before receiving any COVID-19 vaccine. In a multivariable-adjusted model including lifestyles, socioeconomic and clinical factors and also accounting for a composite index of behavioural risk factors (e.g. face mask use, hand sanitiser), a 1-point increase in the MDS was associated, though not significantly, with lower risk of SARS-CoV-2 infection (OR=0.90; 95%CI 0.78-1.04). Among individual dietary components, a high consumption of vegetables and fruits and nuts was associated with lower odds of SARS-CoV-2 infection (OR=0.57; 0.34-0.96 and OR=0.61; 0.37-1.00, respectively). High fish intake was otherwise linked to increased risk of infection (OR=2.05; 1.25-3.36). Nutritional factors associated with reduced risk of infection were dietary fibre (OR=0.50; 0.27-0.93 for 10 g/d increase), vegetable proteins (OR=0.56; 0.33-0.94 for 10 g/d increase) and vitamin C (OR=0.94; 0.89-0.99 for 10 g/d increase). **Conclusions**: Global adherence to the Mediterranean Diet was suggestive of a lower risk of SARS-CoV-2 infection. In particular, large amounts of fruit and vegetables were associated with reduced odds of being infected, as well as diets rich in fibre, vegetable proteins and Vitamin C. The greater risk associated with high fish intake deserves further investigation.

Association between dietary behaviors and BMI modified by the *ALDH2* rs671 polymorphism

Maki Igarashi[1], Shun Nogawa[2], Tsuyoshi Hachiya[2,3], Kyohei Furukawa[1], Shoko Takahashi[2], Huijuan Jia[2], Kenji Saito[1,2], Hisanori Kato[1]

1. Tokyo University (Japan), 2. Genequest Inc (Japan), 3. Genome Analytics Japan Inc. (Japan)

Background and objectives: The rs671 polymorphism in the aldehyde dehydrogenase (*ALDH2*) gene is unique to East Asians. This polymorphism has recently been reported to be associated with several dietary behaviors (DBs) as well as BMI. Therefore, this study aimed to determine whether the effect of DB on BMI is modified by rs671.

Methods: A total of 12,271 Japanese participated in this study. Data from rs671 genotypes from single nucleotide polymorphism arrays and 54 DBs from self-reported online surveys were used. All analyses were stratified by participants' sex. First, linear regression analyses were performed to investigate whether each DB was associated with BMI. Next, linear regression analysis and heterogeneity tests were used to investigate whether the rs671 polymorphism modified the effect of each DB on BMI. Finally, stepwise regression analysis was used

to examine the association between rs671 genotype and drinking habit-specific DBs and BMI.

Results: A total of 33 DBs were significantly associated with BMI for each sex. Genetic heterogeneity was found in all subgroups of participants, including drinkers and non-drinkers. Furthermore, stepwise regression analysis revealed that these associations between DBs and BMI were characterized differently according to sex, drinking habits, and rs671 genotype. In particular, the association characteristics between DB and BMI in drinkers were similar between rs671 genotypes, whereas in non-drinkers, they were not similar across genotypes. Furthermore, a positive association was observed between lactobacillus beverages and BMI in the AA genotype.

Conclusions: This study suggests that the association between DBs and BMI was modified by rs671 polymorphism. Our findings will contribute to the precision nutrition for health maintenance in East Asians.

Elucidation of the causal role of iron deficiency and excess on anemia and on cardiometabolic syndrome in UK White and Taiwan Han Chinese ethnic groups using Mendelian randomization analysis

Vanessa Joy Timoteo[1], Kuang-Mao Chiang[2], Hsin-Chou Yang[3], Yen-Tsung Huang[3], Wen-Harn Pan[1,2]

1. Taiwan International Graduate Program in Molecular Medicine, National Yang Ming Chiao Tung University and Academia Sinica (Taiwan), 2. Institute of Biomedical Sciences, Academia Sinica (Taiwan), 3. Institute of Statistical Science, Academia Sinica (Taiwan)

Background and objectives: Anemia due to iron deficiency remained to be a global public health problem, while several epidemiological studies have implicated elevated iron levels with higher risk of cardiometabolic outcomes. Genetic susceptibility and environmental factors were reported to cause both anemia and a number of cardiometabolic outcomes. However, there has been scarcity of data on the susceptibility genes of iron status, especially among non-European populations. It is also not completely clear whether variants of iron homeostasis genes causally influence the development of cardiometabolic syndrome (CMS). Through Mendelian Randomization (MR), our study elucidates the causal effects of iron deficiency and excess in precipitating the risk of anemia and CMS, respectively.

Methods: We first conducted genome-wide association studies of blood hemoglobin (Hb) concentration among UK Whites and Taiwan Han Chinese (HC). Ethnic-specific genetic risk scores from Hb-associated SNPs (Hb-GRS) were then constructed as instrumental variables for iron status. In our MR analyses, we performed multivariate logistic regressions that investigated the causal associations between tertiles of Hb-GRS, CMS, and cardiometabolic outcomes.

Results: Consistent genome-wide Hb-association of SNPs in *TMPRSS6* (chr 22), *ABO* (chr 9), and *PRKCE* (chr 2) were observed across sexes in both ethnic groups. Specific to the Taiwan HC, the Hb-association with *AXIN1*, together with other loci near the chr 16 alpha-globin gene cluster, was found novel. On the other hand, majority of the Hb-associated SNPs among Europeans were identified along the chr 6 major histocompatibility complex region, which has established roles in immune system control. We then found evidence to support causal associations between increasing tertiles of Hb-GRS and risks for CMS, hypertriglyceridemia, hypertension, diabetes mellitus, overweight and obesity, and hyperuricemia in the Taiwan HC group. We were able to cross-validate the causal associations in the UK Whites.

Conclusions: Such findings suggest the causal role of elevated iron levels in the pathophysiology of metabolic dysfunctions. In addition, the genetic determinants of iron identified among Taiwan HC and UK Whites may be utilized to screen high-risk subgroups for poor iron nutrition and iron overload. These will pave the way for precision nutrition and improve public health in the near future.

Vasorin as a new potential biomarker of metabolic risk in children with obesity and insulin resistance.

Francisco Javier Ruiz-Ojeda[1], Augusto Anguita-Ruiz[2], Gloria Bueno[3], Mercedes Gil-Campos[4], Rosaura Leis[5], Angel Gil[1], Concepción M Aguilera[1]

1. University of Granada (Spain), 2. Barcelona Institute for Global Health (Spain), 3. University of Zaragoza (Spain), 4. University of Córdoba (Spain), 5. University of Santiago de Compostela (Spain)

Background and objectives: Puberty is a time of metabolic and hormonal changes, and it is associated with a reduced insulin sensitivity that recovers at puberty completion in only some children, but not in all. Indeed, our group has demonstrated that IR represents the core in the pathophysiological development of metabolic syndrome in children with obesity. Preliminary epigenetics and transcriptomics data from our group reveal that the gene

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

encoding vasorin (*VASN*), among others, is significantly more methylated (cg00041083) and lower expressed in blood leukocytes of children with IR along with puberty. Therefore, our aim is to get a deeper understanding of the underlying metabolic architecture of IR development in childhood obesity and to study the pathophysiological implication of VASN as a putative predictive biomarker in children with obesity. **Methods:** The study population is a sub-cohort of the PUBMEP research project, consisting of a longitudinal population of 90 pre- and pubertal children with overweight, obesity and normal weight (53 girls). All subjects were classified into experimental groups according to their sex, obesity and insulin resistance (IR) status. They counted on anthropometry, glucose, and lipid metabolism, inflammation and cardiovascular biomarkers as well as VASN serum levels measured. Moreover, a cross-sectional population of 31 children between 6 and 12 years old were recruited. 15 of them were obese and 15 normal-weight at prepubertal age. Visceral adipose tissue (VAT) biopsies were extracted for genome-wide expression analysis and qRT-PCR. VASN expression was determined in the VAT.

Results: Serum VASN protein levels are significantly lower in children with obesity and insulin resistance, both at the prepubertal and pubertal stage. In addition, the gene expression of *VASN* in visceral adipose tissue is decreased in prepubertal children with obesity, indicating a possible relationship between the gene expression in adipose tissue and the observed lower levels of VASN in blood.

Conclusions: These findings exhibit that VASN may be an important biomarker of metabolic status in children with obesity and insulin resistance. Further analysis are needed in order to understand the molecular mechanism of this protein in adipose tissue, as the main metabolic organ involved in obesity and insulin resistance.

Blood DNA methylation signature of 3 dietary patterns

Camille Lassale[1,2], Jorge Dominguez Barragan[1], Jaume Marrugat[1], Ioanna Tzoulaki[3], Roberto Elosua[1]

1. Hospital del Mar Research Institute (IMIM), Barcelona (Spain), 2. CIBER of Pathophysiology of Obesity and Nutrition (CIBEROBN), Carlos III Health Institute, Madrid (Spain), 3. Imperial College London (UK)

Background and objectives: Diet is often mentioned as a key modifier of epigenetic markers, but the association between dietary patterns and DNA methylation has been little studied. We aimed to discover differentially methylated CpG sites across the whole genome associated with 3 dietary patterns in healthy adults.

Methods: In 4 cohorts from Spain, US and UK, including a total of 5339 adults, diet quality was measured using 3 different scores: Mediterranean diet score, the Dietary Approaches to Stopping Hypertension (DASH) score, and Healthy Plant-based Dietary Index. We performed epigenome-wide association studies of leukocyte-derived DNA methylation over 469,761 CpGs, adjusted for age, sex, smoking, total energy intake, blood cells and technical variables in every cohort and meta-analysed the results. We selected those CpGs associated with diet scores with a False Discovery rate of 0.05 (corresponding to a p-value of 10^{-6}) and no or low heterogeneity between cohorts (I^2<50%). We used Mendelian Randomization for those CpGs with a genetic instrument (cis-meQTL) to assess a potential causal relationship with cardiometabolic traits.

Results: We discovered of 154 unique differentially methylated CpGs, associated with 3 dietary patterns: the Dietary Approaches to Stop Hypertension (DASH, 92 CpGs), the Mediterranean diet (41 CpGs), and a Healthy Plant Based Diet (49 CpGs), and 24 were common to two or three of these dietary patterns. When applying a stricter threshold (Bonferroni correction), there were 21 CpGs. We replicated 3 CpGs associated with Mediterranean diet or Healthy Eating Index in a previous publication, which were annotated to SNORA54, NAP1L4, SOCS3 and BCL3 genes. When adjusting for body mass index and physical activity, the association was attenuated by more than 15% for 44 CpGs. In MR, we found that 2 diet-related CpGs were likely causally associated with body mass index, 1 CpG with CVD and 2 CpGs with diabetes.

Conclusions: We discovered 151 novel CpGs differentially methylated associated with 3 healthy dietary patterns. The majority of these CpGs are involved in cardiometabolic ways, and some appear causally associated with adiposity, CVD and diabetes.

Biomedical Network Research Centre in Physiopathology of Obesity and Nutrition (CIBERobn), Institute of Health Carlos III, 28029 Madrid, Spain. (Spain)

Background: MicroRNAs (miRNAs) have gained special attention due to their potential role as cross-kingdom gene expression regulators. Dietary plant miRNAs, which have been termed as xenomiRNAs, could be absorbed and reach specific tissues and organs, in which they might modulate gene expression and shape subject physiology. In addition, xenomiRNAs could be a key mechanism by which dietary patterns might influence metabolism and energy homeostasis. However, several studies refute this hypothesis, suggesting that xenomiRNAs would not be absorbed and display any function on the individuals.

Objectives The main objective of the present work is to determine the interaction between dietary xenomiRNAs and human genes involved in the pathophysiology of obesity and associated comorbidities.

Methods: RNA was isolated from plant foods (legumes, vegetables, nuts, fruits) and serum and faecal samples, before and after an acute ingestion (over 3 days/72 h) of plant-derived products. NGS was performed and plant conserved miRNAs and isoforms were identified. MiRNA candidates were selected according to their abundance, presence in human samples and potential interaction with obesity-related genes. Functional analysis of plant miRNA mimics were carried out in cell cultures (enterocytes, hepatocytes and macrophages), in which expression of target genes and their biological impact were evaluated.

Results: The results suggest that plant-derived miRNAs are abundantly present in vegetables, legumes, fruits and nuts. These miRNAs are detected in human samples and their relative amount increase after an acute ingestion. They also down-regulated specific human genes, whose dysregulation has been associated with obesity onset and/or progression, and displayed a biological relevance. For instance, miRNA156f-3p and miRNA-156f-5p targeted *SMAD4* and *HIF3A* genes, respectively.

Conclusions: Plant foods are rich in miRNAs that resist degradation during digestion, being detected in human samples. In addition, dietary habits reflect the plant miRNA expression profile in human samples. XenomiRs could be eventually internalized to systemic level and could modulate the expression of target genes related to weight balance. Plant xenomiRNAs could be an underlying mechanism by which dietary patterns influence obesity and metabolic disorders outcome, and thus, they could be potential therapeutic targets for obesity treatment and/or biomarkers of dietary response.

Interaction between genetic predisposition and food or beverage intake for incident type 2 diabetes: European Prospective Investigation into Cancer (EPIC) InterAct case-cohort study across 8 European countries

Sherly Li[1,2,3], on behalf of the InterAct Consortium -

1. University of Cambridge (UK), 2. Cancer Council Victoria (Australia), 3. University of Melbourne (Australia)

Background and objectives: There is limited conclusive evidence on whether a person's genetic characteristics modify the relationships between foods and beverages intake and risk for developing type 2 diabetes (T2D). We investigated the interaction between genetic susceptibility and intake of foods and beverages on the risk of developing T2D.

Methods: This prospective study included 9,542 case participants with incident T2D and a subcohort of 12,477 individuals nested within 340,234 participants from eight European countries: European Prospective Investigation into Cancer (EPIC)-InterAct case-cohort study. Genetic risk scores (GRSs) for higher body mass index, insulin resistance and T2D were constructed. Fifteen dietary variables associated with T2D according to published meta-analyses were examined as exposures: fruits, green leafy vegetables, root vegetables, wholegrains and non-white breads, legumes, nuts and seeds, fermented dairy, red meat, processed meat, fish, eggs and egg products, sugar sweetened beverages, coffee and tea. We investigated interactions for each combination of GRS and dietary exposure on T2D incidence using Prentice-weighted Cox regression models fit within each country; estimates were pooled across countries using random-effects meta-analysis.

Results: After accounting for multiple testing, no evidence of statistical interaction was found between any of the GRSs and foods or beverages on either a multiplicative or additive scale.

Conclusions: Genetic susceptibility to higher BMI, insulin resistance or T2D did not modify the association between food or beverage intake and T2D incidence in European populations.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

These findings suggest that currently for the prevention of T2D, stratification of existing population-wide food-based dietary guidance by genetic risk for these metabolic traits is unwarranted.

Multi-ethnic population-based nutrigenetic studies of obesity: Towards implementing precision nutrition in lower middle-income countries

Vimal Karani S[1]

1. University of Reading, UK (UK)

Background and Objectives: The ability of Nutrigenetics and Nutrigenomics to determine what nutrients will produce the desired impact on metabolic balance is at the core of Personalized Nutrition. Individuals differ from each other in their genetic makeup due to which individuals respond differently to various dietary factors. Obesity is a heritable trait that arises from the interactions between multiple genes and dietary factors. Although studies in developed countries have examined these interactions extensively, there are no such studies in lower middle-income countries (LMICs). Nutrigenetics has highlighted the complexity of gene-nutrient interactions, but it offers opportunities to re-evaluate criteria used to set dietary guidelines and the contribution of genetic variation to optimal nutrition for individuals from different ethnic groups.

Methods: To address this missing gap in nutrition science in LMICs, a large-scale collaborative project called GeNuIne (Gene Nutrient Interactions) Collaboration that aims to develop personalised nutrition strategies based on the evidence from nutrigenetic and nutrigenomic studies using cohorts from various ethnic groups has been initiated. In this large-scale collaborative study, gene-nutrient interactions on obesity across multiple ethnic populations such as India, Sri Lanka, Indonesia, Brazil, Ghana, Turkey, Malaysia, Pakistan, Thailand, and Peru are being examined. A genetic risk score analysis was used to examine the combined effect of several genetic variations on obesity-related traits.

Results: While diets high in saturated fatty acids have been shown to increase the genetic risk of obesity in Western and African populations, diets high in carbohydrates and animal proteins were found to increase the genetic risk in South Asians, Southeast Asians and West Asian populations. Furthermore, in Sri Lankan, Indonesian and Brazilian populations, those carrying a high genetic risk for B12 deficiency had an increased risk of metabolic diseases under the influence of dietary protein, fibre, and carbohydrate intakes, respectively; however, in Asian Indians, genetically instrumented metabolic disease risk showed a significant association with low vitamin B12 status.

Conclusion: In summary, these nutrigenetic studies highlight the existence of genetic heterogeneity in gene–diet interactions across ethnically diverse populations, which further implicates the significance of precision nutrition approaches for the prevention and management of obesity.

OAB(T1)2-8
Effect of nutrition, TNF-α -308G>A, and TNFRSF1B 196T>G polymorphisms to the susceptibility of type 2 diabetes mellitus in rural Thais: A cohort study

Pornpimol Panprathip Phienluphon[1], Jirayu Lainampetch[2], Chanchira Phosat[2], Karunee Kwanbunjan[1]

1. Faculty of Tropical Medicine, Mahidol University (Thailand), 2. Faculty of Public Health, Mahidol University (Thailand)

Background and objectives: Dietary habits and a sedentary lifestyle are major factors for type 2 diabetes mellitus (T2DM). Inflammation also affects its pathogenesis as well as the genetic variation of TNF-α and its receptor. This study aimed to investigate the impact of nutrition, TNF-α (rs1800629), and TNFRSF1B (rs1061622) polymorphisms on T2DM in rural Thais.

Methods: This 2-year follow-up study recruited 248 non-diabetes subjects aged 35-70 years who live in Sung Noen District, Nakhon Ratchasima Province, Thailand. Anthropometry and dietary intake were assessed. TNF-α concentrations were determined using ELISA. Single nucleotide polymorphisms of TNF-α (rs1800629) and TNFRSF1B (rs1061622) were identified by PCR-RFLP.

Results: After the 2-year follow-up, 18.6% of the total subjects had developed T2DM. Food patterns between T2DM and the normal group were not different. However, central obesity was found more frequently in the T2DM group. After adjusting for confounding factors, subjects who carry mutant genotype (GA+AA) of the TNF-α gene (rs1800629) were more likely to have a higher risk of T2DM when compared to subjects who carry the wild-type (GG), OR= 2.06 (P = 0.084). The risk of developing T2DM was significantly increased in subjects who carry the variant (TG+GG) of the NFRSF1B gene (rs1061622), OR = 2.53 (P = 0.011). Moreover, the statistically significant differences of TNF-α concentration were found during the follow-up period in this variant group; baseline = 61.55, 1st follow-up = 44.33, and 2nd follow-up = 111.16 pg/mL, (P = 0.009).

Conclusions: This study found that food habits between T2DM and the normal group were quite similar. However, T2DM subjects progressed with more adverse health effects. It may be due to individual genetic alteration. We suggest that the variant

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of TNFRSF1B 196T>G polymorphism is one of the contributing factors to the genetic risk of T2DM in rural Thais.

OAB(T1)2-9
The potential effect of Artificial Sweetener Acesulfame Potassium on Preterm Risk and the activation of Calcium influx via Myosin Light Chain Kinase - Myosin Light Chain 20 related Signaling Pathway

Yi-Fen Chiag[1], Hsin-Yuan Chen[1], Yu-Han Lai[1], Yang-Ching Chen[1], Shih-Min Hsia[1]

1. Taipei Medical University (Taiwan)

Background and objectives: The usage of artificial sweeteners has rapidly increased, which may alter human reproduction and pregnancy procedures, but the phenomenon and related mechanisms are still not clear. We aimed to explore the Acesulfame Potassium (Ace K)'s potential mechanism by which it causes uterine contraction through clinical observation and in vitro, ex vivo, and in vivo studies. **Methods**: Used ex vivo study to analyze its effect on uterine contraction and involved signaling pathway. Used in vitro study to evaluate the calcium concentration. Used the long-term, high-dose exposure to examine Ace K's affection on contractive-related protein expression. By involving a cohort of 613 participants, to assess the dose-responsiveness of Ace K consumption, and categorizing the participants into T0-T3. Calculated the odd ratio of Ace K consumption and the relationship with preterm risk.

Results: Animal study showed the increasing uterine contraction ($p<0.05$, n=4-6) where long-term high-dose exposure induced uterine hypercontraction, cytokine secretion and altered contraction-related protein expression. A cohort trial showed that higher consumption of Ace K may be related to the early delivery through the uterine hypercontraction.

Conclusions: Ace K exposure could induce uterine hypercontraction through the modulation of calcium influx and intracellular calcium accumulation, partially related to the c-Jun N-terminal kinase signaling transduction. Long-term and high-dose exposure could enhance oxytocin-induced hypercontraction by increasing oxytocin receptor and myosin light chain kinase - myosin light chain 20 calcium-related signaling pathway. Suggesting that exposure to Ace K may influence the uterine contraction pattern.

Keyword: Acesulfame potassium, Uterine contraction, Calcium influx, Preterm risk

Microbiota contributes to the outcomes of caloric restriction by deconjugating bile acids and taurine

Kalina Duszka[1], András Gregor[1], Marc Pignitter[1], Veronika Somoza[2], Jürgen König[1]

1. University of Vienna (Austria), 2. Technical University of Munich (Germany)

Background and objectives: We showed that caloric restriction (CR) has anti-inflammatory outcomes in the gastrointestinal tract of mice and it triggers an increase in the levels of free taurine, taurine-conjugated bile acids (BA), and other taurine conjugates in intestinal mucosa while decreasing glutathione (GSH) levels. As CR modifies gut bacteria composition, we decided to investigate whether the microbiota is involved in the intestinal response to CR.

Methods: *ad libitum*-fed and CR mice were submitted various treatments: broad-spectrum antibiotics, microbiota transplant, housing with different types of cage bedding (wooden, cellulose, or corncob), or without bedding as well as feeding high-fibre diets.

Results: The antibiotics treatment diminished CR-specific increase in the levels of free taurine and its conjugates as well as upregulated expression and activity of GSH transferases (GST) in the intestinal mucosa. Further, it diminished a CR-related increase in BAs levels in the liver, plasma, and intestinal mucosa. Transplant of microbiota from CR mice to *ad libitum* fed mice triggered CR-like changes in GST expression, levels of taurine and taurine conjugates in the mucosa of the ileum. The type of cage bedding affected faecal microbiota composition, the levels of BAs and taurine as well as GST expression in the intestine mucosa. Complete removal of cage bedding resulted in decreased BAs deconjugation while feeding high-fibre diet impacted mostly the levels of free taurine.

Conclusions: CR animals supplement their diet with cage-bedding derived fibre. High-fiber consumption leads to breeding microbiota with high BAs-deconjugation capacity resulting in increased levels of free taurine and unconjugated BAs in the intestine of CR animals. Whereas, the trigger to increase synthesis and release BAs from the liver into the intestine is not microbiota-dependent but relies on CR.

OAB(T1)3-2
Transcription co-activator PGC-1α regulates gene expression in Neuromuscular junction

Chihiro Sakamaki[1], Takumi Sugimoto[1], Shinji Miura[2], Yasutomi Kamei[1]

1. Kyoto Prefectural University (Japan), 2. University of Shizuoka (Japan)

Background and objectives: Neuromuscular junction (NMJ) is a synapse between motoneurons and skeletal muscles. It has been reported that morphology changes and decreased function of NMJ occur under aging and various neurodegenerative diseases. Maintaining functionality of NMJ is important to extend healthy life expectancy. Expression of PGC-1α increases by exercise and intake of soy isoflavones. PGC-1α is known to activate mitochondrial biogenesis and energy consumption. To find new target genes for PGC-1α, we have performed microarray analysis using skeletal muscle derived from muscle specific PGC-1α knocked out mouse. As a result, Dok-7 was found, which is expressed at the NMJ on the skeletal muscle side and involved in NMJ formation. Dok-7 is important to form NMJ since deficiency of Dok-7 causes structural defects of NMJ. In this study, we examined whether PGC-1α regulates gene expression of Dok-7.

Methods: We performed gene overexpression or knockdown experiments of PGC-1α, using muscle satellite cells, transfected with either retrovirus or siRNA. Gene expression of Dok-7 and other NMJ related genes were then examined. PGC-1α is known to increase expression of target genes by co-activating nuclear receptors such as ERR. Therefore, we investigated whether ERR binding element exists in 2000 bp upstream of the Dok-7 promoter. Then, we created a plasmid in which 2000 bp upstream of the Dok-7 promoter was integrated upstream of luciferase gene. We used this plasmid with co-expressing PGC-1α and ERRαto examine luciferase activity of Dok-7 promoter.

Results: Gene expression of Dok-7 increased by overexpression of PGC1α, whereas gene expression of Dok-7 showed a decreasing trend by knockdown of PGC-1α. ERR binding elements were present in 2000 bp upstream of Dok-7 promoter. In addition, luciferase activity of Dok-7 promoter was greatly increased by co-expressing PGC-1α and ERRα.

Conclusions: This study showed that PGC-1α increased gene expression of Dok-7 and Dok-7 promoter was significantly increased by co-expressing PGC-1α and ERRα. These results may lead to preventing morphology changes and decreased function of NMJ under aging and neurodegenerative diseases.

Keywords: PGC-1α, Dok-7, ERR, Neuromuscular junction, Skeletal muscles

Loss of FOXOs in skeletal muscle prevents the onset of cancer cachexia-induced muscle atrophy

Mamoru Oyabu[1], Yusuke Ono[2], Shin Fujimaki[2], Kiyoshi Yoshioka[2], Junya Fujimaki[3], Runa Kawaguchi[1], Yukino Hatazawa[1], Shinji Miura[3], Yasutomi Kamei[1]

1. Kyoto Prefectural University (Japan), 2. Kumamoto University (Japan), 3. University of Shizuoka (Japan)

Background and objectives: Cancer cachexia is a multifactorial disease characterized by systemic inflammation, body weight loss, and loss of muscle mass. Evidence has demonstrated that muscle atrophy in cancer cachexia leads to anorexia, frailty, and shortened lifespan. In advanced cancer, approximately 80% of cancer patients develop cancer cachexia, which accounts for up to 20% of cancer death. We previously identified novel FOXO1 target genes in skeletal muscle using skeletal muscle-specific FOXO1 transgenic and starved FOXO1/3a/4 knockout mice (FOXO1,3a,$4^{-/-}$ mice) (Oyabu et al. 2022. ***FASEB J***. In this study, we developed cancer cachexia model of FOXO1,3a,$4^{-/-}$ mice to investigate the role of FOXOs in cancer cachexia-induced muscle atrophy. The objective of this study was to reveal whether loss of FOXO could prevent cancer cachexia-induced muscle atrophy and identify novel FOXOs target genes in cancer cachexia.

Methods: Tumor-bearing FOXO1,3a,$4^{-/-}$ mice were generated by subcutaneous implantation of 6×10^6 Lewis lung carcinoma (LLC) cells dissolved in 100 µL PBS into the right flank of FOXO1,3a,$4^{-/-}$ mice. To create in vitro cancer cachexia model, we co-cultured C2C12 myotubes and LLC cells using cell culture inserts, or LLC-conditioned medium (LLC-CM) was added to C2C12 myotubes.

Results: Cancer cachexia induced muscle atrophy in tumor-bearing WT (wild type) mice, while muscle atrophy was markedly suppressed in FOXO1,3a,$4^{-/-}$mice. As the results of qRT-PCR, FOXO1, FOXO3a, and FOXOs target genes (*Atrogin1*, *MuRF1* etc.) were significantly upregulated in the tumor-bearing WT muscle, but not in FOXO1,3a,$4^{-/-}$ muscle. In addition, several novel FOXOs target genes were identified. Co-culture of C2C12 myotubes with cancer cachexia-inducible LLC cells, or addition of LLC-CM to C2C12 myotubes caused marked myotube atrophy with significant increase of authentic- and novel-FOXOs target genes.

Conclusions: In this study, we found that cancer cachexia-induced muscle atrophy was prevented in FOXO1,3a,$4^{-/-}$ mice and identified novel FOXOs target genes using cancer cachexia model of FOXO1,3a,$4^{-/-}$ mice. Moreover, LLC cells caused marked activation of FOXOs signaling in C2C12 myotubes without other types of cells and direct cell–cell contact. The data obtained from this study further sheds light on FOXOs or their up/downstream factors as potential therapeutic targets of cancer cachexia.

Obesogenic diet consumption impairs mitochondrial function of epithelial cells in mouse jejunum

Thomas Guerbette[1], Manon Brien, Vincent Ciesielski, Agnes Burel[2], Annaïg Lan[1,3], Gaëlle Boudry[1]

1. Numecan institute, INRAE, INSERM, Univ Rennes, Rennes (France), 2. Plateforme MRic (Microscopy Rennes Imaging center), BIOSIT, Rennes (France), 3. UMR PNCA, AgroParisTech, INRAE, Univ Paris-Saclay, Paris (France)

Background and objectives: Obesity and overweight are associated with low-grade inflammation linked to alterations of intestinal barrier and microbiota. Intestinal homeostasis is supported by mitochondrial function of intestinal epithelial cells (IEC), as it provides the energy needed for nutrient absorption, epithelial renewal, and maintaining of intestinal barrier. However, western diet (WD) consumption, characterized by high fat and sugar levels, may impair mitochondrial function as observed in hepatic cells. The aim of this study was to assess whether WD consumption alters mitochondrial function of IEC in mouse jejunum.

Methods: Male C57Bl/6J mice were fed a control diet (CTRL, fat = 10% of energy) or a WD (WD, fat = 58% of energy and drink water supplemented with fructose and sucrose (42 g/L)). After 22 weeks, jejunal IEC were isolated to assess mitochondrial function by Seahorse® technology and gene and protein expressions.

Results: WD mice were obese and characterized by increased visceral adiposity index (2.2±0.3 vs 6.7±0.4 %, P<0.0001) and endotoxemia (LPS-BP: 535.8±38.5 vs 668.7±39.7 ng/mL, P<0.05) compared to CTRL mice. Mitochondrial function analysis of IEC from WD mice revealed a two-fold decrease in basal respiration (60.6±8.9 vs 33.3±6.0 pmol O_2/min/DNA, P<0.05) and significant decrease in gene and protein expressions of subunits from electron transport chain complexes. Moreover, *Pgc1-α*, the main regulator of mitochondrial biogenesis, was 60% less expressed in IEC of WD mice compared to CTRL (P<0.001) while the expression of genes involved in mitochondrial fusion and fission (*Mfn2, Opa1, Fis1* and *Pink1*) was reduced by 10 to 50%. Finally enumerated mitochondria analyzed by electron microscopy, were two-fold less numerous in WD mouse IEC (51±15 vs 25±16, P<0.0001).

Conclusions: In conclusion, in mice, WD consumption induced an alteration of the mitochondrial dynamics associated with a decrease in the number of mitochondria per enterocyte and in the expression of electron transport chain subunits, which in turn caused an important reduction of basal IEC respiration. Those metabolic mitochondrial alterations may be linked to the alterations of intestinal homeostasis and to low-grade systemic inflammation observed in obesity.

Effect of lard-, olive oil- and soybean oil-enriched diet on immunoglobulin A coating of gut bacteria

Mao Teraoka[1], Naoki Nishino[1], Taisei Miyamoto[1], Emiko Katsumata[1], Takeshi Tsuruta[1]

1. Okayama University (Japan)

Background and objectives: Immunoglobulin A (IgA) is a major gut antibody and partly contributes to symbiosis with gut bacteria by selective coating. We recently showed that lard-enriched diet (60%/kcal) feeding reduces the amount of IgA coating fecal bacteria. However, it remains elucidated whether a diet enriched with dietary oils such as olive oil and soybean oil influences on IgA coating of gut bacteria. In this study, we compared the effect of lard-, olive oil- and soybean oil-enriched diet feeding on IgA reactivity to gut bacteria.

Methods: Mice were divided into four groups and fed a control diet (Control group) or a high-fat diet containing lard (HL group), olive oil (HO group), or soybean oil (HS group) at 45%/kcal. At week 27, the feces were collected and suspended with PBS. The supernatant and fecal bacterial pellet were separated by centrifugation. The fecal bacterial pellet was used to detect (a) the total amount of IgA coating bacteria (μg/g feces) by immunoblotting. (b) The total amount of IgA in the fecal supernatant (μg/g feces) was measured by ELISA. The ratio of (a) to (b) was calculated to predict how much amount of IgA was specific for gut bacteria.

Results: There was no significant difference in the total amount of IgA coating bacteria among groups. Inconsistent with the previous study, lard-enriched diet-induced reduction of the total amount of IgA coating bacteria wasn't observed possibly due to the reduced lard content in the diet from 60%/kcal to 45%/kcal. The total amount of IgA in the fecal supernatant was significantly higher in HL group than in other groups while there was no significant difference among Control, HO, and HS group. The ratio of (a) to (b) was significantly reduced in HL group as compared to Control group, but not in HO and HS group.

Conclusion: Our findings suggest that a lard-enriched diet (45%/kcal) intake may increase total IgA secretion while the ratio of bacteria-specific IgA in total IgA may conversely decrease. Meanwhile, olive oil- and soybean oil-enriched diet intake may not influence the amount of total IgA and bacteria-specific IgA secretion.

Potential roles of polyamines on DNA methylation in fetal period

Kyohei Furukawa[1], Moe Miyoshi[1], Huijuan Jia[1], Hisanori Kato[1]

1. The University of Tokyo (Japan)

Background and Objective: Our previous studies have indicated that maternal protein malnutrition in SHRSP rat during pregnancy increases salt sensitivity and changes DNA methylation profile in the renal tissue in offspring. However, the underlying mechanism is still unclear. Polyamine have a variety of physiological roles in the regulation of growth, development and health, and its metabolism utilized decarboxylated S-adenosylmethionine which affect DNA methyltransferase activity. The present study performed *in vivo* and *in vitro* experiments to tested our hypothesis that maternal protein malnutrition decreases polyamine concentration in fetal tissues and polyamines are an important mediator of DNA methylation.

Methods: Nine week-old pregnant WKY/Izm rats were fed 20% (CN) or 9 % (LP) casein diet, and collect kidney, liver and heart samples from maternal and fetal rat at embryo 20 days. HepG2 and HEK293 cells were treated with difluoromethylornithine (DFMO), which is an inhibitor of ornithine decarboxylase (polyamine synthesis enzyme), and 500μM putrescine (Put), 10 μM spermidine (Spd), or 10 μM spermine (Spn). Polyamine concentration in fetal tissues and global DNA methylation ratio in cells were determined by ultra-high performance liquid chromatography (Shimadzu).

Results: In WKY rat, the polyamine concentrations of maternal tissues were not changed by LP diet. Notably, Spd concentration in fetal hepatic and renal tissues was significantly decreased by LP diet compared to CN group. No significant changes were observed in the concentrations of heart polyamine, and Put and Spd in liver and kidney of fetus. In HepG2 cells, DFMO treatment significantly increased the global DNA methylation ratio, and this increase was significantly suppressed by Spd supplementation. Similar trend was observed in HEK293 cells.

Conclusion: This study indicated that maternal protein malnutrition decreased the concentrations of Spd in fetal kidney and liver, and the concentrations of intracellular polyamine, in especially Spd have an important role in mediating cellular DNA methylation. Thus, polyamine could be an important mediator of DNA methylation profile in fetal period. The further investigation such as methylome analysis is required to indicate this possibility.

Transport of vitamin K by ABC transporters

Michinori Matsuo[1]

1. Kyoto Women's University (Japan)

Background and objectives: ABCG5 and ABCG8 are half-type ABC transporters and function as heterodimers on the apical membrane of intestinal epithelial cells and hepatocytes. The ABCG5/ABCG8 heterodimer limits cholesterol absorption in the intestine and increases cholesterol excretion in the liver by transporting cholesterol to bile. NPC1L1, a cholesterol importer, and ABCG5/ABCG8 cooperatively regulate cholesterol absorption and excretion. ABCG5/ABCG8 transports not only cholesterol but also plant sterols, such as sitosterol. Mutations in ABCG5 or ABCG8 genes cause a genetic disease, sitosterolaemia, characterized by high serum levels of cholesterol and plant sterols, leading to premature atherosclerosis. ABCG5/ABCG8 functions in the export of cholesterol from cells and NPC1L1 functions in the import of cholesterol. NPC1L1 has been reported to transport not only cholesterol but also vitamin K. The objective of this study is to examine if ABCG5/ABCG8 transports vitamin K like NPC1L1.

Methods: BHK and HEK293 cells expressing ABCG5/ABCG8 were incubated with vitamin K1 or vitamin K3. Cytotoxicity of vitamin K3 was analyzed by MTT assay and transport of vitamin K1 was analyzed by HPLC assay.

Results: Because high concentrations of vitamin K3 show cytotoxicity, cytoprotective effects of ABCG5/ABCG8 were examined. BHK or HEK293 cells expressing ABCG5/ABCG8 were more resistant to cytotoxicity of vitamin K3 than control cells, suggesting that ABCG5/ABCG8 transports vitamin K3 out of the cells. Addition of vitamin K1 reversed the effect of ABCG5/ABCG8, suggesting that vitamin K1 competitively inhibited the transport of vitamin K3. To examine the transport of vitamin K1 by ABCG5/ABCG8, vitamin K1 levels in the medium and cells were measured by HPLC analysis. Vitamin K1 level in cells expressing ABCG5/ABCG8 was lower than that in control cells, and vitamin K1 efflux from the cells to medium was higher in cells expressing ABCG5/ABCG8.

Conclusions: ABCG5 and ABCG8 are involved in the transport of not only sterols but also vitamin K. ABCG5/ABCG8 and NPC1L1 may play important roles in regulation of vitamin K absorption.

Keywords: ABC transporter, vitamin K, cholesterol, absorption

Functional relationship between phosphatidylcholine profiles and skeletal muscle function—Metabolic analyses of skeletal muscle-specific GDE5 deficient mouse

Rahmawati Aisyah[1], Noriyasu Ohshima[2], Daiki Watanabe[3], Tetsushi Sakuma[1], Yoshiko Nakagawa[4], Thanutchaporn Kumrungsee[1], Shinji Miura[5], Takashi Yamamoto[1], Masanobu Wada[1], Noriyuki Yanaka[1]

1. Hiroshima University (Japan), 2. Gunma University (Japan), 3. National Cerebral and Cardiovascular Center (Japan), 4. Kumamoto University (Japan), 5. University of Shizuoka (Japan)

Background and objectives: Choline plays important roles in cell functions mainly as a precursor for phosphatidylcholine (PC), a predominant phospholipid in mammalian membranes. Glycerophosphodiesterase5 (GDE5) is a novel enzyme which can hydrolyze glycerophosphocholine (GPC) into choline *in vitro*, suggesting its potential role in PC metabolism and turnover *in vivo*. Previous studies strongly suggest that choline metabolism is tightly involved in muscle functions through alteration of membrane phospholipid composition. However, the mechanism on how PC composition is endogenously regulated and its physiological significance in skeletal muscle functions remain unclear. Thus, we aimed to investigate GDE5 roles in choline/PC metabolism and biological importance of PC composition in skeletal muscles.

Methods: Skeletal muscle-specific GDE5 knockout (KO) mice were generated using genome editing technique and Cre/LoxP system, and subjected to lipidomic and metabolomic analyses to examine the metabolic changes due to GDE5 deficiency. Furthermore, we tested fatigability and contractile force of GDE5 KO mice using *in situ* model of muscle fatigue to provide new perspectives on the biological significance of GDE5 in muscle functions. Finally, we employed muscle atrophy models, namely denervation and Duchenne muscular dystrophy, and docosahexaenoic acid (DHA)-rich diet, to further investigate physiological roles of GDE5 and PC composition in muscle functions.

Results: GDE5 deficiency in skeletal muscles, intriguingly, led to not only GPC accumulation but also an alteration in PC composition with a decrease in DHA-rich PCs and an increase in linoleic acid-rich PCs, accompanied by increases in glycolysis-related metabolites and glycogen levels. Interestingly, GDE5 KO showed a significant decrease in muscle strength, possibly due to larger Ca^{2+} leaks from sarcoplasmic reticulum. Both atrophy models showed decreased GDE5 expression and similar PC composition to that of GDE5 KO. DHA-rich diet, by which PC composition was inversely attenuated, resulted in higher contractile force compared to corn-rich diet. Furthermore, GDE5 KO mice exhibited higher fatigue resistance than wild-type mice, likely due to elevated glycogen level in skeletal muscle.

Conclusions: This study provided evidence on GDE5 roles as a key enzyme for regulation of PC composition. Importantly, our study also provides new insights on the potential association between PC composition and skeletal muscle contraction.

Salt intake reduction using umami substance-incorporated food in Japan and the United States

Shuhei Nomura[1,7], Shiori Tanaka[2], Akifumi Eguchi[3], Takayuki Kawashima[4], Daisuke Yoneoka[7], Yuta Tanoue[5], Hisayuki Uneyama[6], Kenji Shibuya[7]

1. Keio University (Japan), 2. National Cancer Center Institute for Cancer Control (Japan), 3. Chiba University (Japan), 4. Tokyo Institute of Technology (Japan), 5. Waseda University (Japan), 6. Ajinomoto Co., Inc. (Japan), 7. Tokyo Foundation for Policy Research (Japan)

Background and objectives: Excessive salt intake is linked to the development of several chronic diseases. Reducing the sodium content of foods is a globally important public health activity to achieve salt reduction and health promotion. We estimated the effect of sodium substitution with umami substances on the daily salt intake reduction among adults in Japan and the United States. The umami substances considered were glutamate, inosinate, and guanilate.

Methods: For Japan, 21805 participants aged 20 years and older from the 2016 National Health and Nutrition Survey (NHNS) were included. A multivariable linear regression approach was employed to estimate the contributions of each food item to daily salt intake, using total salt intake (g/day) as a dependent variable and intake (g/day) from food items and other covariates as independent variables. Possible salt reduction rates for each food item without compromising the taste due to substitution with umami substances were estimated based on an extensive literature review. Then, we estimated the population-level salt reduction based on the contribution of each food to salt intake estimated by the regression model.

A similar approach was applied to the analysis of the United States, which included 4139 participants aged 20 years and older from the 2017-2018 National Health and Nutrition Examination Survey (NHANES).

Results: The average salt intake was 9.95g/day (standard deviation 3.2) and 8.35g/day (3.8), respectively. The salt intake of adults in Japan can be reduced by 12.0-21.1% at the population level by substituting umami substances, which corresponds to 1.27-2.22g of salt reduction. For adults in the United States, salt intake could be reduced by 5.51-10.54% at the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

population level, corresponding to 0.46-0.88g of salt reduction. About 60% of Japanese adults could meet the national dietary goal of 8g/day, while 7.6% could achieve the World Health Organization (WHO)'s recommendation of 5g/day. About 23.73% of adults in the United States could achieve the WHO's recommendation.

Conclusions: Excessive salt intake is a global public health challenge, and reducing the intake is one of the most cost-effective measures to improve population health. We provide essential information on the potential salt reduction from sodium replacement with alternatives.

Precision Nutrition: Concepts and perspectives of future nutrition

Hiroaki Oda[1], Tomoko Banno[2], Tomono Uchida[3], Saiko Ikeda[4]

1. Nagoya University (Japan), 2. Nagoya Women's University (Japan), 3. Aichi Gakusen University (Japan), 4. Nagoya University of Arts and Sciences (Japan)

Background and objectives: After individual characteristics could be determined through genomic analysis, comprehensive multi-omics analysis methods were developed. Furthermore, the development of information technology and artificial intelligence has enabled precise individualization. This type of personalized nutrition is called “Precision Nutrition”. Recently many attempts have been made to individualize by using physical information obtained from wearable devices and other sources. The body clock is not only important for health, but it is also a "constitution" that continues to turn for a certain period of time once it starts turning. Controlling the body clock from a chrono-nutrition perspective is an important strategy in precision nutrition.

Methods and Results: We individualized personal data that is relatively easy to obtain, such as gender, age, physical measurements, and health examination results. This typification allows us to determine the nutrients required for each individual and to calculate a personalized dietary intake. The "N-type Personal Dietary Reference Intakes" was developed as a web tool so that anyone can easily calculate it. We are then constructing a system that proposes healthy diet menus based on the Personal Dietary Reference Intake. We are currently building an individual dish database. The biological clock is one of the "constitution" of the body. “Rhythmome”, which considers totality of biological rhythms on a time axis from seconds to years, can be used in personalized nutrition. To measure the body clock in humans, blood samples are needed to be taken every few hours to examine the rhythm of expression of clock genes. As a non-invasive method, we created a smartphone application ("Chrono-Nutrition Clock") that infers the body's metabolic rhythms by simply recording the timing of meals. By tapping the screen to record the timing of meals, bowel movements, and entering body weight, the application calculates the body clock (metabolic rhythm), bowel clock, and sleep clock. By using this, the approximate body clock can be visualized. In other words, you can see that this is your current "constitution”.

Conclusions: We are now developing the future nutrition “Precision Nutrition” platforms. Some of them have been completed to make a prototype model.

OAB(T1)4-3
Application of a machine learning approach to predict the added sugar content of foods and beverages in the food supply

Mavra Ahmed[1], Guanlan Hu[1], Mary L'Abbe[1]

1. University of Toronto (Canada)

Background and objectives*:* Dietary guidelines recommend limiting the intake of added/free sugars. However, information about added/free sugar content is not provided on food labels in most countries, making it difficult for consumers to avoid products with added-sugar, and limiting the ability of policymakers to identify priority products for intervention. The objective was to apply a machine learning approach to calculate added sugar content in packaged foods and beverages.

Method*:* The added-sugar prediction algorithm was developed using k-nearest neighbors (KNN) and packaged food information from the University of Toronto Food Label Information Program (FLIP) 2017 (n=17,448) and 2020 (n=74,445). Selected food categories (Bakery, beverages, cereals/grains, dairy, desserts, fruits and fruit juices, snacks and sugars/sweets) with added-sugar information calculated from a series of manual steps from FLIP2017 were trained and tested to predict added-sugar content of foods in the same food categories in FLIP2020. Performance metrics included the coefficient of determination (R^2) and mean absolute error (MAE).

Results*:* Predicted and true added-sugar values (mean±sd) from FLIP2017 data were similar for all food categories: Bakery; 15.2±13.6 vs. 15.1±14.4, beverages; 9.8±18.5 vs. 9.4±17.9, cereals/grains; 4.6±8.7 vs. 4.5±8.9, dairy; 3.3±7.0 vs. 3.3±7.4, desserts; 25.1±19.9 vs. 24.3±20.2, fruits/juice; 11.0± 13.9 vs. 11.0±14.5, snacks; 4.7±9.1 vs. 5.1±10.5, sugars/sweets; 47.1±23.1 vs. 46.3±23.9). Predicted added sugar content for FLIP2020 was similar to the true value for FLIP2017 for following (bakery; 14.9±11.6, beverages; 10.6±7.5, cereals/grains;

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

4.01±8.28, desserts; 19.7±15.4, fruits/juices; 13.1±9.1, sugars/sweets; 42.3 ± 20.3, except for dairy (1.8±5.5) and snacks (3.3±7.4). KNN was apt at explaining variance in added-sugar content (R^2 ranging from 0.80 to 0.95) and achieved prediction accuracies with small MAE for all selected categories (range: 0.9g/100g (cereals/grains) to 3.78g/100g (sugars/sweets)).

Conclusions*:* Our findings show that the KNN approach can be used to predict the added-sugar content in packaged products with a high degree of validity, using total sugars and ingredient lists on foods. Being automated, KNN can be applied to large datasets, reducing the reliance on manual calculations. In the absence of mandated added-sugar labelling on products, KNN can be used to monitor the added sugar levels in food supply, informing of potential policy actions to reduce added-sugar intakes.

Social jetlag is associated with gut microbial composition in the ZOE PREDICT cohort

Kate M Bermingham[1], Sophie Stensrud[1], Francesco Asnicar[2], George Hadjigeorgiou[3], Jonathan Wolf[3], Richard Davies[3], Tim D Spector[1], Nicola Segata[2], Sarah E Berry[1], Wendy L Hall[1]

1. Kings College London, London (UK), 2. University of Trento, Trento (Italy), 3. ZOE Ltd, London (UK)

Background and objectives: Social jetlag (SJ), the term for an earlier sleep midpoint during working days compared to free days (usually weekends), is a prevalent form of chrono-disruption. Inconsistent sleep timing is associated with poor diet quality and less favourable cardiometabolic outcomes. Gut dysbiosis may partially mediate the effects of social jetlag on cardiometabolic risk factors. We explored associations between SJ and the gut microbiome in the densely phenotyped PREDICT 1 cohort.

Methods: Participants reporting habitual sleep (males, n=258, females, n=673, 18-65y) were identified from the ZOE PREDICT 1 study, a multi-centre study of 1001 healthy UK individuals (NCT03479866). Demographic information, habitual diet (FFQ), cardiometabolic blood biomarkers, and stool metagenomics were collected. SJ was calculated as a difference of >1.4h in weekday sleep midpoint versus weekend sleep midpoint. Differences in pre-specified microbial species (those previously shown to be associated with more and less healthy plant-based foods) were tested by linear regression analysis following arcsine transformation (adjusted for diet quality and multiple comparison (FDR)).

Results: The SJ group (16% of cohort, n=145) had a higher proportion of males than the non-SJ group (39% *vs* 25%) and were younger (mean±SD) (38.4±11.3y *vs* 46.8±11.7y). Only 5% of the SJ group reported inadequate sleep duration over 7 days (average <7 h/night), similar to non-SJ (3%). SJ was associated with a lower healthful plant-based dietary index (P<0.05). Following adjustment for diet quality, SJ was associated with lower relative abundances of "good bacteria" Firmicutes bacterium CAG:95, Oscillibacter 57_20, Oscillibacter PC13, Eubacterium eligens, and higher for "bad bacteria" Ruminococcus gnavus, Clostridium symbiosum, Clostridium bolteae, and Flavonifracter plautii (all q<0.05), and higher fasting concentrations of glycoprotein acetylation (GlycA), a marker of systemic inflammation (P<0.05), adjusted for sex, age, BMI, ethnicity and socio-economic status.

Conclusions: In a predominantly female cohort with adequate sleep duration, SJ is associated with a less favourable gut microbiome composition, and higher inflammation, with implications for the role of modest circadian misalignments on inflammatory processes that underpin chronic non-communicable diseases.

The effect of Bacillus clausii UBBC07 supplementation on the absorption of essential amino acids from whey protein

Mohamad Tarik[1], Lakshmy Ramakrishnan[1], Nidhi Bhatia[1], Ravindra Goswami[1], Archna Singh[1], Mani Kalaivani[1], Jayanthi Neelamraju[2], Ratna Sudha Madempudi[2]

1. All India Institute of Medical Sciences, New Delhi (India), 2. Centre for Research & Development, Unique Biotech Ltd. (India)

Background and objectives: Gut microbiota composition optimization, through supplementation of strains specific probiotics have been linked to improved essential nutrient absorption and its utilization. Essential amino acids have to be supplied from an exogenous diet because the human body lacks the metabolic pathways required to synthesize these amino acids. This study evaluated the effect of probiotic *Bacillus clausii* UBBC07 supplementation on protein absorption, assessed through circulating plasma free essential amino acids. **Methods**: In this double-blind, placebo-controlled, randomized study, seventy physically active male participants (21.5 ± 3.2 yrs) were enrolled to receive either a probiotic consisting of 2 x 10^9 CFU *Bacillus clausii* UBBC07 along with 20gm whey protein (n=35) or a placebo consisting of 20gm whey protein only (n=35) for 60 days. Plasma amino acids levels were determined at baseline, 30 days, and 60 days using HPLC-FLD. The effect of probiotics was assessed on total essential amino acids (EAAs), total branched-chain amino acids (BCAAs), and total plasma amino acids (TPAAs) via repeated-measures analysis of variance. **Results**: Data from our study indicate that plasma EAAs levels (215.37 pmol/µl, 95%CI: 117.8-312.9, vs 42.6 pmol/µl, 95%CI:-10.8-96.1, p=0.002) and TPAAs levels (859.10 pmol/µl, 95%CI:455.4-1262.8 vs 87.9

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

pmol/µl, 95%CI:-202.0-377.9; p=0.002) were significantly improved in the probiotic group as compared to the placebo group. The total BCAA levels were significantly improved by 23.4% (p=0.005) in the probiotic group as compared to the placebo group. When BCAAs were analyzed individually, significant improvement was revealed in isoleucine by 26 % (p=0.017), leucine by 32.9% (p=0.001), and valine by 19.7% (p=0.029). In repeated-measures analysis of variance, a significant group × time interaction was revealed for EAAs (p=0.015), TPAAs (p=0.004), and BCAAs (p=0.028) as well as isoleucine (p=0.041), leucine (p=0.028) and valine (p=0.042). **Conclusions**: In this study, a significant effect of *Bacillus clausii* UBBC07 supplementation was observed on essential amino acids absorption which would be helpful for vital processes such as building proteins, hormones, neurotransmitters, muscles growth, and nitrogen balance.

Novel microbiome links with diet and cardiometabolic health via previously uncharacterized species from the ZOE PREDICT 1 study

Moreno Zolfo[1], Aitor Blanco-Miguez[2], Francesco Asnicar[2], Kate M Bermingham[3], Gianmarco Piccinno[2], Richard Davies[4], Jonathan Wolf[4], Tim D Spector[3], Sarah E Berry[3], Nicola Segata[2], Emily Rose Leeming[3]

1. Tokyo Institute of Technology, Japan (Japan), 2. University of Trento, Trento (Italy), 3. Kings College London, London (UK), 4. Zoe Ltd, London (UK)

Unhealthy diet and lifestyle, physical inactivity, and smoking are associated with cardiometabolic diseases, and the human gut microbiome is increasingly regarded as one key mediator. The ZOE PREDICT 1 study highlighted that the gut microbiome was predictive for markers of cardiometabolic status and associated with dietary patterns (Asnicar et al. 2021). However, current metagenomic profiling relies on well-characterized microbial genomes that do not cover the fraction of commensal species not yet described through cultivation.

Large-scale metagenomic assembly efforts generated metagenome-assembled genomes (MAGs), including uncharacterized species. We clustered the largest set of MAGs and well-characterized genomes into species-level genome bins (SGB). Markers defined on each SGB were then exploited for improving taxonomic profiling. The ZOE PREDICT 1 cohort was re-profiled and machine learning and association analyses performed on the SGBs present in at least 20% of the samples with the previously identified 19 dietary and cardiometabolic markers.

We identified a new microbial signature of cardiometabolic health and found a novel set of SGBs more strongly associated with the previously assessed dietary and cardiometabolic indices. Overall, the SGB profiles showed stronger associations for 17 out of the 19 markers. Most of the SGBs positively associated with favourable markers were uncharacterized species (9 out of 15), suggesting the important role the hidden fraction of the gut microbiome can have on the overall microbiome functions. Among the cultivated species, five have provisional and unofficial species labels (e.g., *Lachnospiraceae bacterium* NSJ-46 and *Lachnospiraceae bacterium*), while only *Haemophilus parainfluenzae* (SGB ID 9712) was present in the previous signature (Asnicar et al. 2021). The top associations with unfavourable diet and cardiometabolic indices were mainly from well-characterized species and only five were in common with the previous signature.

Findings suggest that the new approach integrating genomic information of uncultured species enables deeper investigations of microbiome samples. Importantly, deeper profiling resulted in stronger links between the microbiome and indices of dietary intake and cardiometabolic health. Considering that the human gut microbiome is a modifiable target through diet and supplementation, these advances may contribute to future precision nutrition approaches to lower the burden of cardiometabolic diseases.

Conflict of Interest Disclosure: TDS and JW are co-founders of ZOE Ltd (ZOE). SEB, FA, and NS are consultants to ZOE Ltd. RD is employed by ZOE Ltd. The other authors declare no competing interests.

Supermarket Transaction Records In Dietary Evaluation – the STRIDE study: validation against self-reported dietary intake.

Victoria Jenneson[1], Darren C Greenwood[1], Graham P Clarke[1], Timothy Rains[2], Bethan Tempest[2], Becky Shute[2], Michelle Morris[1]

1. University of Leeds (UK), 2. Sainsbury's Plc (UK)

Background and objectives: Harnessing new technologies is recommended to deliver scalable objective methods for population dietary assessment. Supermarket transaction data offers great potential to explore small-area dietary patterns and has many advantages over survey methods. However, this data is rarely validated. The STRIDE (Supermarket Transaction Records In Dietary Evaluation) validation study compares dietary estimates from supermarket transactions with self-reported intake from an online Food Frequency Questionnaire (FFQ).

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: Working with a large UK supermarket retailer, loyalty card customers were recruited to one of four waves (accounting for seasonal dietary variation). Participants consented to sharing their transaction records for one year during the study, and one year prior. They additionally completed an online FFQ. The Bland-Altman method was used to calculate the agreement and limits of agreement between transactions and intake for daily energy, sugar, total fat, saturated fat, protein and sodium (absolute and energy-adjusted). Household composition is accounted for in individual purchase estimates.

Results: 1,788 participants from four UK regions consented to the study. 686 participants who completed the FFQ and made purchases during the same period, were included for analysis. Participants were mostly female (72%), with a mean age of 56 years (SD 13). Agreement varied by magnitude and thus a regression equation is presented for estimating intake from purchases. Agreement for absolute measures was poor overall, but was higher for single-person households and households who reported a higher proportion of their total food purchases coming from the retailer. Agreement was stronger for energy-adjusted nutrient estimates, particularly for fat. On average purchase records under-estimated the proportion of total energy intake from fat by just 2%.

Conclusions: The STRIDE study found household purchase records from a single retailer to be a poor proxy for individual-level absolute nutrient intakes. However, close agreement on average for energy-adjusted estimates suggests that purchases are a good indicator of dietary composition. This points to the utility of supermarket transaction records for population dietary assessment, ecological studies, and identifying intervention targets based on dietary patterns. Supermarket transaction data therefore have broad applicability for contributing to the design and monitoring of national and local-level policy interventions.

Conflict of Interest Disclosure: This work was supported by an in-kind data contribution and staff time (for tasks relating to study set-up and data extraction) from a UK supermarket retailer.

Diets enriched in sugar, refined or whole grains differentially influence serum cholesterol concentrations and cholesterol metabolism pathways with concurrent changes in gut microbiota composition in ApoE$^{-/-}$ mice

Huicui Meng[1,2], Haiyan Zhou[1,2], Ke Liu[1,2], Shun Li[1,2], Yilan Zhang[1,2]

1. Shenzhen Campus of Sun Yat-sen University (China), 2. Sun Yat-sen University (China)

Background and objectives: Previous studies have demonstrated differential effects of different types of carbohydrates on cholesterol concentrations in hypercholesterolemic individuals, yet little is known about the underlying mechanisms. Our aim was to compare the effects of diets enriched in sugar, refined or whole grains on serum cholesterol levels, cholesterol metabolism pathways and gut microbiota composition in ApoE$^{-/-}$ mice.

Methods: Forty-five male ApoE$^{-/-}$mice aged 8 week old were randomly fed an isocaloric high whole grain (HWG), high refined grain (HRG) or high sugar (HS) diet for 12 weeks. Diets were matched for similar macronutrient composition (55%E total carbohydrate, 20%E protein, 25%E fat), but differed in types of carbohydrates (accounted for 20%E from different types of carbohydrates). Fecal samples were collected from week 8 to 12 and fasting blood samples and liver and intestine tissues were collected following euthanization at week 12. Fasting cholesterol concentrations, gene expression involved in cholesterol absorption, synthesis, uptake, efflux and bile acid metabolism in liver and intestine, gut microbiota composition and fecal bile acid levels were measured using standard methods.

Results: Fasting serum total cholesterol (TC) and low-density lipoprotein cholesterol (LDL-C) concentrations were higher in HRG and HS compared to HWG groups (P<0.001). The mRNA expression of hepatic IDOL was higher in the HRG than HWG group (P<0.05). The mRNA expression of intestinal LXR-α was lower in the HRG and HS than HWG group, and ABCG5 was lower in the HS than HWG group (P<0.05). HR resulted in higher amounts of fecal secondary bile acids than HWG group (P<0.05). The relative abundance of genus *Akkermansia*, *Alistipes*, *Alloprevotella*, *Bacteroides* and *Clostridia* were lower in HS than HWG group, and they were inversely associated with serum TC and LDL-C levels, fecal secondary bile acid levels and hepatic IDOL gene expression, and positively associated with intestinal LXR-α and ABCG5 gene expression (P<0.05).

Conclusions: Compared to HWG group, HRG and HS increased cholesterol levels via modulating gene expression that promoted cholesterol absorption and secondary bile acid synthesis and inhibited cholesterol uptake and efflux. Gut microbiota composition changed concurrently with these effects, and related to alterations in cholesterol level and metabolism.

Revealing the prevalence of "hidden hunger": global and regional estimates of micronutrient deficiencies among preschool-age children and non-pregnant women of reproductive age

Ty Beal[1], Gretchen A Stevens[2], Mduduzi NN Mbuya[1], Hanqi Luo[3], Lynnette M Neufeld[1]

1. Food and Agricultural Organization of the United Nations (Italy), 2. Independent Research (USA), 3. Emory University (USA)

Background: Micronutrient deficiencies (MNDs) compromise immune systems, hinder child growth and development, and limit human capital worldwide. Yet the only existing estimate of the global prevalence of deficiency was from over three decades ago. It was based only on anemia, which is not necessarily attributable to a MND. We aimed to transparently estimate the global and regional prevalence of deficiencies in one or more micronutrients among preschool-age children (PSC) and non-pregnant women of reproductive age (NPW).

Methods: We reanalyzed and pooled individual-level micronutrient status biomarker data from 24 nationally representative, population-based surveys. We used Bayesian hierarchical logistic regression to estimate the prevalence of deficiency in one or more of three core micronutrients (iron, zinc, and vitamin A for PSC and iron, zinc, and folate for NPW) globally and in seven regions for the period 2005–2019.

Findings: We estimated the global prevalence of deficiency in at least one of three core micronutrients to be 56% (95% uncertainty interval 48 to 64) among PSC, and 69% (59 to 78) among NPW. This translates into a global total of 372 (319 to 425) million PSC and 1.2 (1.0 to 1.4) billion NPW with MNDs. Regionally, three quarters of PSC with MNDs live in South Asia (99 million, 80 to 118), Sub-Saharan Africa (98 million, 83 to 113), or East Asia and the Pacific (85 million, 61 to 110). Over half (57%) of NPW with MNDs live in East Asia and the Pacific (384 million, 279 to 470) or South Asia (307 million, 255 to 351).

Conclusion: There is a large burden of MNDs among women and children worldwide, especially in low- and middle-income countries.

The Efficacy of Fish as an Early Complementary Food on the Growth of Infants aged 6 - 7 Months. A Randomised Controlled Trial.

Given Chipili[1], Averalda Van Graan[3], Carl Lombard[2], Evette Van NieKerk[2]

1. Mukuba University (Zambia), 2. Stellenbosch University (South Africa), 3. South African Medical Research Council (South Africa)

Background: Fish is a good animal source protein for growth and development. The main objective of the study was to assess the efficacy of fish during the early complementary feeding period on infants linear growth in Samfya district of the Luapula Province of Zambia in a 6 months randomised controlled trial.

Method: A randomized controlled trial was conducted from April 2019 to January 2020 in Samfya district, Luapula Province, Zambia. Eligible infants aged 6 - 7 months (n = 238) who attended the under-five clinic at the sampled Shikamushile Rural Health Centre were randomized to receive 12g fish powder (treatment) or 7g of sorghum powder (placebo) for six months. Participants were followed on a weekly basis to distribute the powder, record compliance/powder usage and any morbidities. Anthropometric measurements were taken monthly.

Results: Using STATA (version 16), a linear mixed-effects model was used to do an intention to treat analysis for the primary outcome (length-for-age). There was a significant intervention effect on the growth of infants ($p<0.005$) in the fish powder group compared to the sorghum powder group. Infants in the fish powder showed increased length-for-age z-scores by 1.26 (95% CI: 0.94 - 1.57: P = 0.0001), with most of the increase happening in the first three months.

Conclusion: Our results show that introducing fish early in the complementary feeding period improves the growth of infants. Therefore, fish can potentially be used as an early complementary food in low-income communities with access to fish.

Trial registration: clinicaltrials.gov Identifier: NCT03993860.

OAB(T2)1-3

Body composition of children aged 9-14 years born low birth weight at term.

Anku Malik[1], Yamini Gusain[1], Suzzanne Filteau[2], HPS Sachdev[3], Renuka Pathak[1], Geeta Trilok-Kumar[1]

1. Institute of Home Economics, Delhi University (India), 2. London School of Hygiene and Tropical Medicine (UK), 3. Sitaram Bhartiya Institute of Science and Research (India)

Background and objective: India is facing an epidemic of obesity, that is unfortunately now encompassing children. A high burden of Low Birth Weight (LBW) coupled with an exposure to an obesogenic environment has added to the problem of undernutrition. The coexistence of undernutrition and overnutrition has been explained by Developmental Origin of Health and Disease (DOHaD) hypothesis. However, there is scant literature on the impact of being born full term LBW on physiological health outcomes in Indian children. The present study attempts to therefore fill this gap by assessing the body composition of children aged 9-14 years born LBW at term. **Methods**: A total of four hundred and four full term LBW children (gestation >37 weeks; birth weight:1.8-2.4 kg) from underprivileged areas of Delhi, NCR belonging to the Delhi Infant Vitamin D Supplementation cohort were traced and investigated. The studied parameters included anthropometry and body composition by bioimpedance analysis using Tanita MC-980MA. Standardized z-scores were calculated for anthropometric measures and data was analysed using STATA 16.

Results: The mean birth weight and age of LBW children studied was 2.2 (0.1) kg and 11.3 (0.9) years, respectively. During childhood, a substantial proportion of children had 'normal' BMI for age (67%) and height for age (81.4%) z-score. Data revealed higher percentage of children with MUAC-, skinfold thickness- and waist circumference z-score >1SD than children with z-score < -2 SD indicating adiposity. Sex specific analysis revealed similar results with no statistically significant difference among boys and girls. Body fat percent in these children was 13.9%, with a significantly higher percentage in girls than boys (17.3% vs 10.5%) ($p<0.05$).

Conclusion: Despite being born LBW, the pattern of body composition in term end LBW children is consistent with 'thrifty phenotype' resulting in the adiposity. The results indicate an ongoing change due to nutrition and epidemiological transition which strengthens the proposition that fetal programming affects body composition. Further continued research in these children in adulthood is required to substantiate the DOHaD hypothesis.

Feeding practices among mothers and estimated nutrient intake of children during cooking demonstrations in Southern Benin

Carmelle Mizehoun Adissoda[1], Karimou Modou[1], Geraud S.R. Padonou[2], Joël R. Mahounou[1], Aubierge Flenon[3], Hortis Edjrokinto[1]

1. School of nutrition and Dietetics, Faculty of Health Sciences, University of Abomey-Calavi (Benin), 2. Department of Public Health, Faculty of Health Sciences, University of Abomey-Calavi, Republic of BENIN (Benin), 3. Care International Benin/Togo, Lot 51 Patte d'Oie Cadjehoun - 60 BP 1153. Cotonou, Republic of BENIN (Benin)

Background & objectives: Cooking demonstrations (CDs) improve mother's knowledge on complementary foods, and may be convenient to estimate usual nutrient intake of their offspring. We assessed feeding practices of children aged 12-23 months and the nutrient content of meals consumed during monitored CDs. **Methods**: A total of 38 mother-child dyads were recruited under CARE International Benin's CI4N project. Mothers were invited for CDs at 10 sites constellated in Southern Benin. Children feeding practices were evaluated using a standardized questionnaire and compared to World Health Organization (WHO)'s recommendations. Direct observations and weighing were used to measure the ingredients, final recipes and meals consumed by each child. Energy intake and nutrients content of the meals were estimated using the FAO/INFOODS food composition table for West Africa. **Results:** About 53% of mothers followed WHO's best children feeding practices. Nutrient composition (per 100 Kcal) of the foods prepared at the CDs sites were: protein (6.4±3.8) g, vitamin C (8.2±6.8) mg, iron (2.2±2.1) mg, and zinc (0.9±0.6) mg. Assuming 3 or 4 meals per day, the energy density (kcal/g) of the foods was satisfactory for both breastfed (1.9±1.1 or 2.2±0.9) and non-breastfed (2.4±0 or 2.5±0.7). Meals consumed by the children provided on average 21.9%, 27.3%, and 37.9% of recommended daily intakes for vitamin C, iron, and zinc, respectively. **Conclusion**: More than half of mothers adopted best feeding practices. The meals consumed by the children were energy-dense, but low in essential micronutrients. Efforts towards supporting mothers through CDs to include indigenous micronutrient-dense or fortified foods should be strengthened.

Iodine status and thyroid function in school aged children and pregnant women in Switzerland: Current situation and time trends

Isabelle Herter-Aeberli[1], Maria Andersson[2]

1. ETH Zurich (Switzerland), 2. University Children's Hospital Zurich (Switzerland)

Background: Voluntary salt iodization has been in place in Switzerland for 100 years and the current salt iodine concentration is 25 mg/kg. The iodine status is monitored at regular intervals in school-aged children (SAC) and pregnant women (PW) and the previous national study in 2015 indicated marginal iodine intake in pregnant women. The aim of this study was to monitor iodine status in SAC and PW in 2021/22 and investigate time trends.

Methods: In this cross-sectional national study conducted in 2021-2022 we aim to include 700 SAC and 500 PW. We measured urinary iodine (UIC) in spot urine samples. The current median UIC concentrations were compared with national data from 1999, 2004, 2009, and 2015. We measured thyroglobulin (Tg) in dried blood spots (DBS). Further data that will be available: salt iodine coverage, urinary creatinine concentrations (UCC), urinary sodium concentration in SAC, TSH and T4 in PW.

Results: Preliminary results showed a median (IQR) UIC of 111 µg/l (77, 159) in 167 SAC and 108 µg/l (53, 226) in 446 PW. Based on WHO cut-offs for median UIC, the iodine intake is classified as adequate in SAC, but mildly iodine deficient in PW. The UIC was lower compared to 2015 in both SAC (111 µg/l vs. 137 µg/l, *P*<0.001) and PW (108 µg/l vs. 140 µg/l, *P*<= 0.006). Women consuming iodine containing dietary supplements (54%) had higher UIC (168 µg/l) compared to those not consuming such supplements (89 µg/l, *P*<0.001). Median (IQR) Tg concentration in PW was 25.5 µg/l (17.3, 36.5) and 15.7% had elevated Tg concentration (>43.5 g/l). Median Tg concentration was significantly higher compared to 2015 (23.8 µg/l, *P*<= 0.005). Women consuming iodine containing supplements had lower Tg concentrations (21.5 µg/l) compared to those not containing such supplements (30.3 µg/l, *P*<0.001).

Conclusion: Our preliminary results indicate decreased iodine intake in SAC and PW since 2015. PW not consuming an iodine containing dietary supplement had insufficient iodine intake and elevated Tg. The longstanding salt iodization program in Switzerland must be further strengthened to ensure adequate iodine intake in all population groups.

Keywords: Iodine, Urinary iodine, Thyroglobulin, Salt iodization

Validation of mobile AI-technology assisted dietary assessment in adolescent girls in Vietnam

Phuong Hong Nguyen[1,2], Lan Mai Tran[3], Nga Thu Hoang[4], Bastien Koch[1], Peter McCloskey[5], Rohit Gangupantulu[5], Gloria Folson[6], Boateng Bannerman[6], Bianca C Braga[7], Aulo Gelli[1]

1. International Food Policy Research Institute (USA), 2. Thai Nguyen University of Pharmacy and Medicine (Viet Nam), 3. Emory University (USA), 4. National Institute of Nutrition (Viet Nam), 5. Penn State University (USA), 6. University of Ghana (Ghana), 7. Tufts University (USA)

Background and objectives: There is a gap in the data on dietary nutrient intake of adolescents in low- and middle-income countries (LMICs). Traditional methods for dietary assessment are resource intensive and lack accuracy with regards to portion size estimation. Technology assisted dietary assessment tools have been proposed but constrained by lack of validity testing and feasibility of use in LMICs. We validated FRANI, a mobile Artificial Intelligence (AI) application for dietary assessment in adolescent girls aged 12-18y in Vietnam, against weighed records (WR) and compared performance of FRANI with a traditional 24-hour recall (24HR).

Methods: Dietary intake was assessed on 3 non-consecutive days in 36 adolescent girls using 3 methods: mobile FRANI app, WR and multi-pass 24HR. Equivalence of nutrient intakes was tested using mixed effect models adjusting for repeated measures, using 10%, 15% and 20% bounds. The concordance correlation coefficient (CCC) was used to assess the extent of agreement between methods. Sources of errors were identified for memory and portion size estimation bias.

Results: Equivalence between FRANI app and WR was determined at the 10% bound for energy, protein and fat and four nutrients (iron, riboflavin, vitamin B6 and zinc), and at 15% and 20% bounds for other nutrients except vitamin A and B12. Similar results were observed for relative differences between 24HR and WR with 20% equivalent bound for all nutrients except for vitamin A, B6 and B12. The CCCs between FRANI and WR (0.65-0.81) were slightly lower CCCs between 24HR and WR (0.71- 0.90) for energy and most nutrients. Memory error (food omissions or intrusions) was ~21%; no clear pattern on portion size estimation bias for foods. **Conclusions**: AI assisted dietary assessment and 24HR accurately estimate nutrient intake in adolescent girls. Errors could possibly be reduced with further improvements of AI-assisted food recognition and portion estimation.

Conflict of Interest Disclosure: No conflicts of interest.

Assessing the diet quality of people living with HIV/AIDS in Ghana

Kasim Abdulai[1], Kwasi Torpey[2], Agnes Kotoh[2], Amos Laar[2]

1. University of Cape Coast (Ghana), 2. University of Ghana (Ghana)

Introduction: Nutrition is a very important element of comprehensive care for people living with HIV/AIDS (PLHIV), especially in resource-constrained areas where malnutrition and food insecurity are common. Dietary diversity is a useful indication of nutritional adequacy (diet quality) in people of all ages. The study aimed to assess the nutritional status and diet quality of PLHIV using individual dietary diversity score as a proxy.

Methods: A facility-based cross-sectional study design was employed to select 440 people living with HIV from two hospitals in the Eastern Region of Ghana (Atua Government Hospital and St. Martins De Porres Hospital). Dietary intake was determined using 24-hour recall. A stadiometer and bioimpedance analysis machine were used to obtain anthropometric data. Diet quality was assessed using individual dietary diversity score as a proxy. Data were entered into MS Excel 2016 and transported into *SPSS* version 20 for analysis. Odds ratios and multiple logistic regression were used to identify factors associated with diet quality among the PLHIV. P-value was set at 0.05.

Results: Most of the PLHIV (73%) consumed from 'Starchy staple" food group. Less than 20 percent of the study sample had consumed 'Fruits' and 'Vegetables' (17% and 14% respectively). The mean IDDS was 4.11 (SD = 1.29). Overall, most of the people living with HIV (56%) had medium IDDS which is equivalent to "diet needing improvement', 14% had higher IDDS (good diet), whiles about 31% of the participants actually had poor diet (lower IDDS). Meal frequency (twice) per day (OR: 17.06, CI: 15.928-18.192, p<0.001), meal frequency (thrice) per day (OR: 16.96, CI: 15.892-18.019, p<0.001), First line type of ART (OR: 16.96, CI: 15.892-18.019, p<0.001), and 6-12 months duration on ART (OR: 16.96, CI: 15.892-18.019, p<0.001) were significantly associated with IDDS.

Conclusion: The dietary diversity scores indicated that most PLHIV need to improve their diet. Very few participants consumed a high-quality diet. The poor diet quality consumed by the participants could be attributed to the fact that starchy staples were the most consumed diet among respondents, whereas fruit and vegetable consumption was unsatisfactory.

Conflict of Interest Disclosure: There is no conflict of interest to be disclosed.

OAB(T2)2-2
Evaluation of hemoglobin cutoff levels to define anemia among pregnant women: Biomarkers Reflecting Inflammation and Nutrition Determinants of Anemia (BRINDA) project

Melissa F. Young[1], Hanqi Luo[1], Yi-An Ko[1], Anne M Williams[2], Yaw Addo[1,3], Parminder S Suchdev[1,3]

1. Emory University (USA), 2. University of Otago (New Zealand), 3. Centers for Disease Control and Prevention (USA)

Background/Objectives: Current WHO hemoglobin (Hb) cutoffs (<110 g/L) to define anemia during pregnancy are being revaluated as they are outdated and based on limited data lacking global representativeness. Prior WHO and BRINDA work has applied a statisitical approach to determine the cutoff for 95% of normal individuals. Our objective was to examine Hb cutoffs (defined as the 5th percentile of hemoglobin) overall and by trimester in a large multi-country dataset of iron replete pregnant women.

Methods: Biomarkers Reflecting Inflammation and Nutritional Determinants of Anemia (BRINDA) project provided 14 pregnancy datasets (n=14,077) from 12 countries. Iron replete was defined as: [ferritin>15 µg/L]. We examined the variability between datasets and association between hemoglobin and trimester, and estimated the 5th percentile of hemoglobin as anemia cutoff among iron-replete pregnant women, in pooled meta-analysis and by dataset and trimester.

Results: Our study only included women who were iron replete (n=10, 751). The intra-cluster correlation between datasets was 4.8%, indicating the vast majority of the variation in maternal Hb values during pregnancy was at the individual rather than the dataset level. Pooled Hb at the 5%ile overall during pregnancy was 96.8 g/L [91.4- 102.1] with high heterogeneity across datasets [range: 76 g/L (Niger) - 111 g/L (Mexico]. In five datasets with gestational age data and Hb values for each trimester (n = 5978), the pooled countries' Hb at the 5th %ile was 104.0 [100.0 - 108.1], 99.5 [93.5-105.4], and 98.4 [93.4-103.4] for the first, second and third trimesters, respectively.

Conclusions: Based on analysis from a large multi-country analysis, the majority of countries all had lower pregnancy Hb cutoffs compared to the currently used 110g/L. Only the US and Mexico had Hb cutoff values that were similar to WHO recommendations. Lower Hb cutoffs at the 2nd and 3rd trimester compared to the 1st trimester merits further examination. Further research on the functional consequences of Hb cutoffs with maternal and child outcomes and additional data on Hb by trimester are needed to validate potential revisions in hemoglobin cutoffs during pregnancy.

Université Gaston Berger (Senegal), 6. Centre National de Recherches Scientifiques et Technologiques (Burkina Faso)

Background and Objectives: Micronutrient deficiencies negatively impact morbidity, mortality and child growth and development, thereby contributing to the vicious circle of poor nutrition and poor health and they restrain the development of societies. Recently, an international group of experts (Micronutrient Data Generation Initiative) has called for more data on the global extent of micronutrient deficiencies, to be able to inform policymakers on actions to be taken to improve health. Within the framework of the European Union Funded (2FAS) INSIDER project, we aimed to estimate the prevalence of micronutrient deficiencies in West-Africa.

Methods: We conducted a literature review of scientific papers published since 2009 on the prevalence of micronutrient deficiencies in West Africa (national or sub-national) as well as collected information from (sub-)national representative surveys (DHS, MICS, and micronutrient, iodine and SMART surveys) in order to map micronutrient deficiency prevalence. The analysis focused on children under 5 years of age (CU5) and women of reproductive age (WRA, 15-49 years of age). Prevalence data were used to classify countries according to their public health significance.

Results: Analysis showed that important data gaps existed on current micronutrient status of CU5 and WRA and on contributing factors to anemia and micronutrient deficiencies in West Africa. Only four countries (Sierra Leone, Ghana, Gambia and Côte d'Ivoire) have recent national data with only few micronutrients investigated in addition to anemia (essentially iron, folic acid and Vitamin A). Micronutrient deficiency and etiology differed widely between countries, but prevalence is high. Non-national data confirms these findings with deficiencies of iron, vitamin A and zinc being major public health problems in *CU5* in most countries while in WRA, deficiencies of iron, zinc and folate are most prevalent.

Conclusions: Most of West African countries should implement surveys on micronutrient status and etiology of deficiency to obtain reliable national representative data in order to inform policy makers and plan relevant actions. In addition, national micronutrient surveys have to be regularly conducted, to monitor micronutrient deficiency changes and to assess the impact of interventions addressing malnutrition and health.

The impact of MDCF-2 supplementation in improving linear growth among slum children with moderate acute malnutrition

Ishita Mostafa[1,2], Fahim Mohammad Shah[1], Md. Ashraful Alam[1], Michael J Barratt[3], Jeffrey I Gordon[3], Per Ashorn[2], Tahmeed Ahmed[1,4,5]

1. icddr,b (Bangladesh), 2. University of Tampere (Finland), 3. Washington University School of Medicine (USA), 4. University of Washington (USA), 5. BRAC University (Bangladesh)

Background and objectives: Linear growth faltering or stunting, termed as a length-for-age-Z-score (LAZ) less than −2 SD from the median of the WHO Child Growth Standards, is the most common form of malnutrition with a deleterious effect on health during adulthood. An estimated 150 million children were reported to be stunted globally in 2020, of which more than one third lives in South Asia. In Bangladesh, the prevalence of stunting was 31% in 2017-18. Causes of stunting are multifaceted among which gut microbial dysbiosis has recently been emerged as an important one. Hence, novel microbiota targeted treatments to restore healthy child growth becomes a necessity. In that context a microbiota-directed complementary food formulation-2 (MDCF-2) was invented and was tested on malnourished children.

Methods: Between November 2018 and July 2020, a feeding trial was conducted among 123 moderate acute malnourished (MAM) children aged between 12-18 months living in an urban slum of Dhaka, Bangladesh. The children were randomly allocated into one of the two intervention arms MDCF-2 or ready-to-use supplementary food (RUSF) for 3 months. After the intervention period, these children were followed for a period of 24 months where anthropometric assessments were done at every 6 months to observe the long-term effects of the interventions on growth and development. We used linear-mixed effects models to compare the changes in linear growth between the two groups after controlling for differences in characteristics between the children at baseline.

Results: A total of 118 children completed the intervention. We observed sustained improvement in LAZ of the children who received MDCF-2 compared to the children who received RUSF. The mean (±SD) age of the children was 15.4±2.0 months. The difference in LAZ between the groups were statistically significant at 6 months (95% CI: 0.000, 0.004), 12 months (95% CI: 0.000, 0.003), 18 months (95% CI: 0.000, 0.003) and at 24 months (95% CI: 0.000, 0.003) of follow-up.

Conclusions: The study results imply the effective role of MDCF-2 in sustained improvement of linear growth of children enrolled in this trial.

Development and validation of an online dietary assessment tool for use among different ethnic groups in Ireland

Grace Bennett[1], Shuhua Yang[1], Laura A Bardon[1], Eileen R Gibney[1]

1. University College Dublin (Ireland)

Background and objectives: Diversity of ethnic groups living in host countries is rising globally. According to the latest census, the average growth rate of ethnic groups in Ireland is almost 20% annually. Despite this, health disparities between minorities and host populations are prevalent with ethnic minorities at higher risk of chronic disease and suffer from delayed diagnosis and treatment when compared to host populations. Causes are multifactorial and lifestyle and diet are known risk factors. However, there is a paucity of data which examines dietary intake of ethnic minorities, meaning it is difficult to ascertain where public health interventions are most required to illicit positive lifestyle change. Data harmonisation provides opportunity to better understand dietary intakes of multiple ethnic groups globally by utilising existing data. FNS Cloud will facilitate the accessibility and reuse of dietary data, allowing researchers to answer novel research questions.

Methods: To ensure Foodbook24 caters for diverse food and language options, participants were invited to complete a qualitative record of their diet and two 24-hour dietary recalls via Foodbook24 (Study I). To ensure Foodbook24 is an accurate measure of dietary intake, recalls via Foodbook24 were compared to traditional interviewer-led 24-hour recalls (Study II).

Results: To date n=62 Irish and n=30 Brazilian participants have completed this research. The Foodbook24 food list was deemed extensive, containing over 80% of foods reported by all participants. When compared to interviewer-led 24-hour recalls, minimal significant differences in nutrient and food group intakes were noted for both cohorts suggesting that Foodbook24 is an accurate measure of dietary intake of Irish and Brazilian groups in Ireland.

Conclusions: Preliminary results from Study I and Study II suggests that Foodbook24 accurately measures dietary intake of Irish and Brazilian adults in Ireland. Future analysis will be completed on Irish, Brazilian and Polish groups to ascertain the appropriateness of Foodbook24 in assessing dietary intakes of multiple ethnic groups living in Ireland.

This work was undertaken by University College Dublin a beneficiary in FNS-Cloud (www.fns cloud.eu), which has received funding from the European Union's Horizon 2020 Research and Innovation programme (H2020-EU.3.2.2.3. – A sustainable and competitive agri-food industry) under Grant Agreement No. 863059.

Examining the diet quality of Canadians and the alignment of the proposed Canadian 'high-in' front-of-pack labelling regulations with other front-of-pack labelling systems and dietary guidelines

Jennifer J Lee[1], Mavra Ahmed[1], Alena P Ng[1], Laura Paper[2], Chantal Julia[2,3], Mary R L'Abbe[1]

1. University of Toronto (Canada), 2. Sorbonne Paris Nord University (France), 3. Public Health Department, Avicenne Hospital (France)

Background and objectives: Canada proposed mandatory front-of-pack labelling (FOPL) regulations, where pre-packaged foods meeting or exceeding recommended thresholds for nutrients-of-concern must display 'high-in' symbols. However, there is limited evidence on how the proposed Canadian FOPL regulations (CAN-FOPL) compare to other FOPL systems and dietary guidelines, particularly those for non-communicable diseases. The objectives were to examine the diet quality of Canadians and the alignment of CAN-FOPL against other FOPL systems and dietary guidelines.

Methods: A single-day dietary recall from the nationally representative 2015 Canadian Community Health Survey-Nutrition was used. Three dietary index systems based on nutrient profiling models that underpin CAN-FOPL, French FOPL (i.e., Nutri-score), and dietary guidelines for individuals with diabetes (i.e., Diabetes Canada Clinical Practice Guidelines [DCCP]), and two diet-based dietary index systems, Dietary Approaches to Stop Hypertension (DASH) diet and Healthy Eating Food Index-2019 (HEFI-2019), were applied to the dietary data of Canadian adults (n=13,678). Diet quality was examined by assessing linear trends of nutrient consumption across quintile groups of CAN-FOPL dietary index scores. The alignment of dietary index systems was examined using weighted Pearson's correlations and Bland-Altman plots.

Results: The mean±SD dietary index scores (range: 0-100) for CAN-FOPL, Nutri-score, DCCP, DASH, and HEFI diet were 70.3±9.3, 53.6±13.8, 64.1±9.5, 51.7±13.3, and 54.1±14.5 respectively. Moving from the least healthy to the healthiest quintile in the CAN-FOPL dietary index system, intakes of fibre, vitamin A, and potassium increased, while intakes of free sugars, total and saturated fat, calcium, and sodium decreased. CAN-FOPL showed moderate association with DCCP ($r=0.626$, $p<0.001$), Nutri-score ($r=0.507$, $p<0.001$), and HEFI-2019 ($r=0.498$, $p<0.001$) but poor association with DASH ($r=0.235$, $p<0.001$). Bland-Altman plots revealed good agreement between CAN-FOPL and DCCP with a mean difference of 6.2 [95% LOA=-9.8, 22.2], while revealing greater differences compared with Nutri-score (16.6 [-7.1, 40.4]), DASH (18.6 [-9.6, 46.8]), and HEFI-2019 (16.2 [-8.8, 41.2]).

Conclusions: The proposed CAN-FOPL regulations rate the dietary quality of Canadian adults to be healthier than other dietary index systems. Despite the good agreement between the CAN-FOPL and DCCP dietary index systems, wide differences with DASH and HEFI-2019 suggest potential challenges for Canadians to follow a specific dietary pattern with the proposed CAN-FOPL regulations.

Is MUAC-only screening and admission good enough for early detection and management of acute malnutrition? Lessons from a retrospective birth cohort in Bangladesh refugee camps

Benjamin Guesdon[1], Catherine Schwinger[2], Mansuk Daniel Han[3]

1. ACF-France (France), 2. University of Bergen (Norway), 3. WHO Department of Maternal, Newborn, Child, and Adolescent Health and Ageing (Switzerland)

Background and objectives: For the sake of simplification, active screening with Mid-Upper Arm Circumference (MUAC) below 125mm has become the unique strategy to identify Acute Malnutrition (AM) in children aged more than 6 months. Low Weight-for-Height Z-score (WHZ), a criterion similarly acknowledged as defining AM, is however known to detect an additional number of cases. The large proportion of the caseload missed when using only MUAC has been well described in cross-sectional nutritional surveys. Yet, this is not reflecting the current practice of repeatedly screening the same children with MUAC in the community.

Methods: We have built an unselected retrospective cohort of children in tracking the monthly anthropometric measurements performed as per the Growth Monitoring and Promotion program implemented by ACF since 2009 in the Refugees Camps of Bangladesh. An episode of AM was defined as presence of MUAC below 125mm and/or WHZ below -2, in a child previously free of AM.

Results: Follow-up information was collected for 4131 children born since 2012. In this cohort, 51% of the 2164 AM episodes occurring after 6 months of age were first detected only through WHZ below -2, and 65% of these cases were associated with a short-term history of weight loss, i.e. a decrease in weight during the previous month. In contrast with that, 27% of all AM episodes were first detected only through MUAC below 125mm, and these were associated with an observable weight loss in 35% of the cases. Of note, being measured with a MUAC below 125mm yet with a WHZ above or equal -2 at any point of time after 6 months of age failed to display any significant association with short-term history of weight loss.

Conclusions: Using MUAC below 125mm as the only screening tool, even on a monthly basis, would have missed more than half the caseload of AM episodes occurring from birth till 24 months. Besides, the question also arises as to the possible lack of specificity of MUAC below 125mm as an independent proxy indicator of the rapid loss of body tissue that is supposed to characterise acute malnutrition.

The Ethiopian Healthy Eating Index (Et-HEI): A tool to evaluate diet quality by assessing the adherence to Ethiopian Food-Based Dietary Guidelines

Tesfaye Hailu Bekele[1,2], Jeanne H.M. de Vries[1], Edith J.M. Feskens[1], Anneloes de Weijer[1], Inge D. Brouwer[1], Namukolo Covic[3], Laura Trijsburg[1]

1. Wageningen University and Research (Netherlands), 2. Ethiopian Public Health Institute, Addis Ababa (Ethiopia), 3. International Livestock Research Institute, Addis Ababa (Ethiopia)

Background and Objective: Ethiopia's first Food-Based Dietary Guidelines (FBDG) was officially launched in 2022. This study aims to develop and evaluate the Ethiopian healthy eating index (Et-HEI) for the general population to assess adherence to the FBDG and measure diet quality.

Method: The Et-HEI consists of 11 components, classified as adequacy, moderation, or optimum based on the evidence on diet-disease relationships and contribution to nutrient adequacy. The 11 components are scored between 0 and 10 points to the classified categories. The total Et-HEI scoring ranged from 0 (minimum) to 110 (maximum). Ethiopian women of reproductive age (WRA) were sampled from 494 households of different regions and cities (Amhara, Oromia, Tigray, Southern nations nationality, and Addis Ababa). Two days of 24-hour dietary recall, sociodemographic characteristics, and anthropometric measurements were collected from November to December 2019. For the evaluation, the Et-HEI score was associated with the Minimum Dietary Diversity for Women (MDD-W) and probability of nutrient adequacy. Also, differences in sociodemographic characteristics were assessed over the Et-HEI quartiles.

Results: The Ethiopian WRA consumed a relatively high energy (2570 kcal/day) and protein (1.2 g/kg/day) diet, but they were low in most micronutrients. Their diet primarily consisted of cereals, vegetables, and legumes, with little diversity; women's median Et-HEI and MDD-W scores were 47 out of 110 and 3.5 out of 10, respectively. Almost all women received the maximum score of 10 for sugar and alcohol consumption due to low intakes. Most women did not consume fruits, nuts, or animal-sourced foods, resulting in a median score of 0 for these food groups. The Et-HEI showed an increasing trend in the probability of nutrient adequacy across quartiles except for vitamin B12, niacin, thiamin, and zinc. The women were on average 31 years old, and the majority had no (52%) or primary

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

(31%) education. Most women (65%) had a normal body weight (BMI: 18.5-25 Kg/m2). Women who completed high school and higher had lower adjusted and unadjusted Et-HEI.

Conclusion: The Et-HEI score was low, indicating the study population's consumption patterns were poor compared to the Ethiopian FBDG. There was also low nutrient adequacy for the selected micronutrients.

Validation of the rapid Prime Dietary Quality Screener (rPDQS), a brief dietary assessment tool with simple traffic light scoring

Selma previously: Gicevic Kronsteiner-Gicevic[1,2], Monique Tello[3], Elizabeth Lincoln[4,5], Jordan Kondo[4], Uma Naidoo[4,5], Teresa Fung[2,6], Walter Willett[2,1], Anne N. Thorndike[5,4]

1. Medical University of Vienna (Austria), 2. Harvard TH Chan School of Public Health (USA), 3. Agenus Inc. (USA), 4. Harvard Medical School (USA), 5. Massachusetts General Hospital (USA), 6. Simmons University (USA)

Background and objectives: The 2021 American Heart Association dietary guidance emphasized dietary pattern as a determinant of chronic disease. We aimed to validate a brief dietary screener utilizing simple traffic light scoring that could help guide clinical dietary assessment and counseling.

Methods: We surveyed adults (18 years and over) recruited via CloudResearch online platform and sampled to be representative of the U.S. population. The survey included a 13-item rapid Prime Dietary Quality Screener (rPDQS) and demographic information. All participants also completed an Automated Self-Administered 24-hour (ASA24) Dietary Assessment. Responses to rPDQS items were coded using both traffic light and numeric scoring methods and were compared to food groups, Healthy Eating Index 2015 (HEI-2015) scores and usual nutrient intakes estimated from ASA24s. We calculated deattenuated Pearson's correlation coefficients to account for within-person variation in 24-hour diet recalls.

Results: 482 adults completed one ASA24 and rPDQS. Of these, 190 completed a second ASA24 and rPDQS. 50% were female aged 35 years and over, 66% were non-Latino White, 13% non-Latino Black, 16% Latino, and 5% Asian. Positive, statistically significant correlations, ranging from r=0.46 for vegetables to r=0.62 for whole fruits, as well as gradients in mean food group intakes were found for all rPDQS responses relating to food groups that should be encouraged, while negative statistically significant associations, ranging from r=0.26 for red meats to r=0.50 for processed meats, as well as gradients in mean intakes, were found for all rPDQS responses for food groups that should be limited. Total rPDQS scores correlated with total HEI-2015 (r=0.75). Positive, statistically significant correlations were observed between the rPDQS values and the majority of energy-adjusted nutrients including fiber (r =0.72), polyunsaturated-to-saturated fat ratio (r=0.47), magnesium (r=0.69), potassium (r=0.62), vitamin E (r=0.64), folate (r=0.67), vitamin C (r=0.53) and selected carotenoids, including β-carotene (r=0.72), lutein&zeaxanthin (r=0.62), and β-cryptoxanthin (r=0.52). Finally, we found an inverse correlation with total SFAs (r= -0.38).

Conclusions: The rPDQS is a valid, brief dietary screener that identifies clinically relevant patterns of food intake. The simple traffic light scoring system could help clinicians provide brief, actionable dietary counseling during a visit.

Zinc biofortified rice can be an effective measure for combatting zinc deficiency in young Bangladeshi children where rice is staple

Md Munirul Islam[1], Leslie R Woodhouse[2], Tahmeed Ahmed[1], Afsana Khandaker Mim[1], Rahvia Alam Stithi[1]

1. International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b) (Bangladesh), 2. Western Human Nutrition Research Center, University of California, Davis (USA)

Background and Objectives: Information is needed on zinc absorption from rice cultivars having higher zinc content when conventional rice varieties have been cross-bred with locally available Bangladeshi rice cultivars to enhance their zinc content. Total absorbed zinc (TAZ) from mixed diets containing conventional rice (CR), CR plus zinc fortificant (CR+Zn) or zinc biofortified (ZnBfR) was measured. **Methods**: Forty-seven non-malnourished 36-59 months old children were enrolled in 1 of 2 groups. Using a crossover design, after an one-day acclimatization period in the study ward, children in group A (n = 23) received for 2 days (on study days 2 and 4) a mixed diet containing 150 g CR and on study days 3 and 5 a mixed diet containing 150 g ZnBfR. Children in group B (n = 24) received CR+Zn on study days 2 and 4 and ZnBfR on study days 3 and 5. Fractional zinc absorption (FZA) was measured during each of the diet periods using triple-isotope tracer (oral 67-Zn and 70-Zn; intravenous 68-Zn) ratio technique; TAZ was calculated as the product of total dietary zinc intake (TDZ) and FZA.

Results: TDZ measured from all sources (cooked rice, other foods, tracers, and zinc fortificant) was 4.88, 6.14, and 6.70 mg/d when the children were fed CR-, CR+Zn- and ZnBfR- containing diets, respectively. Mean FZA (% of intake) was 23.0 ± 4.1, 16.9 ± 3.5 and 21.2 ± 4.8 for the respective diets (CR vs ZnBfR: p=0.26; CR+Zn vs ZnBfR: p<0.001; and CR vs. CR+Zn: p<0.001). Mean TAZ

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

from the respective diets was 1.13 ± 0.23, and 1.04 ± 0.20 and 1.40 ± 0.33mg/d. TAZ was not significantly different between CR and CR+Zn diets (p =0.52), but TAZ was significantly greater in ZnBfR when compared with the other two diets (p<0.001 for both).

Conclusions: TAZ from ZnBfR could satisfy daily requirement (3 mg/day) by 47% in children 1-3 years when fed 150g of ZnBfR while it is 28% in 4-8 years. The results confirm that ZnBfR can be a prevention and treatment option for zinc deficiency in young children in population where rice is staple.

Barriers and Facilitators in the Use of Iron and Folic Acid and Vitamin A Supplementation and Improving Dietary Practices: A Qualitative Study in Zinder and Maradi, Niger

Edwige Landais[1], Mathilda Miotto-Plessis, Christophe Bene[2], Elodie Maitre d'Hotel[3], Truong T Mai[4], Jerome W Somé[5], Eric O Verger[1]

1. French Nationale Research Institute for Sustainable Development (IRD) (France), 2. Alliance Bioversity International–CIAT (Netherlands), 3. French Agricultural Research Centre for International Development (CIRAD) (France), 4. National Institute of Nutrition (NIN) (Viet Nam), 5. Institut de Recherche en Sciences de la Santé (Burkina Faso)

Background and objectives: Consumption away from home (CAFH) represents an increasing share of people's food consumption worldwide, although occurring at different pace and differently according to countries and individuals. Two previous systematic reviews that almost exclusively included studies conducted in high-income countries (HIC) reported that overall CAFH negatively affects individual's diet. To our knowledge there is no systematic review focusing on low and middle-income countries (LMIC). Therefore, the objectives of the present review were: i) to describe CAFH in apparently healthy population in LMIC; ii) to investigate the association between CAFH and energy intake and diet quality.

Methods: A structured search strategy was developed to retrieve peer-reviewed articles published in English from March 2011 until May 2021 in three databases. Of the 475 studies retrieved, 40 met the PICOS criteria and were analysed.

Results: Out of the 12 countries represented in the review, there was an over representation of Brazil, China and Malaysia that accounted for almost three-quarters of the included studies. There was no homogeneity in the definition of CAFH, or in the reference period for which CAFH was reported, making comparisons or synthetises difficult. Overall, several factors such as being a male, being young, high socio-economic status, high education and urbanicity were positively associated with CAFH. Studies investigating energy intake (n=6) reported that a higher CAFH was positively associated with a higher energy intake (up to 35% of total intake). Moreover, CAFH was associated with higher sodium, fats and sugar intakes (n=8). Additionally, studies investigating the association between CAFH and diet (n=16) reported that a high CAFH was associated with poorer diet e.g. western/industrialized dietary patterns, higher consumption of ultra-processed foods, ready meals, alcohol and sweet beverages and poorer diet quality score.

Conclusions: As reported in HIC, CAFH in LMICs is non-negligible and varies greatly according to countries and population under investigation. The drivers of this behaviour, as well as its potential impact on energy intake and diet quality seems similar in LMIC compared to HIC. However, more research is needed on a larger scale in LMIC especially with regard to the potential consequences of CAFH for health.

The association between inflammation and infection status and vitamin A status of children 36 – 59 months of in a malaria-endemic rural area in Burkina Faso

Olivier Ouahamin Sombie[1,2], Augustin N. Zeba[2], Adama Kazienga[1], Jean Fidele Bationo[3], Christopher Davis[4], Sherry Tanumihardjo[4], Stefaan De Henauw[1], Souheila Abbeddou[1]

1. Ghent university (Belgium), 2. Institut de Recherche en Sciences de la Santé (Burkina Faso), 3. Centre Muraz (Burkina Faso), 4. Madison University (USA)

Background and objectives: Infections and micronutrient deficiencies are widespread health issues in Africa. Vitamin A (VA) deficiency remains an endemic public health concern, with its health consequences mostly affecting infants, young children and pregnant and lactating women. In Burkina Faso, VA deficiency is especially prevalent during the rainy season. The aim of this study was to assess the association between common infections and inflammatory status and VA status in children living in a malaria endemic rural area in Burkina Faso, and the effect of season on this association.

Material and methodology: Two community-based cross-sectional studies were conducted in a malaria endemic area of Burkina Faso and have included 115 children of 36 - 59 months of age. The ^{13}C-retinol isotope dilution test (RID) determined VA total body store (TBS) and total liver reserve (TLR). Malaria infection was assessed using rapid diagnosis test and malaria smear, intestinal parasites were assessed by stool microscopic examination, and inflammation indicators, C reactive proteins (CRP) and Alpha-1-acid glycoprotein (AGP) were assessed in

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

venous blood by ELISA. The association between VA status and infection status was tested by a multiple linear regression.

Results: No VA deficiency (≤0.1 mmol/g liver) was detected using sensitive RID method in the study population. TBS median (Q25-Q75) was 430.8 (289.9 – 620.6) mmol and TLR median was 0.79 (0.55 - 1.20) mmol/g liver. One-fourth of study participants were found to have hypervitaminosis A (>1.0 mmol/g liver). Elevated CRP and AGP were respectively detected in 9% and 26% children. Malaria was diagnosed in 10 % of the children. Significant but weak association was found between CRP concentration and VA status (β=0.055, p=0.009). There was no association between malaria status, AGP and exposition to digestive parasites with VA status. The association between CRP and VA status has a seasonal pattern (β= 0.591, p= 0.001).

Conclusion: In this area of Burkina Faso where infections are common none of the children had VA deficiency. An association was found between acute inflammatory markers and VA status, which was stronger during the rainy season.

OAB(T2)4-4
PG-SGA and EORTC to assess Nutritional status and QoL of cancer patients: The Mysore experience

Asna Urooj[1], Namratha Kotebagilu Pai[2]

1. University of Mysore (India), 2. Manipal Academy of Higher Education (India)

Background and objectives: Cancer is associated with malnutrition mainly due to disease and treatment induced complications. Early diagnosis of malnutrition risk through nutrition screening followed by comprehensive and timely interventions reduces mortality associated with malnutrition. The Scored Patient-Generated Subjective Global Assessment (PGSGA) method has been proved efficient in identifying cancer patients with nutrition challenges and guiding appropriate interventions. This tool has not been extensively used in the management of cancer patients in India. This study assessed the nutrition and functional status of cancer outpatients receiving treatment at 3 cancer hospitals of Mysuru, India. **Methods**: Adopting a hospital based descriptive cross-sectional approach, 202 Cancer out-patients with confirmed stage 1-4 cancers, physically stable,>18 years, undergoing treatment were recruited and assessed using Scored PG-SGA, EORTC and ECOG tools. Food intake and food frequency data was also obtained. Statistical tests employed were proportions, measures of central tendency and Spearman test.

Results: Among the 202 (M-137, F-65), 98 had Head & Neck (HNC) and 104 had other cancers. Most participants had stage 2, 3 and 4 cancers, only 12.9% of participants were well nourished

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

(SGA-A), 59.1% moderately malnourished (SGA-B) and 28% severely malnourished (SGA-C) with significant differences. Functional status and QoL by ECOG and EORTC revealed mild (40.6%) to moderate (36.6%) deficit in the functioning due to disease and treatment induced complications, HNC patients were greatly affected as reflected by a significantly (0.0001) low overall QoL score. Patients with HNC had higher Nutrition impact symptoms due to difficulty in food intake. 24-h recall revealed deficits in energy, protein and carbohydrate while severe deficits were noted in magnesium, potassium, carotene and B-complex vitamins. Nutritional status showed strong inverse correlation (Spearman p=-0.569) with quality of life.

Conclusion Nutritional status assessment and support should be considered a valuable measure within the overall oncology strategy. The PG-SGA is able to identify cancer patients both at risk of malnutrition and those severely malnourished. It also provides a guideline on the appropriate nutrition intervention hence an important tool in nutrition management of cancer patients.

Wild edible plants importance for dietary diversity in women of reproductive age in rural region of Chad

Garba Issa Mahamat[1], Francois Kayitakire[2], Marta Mascareñas[3], Estefanía Custodio[4]

1. Ministere de la Sante Publique_M0H (Chad), 2. François Kayitakire, European Commission Joint Research Centre (Italy), 3. Marta Mascareñas, Universidad de Santiago de Compostela (Spain), 4. Estefanía Custodio, Instituto de Salud Carlos III (Spain)

Background and objectives: Dietary diversity among women of reproductive age is a proxy of appropriate micronutrients intake, key for their health and development. Wild foods have been suggested as a possible source of this diversity. The objective in this study was to assess the relationship between the Minimum Dietary Diversity for Women of Reproductive age (MDD-W) indicator and the collection of Wild Edible Foods (WEF).

Methods: Our study took place in the region of Guerá (Chad), during March 2019. It was a cross-sectional study in which 984 women were interviewed. Sociodemographic, dietary data, food collection and production, and food security information were obtained. We divided WEF into 4 groups: “Fruits”, “Plants”, “Nuts and Seeds” and “Animals”. MDD-W and the Household Food Insecurity Access Scale (HFIAS) scores were obtained using standard procedures. We created a Food Production Diversity Score (FPDS) to assess households´farm diversity. We did bivariate analyses to evaluate the association between MMD-W and WEF; then carried out a multivariable regression adjusting by education, HFIAS and FPDS.

Results: One in three women achieved MDD-W (32,8%). Fruits were the most collected WEF (75.2%), followed by Plants (38.5%), Animals (10%) and Nuts and Seeds (5%). At least some primary education was present in 51.5% of the households. Average HFIAS was 16.6 with a standard deviation of 5.4, and the average FPDS was 2.9 with a standard deviation of 1,4. The association between MDD-W and the collection of WEF was significant at the bivariable level (p=0.049), as well as the consumption of wild plants (p<0.001) and wild fruits (p=0.04). However, in the multivariable regression only the collection of wild plants remained significant p<0.001, the likelihood to achieve MMD-W among households collecting wild plants was 1.8 (IC95%: 1.3-2.3). The covariates were all significant: HFIAS (OR:0.91; IC95%:0.88-0.94), FPDS 5-8 (OR: 2.0; IC95%: 1.3-3.0) and household education (OR:1.4; IC95%: 1.1-1.9). **Conclusions**: Wild plants have been proved to have a notable association with MDD-W in this region. This must be considered while planning nutrition-sensitive and ecological programmes.

Dietary iodine intake of women of reproductive age living in rural Bangladesh based on the Bangladesh Integrated Household Survey (BIHS) 2015

Bregje Susanna Marie van Asperen[1], Nicole J E Verhagen[1], Karin J Borgonjen-van den Berg[1], Alida Melse-Boonstra[1]

1. Wageningen University and Research (Netherlands)

Background: Iodine deficiency is a persistent problem among vulnerable population groups in Bangladesh, but there is little insight in dietary sources of iodine intake.

Objective: To estimate dietary iodine intake from food and salt among reproductive-aged women in rural Bangladesh.

Methods: Food composition data for iodine were retrieved from existing databases and literature, based on which a food composition table (FCT) was compiled for Bangladesh. Next, we analyzed household and individual 24-hour recall data from the midline round of the Bangladesh Integrated Household Survey (BIHS-2015) conducted by IFPRI and USAID, from which we selected 15-49 y-old women (n=7,154). We used summary statistics to describe dietary iodine intake by food source, and ANOVA and multiple linear regression to assess associations and differences between sub-groups, such as for pregnancy and lactation status and socio-demographic factors. Intake adequacy was calculated by comparing average dietary intake with the EAR (non-pregnant non-lactating: 95 µg/d; pregnant: 160 µg/d; lactating: 200 µg/d).

Results: The FCT contained 301 food items divided over 13 food groups, being cereals; pulses; edible oil; vegetables; leafy

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

vegetables; meat, eggs and milk; fruits; fish (large); fish (small); spices; other food; drinks and beverages; and foods prepared outside the home. Median dietary iodine intake of the study population was 204 µg/day, and most dietary iodine (56%) was derived from iodized salt consumption. Overall, 34% of non-pregnant non-lactating women, 48% of pregnant women, 51% of lactating women, and 55% of those both pregnant and lactating had an intake below their EAR. Iodine intake did not differ significantly between groups defined by pregnancy (p=.19) and/or lactation status (p=.48). Of the socio-demographic factors, region (p<0001), literacy (p<0001), main occupation (p<01), and month of 24-h recall (p<001) explained 10% of the total variation in dietary iodine intake (R^2=.10, p<0001). Iodine intake was lowest in women living in the regions Rangpur (61 µg/d), Rajshahi (125 µg/d), and Khulna (171 µg/d). Iodine intake was furthermore linked to education level and knowledge on iodized foods.

Conclusions: Insufficient iodine intake remains a significant health issue among reproductive-aged women in rural Bangladesh, particularly for those living in the North-West.

Keywords: iodine, Bangladesh, reproductive-aged women, 24-hour recall, food composition data

Variability in human milk intake estimation with respect to temperature and humidity assumptions in Dose to Mother technique

Jeswin Baby[1,2], Pernille Kaestel[5], Thomas Preston[3], Anura Kurpad[4], Tinku Thomas[4]

1. St John's Research Institute, Bangalore (India), 2. Kannur University, Kerala (India), 3. University of Glasgow (UK), 4. StJohn's Medical College (India), 5. International Atomic Energy Agency (Austria)

Background: The Dose to Mother (DTM) technique is a stable isotopic method used to safely quantify the human milk intake of babies. A dose of deuterium oxide is administered to the lactating mother, which gets transferred to the breast-fed baby through milk. A two-compartment model is used to mathematically estimate this water transfer, whole body water kinetics, and milk intake. Several assumptions are involved in the computation requiring an examination of the underlying assumptions on the water kinetics and human milk intake estimates.

Methods: We used DTM datasets collected from Bangalore, India. We used data simulation techniques to examine different temperature and humidity conditions and applied more representative values for updating estimates of non-oral and non-milk water intake and fractionation losses. We considered indoor temperature variation from 20°C to 30°C and indoor relative humidity from 40% to 70% as obtained from multiple studies that reported the distribution of indoor temperature and humidity across different parts of the world. The kinetic variables remain unaffected in this simulation exercise.

Results:The non-oral water intake varied from 17.7% to 31.7% of the total water intake and the water loss subject to fractionation varied from 0.7% to 1% of the total water output. The non-milk oral intake estimate of a child with an actual estimate of 91 g/day varied from 72 to 252 g/day over the range of temperature and humidity considered. Fractional water turnover of the mother was 0.11 kg/day, 0.73 kg/day was the oral milk intake of the baby from the mother and the total water loss in baby was 1.26 kg/day.

Conclusions:

Geographical region and seasonal variation in temperature and relative humidity could affect the estimate of human milk intake by the DTM technique. Further research on the effect of local atmospheric conditions on DTM estimates is required.

Keywords: Dose to mother technique, Exclusive Breast feeding

OAB(T2)4-8
Correspondence between total whole grain intake and whole grain intake surrogate estimats in the Finnish adult population

Rilla Tammi[1], Satu Männistö[1], Heli Reinivuo[1], Heli Tapanainen[1], Jenna Rautanen1, Niina Eerika Kaartinen[1]

1. Finnish Institute for Health and Welfare (Finland)

Background and objectives: Whole grain is considered one of the core components in diets promoting health and environmental sustainability. However, inconsistencies in the current whole grain intake estimation possibly weaken the associations between whole grain intake and health outcomes. For example, surrogate estimates (e.g., whole grain bread) have been frequently applied instead of total whole grain intake. Yet, research of these estimates in relation to total whole grain intake is largely missing. We aimed at examining the correspondence of two potential surrogate estimates, dietary fiber and rye bread intake, with total whole grain intake in Finnish adults.

Methods: The data comprised 5094 adults aged 18—74 years participating in the population-based FinHealth 2017 Study. Subgroup analyses were implemented by sex, age (median as cut-off) and education (low/medium vs. high). Dietary intake was assessed by a validated 134-item FFQ. Food, nutrient, energy and whole grain intakes were calculated utilizing the Finnish Food Composition Database Fineli®.

Results: Daily total whole grain intake was 61 g (7.7 g/MJ) in women and 71 g (7.2 g/MJ) in men. The partial (energy-adjusted) Spearman's rank correlation coefficients were 0.68 between total whole grain and dietary fiber intake and 0.83 between total

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

whole grain and rye bread intake. Total whole grain had a higher correlation with dietary fiber in men than women (0.75 vs. 0.64, $p< 0.0001$) and in low/medium educated than high educated participants (0.70 vs. 0.66, $p<=0.03$). The correlation between total whole grain and rye bread intake did not differ between subgroups. No differences appeared between age groups. Of the participants, 88% were categorized in the same or adjacent quintile by unadjusted total whole grain and dietary fiber intakes, while the proportion regarding total whole grain and rye bread intake was 93%.

Conclusions: Overall, rye bread appears to be a good surrogate for whole grain in Finnish adults. Dietary fiber also corresponded reasonably well to whole grain intake. However, consideration of sex and education in applying dietary fiber is needed when examining whole grain intake in relation to health outcomes. Further research is warranted in other populations as dietary sources for whole grains differ across countries.

Can body composition and food structure affect glycemic variability?

Darel Wee Kiat Toh[1], Shalini Ponnalagu[1], Christiani Jeyakumar Henry[1,2]

1. Clinical Nutrition Research Centre (CNRC), Singapore Institute of Food and Biotechnology Innovation (SIFBI), Agency for Science, Technology and Research (A*STAR) (Singapore), 2. Department of Biochemistry, Yong Loo Lin School of Medicine, National University of Singapore (Singapore)

Background and objectives: Postprandial glycemic homeostasis provides holistic insights into glucoregulatory mechanisms in vivo. However, the reproducibility of these measurements has become increasingly challenged. At present, there is paucity in clinical evidence investigating the stability of acute glycemia, particularly for the Asian phenotype. The present research aims to critically evaluate the intra- and inter-individual reliability of postprandial glycemic indicators, and examine potential factors underlying the observed inconsistencies.

Methods: This is a secondary analysis of combined data from three crossover acute trials (n=62) adopting a similar protocol. Healthy, young Singaporean adults (29 ± 10 years) were administered glucose (50 g) in triplicate and capillary blood was collected at regular intervals for glucose analysis. The test was repeated with other high-carbohydrate foods (sucrose, isomaltulose, jasmine/Bapatla white rice, Bapatla brown rice, mee pok noodle, semolina spaghetti/penne and wholegrain spaghetti/penne; available carbohydrate matched) without replicates. Fasting plasma insulin, anthropometry, body composition (bioelectrical impedance) and blood pressure were additionally measured.

Results: Intra-individual consistencies (i.e. for glucose profile, plasma insulin and insulin resistance) were largely moderate according to the respective intraclass-correlation coefficients (ICCs). Specifically, intra-individual variability was highest at 15 min (ICC: (95 % CI): 0.47 (0.32, 0.61)) and lowest at 60 min (0.71 (0.60, 0.80)). There were also no clear improvements in consistency after an extended postprandial duration (incremental area under curve; $iAUC_{120min}$ ICC: 0.58 (0.44, 0.70), $iAUC<_{180min}$ ICC: 0.53 (0.39, 0.57)). Among the demographic, anthropometric and cardio-metabolic health-related indicators, intra-individual relative variability (for $iAUC_{120min}$) was positively correlated with BMI ($r_{Pearson's}$: 0.383; P = 0.002) and fat-mass index ($r_{Pearson's}$: 0.315; P = 0.010). Moreover, a food's structure and nutritional profile could also influence inter-individual rank-order stability (between the $iAUC_{120min}$ for glucose and a range of test foods). Compared to minimally processed foods like jasmine white rice, glycemic variability was prominent for more complex food systems such as pasta.

Conclusions: Postprandial glycemia is vulnerable to variability. This is particularly prominent among individuals with increased adiposity and may also be influenced by the nature and complexity of the food administered. Collectively, this emphasizes the need for a careful re-evaluation on the utility of these existing clinical tools.

Background and objectives: Maternal supplementation of docosahexaenoic acid (DHA) during pregnancy has been recommended due to its role in infant development, but its effect on materno-fetal DHA status is not well established. We evaluated the associations between DHA supplementation in pregnant women with obesity or gestational diabetes mellitus (GDM) and maternal and neonatal DHA status.

Methods: Serum fatty acids (FA) were analyzed in 641 pregnant women (24 weeks of gestation) and in 345 venous and 166 arterial cord blood samples of participants of the NELA cohort.

Results: Obese women (n = 47) presented lower DHA in serum than those lean (n = 397) or overweight (n = 116) before pregnancy. Linoleic acid in arterial cord was elevated in obese women, which indicates lower fetal retention. Maternal DHA supplementation (200 mg/d) during pregnancy was associated with enhanced maternal and fetal DHA levels regardless of pre-pregnancy body mass index (BMI), although higher arterial DHA in overweight women indicated an attenuated response. Maternal DHA supplementation was not associated with cord venous DHA in neonates of mothers with GDM. The cord arteriovenous difference was similar for DHA between GDM and controls.

Conclusions: Maternal DHA supplementation during pregnancy enhanced fetal DHA status regardless of the pre-pregnancy BMI while GDM may reduce the effect of DHA supplementation in newborns.

Dietary restriction in normal weight-individuals: using a web-based 24-hour dietary recall during 2 weeks

Anna Brytek-Matera[1], Magdalena Mroz[2], Pawel Jagielski[3], Joanna Sitarska[2], James Gross[4]

1. SWPS University of Social Sciences and Humanities (Poland), 2. University of Wroclaw (Poland), 3. Jagiellonian University Medical College (Poland), 4. Stanford University (USA)

Background and objectives: Previous studies have found that higher levels of dietary restriction is associated with relatively lower *ad libitum* food intake (Graham et al., 2014). The present study aimed at assessing dietary restriction and its association with dietary patterns in a community-based sample of adults by using a standardized dietary assessment method.

Methods: A total of 105 women (M_{age} = 30.30 ± 9.04) with normal body weight according to body mass index (M_{BMI} = 23.43 ± 4.34) completed the Automated Self-Administered 24-Hour (ASA24®) Dietary Assessment Tool over a two weeks period in their natural settings as well as the Three-Factor Eating Questionnaire.

Results: Compared to women with low levels of dietary restriction, women with high levels of dietary restriction reported higher intake of fruit juice, citrus and non-citrus juices ($F= 4.86$; $p<0.05$; $\eta2= 0.08$), higher intake of yogurt ($F= 5.02$; $p<0.05$; $\eta2= 0.09$) and higher intake of alcoholic beverages and alcohol ($F= 8.24$; $p<0.01$; $\eta2= 0.13$). Higher levels of dietary restriction were associated with a higher consumption of dark green, red and orange vegetables, higher consumption of alcoholic beverages and alcohol and lower consumption of seafood (finfish, shellfish, other seafood) high in 3 fatty acid as well as lower consumption of refined grains. In addition, a higher dietary restriction mean score was found in those women who consider themselves to be healthy eaters. The regression analysis found that dietary restriction was associated with a lower intake of seafood high in omega 3 fatty acids ($B=-1.64$; $p < 0.01$).

Conclusions: The current study may be helpful for demonstrating which foods may likely to be associated with dietary restriction. Nutritional interventions should be considered to benefit dietary patterns of adults.

Multi-country validation of standard minimum dietary diversity indicators as proxies for micronutrient intake in school-aged children

Loty Diop[1], Elodie Becquey[1], Aulo Gelli et al.[1]

1. International Food Policy Research Institute (USA) Minimum dietary diversity, School-aged children,

Background and objectives: Micronutrient deficiencies impair school-aged children's physical and mental development, yet data on micronutrient intake in this population remain scarce, particularly in low- and middle-income countries. As assessing micronutrient intake relies on time and skills-intensive quantitative dietary assessment, there is a need for more operational indicators to monitor diet adequacy in this age group. The present study aimed to conduct a multi-site evaluation of the performance of two food group scores (FGS) and related dichotomous indicators (DI), previously validated in women of reproductive age and 6-to-23-month-old children, in predicting micronutrient intake and its adequacy in 4-to-8-year-old children.

Methods: We conducted secondary data analysis of six 24-hour recall datasets, collected in 4 African countries (Burkina Faso, Malawi, Uganda, and Zambia) and 2 Indian states (Gujarat and Maharashtra), including 7,042 children aged 4-8 years. Micronutrient adequacy was assessed by the Mean Probability of Adequacy (MPA) of intake over 11 micronutrients. Predictors of MPA were FGS-10 (10 food groups from the FAO/FHI360 Minimum Dietary Diversity (MDD) for Women guidelines), and related MDD-W (FGS-10>=5); and FGS-8 (8 groups from the WHO IYC Feeding MDD guidelines), and related MDD-IYC (FGS-8>=5).

Results: Mean MPA and FGS were higher in Uganda (Mean MPA=0.69±0.15; FGS-10=4.7±1.4; FGS-8=4.0±1.0) and Zambia (0.67±0.17; 4.8±1.2; 4.1±0.8), lower in Gujarat (0.28±0.14; 2.8±0.7; 2.8±0.7), and intermediate in Malawi (0.36±0.21; 3.7±1.2; 3.2±0.9), Burkina Faso (0.39±0.24; 3.1±1.0; 3.0±0.9) and Maharashtra (0.36±0.20; 3.9±1.4; 3.6±1.0). FGS-10 and FGS-8 were positively associated with MPA in all sites (correlation coefficients=0.34-0.58, p-values<0.001). Area under the receiver operating characteristic curve values were moderate to good (0.63-0.82) for both FGS as predictors of MPA>=0.7, except for Gujarat where no child reached this level of MPA. MDD-W was the best DI for Burkina Faso, Malawi, Uganda and Zambia, while FGS-10>=6 was better for Maharashtra. For Burkina Faso, Maharashtra and Malawi, MDD-IYC was the best DI, but FGS-10>=4 was more suitable for Uganda and Zambia.

Conclusions: FGS-10 and FGS-8 are simple proxies to monitor diet adequacy in 4-to-8-year-old children. When DI are deemed necessary, MDD-W and MDD-IYC may be used in African settings. For Indian contexts similar to Maharashtra, higher cut-offs might be considered.

The effects of oral ferrous bisglycinate supplementation on hemoglobin and ferritin concentrations in adults and children: A systematic review and meta-analysis of randomized controlled trials

Crystal D Karakochuk[1,2], Jordie AJ Fischer[1], Arlin M Cherian[1], Jeffrey N Bone[1,2]

1. The University of British Columbia (Canada), 2. BC Children's Hospital Research Institute (Canada)

Background: Iron deficiency and anemia have serious consequences, especially for children and pregnant women. Iron salts are commonly provided as oral supplements to prevent and treat iron deficiency, despite poor bioavailability and frequently reported adverse side effects. Ferrous bisglycinate is a novel amino acid iron chelate that is thought to be more bioavailable and associated with fewer gastrointestinal (GI) adverse events as compared to iron salts.

Objective: We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) to evaluate the effects **of ferrous bisglycinate supplementation** as compared to other iron supplements on hemoglobin and ferritin concentrations and GI adverse events.

Methods: A systematic search of electronic databases and grey literature was performed up to July 17, 2020, yielding 17 RCTs that reported hemoglobin or ferritin concentrations following at least 4 weeks supplementation of ferrous bisglycinate compared to other iron supplements in any dose or frequency. The search was registered in PROSPERO (CRD42020196984).

Random-effects meta-analyses were conducted among trials of pregnant women (*n*=9) and children (n=4); pooled estimates were expressed as standardized mean differences (SMDs). Incidence rate ratios (IRR) were estimated for GI adverse events using Poisson generalized linear mixed-effects models. The remaining trials in other populations (*n*=4; men and non-pregnant women) were qualitatively evaluated.

Results: Compared with other iron supplements, supplementation with ferrous bisglycinate for 4-20 weeks resulted in greater SMDs (95% CI) in hemoglobin concentrations in pregnant women (0.54 [0.15, 0.94] g/dL; p<0.01) and fewer reported GI adverse events (IRR [95% CI]: 0.36 [0.17, 0.76]; p<0.01). There were minimal differences for outcomes of ferritin in pregnant women and children or hemoglobin in children.

Conclusions: Ferrous bisglycinate shows some benefit over other iron supplements in increasing hemoglobin concentration and reducing GI adverse events among pregnant women. More trials are needed to assess the efficacy of ferrous bisglycinate against other iron supplements in other populations.

Wholegrain intake, growth and metabolic markers in Danish infants and toddlers – a longitudinal study

Marie Terese Barlebo Madsen[1], Anja Biltoft-Jensen[2], Ellen Trolle[2], Lotte Lauritzen[1], Kim Michaelsen[1], Camilla Damsgaard[1]

1. University of Copenhagen (Denmark), 2. Technical University of Denmark (Denmark)

Background and objectives: wholegrain intake is linked to lower risk of lifestyle diseases, but little is known about its role in diet, growth and metabolic health during the first years of life. We characterized wholegrain and dietary fibre intake in 439 Danish children at 9 and 36 months of age and explored associations with height z-scores (HAZ), body mass index z-scores (BMIZ) and metabolic markers.

Methods: we used pooled data from two infant cohorts and estimated intakes of total wholegrain, dietary fibre and wholegrain subtypes from 7-day dietary records. Associations with HAZ, BMIZ and non-fasting plasma low-density (LDLC) and high-density-lipoprotein cholesterol, triacylglycerol, insulin and glucose were analysed in mixed models, adjusted for potential confounders.

Results: median (25th, 75th percentile) wholegrain intake was 7.5 (4.9, 10.5) and 6.5 (4.6, 9.0) g/MJ at 9 and 36 months. Neither wholegrain nor dietary fibre intake were associated with HAZ (P<=0.09). At 36 months, wholegrain intake was inversely associated with LDLC (P=0.05) and directly with glucose (P<0.001). In secondary analyses, wholegrain rye was inversely associated with glucose at 9 months and insulin at 36 months (both P=<0.03). Oat and wheat wholegrain were directly associated with glucose (both P=<0.01) and wheat with BMIZ (P=0.02) at 36 months.

Conclusion: Danish infants and toddlers have high intakes of wholegrain and dietary fibre, with no indication of compromised growth. In line with studies in adults, wholegrain intake was inversely associated with LDLC. The observed direct association between wholegrain intake and plasma glucose and associations with wholegrain subtypes should be investigated further.

Effect of optimal feeding practices on child development at 2y and 6-7y: a path analysis within the Vietnamese cohort

Usha Ramakrishnan[1], Phuong Hong Nguyen[2,3], Melissa Fox Young[1], Reynaldo Martorell[1], Lan Mai Rran[1]

1. Emory University (USA), 2. International Food Policy Research Institute (USA), 3. Thai Nguyen University of Pharmacy and Medicine (Viet Nam)

Background and objectives: Optimal feeding practices are critical for child growth and development, yet limited evidence exists on the long-term effects of early feeding on child development. This study examined the relationships between infant feeding practices and child development at 2y and 6-7y.

Methods: We analyzed data of 726 children whose mothers participated in a randomized controlled trial of preconception supplementation in Vietnam. Early initiation of breastfeeding (EIBF), exclusive breastfeeding (EBF) in the first 6 months of age, and minimum dietary diversity at aged 1y were assessed based on WHO guideline. Child development was measured by the Bayley Scales of Infant Development-III at 2y and the Wechsler Intelligence Scale for Children®—IV at 6-7y. We used multivariable regression and structural equation models to examine the relationships between infant feeding practices and child development at 2y and 6-7y.

Results: Breastfeeding was suboptimal; 52% of children had EIBF and 62% had EBF. Mean breastfeeding duration was 18 months and 80% achieved diverse diet (at least 4 food groups) at aged 1y. Optimal breastfeeding practices were positively associated with motor development at 2y (β= 0.20, 95%CI: 0.04, 0.35 for EIBF and 0.14, 95% CI: -0.02, 0.30 for EBF) and cognitive development at 6-7y (β= 0.23, 95%CI: 0.09, 0.38 for EBF). EIBF was directly associated with motor and cognitive development at 2y (β= 0.17, 95%CI: 0.03, 0.32 for motor and 0.12, 95%CI: -0.02, 0.26 for cognition) which in turn were associated with cognitive development at 6-7y (β= 0.11, 95%CI: 0.05, 0.18 for motor and 0.26, 95% CI: 0.20, 0.33 for cognition). The indirect path mediated by motor and cognitive development at 2y explained 33-40% of the relationship between EIBF and cognitive development at 6-7y. We also found a direct association of EBF with cognitive development at 6y (β=0.23, 95% CI: 0.09, 0.37). There were no significant associations between breastfeeding duration or dietary diversity with child development.

Conclusions: Breastfeeding practices during infancy directly and indirectly affected child development at early and middle childhood. Interventions to support optimal breastfeeding practices during infancy are needed to promote learning readiness as children begin formal schooling.

Keywords: Breastfeeding, Child development, Early and middle childhood

OAB(T3)1-3

The relationship between dental caries, sweet treat consumption and overweight: a longitudinal study in school-aged children

Sohvi Lommi[1,2], Jukka Leinonen[3], Pirkko Pussinen[1], Jussi Furuholm[1], Kaija-Leena Kolho[4,5], Heli Viljakainen[2,1]

1. University of Helsinki (Finland), 2. Folkhälsan Research Center (Finland), 3. UiT The Arctic University of Norway (Norway), 4. University of Helsinki and Helsinki University Hospital (HUS) (Finland), 5. Tampere University (Finland)

Background and objectives Dental caries and obesity are highly prevalent chronic conditions in industrialized countries and appear to carry a shared risk factor, that is, dietary sugar. This study aims to examine the longitudinal relationship between caries and overweight in school-aged children, and define the role of select sugary drinks and foods ("sweet treats") in that relationship.

Methods We utilized data from the Finnish Health in Teens cohort study and included 3863 children with a mean (SD) age of 11.1 (0.8) years at baseline recruitment and information available on history of cavitated caries lesions (decayed, missing, and filled teeth on permanent dentition, DMFT) and body mass index (BMI). Children with DMFT = 0 were considered caries-free and those with DMFT>0 as having caries. Based on the BMI, measured at baseline and follow-up, we categorized the children into two groups: non-overweight or overweight according to age- and sex-specific cutoffs. Only children who were non-overweight at baseline were included in the study. We estimated weekly consumption frequency of sweet treats as a sum score. Using Cox regression, we defined the crude relationship between dental caries and risk of overweight at follow-up (model 1), and further considered the role of sweet treat consumption (model 2) and other possible confounders (demographics and physical activity; model 3) in that relationship, shown as hazard ratios (HR) with 95% confidence intervals (CI).

Results Mean DMFT index was 0.7 (1.5). Of the children, 29.1% (n = 1126) had history of caries, and 5.6% (n = 217) became overweight during the mean follow-up time of 2.6 (0.8) years. Caries was not associated with becoming overweight either in the crude model (HR 1.07, 95% CI 0.81–1.42) or in the models controlled for sweet treat consumption (0.94, 0.80–1.24) or other possible confounders (0.94, 0.68–1.20).

Conclusions This sample of school-aged children was caries-wise fairly healthy. Caries was not associated with development of overweight, and controlling the analysis for sweet treat consumption and other factors did not change that. Analyses should be repeated in populations with a poor caries status and with a longer follow-up time.

Growth patterns and factors associated with overweight/obesity among infants at the age of 2 years: Findings from a cohort study in Malaysia

Nurliyana Abdul Razak[1], Zalilah Mohd Shariff[2], Wan Ying Gan[2], Kit-Aun Tan[2]

1. UCSI University (Malaysia), 2. Universiti Putra Malaysia (Malaysia)

Background and objectives: Childhood obesity is a global public health issue and is associated with obesity and its related diseases in adulthood. This study aimed to determine growth patterns and factors associated with overweight/obesity among infants at the age of 2 years.

Methods: This cohort study followed-up 117 at-term infants from birth to 2 years in Seremban, Malaysia. Maternal pre-pregnancy BMI, infant's sex, gestational age, birth weight and length were obtained from patient health clinic card. Mothers were interviewed on infant feeding practices and infant's dietary intake. Weight and length were measured every 6 months from 6-24 months. Weight-for-length z-score (WLZ) was determined and a WLZ of >+1 SD was categorized as being overweight/obese.

Results: The prevalence of overweight/obesity at the age of 2 years was 9.4%. WLZ increased at a rate of 0.11 over the first 2 years of life (*B*=0.11, *SE*=0.04, *p*<.01). Infants with low WLZ at birth had a more rapid linear increase in the WLZ over time (*B*=-0.23, *SE*=0.07, *p*<.01). None of the infants who were overweight/obese at 2 years was overweight/obese at birth, but 36.4% of them became overweight/obese at 6 months of age. Overweight/obese infants had higher dietary diversity score (*M*=5.27, *SD*=1.19 vs *M*=4.35, *SD*=1.42) and higher energy intake (*M*=1112 kcal, *SD*=126 vs *M*=1002 kcal, *SD*=133) than infants who were not overweight/obese at 2 years (*p*<.05). Being overweight/obese at 6 (Adj OR=6.75, 95% CI=1.58-28.76), 12 (Adj OR=15.32, 95%CI=2.99-78.47) and 18 (Adj OR=15.57, 95%CI=2.96-81.90) months, and higher dietary diversity score at 2 years (Adj OR=1.78, 95%CI=1.03-3.07) were associated with higher likelihood of being overweight/obese at 2 years.

Conclusions: Overweight/obesity developed at the age of 6 months and continued throughout the complementary feeding period. Infants receiving a wide variety of foods were at higher risk of being overweight/obese at 2 years. Proper complementary feeding is important for healthy growth of infants.

Infant feeding practices and risk of allergic diseases and sensitisation during the first year of life – a birth cohort study

Fui Chee Woon[1], Yit Siew Chin[1], Marijka Batterham[2], Intan Hakimah Ismail[1], Yoke Mun Chan[1], Amir Hamzah Abdul Latiff[3], Wan Ying Gan[1], Geeta Appannah[1]

1. Universiti Putra Malaysia (Malaysia), 2. University of Wollongong (Australia), 3. Pantai Hospital Kuala Lumpur (Malaysia)

Background and objectives: Allergic diseases are one of the most common and earliest developing health issues in early childhood. Growing evidence shows that allergic diseases, which occur more frequently in developed countries, are increasing in developing countries. Infant feeding is one of the major environmental exposures that affects the immune system and the subsequent risk of childhood allergies. This study aims to determine whether compliance with WHO recommendations for infant feeding is protective against allergy risk during the first year of life.

Methods: This prospective cohort study included 380 mother-child pairs recruited from selected public health clinics at the state of Selangor and the Federal Territory of Kuala Lumpur, Malaysia. Infant feeding practices and allergic outcomes including eczema, food allergy, and wheeze were assessed at 3, 6, and 12 months of age based on parental reports. Food and inhalant allergen sensitisation were assessed based on serum allergen-specific IgE test. **Results:** About 46.6% of the infants were exclusively breastfed until 6 months, 97.1% had timely initiation of complementary feeding, 10.5% met minimum dietary diversity (MDD) at 6 months, and 54.5% met MDD at 12 months. A total of 27.6% of the infants had eczema, 3.8% had IgE-mediated food allergy, 6.1% had wheeze, 27.4% had food sensitisation, and 10.8% had inhalant allergen sensitisation during the first year of life. After adjustment for confounding variables, results from the multivariable generalised linear mixed model showed that higher odds of food sensitisation were found in infants who met MDD at 6 months (OR = 2.34, 95% CI = 1.04-5.28). No associations were found between exclusive breastfeeding and introduction of complementary feeding with allergic outcomes.

Conclusions: The present study does not support an association between exclusive breastfeeding and timely initiation of complementary feeding with allergic outcomes in infants during the first year of life. Infants introduced to a high diversity of foods at 6 months had an increased risk of food sensitisation at 12 months. More studies in developing countries are needed and the underlying mechanisms should be explored to provide evidence for infant feeding recommendations for allergy prevention.

Keywords: Allergic diseases, Sensitisation, Feeding practices, Diet diversity, Infants

Longitudinal changes in body composition in term South Indian infants with different growth patterns during early infancy.

Ramya Padmanabha1, Deepa Puttaswamy[1], Suman Rao[2], Tinku Sarah Thomas[3], Rebecca Kuriyan Raj[1,3]

1. St John's Research Institute (India), 2. St John's Medical College Hospital (India), 3. St John's Medical College (India)

Background: Growth and body composition trends during early life have both short and long-term implications- especially in Indians, who are postulated to have the "thin, fat phenotype". However longitudinal studies using accurate methods to measure body composition during early life in Indian infants, based on their growth trajectories are scarce.

Objectives: To assess longitudinal changes in body composition during early infancy in term South Indian infants, categorised by their growth pattern at 6-months of age.

Methods: Two hundred and twenty-three term healthy new-borns were longitudinally followed from birth to 6-months of age. Anthropometric measurements, maternal details and feeding practices were assessed sequentially at birth, 1.5, 3.5 and 6-months. Body composition was measured using air-displacement plethysmography (PEA POD, Software version 3.5.0, 201, COSMED USA) at each timepoint. The infants were categorised as: catch-down growth (CDG), steady growth (SG), and catch-up growth (CUG), based on the decrease/increase in WHO weight for age z-score by 0.67 SD from birth to 6-months. Linear mixed model was performed to evaluate longitudinal changes in %fat mass (FM) across the growth categories.

Results: About 79% of infants were appropriate for gestational age (AGA) and 21% were small for gestational age (SGA), defined by INTERGROWTH new-born size standards. The prevalence of CDG, SG and CUG were 22%, 48% and 30%, respectively. The proportion of CUG was significantly higher in SGA babies compared to AGA (47.8% vs 25.4%, $p<0.001$), while CDG was higher in AGA babies compared to SGA (25.4% vs 6.5%, $p<0.001$). The %FM estimates were significantly lower in the CUG infants at birth compared to SG infants (8.9 ± 3.8% vs 11.2 ± 3.4%), but higher than SG group at 6 months of age (29.0 ± 5.2% vs 26.2 ± 4.7%). The %FM accretion from birth to 6-months was significantly higher in CUG infants by 1.8%, compared to SG infants. The higher fat accretion between CUG and SG was noted in both SGA and AGA infants.

Conclusion: The %FM accretion was higher in the CUG group, compared to SG group at 6-months of age, indicating preferential fat growth in these infants.

Long-term whole egg supplementation promotes growth and *Bifidobacterium* and *Lachnospira* genus, without increases blood cholesterol levels in primary school children.

Sophida Suta[1], Pichanun Mongkolsucharitkul[1], Kitti Sranacharoenpong[2], Patcha Phuangsombut[1], Sakda Khoomrung[1], Apinya Surawit[1], Bonggochpass Pinsawas[1], Suphawan Ophakas[1], Thamonwan Manosan[1], Korapat Mayurasakorn[1]

1. Faculty of Medicine Siriraj Hospital, Mahidol University (Thailand), 2. Institute of Nutrition, Mahidol University (Thailand)

Background and objectives: Protein-energy malnutrition is a major nutritional problem in the world. The lack of enough quantity or quality of protein intake negatively affects growth and development, especially in children. A school lunch program has been used to ameliorate the burden of malnutrition in Thailand since 1952. However, today over 20 % of children are still stunted and wasted, particularly in rural areas. One egg contains an excellent source of proteins and nutrients with a cheap price. We investigated the long-term effects of egg supplementation on growth, biochemical indexes, and microbiota in primary school children.

Methods: A randomized controlled, cluster experimental study was performed at 6 rural schools in Central, Eastern, and Western Thailand. 635 students (8 - 14 years old) were recruited. Subjects were randomly assigned into 3 groups, based on weight for age: 1) Whole eggs (WE) - consume 10 additional eggs per week [n = 238] 2) Egg substitute (ES) - consume yolk-free egg substitute equivalent to 10 eggs per week [n = 200], and 3) control group (C, [n = 197]). The anthropometric, biochemical indexes, and microbiota were measured at week 0, week 13th, and week 35th.

Results: At baseline, 14% were under-weighed, 9% were stunted, and 16% were wasted. At 35th weeks, weight and height changes were markedly increased in WE compared with C (3.56 ± 0.93 kg, p<0.001 and 5.11 ± 0.92 cm, p<0.001). No significant differences in weight and height were observed between the ES and C groups. Prealbumin levels were higher (1.53 ± 0.33 mg/dL, p<0.001) in WE but not ES as compared with C. There were significant decreases in total cholesterol, triglycerides, and LDL cholesterol in WE but not ES as compared with C. Additionally, HDL cholesterol tended to increase in WE (0.66 ± 0.99 mg/dL, *ns*) as compared with C. *Bifidobacterium* and *Prevotella* were significantly increased in relative abundance amounts in WE. The differential abundance analysis also indicated that *Lachnospira* significantly increased and *Varibaculum* significantly decreased after whole egg supplementation.

Conclusions: Long-term whole egg supplementation significantly improves growth in children, which simultaneously promotes health-benefit gut bacteria.

Association between child anthropometry and inattention and hyperactivity among early school age children in rural Nepal.

Eleonor Zavala[1], Parul Christian[1], Subarna K. Khatry[2], Steve LeClerq[1,2], Lee Shu Fune Wu[1], Joanne Katz[1], James M. Tielsch[3], Laura E. Murray-Kolb[4]

1. Johns Hopkins Bloomberg School of Public Health (USA), 2. Nepal Nutrition Intervention Project - Sarlahi (NNIPS) (Nepal), 3. Milken Institute School of Public Health, George Washington University (USA), 4. College of Health and Human Sciences, Purdue University (USA)

Background and objectives: To study the association between child height-for-age (HAZ) and body mass index (BMI) z-scores and behavioral difficulties among school-age children in rural Nepal.

Methods: In a cohort follow-up of children 7 to 9 years of age (n=1,927), whose mothers participated in a randomized trial of micronutrient supplementation, and who were subsequently enrolled in a preschool micronutrient supplementation trial, we assessed behavior using the Conners' Parent and Teacher Rating Scales-Revised (CPRS-R and CTRS-R). Psychometric analyses revealed a two-factor model capturing behavioral domains of "inattention" and "hyperactivity/oppositionality". Summary scores derived from the two-factor models were transformed to t-scores and dichotomized with the bottom two tertiles as "low" and the top tertile as "high", indicating more behavioral difficulties. Logistic regression was used to examine the association of HAZ and BMIZ on behavioral outcomes before and after adjusting for socioeconomic status, HOME Inventory score, and child schooling history. **Results**: Mean (SD) HAZ and BMIZ was -1.88 (0.86) and -1.18 (0.82). In unadjusted models, higher HAZ was associated with lower odds of parent-reported inattention and hyperactivity/oppositionality (OR: 0.82, 95%CI: 0.71, 0.93; OR: 0.86, 95%CI: 0.76, 0.97), and teacher-reported hyperactivity (OR: 0.78, 95%CI: 0.68, 0.90). After adjusting for child age, sex, supplement allocation in both trials, and household socioeconomic status, a one-unit increase in HAZ was associated with a 16% and 21% reduction in the odds of parent-reported inattention (OR: 0.84, 95%CI: 0.73, 0.97) and teacher-reported hyperactivity (OR: 0.79, 95%CI: 0.60, 0.90), respectively. Adjusting for HOME scores and pre-primary schooling attenuated the association between HAZ and parent-reported inattention (OR: 0.88, 95%CI: 0.76, 1.02) and hyperactivity/oppositionality (OR: 0.96, 95%CI: 0.84, 1.11), suggestive of a protective effect of these factors. However, higher HAZ remained significantly associated with lower odds of teacher-reported hyperactivity in fully adjusted models (OR: 0.81, 95%CI: 0.70, 0.94). BMIZ was not associated with any behavioral outcomes.

Conclusions: Lower HAZ is associated with higher inattention and hyperactivity/oppositionality in school-age children in Nepal, a risk mitigated by the home environment and pre-primary schooling. These findings reinforce the need for multi-sectoral interventions to improve child nutrition and development.

Dietary pattern with more fruits and vegetables in children of recent U.S. immigrants is associated with better nutrient intake and weight status

Thanit Vinitchagoon[1], Fang Fang Zhang[1], Rebecca Fauth[2], Erin Hennessy[1], Alison Tovar[3], Silvina Choumenkovitch[1], Aviva Must[4], Christina Economos[1]

1. Friedman School of Nutrition Science and Policy, Tufts University (USA), 2. School of Arts and Sciences, Tufts University (USA), 3. School of Public Health, Brown University (USA), 4. School of Medicine, Tufts University (USA)

Background and objectives: With increased time residing in the US, the risk for developing obesity is increased among immigrant adults and their children. It is unclear, however, if certain dietary patterns contribute to this risk. This study examines whether a more healthful dietary pattern is associated with improved nutrient intake and weight status in children of recent immigrants from Brazil, Haiti, and Latin American countries.

Methods: This cross-sectional analysis used baseline data from children of families (n=239) who participated in Live Well, a randomized controlled trial targeting recent immigrant families in Greater Boston, MA., between 2009 and 2011. Food group and nutrient intake were assessed using the Block 2007 Food Screener. Children's weight and height were measured. Dietary patterns were derived from food group data using principal component analysis. Each child was assigned a factor score quartile based on the agreement with each dietary pattern, with Q4 being the highest and Q1 being the lowest. Multiple linear regression examined the association between quartiles for dietary patterns and nutrient intake, and multiple logistic regression examined the association between quartiles for dietary patterns and odds of being overweight/obese. Models were adjusted for total energy intake and other covariates.

Results: The prevalence of overweight/obesity in this population (age 6.2 ±2.6 years) is 46.9%. Two dietary patterns emerged: “Meals and Sweets” (MS) and “Fruits and Vegetables” (FV). Children in Q4 for FV had a lower percentage of energy from fat (p<.01), lower saturated fat, lower added sugar, higher iron (p<.05), higher dietary fiber, and higher potassium intake (p<.001) than those in Q1. Children in Q4 also had lower odds of being overweight/obese than those in Q1 (OR= 0.29; 95% CI = 0.11 – 0.79). Less favorable nutrient intake was observed for MS with no association with odds of being overweight/obese.

Conclusions: A dietary pattern characterized by more fruits and vegetables was associated with improved nutrient intake and decreased odds of being overweight/obese in children of recent immigrants. Further studies should confirm these findings and explore the relationship between dietary patterns among mother-and-child dyads to see whether similar results occur across generations.

Background and objectives: Physical development is a crucial indicator for revealing the growth and development of infants. While iodine deficiency or excess during pregnancy for their infants' physical development has scarcely been studied. This prospective cohort study aimed to evaluate the effects of maternal iodine nutrition during pregnancy on their infants' physical development.

Methods: From March 2016 to December 2018, mother-infant pairs from Tanggu, Tianjin and Wuqiang, Hebei were recruited in this prospective cohort study. Blood and urine samples were collected to determine thyroid function and urinary iodine concentration (UIC) during pregnancy. Infants' weight, length and head circumference were measured at 18-24 months

Results: A total of 469 mother-infant pairs were included in this study. There were 245 boys (52.2%) and 224 girls (47.8%). The average pregnancy age, gestational week and infants' age were 28.6 ± 3.1 years, 39.5 ± 1.3 weeks and 20.9 ± 3.0 months, respectively. Maternal and infants' median UIC was 161 (111, 251) μg/L and 217 (121, 361) μg/L, suggesting iodine sufficiency according to WHO/UNICEF/ICCIDD-recommended criteria. The Z-score of HC for age of infants with UIC in 100-149 μg/L during pregnancy was higher than those with UIC<100 μg/L and 150-249 μg/L, the difference was 0.56 and 0.46 (*P*=0.002, *P*=0.007), respectively. While no difference was found in maternal UIC and infants' length and weight. There was no difference between maternal thyroid function and infants' physical development.

Conclusions: The Z-score of HC for age was higher in infants with maternal UIC within 100-149 μg/L, rather than 150-249 μg/L, which imply that the criteria recommended by

OAB(T3)3-3
Health behavior clusters, temperament and weight status among Finnish preschoolers

Henna Vepsalainen[1], Liisa Korkalo[1], Anna M Abdollahi[1,2], Reetta Lehto[2], Elina Engberg[2], Marja H Leppänen[2], Carola Ray[2], Eva Roos[2,3], Maijaliisa Erkkola[1], on behalf of the DAGIS research group

1.University of Helsinki (Finland), 2. Folkhälsan Research Center (Finland), 3. Uppsala University (Sweden)

Background and objectives: Studies have shown that health behaviors, such as sedentariness and screen time, physical activity (PA), sleep, and food consumption associate with weight status, and these behaviors tend to cluster already at preschool-age. The current study investigated health behavior clusters among 3–6-year-olds and sought to determine whether the clusters associated with sociodemographic factors, temperament dimensions (negative affectivity, surgency, effortful control), and weight status.

Methods: Altogether 864 children were included. We used food records (3–5 days) to measure dietary intake and 7-day sedentary behavior diary to assess screen time and sleep habits. Accelerometers were used to assess PA and sleep duration during 7 days. Temperament dimensions were assessed using the Children's Behavior Questionnaire. Researchers measured the children's weight and height and categorized the participants into normal weight or overweight based on BMI. We used finite mixture models to identify health behavior clusters and Student's t-test and Chi-squared tests to compare sociodemographic factors, temperament dimensions, and weight status between the participants in the health behavior clusters.

Results: We identified two distinct health behavior clusters. Of the participants, 440 (51%) were categorized into the cluster labelled “Unhealthy diet, excessive screen time”, which was characterized by unhealthier dietary choices (i.e. lower use of vegetables and rye bread, higher use of sweets and juice) and higher screen time. The second cluster was labelled “Healthy diet, moderate screen time”. PA and sleep were not decisive in clustering. Compared to the participants in the “Unhealthy diet, excessive screen time” cluster, the participants in the “Healthy diet, moderate screen time” cluster were younger (4.6 y vs. 4.8 y, p=0.001), had lower negative affectivity (3.6 vs. 3.8, p=0.05), and higher educated parents (41% vs. 29% of parents had master's degree, p=0.001). No differences were detected regarding gender, other temperament dimensions, or weight status.

Conclusions: The findings suggest that increasing age, higher negative affectivity and lower parental education associate with less beneficial health behaviors already among 3–6-year-olds. To promote future health, parents need support in maintaining beneficial health behaviors as the child grows. In addition, tailored support acknowledging the child's temperament could be profitable.

Diet quality during pregnancy and child brain morphology: A prospective population-based study

Yuchan Mou[1], Pauline W. Jansen[1], Tonya White[1], Trudy Voortman[1,2]

1. Erasmus University Medical Center (Netherlands), 2. Wageningen University & Research (Netherlands)

Background and objectives: Diet quality during pregnancy has been associated with neurodevelopmental outcomes and cognitive performance in children. However, little is known about the underlying neurobiological mechanisms. We aimed to examine associations of diet quality during pregnancy with pre-adolescent brain morphology, including measures of volumetric and white matter microstructure.

Methods: We included 2249 mother-child dyads from the Generation R Study, a population-based cohort in the Netherlands. Dietary intake during pregnancy was assessed with a 293-item food-frequency questionnaire and pre-defined diet quality scores were calculated including 15 food components (total scores ranging from 0-15), reflecting adherence to national dietary guidelines. Child brain scans were collected using MRI (including diffusion tensor imaging) at the age of 10 years. Structural brain volumes, including total brain, cerebral white matter, cerebral gray matter and subcortical volumes, were extracted by FreeSurfer. White matter microstructure was quantified by global fractional anisotropy and mean diffusivity.

Results: After adjustment for child age, sex, socioeconomic factors, maternal age at enrollment, smoking and psychopathological symptoms during pregnancy in multiple regression models, we found that mothers' higher diet quality was associated with a larger total brain volume (B = 3.52, 95%CI: 0.91, 6.12), cerebral white matter (B = 1.53, 95%CI: 0.26, 2.79) and cerebral gray matter volumes of children at age 10 years (B = 1.75, 95%CI: 0.40, 3.11). All associations remained after multiple testing correction. Furthermore, the association of total brain volume was independent of child diet quality at age eight years. Diet quality during pregnancy was not related to child white matter microstructure at age 10 years.

Conclusions: Our findings from a large population-based setting suggested long-term global effects of diet quality during pregnancy on child brain structural alterations. These findings indicate the importance of dietary intake during pregnancy for children's brain development, which calls for more research and prevention strategies on overall diet during pregnancy.

Intra-uterine maternal haemoglobin concentration is associated with cognitive function in stunted adolescents: results from a 17-year retrospective cohort study in Indonesia

Muhammad Asrullah[1], Hastrin Hositanisita[2], Monique L'Hoir[1], Siti Muslimatun[3], Edith J.M. Feskens[1], Alida Melse-Boonstra[1]

1. Wageningen University and Research (Netherlands), 2. Alma Ata University (Indonesia), 3. Indonesia International Institute for Life Sciences (Indonesia)

Background and objectives: Maternal anaemia is a major public health problem that has a negative impact on the neurodevelopment of children under the age of five, but its impact on long-term cognitive performance is largely unknown. This study aims to investigate the association between intra-uterine maternal haemoglobin (Hb) concentration and cognitive function of their offspring during adolescence.

Methods: We performed secondary analysis on the retrospective cohort data of 363 paired pregnant mothers and their offspring at 10-14 years of age from the Indonesia Family Life Survey (IFLS) conducted in 1997 - 2014. Cognitive function was measured as the total score on the Raven's Progressive Matrices test. Multiple linear regression models with maternal Hb as exposure and cognitive function as outcome were explored, with adjustments for maternal age, maternal height, and socioeconomic status.

Results: The weighted anaemia prevalence was 49.3% in pregnant mothers and 22.2% in adolescents. The mean total cognitive score of adolescents was 12.4 out of 17. Adolescents who were stunted, anaemic, and living in a rural area had a significantly lower cognitive score than their counterparts. In the adjusted model, maternal Hb was not associated with adolescent cognitive function (β: 0.14; 95%CI: -0.05 – 0.34). However, the effect of maternal Hb level on cognitive function of their offspring was modified by stunting status (stunted β: 0.44; 95%CI: 0.05 – 0.82 and non-stunted β: 0.01; 95%CI: -0.02 – 0.24).

Conclusions: For each 1 g/dL increase in Hb, cognitive scores increased by 0.44, but only in stunted adolescents. This study shows that adverse cognitive outcomes at adolescent age is likely multi-causal and can best be addressed by tackling pregnancy-related anaemia as well as warranting good nutrition for growth and development during childhood.

Symptoms of depression among Mexican adolescent girls in relation to iron status, anemia, body weight, and gut microbiota composition: results from a Latent Class Analysis

Arli Guadalupe Zarate Ortiz[1], Hans Verhoef[1,2], Edith JM Feskens[1], Ana Carla Cepeda Lopez[3], Alida Melse-Boonstra[1]

1. Wageningen University (Netherlands), 2. Medical Research Council (MCR) Unit The Gambia at London School of Hygiene & Tropical Medicine (Gambia), 3. University of Texas Health Science Center (USA)

Background and objective: Depression is a common problem among adolescents. Previous observational research reported an association between nutritional status and gut microbiota composition with depression. This study examined the association between symptoms of depression and iron status, anemia, body weight, and gut microbiota composition among Mexican adolescent girls.

Methods: In this cross-sectional study, we collected data from 408 girls aged 12-20 years. Depressive symptoms were assessed by the 6-item Kutcher Adolescent Depressive Scale, and latent class analysis (LCA) was used to identify and characterize distinct groups of girls based on symptoms of depression. Iron status and inflammation were assessed using ferritin and soluble transferrin receptor, C-reactive protein and alpha-1-acid glycoprotein. Multiple logistic and linear regression were applied to model class membership as a function of iron status, anemia, and body weight. Fecal samples were collected from a subsample of 139 girls. The relative quantification of bacterial taxa was done using 16S ribosomal RNA gene amplicon sequencing.

Results: LCA yielded three classes of symptoms of depression; 44.4% of the adolescents were “unlikely to be depressed”, 41.5% were “likely to be depressed”, and 14.1% were “highly likely to be depressed”. Our analyses demonstrated that iron deficient girls had greater odds of being “likely depressed” (odds ratio, OR=2.01, 95% CI 1.01-3.00) or “highly likely depressed (OR=2.80, 95% CI 1.76-3.84). Linear regression analyses revealed that lower hemoglobin concentrations and higher body weight increased the probability of being “likely depressed”. Beta-diversity revealed no differences in bacterial composition between participants within the different classes of symptoms of depression. Phyla and genera were not shown to be different between classes of depression. However, variables of iron and inflammatory status, that may be associated with depression seemed to explain some of the variation in beta diversity.

Conclusion: This study showed that iron deficient adolescent girls were more likely to suffer from symptoms of depression, and that lower concentrations of hemoglobin and higher body weight increased the probability of experiencing symptoms of depression. No differences in microbiota composition were observed across the three classes of symptoms of depression. However, and the findings suggest a potential link between iron metabolism, inflammation, and depression.

Women's empowerment, childhood nutritional outcomes and the mediating role of household headship structure: Evidence from sub-Saharan Africa

Aaron Kobina Christian[1], D. Yaw Atiglo[1], Micheal Adu Okyere[2], Akua Obeng-Dwamena[1], Grace S. Marquis[3], Andrew D. Jones[4]

1. University of Ghana, Legon-Accra (Ghana), 2. Xiamen University, Xiamen, China (China), 3. McGill University, QC Canada (Canada), 4. University of Michigan, Michigan, USA (USA)

Background and objectives: Women's empowerment influences childhood nutrition through different complex mechanisms. In this study, we aimed to determine the association of women's empowerment with anemia, stunting, and their co-occurrence among children aged 6–59 months while accounting for the mediating role of household headship structure. **Methods**: Data on 25,665 woman-child dyads from the most recent Demographic and Health Survey (2015–2018) from eight sub-Saharan African countries were analyzed. Childhood anemia (hemoglobin concentration <110 g/L) and stunting (height-for-age z score <-2) were calculated. Women's empowerment was measured as a composite index of participation in household decision making, attitude towards domestic violence, and assets ownership. **Results**: Applying the Lewbel 2-stage least squares method with migration as an instrument variable, an increase in women's empowerment index reduces their child's likelihood of being anemic and the co-occurrence of anemia and stunting (Coeff (SE); -0.114 (0.025) and -0.072 (0.032), respectively). Specifically, asset ownership and decision-making dimensions of empowerment significantly reduce anaemia and, the co-occurrence of anemia and stunting among children. Migrant women were more empowered than non-migrant women. Children of empowered women belonging to male-headed households were more likely to be anemic and, be anemic and stunted concurrently compared to their counterparts whose mothers belonged to female-headed households (0.031 (0.008). **Conclusion**: Interventions designed to improve childhood nutrition through women's empowerment approaches need to be hinged on asset and instrumental agency of women and acknowledge the mediating effect of household headship typology.

OAB(T3)2-3

Perceived Food Environments and Household Dynamics related to nutrition among Mother and Grandparents of Young Children in Cambodia

Sam Un Un[1]

1. GIZ (Cambodia)

Background and objectives: Food environments may influence the nutrition transition in Cambodia. Along with the nutrition transition, food environments have also changed with development over time. Dietary choices and snack consumption data among children and mothers in Cambodia are limited. However, the trends of snack consumption observed among young children and the mother's weight status urge further investigation of food environments, food sources and household dynamics. The objective was to understand mothers' and grandparents on their perceptions of food environments and household dynamics around nutrition.

Methods: The study emerges from a larger study using a mixed-method approach, while this only study focuses on the qualitative focus group discussion (FDG). The study was conducted in Phnom Penh (*n*=1 grandparents), Kampot (*n*=4 parents and *n*=3 grandparents) and Kampong Thom province (*n*=4 parents and *n*=3 grandparents).

Results: The FGD participants generally mapped their food sources to come from 1) Nature, fields, forests, rivers, 2) Own fields, gardens, or livestock, 3) Neighbour and friends, 4) Village farmers, 5) Shops, 6) Mobile vendors, and 7) street vendors. The options allow households to balance dietary diversity requirements against an often-limited financial capacity and distance to alternatives. Neighbourhood relations facilitate a food-type arrangement for trade and sharing. Nutritious foods are generally sourced from the first four source categories. By comparison, snacks, processed foods, and desserts are among the last three, although nutritious options are also found here. Mothers are the primary caregiver and grandmothers when the mother is unavailable due to work commitments. Other family members may also provide support (father, aunt, uncle, grandfather, or siblings). The mother and grandmother make the decisions on food in the household. The father may have a say on occasion concerning food preference. Mothers and grandmothers determine where food is sourced, money spent, the type of food purchased, and who cooks the food.

Conclusions: Most healthy and diverse foods are sourced from nature, own production, or village farmers, while mothers and grandmothers are the primary ones responsible for childcare and decision-makers for food consumed by the whole family and hence deciding most nutritional intake in the family.

OAB(T3)2-4

The Importance of Gender Equality in Addressing Adolescent Malnutrition in Bangladesh

Miriam Chang[1], Melani O'Leary[1], Julius Sarkar[2], Asrat Dibaba[1]

1. World Vision Canada (Canada), 2. World Vision Bangladesh (Bangladesh)

Background and objectives: Adolescent girls in Bangladesh face threats to their nutritional wellbeing and human rights, including gender-based violence, gender-based food taboos and early marriage. Nationally, 48.6% of girls (15-19 years) have anaemia. Less than half of Bangladeshi females (10-49 years) have access to an adequately diverse diet and adolescent girls are at least twice as likely as boys to go to sleep hungry, skip meals, and take smaller meals (GAIN-2018).

Methods: Enhancing Nutrition Services to Improve Maternal and Child Health (ENRICH) project, funded by Global Affairs Canada, aimed to reduce malnutrition in the first 1000 days through nutrition-specific and nutrition-sensitive interventions. To address the gender inequalities that contribute to poor nutrition among adolescent girls, ENRICH created Adolescent Girl Power Groups (AGPGs). AGPGs provided life/livelihood skills for a meaningful/sustainable contribution to girls' nutrition and promoted micronutrient supplementation, gender-equal food production/consumption practices, eradication of early marriages, economic empowerment, and greater participation of girls' decision-making related to nutrition.

Results: AGPGs contributed to improved knowledge/self-confidence and changes in girls' power/decision-making. Most girls reported they had sufficient information to make important nutrition decisions and had more control over decisions related to diet, with 87% stating that they make their own decisions about what/when or how much they eat. Furthermore, 99% of girls stated they currently did not have any dietary restrictions not of their own volition. Recent endline results confirmed positive shifts in household gender norms with improvements in equitable decision-making for working/earning income, contraception use, health-seeking behaviors, and spending money on food. Health facility assessments revealed increases in gender sensitivity training and gender equality policies, fostering a supportive environment for girls to claim their nutrition rights.

Conclusions: The AGPG approach empowered adolescent girls to claim their nutrition-related rights and act as change agents in their families/communities. The AGPG model shows the transformative power of an empowerment approach and ultimately demonstrates that progress towards improved nutrition outcomes is possible when girls exercise agency over strategic life decisions, have access to and control over resources, and experience the informal and formal structures around them as enabling their opportunity to improve their rights to good nutrition.

Revisiting hydration and density of fat-free mass in Indian children and adolescents using 4-compartment model: Implications for estimation of body composition using 2-compartment models

Sulagna Bandyopadhyay[1], Deepa P[1], Mamatha P. Phillip[1], Jayakumar J[1], Julia L. Finkelstein[1,2], Sumithra Selvam[3], Anura V Kurpad[4], Rebecca Kuriyan[1]

1. Division of Nutrition, St. John's Research Institute, St. John's National Academy of Health Sciences, Bengaluru, Karnataka (India), 2. Division of Epidemiology and Biostatistics, St. John's Research Institute, St. John's National Academy of Health Sciences, Bengaluru, Karnataka (India), 3. Division of Nutritional Sciences, Cornell University, Ithaca, NY (USA), 4. Department of Physiology, St. John's Medical College, St. John's National Academy of Health Sciences, Bengaluru, Karnataka (India)

Background and objectives: As the burden of childhood overweight/obesity increases, accurate methods are needed to evaluate body composition. Hydrometry and densitometry are commonly used 2-compartment (2C) models to assess paediatric body composition. The accuracy of 2C models in estimating body fat depends on the validity of literature reported constants for hydration (HF) and density of fat-free mass (D_{FFM}). Empirical data on these constants, particularly in South Asian children/adolescents with postulated thin-fat phenotype, are lacking. The objectives were 1) to derive prediction equations for HF and D_{FFM} using 4C model in children/adolescents from South India, 2) to test the validity of the equations to estimate percent fat mass (%FM) using 2C models, compared to 4C model.

Methods: The cross-sectional study included 300 children/adolescents (45% male), aged between 6-15y from Bengaluru, India. Total body water, bone mineral content and body volume were measured using deuterium dilution, dual energy X-ray absorptiometry and air displacement plethysmography, respectively to obtain HF, D_{FFM} and %FM (using 2C and 4C models). Multiple linear regression models were used to derive prediction equations for HF and D_{FFM} in a randomly selected testing sample (n=150). Agreement between %FM obtained from 2C models (using predicted constants from regression equation) and 4C model were evaluated in a validation sample (n=150).

Results: The prevalence of underweight and overweight/obesity were 5% and 17%. The mean (±SD) HF and D_{FFM} were 72.6±2.5% and 1099.9±8.7 g/mL, respectively. The significant predictors for HF were sex and BMI-for-age-z-scores (BAZ), while for D_{FFM} were age, sex and BAZ. The prediction equation for HF% was 71.542+(0.379×BAZ) + (3.019×Male sex), [R^2=0.38, SEE=2.04%], and for D_{FFM} g/mL was 1095.7+(0.711×Age) +(-1.256×BAZ) + (-10.276×Male sex), [R^2=0.41, SEE=6.98 g/mL]. The mean bias of %FM from hydrometry and densitometry using the literature reported HF and D_{FFM} were -3.6±2.9% (p<0.001) and 5.4±3.3% (p<0.001) against 4C estimates, which reduced to -0.45±2.0% (p<0.01) and 0.49±2.2% (p<0.01) using the predicted constants.

Conclusions: Previously published HF and D_{FFM} could induce errors in %FM estimates in Indian children/adolescents, possibly due to the ethnic/phenotypic differences. The equations derived in the present study provided reliable estimates of %FM using hydrometry and densitometry models; however, needs to be confirmed in larger sample.

Sustained effects of small-quantity lipid-based nutrient supplements provided during the first 1000 days on child growth at 9-11 years in a randomized controlled trial in Ghana

Elizabeth Leah Prado[1], Helena Bentil[1,2], Seth Adu-Afarwuah[3], Charles Dale Arnold[1], Paul Hastings[1], Amanda Guyer[1], Mavis Osipi Mensah[3], Adom Manu[3], Kathryn Dewey[1], Brietta Oaks[2]

1. University of California, Davis (USA), 2. University of Rhode Island (USA), 3. University of Ghana (Ghana)

Background and Objective: There is limited research on the impact of nutritional supplementation in the first 1000 days on long-term child growth. We aimed to investigate the effects of pre- and post-natal small-quantity lipid-based nutrient supplements (SQ-LNS) on child growth at age 9-11 years.

Methods: The International Lipid-Based Nutrient Supplements (iLiNS) DYAD-Ghana trial was a randomized controlled trial conducted in 2009-2014. 1320 pregnant women ≦ 20 weeks gestation were randomly assigned to receive daily (1) iron and folic acid during pregnancy and placebo during 6 months postpartum, (2) multiple micronutrients (18) during pregnancy and 6 months postpartum, or (3) SQ-LNS (20 g/d) for pregnant women during pregnancy and 6 months postpartum and SQ-LNS for children from 6 to 18 months of age. In 2021, we assessed child growth at age 9-11 years using height-for-age z-score (HAZ), BMI-for-age, waist -to-height ratio, triceps skinfold and mid-upper arm circumference. Models were adjusted for child's age at measurement.

Results: We re-enrolled and assessed outcomes in 966 children. LNS children had a marginally higher HAZ (p=0.060) than non-LNS children [mean (SD) of −0.04 (0.96) vs −0.16 (0.99)]. There were no other group differences. For child HAZ, there was an interaction with child sex (p-interaction = 0.075) and maternal pre-pregnancy BMI (kg/m^2) (p-interaction = 0.002). Among females, HAZ was higher in the LNS [0.08 (0.07)] than non-LNS [-0.16 (0.05)] group (p = 0.010); among males, the LNS [-0.16 (0.08)] and non-LNS, [-0.16 (0.06)] groups did not differ (p=0.974). Among women with BMI <25, HAZ was higher in the LNS [-0.04 (1.00)] than non-LNS [-0.30 (0.94)] group (p = 0.003);

among women with BMI ≧ 25, the LNS (-0.03 (0.90 SD)) and non-LNS, (0.07 (1.02 SD)) groups did not differ (p=0.321).

Conclusions: Children who received pre- and post-natal SQ-LNS tended to have higher HAZ overall than non-LNS children. In exploratory effect modification testing, SQ-LNS positively affected HAZ among female children and children of non-overweight/obese women. LNS did not increase BMI-for-age. This sustained impact of LNS suggests it may be a useful tool for improving long-term child growth.

OAB(T3)4-1
Circadian rhythm during pregnancy and its association with infant growth in the first 6 months of life: results from MY-CARE cohort study

Satvinder kaur Nachatar Singh[1], Ai Ni Teoh[1], Nurul Husna Mohd Shukri[2], Shibata Shigenobu[3], Takahashi Masaki[4], Siti Raihanah Shafie[2], Normina Abdul Bustami[1]

1. UCSI University (Malaysia), 2. Universiti Putra Malaysia (Malaysia), 3. Waseda University (Japan), 4. Tokyo Institute of Technology (Japan)

Background & Objectives: Circadian rhythm refers to the internal 24h clock that synchronizes behavioral and physiological activities to the time of the day. Disruption or misalignment of circadian rhythm during pregnancy has been associated with adverse maternal and birth outcomes. However, less is known about the role of maternal circadian rhythm on infant growth in healthy pregnancies.

Methods: This prospective cohort study aimed to determine circadian rhythm during pregnancy and its effect on infant growth in the first 6 months of life among 70 healthy primigravidas. All primigravidas provided salivary samples at 5 time-points over a 24h day for melatonin and cortisol assay. Circadian parameters of melatonin and cortisol rhythm including mean, amplitude, area under the curve (AUC), peak melatonin, awakening cortisol level, and diurnal cortisol slope were examined. Infant's anthropometric data at 1, 3, and 6 months was collected from clinic records.

Results: Pregnant women in this study displayed a rhythmic profile of melatonin and cortisol secretions that were largely maintained across trimesters. Salivary melatonin rhythm was characterized by a gradual increment towards the night, reaching the peak at the middle of the night and declining from the morning. In contrast, salivary cortisol rhythm was characterized by a maximal cortisol level in the morning, followed by a steep decline over the day. As the pregnancy progressed, the overall melatonin levels remained stable whereas cortisol levels were increased by 1.4-fold. Reduced mean melatonin level across trimesters was associated with a lower infant LAZ (β=1.79, p=0.012) but a higher infant WLZ (β=-1.74, p=0.030) in the first 6 months, suggesting that reduced melatonin output had a more significant influence on infant's linear growth. Additionally, increased melatonin peak (β=-0.37, p=0.027), melatonin AUCG (β=-0.38, p=0.034), and reduced awakening cortisol level (β=-1.74, p=0.030) across trimesters were associated with a lower infant head circumference growth in the first six months.

Conclusions: Findings show that altered maternal circadian rhythm, as measured by melatonin and cortisol, during pregnancy has a programming role on infant's linear growth and brain development in the first six months. This suggests the potential of circadian-based intervention targeting maternal circadian rhythm to promote optimal infant growth.

OAB(T3)4-2
Nutrition o'clock: The role of chrononutrition on maternal cortisol rhythm and pregnancy outcomes

Ai Ni Teoh[1], Satvinder Kaur[1], Nurul Husna Mohd Shukri[2], Shigenobu Shibata[3], Siti Raihanah Shafie[2], Normina Abdul Bustami[1], Masaki Takahashi[4]

1. UCSI University (Malaysia), 2. Universiti Putra Malaysia (Malaysia), 3. Waseda University (Japan), 4. Tokyo Institute of Technology (Japan)

Background and objectives: Chrononutrition is an emerging, modifiable approach to metabolic health and weight management. Understanding the role of chrononutrition during pregnancy provides new insights into dietary-based preventive approaches for optimal pregnancy outcomes. This prospective cohort study aimed to determine chrononutrition pattern during pregnancy and its association with maternal cortisol rhythm and pregnancy outcomes among 123 healthy primigravidas.

Methods: During their second and third trimester, women completed a 3-day food record. Subsamples provided salivary sampling at 5 time-points over a 24h day for cortisol assay. Data on pregnancy outcomes were collected from clinic records.

Results: In this study, the prevalence of low birth weight and preterm birth was 12.3% and 9.8%, respectively. A total of 28.9% and 38.0% of women had inadequate or excessive gestational weight gain (GWG), respectively. Pregnant women displayed a rhythmic diurnal cortisol decline with the mean level elevated by 1.4-fold as pregnancy advanced. Breakfast skippers displayed a lower awakening cortisol level in the second and third trimester (β=-0.38, p=0.012 and β=-0.31, p=0.038, respectively). Reduced

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

or steeper morning and evening cortisol slopes following higher energy intake were observed. At the macronutrient level, temporal protein and fat intakes in the earlier times of the day (at 7:00-11:59h, 12:00-15:59h, and 16:00-18:59h) were associated with an altered mean level and amplitude of cortisol rhythm. In terms of pregnancy outcomes, late-night eating in the second trimester was associated with a longer gestation length (B=0.66, p=0.014). Women with a longer eating window during the third trimester had a lower birth weight infants (B=-0.25, p=0.024). In the second trimester, higher energy and carbohydrate intake in the morning during 7:00-11:59h (B=0.06, p=0.044 and B=0.11, p=0.030) predicted a higher risk of excessive GWG. Conversely, lower energy intake during 19:00-23:59h (B=-0.07, p=0.031) in the third trimester was associated with a higher risk of excessive GWG. **Conclusions:** Findings point to the role of maternal chrononutrition on circadian cortisol rhythmicity and pregnancy outcome disparities in healthy pregnancies. Incorporating chrononutrition aspects in dietary intervention for optimal GWG and birth outcomes can be considered.

OAB(T3)4-3

Adherence to plant based diets in pregnancy in its association with birth outcomes and pregnancy complications in the Danish National Birth Cohort.

Thorhallur Ingi Halldorsson[1,3], Signe Hedgaard[2], Anne Ahrendt Bjergaard[3], Sjurdur F Olsen[3], Kristina M Renault[2]

1. Faculty of Food Science and Nutrition University of Iceland (Iceland), 2. Dept. of Obstetrica and Gynecology, Hvidovre Hospital (Denmark), 3. Center for Fetal Programming, Department of Epidemiology, Statens Serum Institut, Copenhagen (Denmark)

Background and Objectives: Due to increased environmental concerns and awareness, plant-based diets with limited (e.g. lacto-ovo- and pesco-pollo-vegetarians) or no (e.g. vegans) consumption of foods of animal origin have become increasingly popularity. Although such diets have many nutritional benefits the strictest forms may pose nutritional challenges, particularly during vulnerable life stages such as pregnancy. The aim of this study was to examine associations between adherence of different plant-based diets in pregnancy in relation to measures of fetal growth and pregnancy complications.

Methods: A sample of 66,739 women form the Danish National Birth Cohort who were recruited between 1996 to 2002. All women filled out a comprehensive food frequency questionnaire in mid-pregnancy, which included questions on adherence to plant-based diet. Information on birth outcomes and pregnancy complications were extracted form National Registries.

Results: Out of 66,739 women included in the study 666, 183 and 18 defined themselves as pesco-pollo-vegetarians, lacto-ovo-vegetarians or vegans in mid-pregnancy, respectively. No major differences in macro and micronutrients composition were observed between non-vegetarians and those defining themselves as pesco-pollo-vegetarian. Mean protein intake, as % of energy (%E) was, however, somewhat lower among lacto-ovo-vegitarians(13.3 %E) and more so by those defning themselves as vegans (10.4 %E) compared non-vegetarians (15.0 %E). Similar contrasts were also observed for some other nutrients including calcium and vitamin B12. In terms of birth outcomes, those defining themselves as vegans had on average -221 gram (95% confidence interval: -436, -6) lower birth weight compared to those not adhearing to vegetarian diets. The prevalence of low birth weight (<2500g) and preeclampsia was also significantly higher among vegans compared to non-vegetarian diets. No significant differences were observed for the other diets.

Conclusions: Our results, although based on small numbers, suggests that adhering to strict vegan diets may result in lower birth weight and increased prevalence of pregnancy complication. No differences in birth outcomes or pregnancy complications were observed for less strict vegetarian diets.

adherence to plant-based diet. Information on birth outcomes and pregnancy complications were extracted form National Registries.

Results: Out of 66,739 women included in the study 666, 183 and 18 defined themselves as pesco-pollo-vegetarians, lacto-ovo-vegetarians or vegans in mid-pregnancy, respectively. No major differences in macro and micronutrients composition were observed between non-vegetarians and those defining themselves as pesco-pollo-vegetarian. Mean protein intake, as % of energy (%E) was, however, somewhat lower among lacto-ovo-vegitarians(13.3 %E) and more so by those defning themselves as vegans (10.4 %E) compared non-vegetarians (15.0 %E). Similar contrasts were also observed for some other nutrients including calcium and vitamin B12. In terms of birth outcomes, those defining themselves as vegans had on average -221 gram (95% confidence interval: -436, -6) lower birth weight compared to those not adhearing to vegetarian diets. The prevalence of low birth weight (<2500g) and preeclampsia was also significantly higher among vegans compared to non-vegetarian diets. No significant differences were observed for the other diets.

Conclusions: Our results, although based on small numbers, suggests that adhering to strict vegan diets may result in lower birth weight and increased prevalence of pregnancy complication. No differences in birth outcomes or pregnancy complications were observed for less strict vegetarian diets.

M–SAKHI Mobile health solutions to help community providers promote maternal and infant nutrition and health using a community–based cluster randomized controlled trial in rural India

Michael John Dibley[1], Archana B Patel[2,3], Priyanka N Kuhite[2], Neeloy Ashraful Alam[1], Amrita Puranik[2], Samreen Khan[2], Patrick Kelly[1], Michelle D' Almeida[1], Tracey Laba[4], Sumithra Muthayya[5]

1. The University of Sydney (Australia), 2. Lata Medical Reserach Foundation (India), 3. Datta Meghe Institute of Medical Sciences (India), 4. The University of South Australia (Australia), 5. The Sax institute (Australia)

Background and objectives: Interventions that focus only on improving infant nutrition have had limited success in reducing stunting. We developed a mobile phone-based pregnancy and child-care behaviour change communication intervention, M–SAKHI. We introduced it in villages in Central India for pregnant women until their infants were 12 months. The trial's primary objective was to reduce under-five child stunting (height–for–age <-2 z-score) in intervention compared to control.

Methods: Using a cluster randomised controlled trial, we allocated 40 clusters (244 villages, 2501 pregnant women; 1296 in control and 1250 in intervention) to Usual MCH Care or M–SAKHI with Usual Care. The M–SAKHI intervention provided weekly voice messages, text messages, and counselling calls. Also, we held monthly face-to-face meetings with trained community health workers who collected real-time data that triggered client-specific messages, provided counselling, and played health videos and voice messages embedded in the M–SAKHI App. An independent team of trained interviewers and anthropometrists collected the outcome data monthly with special-purpose data capture programs on android tablets. In an intention to treat analysis, we estimated relative risk (RR) and 95% confidence intervals by fitting a multilevel mixed-effect generalised linear model using Poisson regression. We prospectively registered the trial with number: CTRI/2018/02/011915

Results: We recruited 1251 and 1250 women in usual care and M–SAKHI arms, respectively, resulting in 1180 and 1171 livebirths, of which 1125 and 1136 were available at the 18-month outcome evaluation. Over the 18 month follow-up, we evaluated 7,351 and 7,445 anthropometric measurements in control and intervention arms. There was a 10% reduction in the risk of stunting (RR0.90, 95%CI0.75–1.07) but with a significant interaction by age (p=0.004). We found a significant reduction in stunting at 10–month (RR0.73, 95%CI0.59–0.90, absolute reduction 15.8% to 11.7%) and 12–month (RR0.80, 95%CI 0.66–0.97 absolute reduction 19.1% to 14.9%) visits. During the 12 months we delivered the intervention, there was a 24% reduction in stunting risk (RR0.76, 95%CI0.63–0.92) but no effect afterwards.

Conclusions: The M–SAKHI intervention reduced child stunting while delivered, but the effect was not sustained once the communications program ceased.

Neurodevelopment scores are associated with multiple components of nurturing care in the 24 month old offspring of participants in the multi-country "Women First" preconception maternal nutrition trial

Nancy F Krebs[1], Lester Figueroa[2], Sumera Aziz Ali[3], Deepa Metgud[4], Adrien L Lokangaka[5], Jamie Westcott[1], Abhik Das[6], Dhuly Chowdhury[6], K Michael Hambidge[1], Women First Study Group

1. University of Colorado School of Medicine (USA), 2. Institute of Nutrition in Central America and Panama (INCAP) (Guatemala), 3. Aga Khan University (Pakistan), 4. KLE Academy of Higher Education and Research (Deemed-to-be-University) Jawaharlal Nehru Medical College (India), 5. Kinshasa School of Public Health (Democratic Republic of the Congo), 6. RTI International (USA)

Background and Objectives: Neurodevelopment in young children in low resource settings is optimized by components of both physical health and nurturing environments. The impact of a 3-arm maternal nutrition intervention delivered from preconception or 12 wk gestation (or none) through to delivery was assessed along with post-natal growth and nurturing care indicators on the Bayley Scales of Infant Development-III (BSID) at 24 mo in offspring of participants in the four LMIC countries in the Women First (WF) trial.

Methods: Anthropometry measurements were obtained at birth and 6-mo intervals thereafter; BSID and Family Care Indicators (FCI) were completed at 24 mo in a random sub-set of the WF offspring, representing 2/3 of infants with valid birth measurements. Multiple covariates (intervention arm, site, cluster within site, maternal education, age, SES, FCI subscales, LBW, and anthropometry Z-scores at 6 mo and change (D) from 6 to 24 mo, e.g. length-for-age, D-$LAZ_{6\text{-}24}$) were considered as predictors and were adjusted for in a general linear model to predict adjusted mean differences (AMD) in scores of cognitive(C), motor(M), and social-emotional (SE) subscales of the BSID.

Results: 1,386 infants (93% of sub-set randomized for BSID assessment, approximately equal across 3 arms) were included in the analysis. Differences in BSID subscales associated with intervention arm were significant in only one site. Maternal education, FCI play materials, and WAZ at 6 mo were predictive of all 24-month BSID subscale scores. Four covariates positively associated ($p <= 0.01$) with all subscales were: maternal secondary education (AMD 3.6(C), 3.35(M), 2.8(SE)); D-$LAZ_{6\text{-}24}$ (AMD 1.98(C), 3.15(M), 2.06(SE)); BW>2500 g (AMD 1.64(C), 2.20(M), 2.31(SE)); and FCI play materials (AMD 1.46(C), 1.36(M), 1.72(SE)). No other anthropometric or maternal variables were consistently associated with any BSID subscales across all sites.

Conclusion: These findings underscore the multiple critical components of nurturing care for early child development, including the caregiver, adequate birth weight, healthy linear growth, and opportunities for learning. Results also suggest that the positive effects of maternal nutrition supplementation started before and or in early pregnancy on birth length and postnatal linear growth may have enduring downstream benefits for children's neurodevelopment.

Comprehensive behavioral analyses of male and female mice derived from mothers fed a diet high in omega-6 and low in omega-3 fatty acids

Nobuyuki Sakayori[1], Kazuki Fujii[2], Masanori Katakura[3], Keizo Takao[2], Makoto Sugita[1]

1. Hiroshima University (Japan), 2. University of Toyama (Japan), 3. Josai University (Japan)

Background and objectives: Most animals cannot synthesize omega-6 (n-6) or omega-3 (n-3) polyunsaturated fatty acids (PUFAs), which are essential nutrients for normal brain development and function. These PUFAs are generally competitive in various metabolic processes, and the n-6/n-3 ratio of PUFAs that compose our body warrants particular attention. Regarding recent nutritional trends leading to foods that are high in n-6 PUFAs and low in n-3 PUFAs, we previously reported that intake of an n-6-high/n-3-low diet by pregnant mice induces offspring's enhanced anxiety-related behaviors and hedonic feeding behaviors in adulthood, although the offspring were raised on a well-balanced control diet after birth. This study aims to comprehensively understand the behavioral consequences of the offspring exposed to the n-6-high/n-3-low diet in utero.

Methods: Female wild-type mice were fed either the well-balanced control diet or the n-6-high/n-3-low diet, and the mice were mated and maintained on their respective diet through gestation. At the day of birth, the lactating mothers were exposed to a standard lab chow by replacing the control diet or the n-6-high/n-3-low diet. Offspring after weaning were continued to feed the lab chow. Male and female offspring in adulthood were subjected to a comprehensive behavioral test battery including the open field test, elevated plus-maze test, social interaction test, three-chamber social approach test, rotarod test, Porsolt forced swim test, and several learning tests. The offspring's brain fatty acids were also investigated.

Results: We newly identified significant behavioral differences between the two dietary groups; both male and female offspring exposed to the n-6-high/n-3-low diet in utero showed a decreased social behavior and an impairment in pattern separation, and female offspring exposed to the n-6-high/n-3-low diet in utero showed hyperactivity, compared to those exposed to the control diet in utero. We also confirmed that the brain n-6 and n-3 PUFAs, especially arachidonic acid and docosahexaenoic acid, were increased and decreased, respectively, in the embryos exposed to the n-6-high/n-3-low diet in utero compared to those exposed to the control diet in utero.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: Our findings show that maternal intake of PUFAs during pregnancy can have long-lasting effects on offspring's various behaviors in adulthood.

Conflict of Interest Disclosure: The authors declare no conflict of interest.

Thyroid Volume and Nodules in Iodine-Sufficient Pregnant Women

Naifan Zhang[1], Wanqi Zhang[1,2,3], Wu Wen[1], Yanting Chen[1,4], Wenxing Guo[1], Ying Yang[1], Kexin Zhang[1], Ziyun Pan[1], Wen Chen[1], Long Tan[1]

1. Tianjin Medical University (China), 2. Tianjin key Laboratory of Environment (China), 3. Tianjin Medical University General Hospital (China), 4. Guangdong Medical University (China)

Background and objective: Few studies about risk factor of thyroid goiter and TNs were conducted in iodine-sufficient regions. The study aimed to evaluate the iodine nutrition and the potential risk factors of thyroid goiter and nodules in Chinese pregnant women living in an adequate iodine city.

Methods: From April 2015 to May 2017, a total of 2002 pregnant women from Tianjin provinces in China were recruited, thyroid volume (TV) and nodules (TNs), urinary iodine concentration (UIC) and thyroid function were measured.

Results: The median UIC was 158 (106-230) μg/L and 45.5% of pregnant women had a UIC lower than 150 μg/L. TV increased during pregnancy (P<0.001). Increment in TV was found in pregnant women with higher body mass index (BMI), thyroid stimulating hormone (TSH), thyroglobulin (Tg) and positive thyroid peroxidase antibody (TPOAb) and thyroglobulin antibody (TgAb). TV was positively correlated with BMI and negatively related with TSH. Total thyroid goiter rate (TGR) and thyroid nodules rate (TNR) were 1.6% and 11.7%, respectively. Logistic regression analysis showed that BMI ranged from 24-27.9 and >28.0 kg/m^2, Tg> 40μg/L and positive TgAb increased the risk of TG (odds ratio, OR=3.79, 3.88, 5.41 and 4.69, respectively). >30 years old and Tg>40μg/L were independent risk factors of TNs (OR=1.43 and 2.40, respectively).

Conclusions: BMI (>24.0 kg/m^2), Tg (>40μg/L) and positive TgAb may increase the risk of thyroid goiter, and age (>30 years old) and Tg (>40μg/L) were related to high risk of TNs. Continuous monitoring of iodine nutrition during pregnancy should be strengthen, especially in pregnant women with subtle thyroid dysfunction, even in iodine-sufficient regions.

Strengthening nutrition interventions in antenatal care services improved consumption of iron-folic acid supplements and early breastfeeding practices in Burkina Faso

Sunny S. Kim[1], Rock R. Zagré[2], Césaire T. Ouédraogo[3], Celeste Sununtnasuk[1], Rasmané Ganaba[4], Maurice G. Zafimanjaka[5], Manisha Tharaney[6], Purnima Menon[7]

1. International Food Policy Research Institute (USA), 2. International Food Policy Research Institute (Senegal), 3. International Rescue Committee (Mali), 4. AFRICSante (Burkina Faso), 5. FHI Solutions (Burkina Faso), 6. FHI Solutions (Cote d'Ivoire), 7. International Food Policy Research Institute (India)

Background and objectives: Routine antenatal care (ANC) offers opportunities to receive a broad range of services including support for adequate nutritional care for pregnant women and their newborns. Alive & Thrive (A&T) aimed to strengthen provision of iron-folic acid (IFA) supplementation and interpersonal counseling on maternal nutrition and breastfeeding through government ANC services and community-based contacts in two regions in Burkina Faso. We assessed the impacts of intensified nutrition interventions during ANC (A&T) and standard ANC services (control) on intervention coverage and maternal nutrition practices.

Methods: A cluster-randomized design compared 40 health center catchment areas in A&T areas to 40 in control areas. Repeated cross-sectional surveys in 2019 and 2021 (960 pregnant women and 1920 women with children 0-5 months of age per survey round) provided data on impact indicators and intervention exposure. We derived difference-in-difference effect estimates (DID), adjusted for geographical clustering, for maternal dietary diversity, IFA consumption, and early breastfeeding practices.

Results: More women in A&T areas had 4+ ANC visits (DID: 8.5 percentage points [pp]) and 4+ community-based contacts during their last pregnancy (DID: 14.7 pp) and started ANC during the first trimester (DID: 11.3 pp), compared to control areas. A larger improvement in exposure to nutrition counseling during ANC was achieved in A&T areas than in control areas (DID: 39.5 pp). Women in A&T areas consumed more IFA supplements during pregnancy than in control areas (DID: 21 tablets). Both early initiation of breastfeeding and exclusive breastfeeding also improved (DID: 17.1 pp and 8.3 pp, respectively). However, dietary diversity (4 out of 10 food groups) and mean probability of adequacy of micronutrients intake (14%) among pregnant women remained low in both areas.

Conclusions: Strengthening maternal nutrition interventions delivered through government ANC services was feasible and effective in improving maternal nutrition practices, despite implementation during the COVID-19 pandemic. Continued efforts to strengthen the delivery and use of maternal nutrition services may be required for greater behavior changes, as well as to address family support, social norms, and other factors to improve maternal diet.

OAB(T3)5-2
Impact of Behaviour Change Comunication Intervention on Responsive Feeding Practices of Caregivers of Infants and Young Children, 6-23 months in Ghana

Reginald Adjetey Annan[1], Akosua Achiaa Akosah[1], Satoru Okonogi[2], Takeshi Sakurai[2]

1. Kwame Nkrumah University of Science and Technology (Ghana), 2. University of Tokyo (Japan)

Background and objectives: The World Health Organisation's Complementary Feeding (CF) guidelines include the application of psychosocial care during feeding, known as Responsive Feeding (RF). RF emphasises feeding infants directly and assisting older children when they feed themselves, being sensitive to their hunger and satiety cues, feeding slowly and patiently, encouraging children to eat, but not forcing them. We investigated the factors associated with RF practices, and impact of BCC focused on appropriate CF, on RF and Feeding During Illness and Recovery (FDIR) Practices of caregivers of infants, 6-23 months in Bosomtwe District, Ashanti Region, Ghana.

Methods: We recruited 525 mother-infant pairs at baseline; 322(61.3%) received BCC, while 203 (38.6%) served as controls. Education, counselling and demonstrations on appropriate CF according to WHO's guidelines were provided for six months to the BCC group, but not the controls. Structured questionnaires were used to collect data on RF and FDIR practices before and after the BCC intervention. Crude models, Mann-Whitney U tests and paired sample T-tests were used for statistical analysis of the data.

Results: Mean age of the caregivers at baseline was 29.3 years, and 11.4 months for their children. Children age and gender in intervention versus controls were similar at baseline. Only 6.3% of caregivers practised good RF and just 3% practiced good FDIR, baseline, and caregivers' socio-demographic characteristics were not associated with RF and FDIR practices. Caregivers', with poor RF practices at baseline had lower odds for good FDIR (OR= 0.03, p< 0.001, 95%CI=0.01-0.1). Also at baseline, similar proportions of caregivers in BCC (94.4%) and controls (92.6%) practiced poor RF (chi square 0.7, p=0.408), but these reduced significantly post intervention in the BCC (40.2%) group, and only marginally in the controls (86.8%, p<0.001). Likewise, more BCC receiving caregivers had good FDIR post intervention than the controls. Contrary to baseline observations, whereby the BCC group had increased odds for poor RF (OR= 1.3, p<=0.410, 95%CI=0.7-2.7), post intervention, caregivers in the BCC group had reduced odds for poor RF (OR= 0.1, p<0.001, 95%CI= 0.01-0.1).

Conclusions: BCC on appropriate CF following to WHO's guidelines improved RF and FDIR practices among caregivers of infants and young children in Ashanti Region, Ghana.

OAB(T3)5-3
The association of maternal diet and breast milk fatty acid composition

Inga Petersohn[1,3], Anneke H. Hellinga[2], Linde van Lee[3], Nicole Keukens[1], Edith EJM Feskens[1], Elske EM Brouwer-Brolsma[1]

1. Wageningen UR (Netherlands), 2. UMC Utrecht (Netherlands), 3. Ausnutria B.V. (Netherlands)

Background and objectives: Exclusive breastfeeding during the first six months after birth provides the infant with the most optimal start for life. Maternal diet is suggested to influence the composition of breast milk. However, little is known about the exact impact on nutrient level. Breast milk fatty acid content has been studied most in this context, therefore, this review aims to summarize the evidence on the role of maternal diet in breast milk fatty acid composition.

Methods: A systematic PubMed search was carried out, limited to articles published between January 2015 and March 2021, based on the latest inclusion date of the earlier review on this topic of Bravi et al., 2016. Studies were included if they provided quantitative information and were conducted among apparently healthy mothers, of healthy term infants. This review combines the latest results published and those articles identified by Bravi and colleagues.

Results: In total, 17 new publications were identified and combined with 12 studies described by Bravi et al. Among all fatty acids, PUFAs were studied most, by far. Maternal fish intake was predominantly significantly positively associated with breast milk ALA (r= 0.28 – 0.42), DHA (r= 0.24 – 0.46) and EPA (r= 0.25 – 0.28) content. Interestingly, seafood consumption showed mainly negative significant associations, for example with breast milk LA (r= -0.28 – -0.32), DPA (r= -0.32 – -0.51) and total PUFA (r= -0.26 – -0.31). Both, maternal DHA and EPA intake were significantly positively correlated with breast milk DHA content. ALA, EPA, total PUFA, n-3 PUFA, n-6 PUFA and SFA in breast milk were often positively associated with maternal dietary intake. Negative correlations were observed for maternal SFA intake and several fatty acids in breast milk.

Conclusions: There are convincing indications that maternal diet is associated with breast milk fatty acid content, especially for fish intake and DHA concentrations. Yet, for most fatty acids in breast milk, it remains difficult to draw conclusions due to differences in study quality and large diversity in assessed exposure and outcome combinations. More high-quality studies assessing maternal diet and breast milk composition are needed, with strict sampling protocols and appropriate sample sizes.

High consumption of unhealthy commercial foods and beverages tracks across the complementary feeding period among young children in rural/peri-urban Cambodia

Guy-Marino Hinnouho[1], Elaine Ferguson[2], Amy MacDougall[2], Hou Kroeun[1], Sophonneary Pra[3], Chea Mary[3], Alissa Pries[1]

1. Helen Keller International (USA), 2. London School of Hygiene and Tropical Medicine (UK), 3. Ministry of Health (Cambodia)

Background and objectives: Consumption of unhealthy commercial foods and beverages (UCFB) is common among infants and young children (IYC), including IYC living in low- and middle- income countries (LMIC). Such foods can displace consumption of other nutritious foods and reduce dietary adequacy, however, there is limited evidence on how this consumption pattern tracks across the complementary feeding period. This study assessed UCFB consumption patterns of children 10.0 – 18.9 months of age living in rural/peri-urban Kandal province, Cambodia during the complementary feeding period.

Methods: From June 2021-January 2022 we implemented a longitudinal cohort study among 567 caregivers of children aged between 10.0-13.9 months at recruitment. Data was collected monthly across 6 timepoints via a phone survey, including an interviewer-administered questionnaire and a weekly food frequency questionnaire, which captured the child's consumption of foods across nine categories of UCFB. The number of times UCFB were consumed in the previous week was calculated, with a possible range of 0-63 times. UCFB consumption patterns were identified using a mixed-effects Poisson regression model. Logistic regression was used to explore the odds of being high consumer of UCFB at 10.0-13.9 months and at 16.0-19.9 months.

Results: Median [IQR] number of times UCFB were consumed in the previous week increased from 4 [1-8] at 10.0-13.9 months to 11 [7-16] at 16.0-19.9 months. Four UCFB consumption patterns were identified across the complementary feeding period: 1) maintaining a healthy consumption pattern (6.1%); 2) developing an unhealthy consumption pattern (43.7%); 3) improving an unhealthy consumption pattern to a healthy one (4.9%); and 4) maintaining an unhealthy consumption pattern (45.3%). High consumers of UCFB at 10.0-13.9 months had a 4.7 times odds of being high consumers of UCFB at 16.0-19.9 months ($p< 0.001$).

Conclusions: This study found a high prevalence of UCFB consumption patterns in the diets of children 10.0 – 18.9 months. Our findings indicate that high UCFB consumption began during infancy and tracked into childhood. Early interventions are needed to improve infant and young child feeding practices among children under two years of age living in rural/peri-urban Kandal province, Cambodia.

Learnings from implementers of small quantity lipid-based nutrient supplement (LNS-SQ) programs for children and pregnant and lactating women in Honduras, Niger, and Somalia to strengthen programming and scale-up

Akriti Singh[4], Kali Erickson[2], Alfred Hylton-Dei[3], Kavita Sethuraman[1]

1. USAID Advancing Nutrition/NCBA CLUSA (USA), 2. Independent Consultants (Guatemala), 3. USAID Advancing Nutrition/JSI Research and Training Institute, Inc. (USA), 4. USAID Advancing Nutrition/Helen Keller International (USA)

Background and objectives: Small quantity lipid-based nutrient supplements [LNS-SQ], a fortified product, fills nutrient gaps during the complementary feeding period, pregnancy, and while lactating. Strong evidence shows that LNS-SQ effectively reduces stunting, wasting, anemia, and mortality among children aged 6–24 months. A small, but growing number of studies show that LNS-SQ supplementation of pregnant women has positive birth outcomes. However, less is known about the challenges and opportunities for expanding the use of this product and the best approaches to do so. The objectives of this study were to (1) document factors that promoted and/or hindered successful implementation of LNS-SQ programs in highly food insecure emergency contexts, and (2) garner perspectives on considerations for scaling-up.

Methods: We used qualitative methods and convenience sampling to conduct this study in three USAID International Food Relief Partnership–funded LNS-SQ programs in Honduras, Niger, and Somalia. In each country, we interviewed program staff (Niger: 7; Somalia: 8; Honduras: 8) and program participants: caregivers of children 6–24 months (Niger: 18; Somalia: 24; Honduras: 24); and pregnant and lactating women [PLW] (Somalia: 23; Honduras: 24). We also visited warehouses and distribution sites. We coded and analyzed interview transcripts and site visit checklists for themes related to program implementation and considerations for scale-up.

Results: In Niger and Somalia, program participants reported high acceptability of LNS-SQ, but dissatisfaction with the quantity of the product. In Somalia, PLWs requested porridge along with LNS-SQ citing high food insecurity. In both countries, program staff were confident that they could implement the program; however, lack of standard operational guidance on

LNS-SQ-related communication, targeting, and duration of supplementation influenced the quality of implementation. In Niger, program staff reported higher vaccination rates and lower cases of wasting among children who participated in the LNS-SQ program. Considerations for scaling up from program staff, in both countries, included integrating LNS-SQ with the health system. Honduras results forthcoming.

Conclusions: Global organizations need to provide program guidance on how and where to implement LNS-SQ. In areas of high food insecurity, LNS-SQ with a household ration or another specialized nutritious food may be appropriate to improve the nutritional well-being of children and PLW.

The medical nutrition therapy of "food order" and "frequent meals" improves ketonuria in women with gestational diabetes mellitus

Saeko Imai[1], Risa Nakano[1], Ayasa Nitta[2], Kaoru Kitta[1], Takashi Miyawaki[1], Shintaro Kajiyama[3,4,5], Shizuo Kajiyama[4,5]

1. Kyoto Women's University (Japan), 2. Otsu City Hospital (Japan), 3. Japanese Red Cross Kyoto Second Hospital (Japan), 4. Kajiyama Clinic (Japan), 5. Kyoto Prefectural University of Medicine (Japan)

Background and Objectives: Gestational diabetes mellitus (GDM) is defined as glucose intolerance first discovered in pregnancy. A ketonic state in diabetic pregnant women has been associated with decreased intelligence in offspring. The aim of this study was to explore the effect of medical nutrition therapy in GDM patients with positive ketonuria.

Methods: The GDM patients with positive ketonuria received individual self-management education of medical nutrition therapy by registered dietitians in Kajiyama Clinic. The dietary advice was patients-centered and focused on "food order" which was consuming vegetable first, then the main dish, and the carbohydrate last. The dietary education of "frequent meals" (4 to 5 meals a day) was also recommended, especially consume a meal between lunch and dinner. The targets of the dietary intervention were to achieve postprandial 2-hour glucose concentration < 120 mg/dl and improve ketonuria. The dietary counseling was conducted 2 sessions for the first month and 1 session/month for 3 months.

Results: A total of 438 GDM, 105 (24%) had positive ketonuria and 333 (76%) had negative ketonuria. The prevalence of BMI in patients with positive ketonuria was lean 21% (BMI < 18.5), normal weight 67% (18.5< BMI < 25.0), and overweight 12% (25.0 < BMI). The ratio of the lean patients with positive ketonuria was higher than 13% that of patients with negative ketonuria. The 99% of the patients with positive ketonuria improved to negative ketonuria after intervention. The intake of carbohydrate per day increased significantly from 119 ± 50 g to 174 ± 44 g after intervention.

Conclusion: Many GDM patients suffer from morning sickness or restrict excessive carbohydrate intake after diagnosis, as a result, a quarter of the patients showed positive ketonuria. The medical nutrition therapy focused on "food order" and "frequent meals" by registered dietitian was effective to improve ketonuria in patients with GDM.

Keywords: gestational diabetes mellitus, medical nutrition therapy, ketonuria, food order, frequent meals

Background: Rapid conversion from prediabetes to diabetes and postprandial hyperglycemia (PPHG) is seen in Asian Indians. These should be the target of dietary strategies.

Objectives: We hypothesized that dietary intervention of preloading major meals with almonds in subjects with prediabetes will decrease overall glycemia and PPHG.

Design: In acute crossover randomized study, the effect of a single preload of almond (20 g) given before oral glucose tolerance test (OGTT) was evaluated. The sub-acute phase study using continuous glucose monitoring system (CGMS) for three days after preload of almonds before major meal, was a free-living, open-labelled, crossover randomized control trial, where control and premeal almond load diets were compared for glycaemic control (n=60, 30 each period. The study was registered at clinicaltrials.gov (registration no. NCT04769726).

Results: In the acute phase, the overall AUC for blood glucose, serum insulin, C-peptide, and plasma glucagon post-75 gm oral glucose load was significantly lower for treatment *vs*. control arm (p< 0.001). Specifically, PPHG was significantly lower (18.05%, and 10.07% during OGTT and CGMS, respectively) in the almond preload treatment arm *vs*. control arm. The CGMS data analysis revealed that premeal almond load significantly improved 24-h glucose variability; SD of mean glucose concentration and mean of daily differences. Significant improvement was also seen in several predefined parameters reflecting daily glycaemic control; mean 24-h blood glucose concentration (M), time spent above 140 mg/dL of blood glucose, together with the corresponding AUC values. In addition, significantly lower values were observed for peak 24-h glycaemia, minimum glucose level during night, PPHG and

overall hyperglycaemia (AUC) in the treatment arm *vs.* the control arm.

Conclusion: Incorporation of 20 g of almonds, 30 min before each major meals led to significant decrease in PPHG, insulin, C-peptide, glucagon levels, free fatty acid levels, and decreased several glycemia parameters on CGMS in subjects with prediabetes.

Determinants of anthropometric and socioeconomic risk factors associated with the postprandial blood glucose level in diabetic women of urban Karnataka in India: a hospital-based cross-sectional study

Jennifer Saulam[1], Fumiaki Mikami[1], Hideto Yokoi[1]

1. Kagawa University Hospital (Japan)

Background and Objective: Currently, India is housing the second-highest number of people with diabetes (74.2 million) in the world. This mounting number implies a considerable health burden due to diabetes in India in the future. The study aimed to identify the determinants of anthropometric and socioeconomic risk factors associated with the oral glucose tolerance test (OGTT) in diabetic urban women in Karnataka.

Methods: For this cross-sectional study a total of 300 diabetic women aged 35 years and older were randomly selected from six private and four government hospitals in the Vijayapura district of urban Karnataka in India. The primary outcome variable, postprandial blood glucose level was measured by OGTT of the diabetic women. Multivariate linear regression analysis was used to identify significant correlates of OGTT.

Results: The respondents were middle-aged urban women, with a mean age of 58.3 years. About one-third of them had no formal education. The mean (SD) BMI was 24.4 (3.2) which was above the overweight cut-off point for Asians and 12.6% of the women were obese. They had a mean (SD) waist-hip ratio of 0.89 (0.9) which was above the cut-off point for the increased metabolic risk. The mean (SD) value of the OGTT in diabetic women was 234.1 (36.5) mg/dL. When using the multivariate regression model, waist-hip ratio, higher family income, and educational status were found significantly associated with the OGTT of these urban diabetic women of Karnataka. The predictor variables in our model explained 56% variance in OGTT. OGTT value would be expected to be significantly 6.21 mg/dL higher for every 0.01 cm increment in the waist-hip ratio. Women belonging to the families of higher monthly income quartile (more than 650 USD) had increased OGTT values as compared to the women from lower monthly income (less than 260 USD) quartile.

Conclusions: Increased waist-hip ratio, higher family income, and educational status were found to be the significant risk factors of increased postprandial blood glucose levels in urban women in Karnataka. Effective and tailor-made holistic public health initiatives are required to prevent and respond to the diabetes crisis in the urban women of India.

Dairy Product Consumption in Relation to Incident Prediabetes and Longitudinal Insulin Resistance in the Rotterdam Study

Isabel Slurink[1], Trudy Voortman[2,3], Carolina Ochoa-Rosales[2,4], Fariba Ahmadizar[5], Maryam Kavousi[2], Nina Kupper[1], Tom Smeets[1], Sabita Soedamah-Muthu[1,6]

1. Tilburg University (Netherlands), 2. University Medical Center Rotterdam (Netherlands), 3. Wageningen University & Research (Netherlands), 4. Universidad de Concepción (Netherlands), 5. University Utrecht Medical Center (Chile), 6. University of Reading (UK)

Background and objectives: Evidence suggests neutral or moderately beneficial effects of dairy intake on type 2 diabetes mellitus risk. Nevertheless, evidence on associations with prediabetes and insulin resistance, early type 2 diabetes phases, remains inconsistent. Considerable heterogeneity between results underlines the need for extensive longitudinal studies. We aimed to examine associations of dairy intake with prediabetes risk and longitudinal insulin resistance in the prospective population-based Rotterdam Study.

Methods: The analytic sample consisted of 6770 participants (aged 62±4 years, 59% female) free of (pre-)diabetes at baseline from the Rotterdam Study. Dairy intake was measured at baseline with food frequency questionnaires. Data on prediabetes and the homeostatic model assessment of insulin resistance (HOMA-IR) were available from 1993–2015. Prediabetes was defined as fasting blood glucose levels of 6.1–6.9 mmol/L or non-fasting levels of 7.7–11.1 mmol/L. Associations with these outcomes were analyzed with dairy intake in quartiles (Q4vsQ1) and continuous using multivariable Cox proportional hazard models and linear mixed models.

Results: During a mean follow-up of 11.3±4.8 years, 1139 incident prediabetes cases were documented (18.8%). In models adjusting for sociodemographic, lifestyle and dietary factors, a higher intake of high-fat yogurt was associated with a lower prediabetes risk (HR_{Q4vsQ1} 0.70, 95%CI 0.54–0.91 and $HR_{serving/day}$ 0.67, 0.51–0.89). In addition, a higher intake of high-fat milk was associated with a lower prediabetes risk (HR_{Q4vsQ1} 0.81, 0.67–0.97, $HR_{serving/day}$ 0.88, 0.79–0.99). Associations were found for low-fat dairy, low-fat milk, and total cheese with a higher

prediabetes risk ($HR_{serving/day}$ ranging from 1.05–1.07, not significant in quartiles). Associations with longitudinal HOMA-IR were similar to prediabetes for high-fat yogurt, low-fat dairy and low-fat milk. Fermented dairy, low-fat yogurt, high-fat cheese, cream and ice cream were not associated with the outcomes.

Conclusions: In this large cohort study with long-term follow-up, a higher intake of high-fat yogurt was associated with a lower prediabetes risk and lower longitudinal insulin resistance. Additionally, high-fat milk was associated with a lower prediabetes risk. Some low-fat dairy types were inconsistently associated with these outcomes. Further studies are needed to confirm associations and to examine the influence of confounding by population characteristics.

Medicine and Psychology School, Autonomous University of Baja California, 22390 Tijuana, Baja California, (Mexico), 4. Department of Nutrition, Food Science, and Physiology, University of Navarra, 31008 Pamplona, (Spain), 5. Centro de Investigación Biomédica en Red Fisiopatología de la Obesidad y Nutrición (CIBERobn), Instituto de Salud Carlos III, 28029 Madrid, (Spain)

Background and objectives: Dietary compounds, including many bioactive lipids, are metabolized by bacteria in the gastrointestinal tract, generating circulating metabolites with potential metabolic and endocrine activities. Alterations in the intestinal microbiota (dysbiosis) found in individuals with obesity or insulin resistance may affect the composition of the metabolome, playing a fundamental role in the development of the associated metabolic alterations. In this work we have analyzed the alterations in the gut microbiome and plasma metabolome associated with insulin resistance in a Spanish population.

Methods: A total of 361 volunteers from the Obekit trial (65 normal-weight, 110 overweight and 186 obese) were classified according to two variables: serum insulin levels (above 8 U/mL) and triglyceride-glucose index (TGI; TGI above 4.5). Those individuals who did not exceed the threshold value in any variable were considered as LOW insulin resistance group, while those subjects who did exceed the threshold value in 1 or 2 variables as HIGH insulin resistance group. Sequencing of the V3-V4 region of the 16S rRNA gene was performed in fecal samples from all participants, and differential abundance analyses for phylum, family and genera were performed using the MicrobiomeAnalyst web-based platform. Untargeted metabolomic analysis in plasma samples of individuals from the HIGH and LOW insulin resistance groups was performed, and principal component analysis (PCA), partial least squares-discriminant analysis (PLS-DA) and volcano plot were carried out for the pattern recognition and characteristic metabolites identification.

Results: Individuals with HIGH insulin resistance exhibited a significant reduction in the Shannon and Simpson alpha diversity indexes, a reduction in Firmicutes and Actinobacteria, and an increase in Bacteroidetes and Proteobacteria. Coriobacteriaceae family was found to be significantly less abundant in individuals with HIGH insulin resistance. Untargeted metabolomic analyses revealed differentially abundance of bioactive sphingolipids, such as sphingomyelin (SM), ceramide (Cer) or sphingosine-1-phosphate (S1P), between individuals with HIGH and LOW insulin resistance.

Conclusions: Differences in gut microbiota composition might affect the metabolism of different bioactive molecules such as sphingolipids, whose activity seems to be associated with the development of insulin resistance.

The influence of lifestyle interventions on continuously measured glucose levels in people with type 2 diabetes: an N-of-1 analysis.

Iris M. de Hoogh[1], Tim Snel[2], R. J.M. Kamstra[1], Tanja Krone[1], Hannah E. Eggink[1], Hanno Pijl[3], Albert A. de Graaf[1]

1. The Netherlands Organization for Applied Scientific Research (TNO) (Netherlands), 2. Roche Diabetes Care Nederland B.V. (Netherlands), 3. Leiden University Medical Center (LUMC) (Netherlands)

Background and objectives: Individuals with T2D might benefit from different types of lifestyle interventions, depending on their underlying pathophysiology. Measuring the effects of lifestyle on continuous glucose levels can provide insight into the potential of personalized lifestyle advice. In this study we aim to investigate the effects of four lifestyle interventions on continuously measured glucose levels in people with T2D.

Methods: Forty individuals with T2D treated with lifestyle advice and/or metformin were recruited. During half a year, participants underwent 11 monitoring periods of four days, including three control periods and eight intervention periods. The lifestyle interventions included a low-carbohydrate diet (LC), a Mediterranean diet (Med), walking after every meal (Walk) and five minutes of physical exercise every hour (Active). All four interventions were followed twice. During the monitoring periods, participants used a continuous glucose monitor, and self-monitored their lifestyle. To investigate the effect of the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

interventions on individual glucose levels we used an n-of-1 approach or linear mixed model.

Results: Preliminary results are presented for the first 19 participants. At baseline participants had a mean age of 61.5 ± 5.3 years, BMI of 29.6 ± 3.4 kg/m2, HbA1c of 53.0 ± 10.2 mmol/mol and fasting plasma glucose of 7.8 ± 1.1 mmol/L. Results from the linear mixed model including monitoring period, subject and HbA1c showed that the mean daily glucose during the control period was 8.7 ± 0.5 mmol/L, and that all four interventions resulted in lower average daily glucose levels with the largest effect for the LC intervention (-0.83 ± 0.29 mmol/L), followed by the Walk (-0.36 ± 0.20 mmol/L), Active (-0.25 ± 0.16 mmol/L) and Med (-0.17 ± 0.24 mmol/L) intervention. During the IUNS-ICN, longitudinal data and accompanying n-of-1 analysis for the total study population (n=40) will be presented, to provide insight in what factors may explain the differential response to interventions between individuals.

Conclusion: Preliminary analyses for the first 19 participants show a differential response to the four lifestyle interventions, with the highest glucose values during the Med and the lowest during the LC intervention. However, individual differences seem to exist in response to these lifestyle interventions.

No sugarcoating: Development of digital nutrition modules for prediabetics based on real-life experiences

Choon Ming Ng[1], Kah Woon Teoh[1], Chun Wie Chong[1], Shaun Wen Huey Lee[1]

1. Monash University Malaysia (Malaysia)

Background and objectives: Prediabetes is the intermediate state between normal glycemia and diabetes. A person with prediabetes is at risk of serious health complications. A healthy lifestyle is essential for managing prediabetes, and effectiveness is enhanced when taking into account life circumstances. Hence, this study aimed to develop evidence-based nutrition modules, addressing the current needs of prediabetics based on qualitative data.

Methods: One-to-one in-depth semi-structured interviews were conducted among prediabetics to gain insights into the facilitators and challenges relating to a healthy lifestyle. Malaysian prediabetics (aged 18 years and above) were recruited purposively until saturation was reached. Interview recordings were transcribed verbatim using Otter.ai and manually checked. NVivo Plus software assisted in the thematic analysis of the qualitative data. Considering the qualitative findings, nutrition modules were developed by nutritionists and dieticians using evidence-based information, alongside the animation software Vyond and design tool CanvaPro. The modules were further pilot tested among prediabetics to gain feedback on the usability aspect.

Results: Major themes emerged including (1) barriers- lack of support from healthcare professionals, financial constraints, lack of time, food/taste preferences, restrictions due to the Covid-19 pandemic; (2) enablers- family support, motivations to be healthy, habit formation, clear and simple nutrition-related information, food skills, the use of technology and incentive-based rewards. Addressing the current needs, comprehensive yet concise modules were developed in the form of digital infographics and videos. Various topics were covered, including energy balance, starchy foods, sugar, sweeteners, glycemic index, fats, healthful foods, processed foods, meal plans for prediabetics, food skills (cooking methods, food labels) and lifestyle (physical activity, alcohol, smoking, stress, sleep). Overall, positive feedback was received in terms of the modules' practical usability, content, design, and language structure.

Conclusions: Prediabetes presents a window of opportunity to prevent diabetes. Lifestyle changes and dietary guidance that consider current challenges individuals face are likely to be more effective and sustainable. Key factors to incorporate in the management of prediabetes include practical and straightforward nutrition knowledge along with the motivations to support healthy behaviors. The modules developed are useful for prediabetics and healthcare professionals to provide high-quality interventions tailored to the current needs.

Mediterranean diet and aerobic exercise modulate immunometabolism-related genes in overweight individuals with pre-diabetes

Antonio de Miguel Albarreal[1], Elena Grao Cruces[1], Rocio Vasquez Artiles[1], Maria del Carmen Millan Linares[1], Sergio Montserrat de la Paz[1]

1. Seville University (Spain)

Background and objectives: According to the World Health Organization (WHO), in 2030, diabetes will be one of the leading causes of death. In the early phases of the disease, a pre-diabetic stage develops with impaired fasting glucose associated with a chronic low-grade inflammation. Lifestyle modifications while

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

the patient is still in the pre-diabetes stage have been shown to be effective in preventing or delaying the onset of diabetes. Herein, the main objective of this study is to evaluate the effects of Mediterranean diet-associated patterns and aerobic exercise on immunometabolism-related genes in overweight individuals with prediabetes.

Methods: All participants followed a low-energy diet (5.5 MJ/1315 kcal/daily) and aerobic exercise following WHO recommendation (at least 150 minutes of moderate-intensity aerobic physical activity each week) for 12 weeks. Participants were recruited from Marchena (Seville, Spain). Those eligible for inclusion were individuals with abdominal obesity (waist circumference **>** 94cm in men and **>** 88cm in women) and pre-diabetes (HOMA-IR **>** 2,78). Anthropometric and biochemical measures were carried out at baseline, 3, 6, and 12 weeks. At these points, peripheral blood mononuclear cells (PBMCs) were isolated and were used to analyse the effects of the nutritional and physical intervention on immunometabolism-related genes by using RT-qPCR.

Results: In total, 20 individuals (15 women, 5 men) attended the baseline visit and completed the follow-up visit. All the participants had a significantly decrease in BMI, lean mass, fat mass, glucose, TC, TG, HDL-C and LDL-C. $p < 0.05$). The results showed that there were differences in multiple lipid *CD36*, *PPARG* and glucose metabolism *SREBP-1, ACLY, GLUT1, GLUT3, GLUT5* and immune response, *C3*, *IL-1B, IL-6, IL-10, IL-13, IL-17, IL-18, TNFA, IL1R1, IL1R2, TNFRII* between the pre- and post-intervention analysis.

Conclusions: In overweight patients with pre-diabetes, Mediterranean diet-associated patterns and aerobic exercise improves insulin sensitivity and decreases risk of progression toward diabetes by modulating immunometabolism related genes.

Keywords: Mediterranean Diet, Aerobic Exercise, Immunometabolism, Diabetes, Insulin Resistance

The association of dietary Inflammatory Index with long-term all-cause and cardiovascular mortality risk: NIPPON DATA80

Gantsetseg Ganbaatar[1], Yukiko Okami[1], Aya Kadota[1], Namuun Ganbaatar[1], Yuichiro Yano[1], Keiko Kondo[1], Tomonori Okamura[2], Akira Okayama[3], Hirotsugu Ueshima[1], Katsuyuki Miura[1]

1. Shiga University of Medical Science (Japan), 2. Keio University (Japan), 3. Research Institute of Strategy for Prevention (Japan)

Background and objectives: Pro-inflammatory diet may increase the risk of cardiovascular disease (CVD) and all-cause mortality risk. It is confirmed in other countries, but Japanese studies are scarce. The aim of this study was to examine the association of pro-inflammatory diet with all-cause and CVD mortality risk in a long-term follow-up study of representative Japanese population.

Methods: NIPPON DATA80 is a prospective cohort study of the National Survey on Circulatory Disorders and the National Nutrition Survey conducted in 1980 in 300 randomly selected districts throughout Japan. We excluded those who had missing information, CVD history at baseline, extreme energy intake, and loss to follow-up, leaving 9,142 individuals at baseline (56% women, 30–92 years). Twenty nutrient parameters (protein, total fat, carbohydrate, vitamin A, vitamin B1, vitamin B2, vitamin C, niacin, vitamin E, magnesium, fiber, cholesterol, saturated fat, monounsaturated fatty acid, polyunsaturated fatty acid, n-6 fatty acid, n-3 fatty acid, total trans fatty acid, β-carotene) derived from a 3-day weighing dietary records were used to calculate the Dietary Inflammatory Index (DII) scores. We used energy-adjusted DII (E-DII) by the residual method. Higher E-DII score indicates that diet is more pro-inflammatory. The ICD-9 and ICD-10 ascertained mortality from CVD (393–459 (ICD-9) and I00–I99 (ICD-10)) in 29-year follow-up period until 2009. Cox proportional hazards model was performed to calculate hazard ratios (HRs) adjusted for age, sex, body mass index, smoking status, drinking status, serum total cholesterol, diabetes history, hypertension status and sodium intake. We also examined the interaction between E-DII and sex.

Results: There were 3,412 all-cause and 1,162 CVD deaths during an average follow-up of 24.4 years. The mean of E-DII score was -0.44 (SD: 1.14). The multivariable-adjusted HR per 1 standard deviation increase of E-DII score was 1.09 (95%CI: 1.06 -1.13) for all-cause mortality, 1.15 (95%CI: 1.08 -1.22) for CVD mortality, 1.24 (95%CI: 1.08 -1.42) for coronary heart disease mortality and 1.13 (95%CI: 1.03 -1.24) for stroke mortality. There were no interactions between E-DII and sex.

Conclusions: The E-DII score was positively associated with the long-term risk of all-cause and CVD mortality in a nationally representative Japanese population.

Dietary amino acids and risk of stroke subtypes: a prospective analysis of 356,000 participants in seven European countries.

Tammy Y.N. Tong[1], on behalf of the EPIC-CVD consortium

1. Cancer Epidemiology Unit, Nuffield Department of Population Health, University of Oxford (UK)

Background and objectives: Little is known about the relevance of dietary amino acids to risk of stroke subtypes. We examined the associations of dietary amino acids with ischaemic

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

and haemorrhagic stroke in the EPIC (European Prospective Investigation into Cancer and Nutrition) study.

Methods: We analysed data on 356,142 people from seven European countries (Denmark, Germany, Italy, the Netherlands, Spain, Sweden and the United Kingdom). Dietary intakes of 19 individual amino acids were obtained using validated country-specific food frequency questionnaires, calibrated using additional 24-hour recalls. Blood pressure was measured at recruitment in 267,642 (75%) participants. Multivariable Cox regressions adjusted for socio-demographic characteristics, lifestyle factors and medical history were used to estimate hazard ratios (HRs) of ischaemic and haemorrhagic stroke for 1 standard deviation (SD) differences and fifths of intakes of each individual amino acid.

Results: After a mean follow-up of 12.7 years, 4295 people had an ischaemic stroke and 1375 people had a haemorrhagic stroke. After mutual adjustment for all amino acids and corrected for multiple testing, higher intake of proline was found to be associated with 12% lower risk of ischaemic stroke (HR [95% CI] of 0.88 [0.82-0.94] for 1SD higher calibrated intake in multivariable-adjusted model). The association was independent of systolic and diastolic blood pressure. Among dietary sources of protein, intake of proline was most strongly correlated with intake of dairy protein (Pearson correlation coefficient r=0.73) in the current study. Higher intakes of isoleucine, leucine, valine, phenylalanine, threonine, tryptophan, glutamic acid, serine and tyrosine were associated with lower risks of ischaemic stroke in the multivariable model, but all these associations attenuated when adjusted for proline. For haemorrhagic stroke, no statistically significant associations were observed in the continuous analyses after correcting for multiple testing.

Conclusions: Higher intakes of proline were associated with lower risks of ischaemic stroke, independent of other dietary amino acids. Further studies are needed to assess the casual relevance and possible implications for prevention.

Departments of Surgery and Medicine, The Warren Alpert Medical School, Brown University (USA)

Background and Objectives: The Portfolio Diet is a plant-based dietary pattern of established cholesterol-lowering foods. The diet has been shown to improve a number of cardiovascular disease (CVD) risk factors, including low-density lipoprotein cholesterol (LDL-C), blood pressure, and C-reactive protein (CRP) in clinical trials, and has been associated with lower CVD incidence in a prospective cohort. As yet, there have not been any large prospective studies directly assessing the relation of the Portfolio Diet to total and CVD mortality.

Methods: We followed 109,445 postmenopausal women initially free of CVD, diabetes, and cancer in the Women's Health Initiative (WHI) Clinical Trials and Observational Study from 1993 to 2021. Adherence to the Portfolio diet was assessed using an *a priori* diet index based on six food categories (high in plant protein [soy & pulses], nuts, viscous fiber, phytosterols and monounsaturated fat, and low in saturated fat and dietary cholesterol) via a food frequency questionnaire at baseline and year three. Adjusted hazard ratios (HRs) and 95% confidence intervals [CIs] for CVD incidence and death and total mortality were calculated using Cox regressions, adjusted for potential confounders (including age, race/ethnicity, family history, lifestyle and dietary factors, and medication use).

Results: Over a mean of 17.4 years of follow-up, there were 11,597 cases of incident total CVD, 4,695 cases of coronary heart disease (CHD), 4,215 cases of stroke, 7,624 cases of CVD death, and 28,162 total deaths. Comparing the highest to the lowest quartile in the fully adjusted model, higher adherence to the Portfolio diet was associated with a reduced risk of total CVD (HR=0.89 [95% CI 0.83-0.95]), CHD (0.85 [0.77-0.95]), CVD death (0.93 [0.86-1.01]), and total mortality (0.89 [0.85-0.92]). No association was found with stroke (1.03, [0.92-1.16]).

Conclusions: In postmenopausal women, higher adherence to the Portfolio diet was inversely associated with total CVD, CHD, and total mortality, but not stroke. These prospective data provide the notion that the plant-based Portfolio diet may have direct benefits on CVD and mortality prevention in postmenopausal women.

Partial substitution of red meat with plant-based foods and the risk of cardiovascular diseases: a pooled analysis of three Finnish cohorts

Niina E. Kaartinen[1], Mirkka Maukonen[1], Kennet Harald[1], Heli Tapanainen[1], Meri Simojoki[1], Essi Päivärinta[2], Anne-Maria Pajari[2], Satu Männistö[1]

1. Finnish Institute for Health and Welfare (Finland), 2. University of Helsinki (Finland)

Background and objectives: Cardiovascular diseases (CVD) constitute a major burden to public health and welfare worldwide. High consumption of red meat has been associated with increased risk of CVD whereas high consumption of plant-based foods is linked to decreased risk of these diseases. Moreover, a shift from animal-based foods to plant-based foods is necessitated to enhance environmental sustainability. We aimed to investigate whether moderate partial substitution of red meat (beef, pork, lamb, game, offal) with plant-based foods (legumes, vegetables, fruit, cereals, and different combinations of these) is associated with the risk of CVD in Finnish adults.

Methods: We used data from three Finnish cohorts (pooled n=14 915, 44% men, age 25 years or over at baseline, 10.8 years median follow-up with 1263 incident CVD cases). A validated food frequency questionnaire served dietary assessment. In the substitution models, 100 g/week of red meat were substituted with similar amounts of plant-based foods. Cohort-specific hazard ratios (HR) were calculated using Cox proportional hazards multivariable model adjusting for relevant confounders. Pooled HRs were estimated from the cohort-specific HRs using a random-effects model.

Results: We found a small statistically significant reduction in CVD risk in women when red meat was partially substituted with cereals (HR 0.96, 95% CI 0.93-0.99, P=0.020). In addition, a reduction was observed, when red meat was partially substituted with the combination of cereals and legumes in the unadjusted model (HR 0.96, 95% CI 0.932-1.00, P=0.029) slightly attenuating in the fully adjusted model (HR 0.97, 95% CI 0.94-1.00, P=0.086). In men, no significant associations were observed for the corresponding substitutions (cereals: HR 1.01, 95% CI 0.985-1.032, P=0.49, cereals and legumes: HR 1.01 95% CI 0.98-1.03, P=0.50). Furthermore, no significant associations were found for the other studied plant-based substitutes.

Conclusions: The partial substitution of red meat with cereals was associated with reduced CVD risk in women. The results suggest that even a small change in diet may be beneficial in terms of reducing CVD risk. Such dietary changes are also needed to ameliorate environmental sustainability. The sex difference in results warrant further study.

Non-alcoholic fatty liver disease and risk of mortality and type 2 diabetes after myocardial infarction: a prospective analysis in the Alpha Omega Cohort.

Luc Heerkens[1], Laurens van Kleef[2], Trudy Voortman[1,2], Johanna Marianne Geleijnse[1]

1. Wageningen University & Research (Netherlands), 2. University Medical Center Rotterdam (Netherlands)

Background and objectives: Non-alcoholic fatty liver disease (NAFLD) has been associated with a higher risk of cardiometabolic disease in population-based studies. Little is known about these associations in patients with a history of myocardial infarction (MI). We examined the Fatty Liver Index (FLI) ≧60, as a validated marker of NAFLD, in relation to risk of cardiovascular disease (CVD) mortality, all-cause mortality and type diabetes (T2D) among post-MI patients.

Methods: We included 4165 Dutch patients from the Alpha Omega Cohort aged 60-80 years who had an MI ≦10 years prior to study enrolment. FLI was based on BMI, waist circumference, triglycerides, and gamma-glutamyltransferase. Cause-specific mortality was monitored from enrolment (2002-2006) through December 2018, and T2D incidence was monitored during the first 40 months of follow-up. Multivariable Cox regression was used to obtain hazard ratios (HR) with 95% confidence intervals (95% CI) for fatal endpoints in FLI categories, using FLI <30 (indicating no NAFLD) as the reference. Analyses were repeated in strata of obesity (BMI <30; BMI ≧30) and prevalent T2D, using FLI <60 as the reference. In 3201 non-diabetic patients we studied FLI ≧ 60 with T2D incidence compared to FLI <60.

Results: Patients had a mean FLI of 62.3 (± 22.8) of which 10% had FLI <30 and 60% had FLI ≧60. Patients with FLI ≧60 were more likely to be male (80%) and had more often diabetes at baseline (25%) compared to patients with FLI <30. During a

median follow-up of 12 years (46,072 person-years) we observed 1934 deaths of which 795 were due to CVD. Patients with FLI ≧ 60 had a higher risk of CVD mortality (HR: 1.59 [1.21, 2.12]) and all-cause mortality (HR: 1.20 [1.02; 1.42]) compared to patients with FLI <30. Results remained similar in strata of T2D and BMI <30, but were non-significant in obese patients. FLI ≧60 was associated with T2D incidence (182 cases; HR: 2.78 [1.95, 3.96]).

Conclusions: NAFLD, based on FLI ≧60, was a predictor for CVD mortality, all-cause mortality, and T2D in post-MI patients. These results may have implications for risk prediction and multidisciplinary disease management.

OAB(T4)2-6

Association between food preference and health outcomes: findings from the UK Biobank prospective cohort study.

Solange Parra-Soto[1], Jirapitcha Boonpor[1], Carolina Araya[1], John C Mathers[2], Frederick K Ho[1], Jill P Pell[1], Carlos Celis-Morales[1]

1. University of Glasgow (UK), 2. Newcastle University (UK)

Background and objectives: Food preferences are a key influence on food consumption. However, most available evidence focuses on cross-sectional associations between food preferences and obesity. Therefore, we aimed to determine associations between food preferences and risk of cardiovascular diseases (CVD), type 2 diabetes (T2D), cancer and all-cause mortality (ACM) in a prospective cohort study.

Methods: 173,212 participants (57.1% women; mean age 55.8 years) from the UK Biobank cohort were included. The median follow-up was 9.2 years (interquartile range 9.6 to 9.9). Based on self-reported food preferences, liking was measured using a 9-point hedonic scale, from 1 (extremely dislike) to 9 (extremely like). 17 food groups were included in the preference for High Fat Savoury (HFS), 9 in High Fat Sweet (HFSw), 17 in Low fat Savoury (LFS) and 13 in Low fat Sweet (LFSw). Cox proportional hazard models were used to investigate associations with incidence of CVD, T2D, and colorectal, lung, breast, prostate cancer, all-cause cancers, and ACM. Results are presented as Hazard Ratio (HR) with 95% Confidence Interval (CI) per one point increment in the hedonic scale.

Results: Individuals had a 13% higher risk of T2D per 1-point increment in the HFS hedonic scale (HR 1.13; 95%CI: 1.08-1.18). Individuals with preference for HFSw food had an increased risk of ACM (HR 1.08; 95%CI: 1.01-1.15), colorectal (HR 1.07; 95%CI 1.02-1.11), prostate cancer (HR 1.04; 95%CI 1.01-1.07), and all-cause cancer (HR 1.03; 95%CI 1.01-1.04). They also had a lower risk for CVD and T2D. Individuals with preference for LFS food had lower risk of ACM (HR 0.85; 95%CI 0.79-0.92), T2D (HR 0.90; 95%CI 0.86-0.94), colorectal cancer (HR 0.90; 95%CI 0.85-0.95), CVD (HR 0.94; 95%CI 0.93-0.96), and all-cause cancer (HR 0.97; 95%CI 0.96-0.99). Those with preference for LFSw food had lower risk of T2D (HR 0.90; 95%CI 0.86-0.95), colorectal cancer (HR 0.94; 95%CI 0.89-1.00), and CVD (HR 0.96; 95%CI 0.94-0.98).

Conclusion: Preferences were associated differentially with specific health outcomes. Preference for HFS food was associated with higher T2D risk, whilst preference for LFS food and LFSw food was associated with lower risk of mortality, CVD, T2D, and some cancers.

Association between dairy intake and risk of incident functional disability in Japanese older adults: the Ohsaki Cohort 2006 Study

Yukai Lu[1], Yumi Sugawara[1], Sanae Matsuyama[1], Marina Tanitame[1], Ichiro Tsuji[1]

1. School of Public Health, Tohoku University Graduate School of Medicine (Japan)

Background and objectives: Only a few studies have examined the association between dairy intake and incident functional disability, and it remains unclear whether increasing dairy intake may protect against functional disability. Thus, this study aimed to investigate this association in Japanese older adults.

Methods: We conducted a longitudinal analysis of dairy intake and incident functional disability in a prospective cohort study of 11,911 (44.4% men) disability-free Japanese individuals aged ≧65 years in 2006, who were followed up for up to 13 years. Data on milk, yogurt, and cheese intake were obtained using a validated 39-item food frequency questionnaire at baseline. Total dairy intake was calculated as the sum of milk, yogurt, and cheese intake and then categorized by quintiles (Q1 to Q5). Data on incident functional disability were retrieved from the public Long-term Care Insurance database. Participants were followed-up from December 16, 2006 to November 30, 2019. Cox proportional hazards models were used to estimate the multivariable-adjusted hazard ratios (HRs) and 95% confidence intervals (95% CIs) for incident functional disability.

Results: During 107,344 person-years of follow-up, 5,749 cases (48.3%) of incident functional disability were documented. Results suggested that total dairy intake was not associated with risk of incident functional disability. Compared with Q1 (the lowest quintile), the multivariable-adjusted HRs (95%CIs) were 0.98 (0.90-1.06) for Q2, 0.94 (0.86-1.02) for Q3, 0.97 (0.89-1.05) for Q4, and 1.04 (0.95-1.13) for Q5 (the highest quintile) *p* for trend=0.529). We also examined the association between each dairy product (i.e., milk, yogurt, and cheese) intake frequency and incident functional disability, but no association was found. Furthermore, a sensitivity analysis was conducted by excluding

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

cases of functional disability documented in the first three years, but the null findings remained unchanged.

Conclusions: Our study suggests that dairy intake is not associated with incident functional disability in Japanese older adults.

Department of Biosciences and Nutrition, Karolinska Institutet, Huddinge, (Sweden)

Background and objectives: Effects of an exercise intervention on human molecular profiles (epigenomics and transcriptomics) are unstudied in the pediatric population. Here, we aimed to investigate the effects of a 20-week exercise intervention on whole blood genome-wide DNA methylation signatures (CpG sites level) and the consequent changes on transcriptome profile (RNAseq) in boys and girls with overweight/obesity (OW/OB).

Methods: Twenty-three children (10.05 ± 1.39 years, 56% girls) with OW/OB, were randomized to either a 20-week exercise intervention (exercise group [EG]; n=10; 4 boys/ 6 girls), or to usual lifestyle (control group [CG] (n=13; 6 boys/ 7 girls). Whole blood genome-wide DNA methylation and transcriptome profile (RNA-seq) analyses were performed before and after the intervention period.

Results: Changes in the DNA methylation sites of 485 and 386 CpGs were induced by the exercise intervention (compared to the control group) in boys and girls respectively ($p < 0.001$). These CpG sites mapped to loci enriched in distinct gene pathways related to metabolic diseases, fatty acid metabolism, and immune function in boys or girls ($p < 0.05$). In boys, changes on the DNA methylation status of 87 CpG sites (from the subset of 485 significant CpGs) associated with changes in the gene expression levels of 51 gene transcripts which were regulated by exercise ($p < 0.05$). Among girls, changes on DNA methylation at 46 CpG sites (from the initial 386 significant CpGs) were associated with changes in the gene expression levels of 30 gene transcripts affected by exercise. Gene transcripts affected by exercise-induced DNA methylation were related to obesity, metabolic syndrome, and inflammation. Nevertheless, none of the presented analyses survived multiple testing correction (FDR > 0.05).

Conclusions: Our multi-omics approach reveals that exercise may regulate gene pathways involved in metabolism and immune functions in blood cells of boys and girls with OW/OB. Our preliminary results provide important first step to characterize the molecular response to exercise interventions in pediatric population. Future randomized controlled trials involving larger sample sizes are needed.

Comparison of the effects of different fats and oils on obesity and their mechanism

Midori Seike[1], Hitoshi Ashida[1], Yoko Yamashita[1]

1. Kobe University (Japan)

Background and objectives: Excessive fat intake causes the onset and exacerbation of lifestyle diseases. Although fat has high-calory, it has been reported that certain fats and oils do not induce lifestyle-related diseases. Therefore, it is important to choose the types of fats and oils to maintain health. However, the comparison of the effects of fats and oils on the onset of lifestyle diseases and their mechanisms are not fully understood. In this study, we compared the effects of six fats and oils on obesity and their mechanism in mice.

Methods: C57BL/6J male mice were fed standard diet (SD) and high-fat diets (HF) for 15 weeks. SD contained 5% (w/w) corn oil, while HF contained 20% (w/w) fats or oils as follows: lard (Lard), palm oil (Palm), rapeseed oil (Rape), high oleic safflower oil (Saff), corn oil (Corn) and flaxseed oil (Flax). At the end of experiment, liver, white adipose tissue, and brown adipose tissue were collected and weighed. The liver and adipose tissue were subjected to the estimation of lipid and energy metabolisms.

Results: Final body weight and white adipose tissue weight in HF-Lard and HF-Palm groups were significantly higher than those of SD group, but they didn't change in HF-Corn and HF-Flax

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

groups. In the liver, the protein expression levels of lipogenesis-related proteins, ACC and FAS, in HF-Flax group tended to decrease those in other groups. In the epididymal white adipose tissue, the protein expression level of CPT1A tended to decrease in HF-Lard, HF-Palm, and HF-Saff groups, while increase in HF-Flax group compared with SD group. Significant difference was observed in HF-Flax group against other three groups. Protein expression of UCP-1 significantly increased in brown adipose tissue of HF-Corn and HF-Flax groups compared with SD, HF-Lard, and HF-Palm groups.

Conclusions: Increase in the white adipose tissue weight in HF-Lard and HF-Palm groups was expectedly observed due to rich in saturated fatty acids. Among the polyunsaturated fatty acids-rich groups, HF-Flax group was superior for amelioration of lipid and energy metabolism, suggested that an intake of α-linoleic acid-rich oil may not induce obesity by maintaining lipid metabolism and increasing energy metabolism.

Keywords: fat and oil, obesity, flaxseed oil, α-linolenic acid, polyunsaturated fatty acid

Dietary patterns, genetic risk, and incidence of obesity: application of reduced rank regression in 11,735 adults from the UK Biobank study

Katherine M Livingstone[1], Barbara Brayner[1], Carlos Celis-Morales[2], Joey Ward[2], John C Mathers[3], Steven J Bowe[1]

1. Deakin University (Australia), 2. University of Glasgow (UK), 3. Newcastle University (UK)

Background and objectives: Few studies have derived dietary patterns based on intake of discretionary foods and beverages and examined associations with genetic risk and obesity. We examined associations between dietary patterns based on discretionary foods, saturated fatty acids (SFA), and fiber, with a polygenetic risk score (PRS) for obesity and risk of overall obesity, central obesity and high body fat (BF) up to 9.7 years later.

Methods: Data from 11,735 adults from the UK Biobank cohort study were used. Dietary patterns were derived from 24-hour dietary assessments using reduced rank regression (response variables: discretionary foods and beverages [%E]; SFA [%E]; fiber density [g/MJ]). Cox proportional hazard models were used to investigate associations between dietary patterns and incident overall obesity, central obesity and high BF, with interactions by PRS.

Results: Three dietary patterns (DP) were identified. DP1, correlated positively with discretionary foods and SFA, inversely with fiber, was associated with higher risk of central obesity (hazard ratio: 1.08; 95% confidence interval: 1.02, 1.14). DP2, correlated positively with discretionary foods and fiber, inversely with SFA, and was not associated with obesity incidence. DP3, correlated positively with SFA and fiber, inversely with discretionary foods, was associated with lower risk of central obesity (hazard ratio: 0.92; 95% confidence interval: 0.87, 0.98). There was limited evidence of interactions with PRS.

Conclusions: A dietary pattern high in high-SFA and low-fiber discretionary foods and beverages was associated with higher risk of obesity, independent of genetic predisposition.

OAB(T4)3-4

Effect of online weight management intervention for adults with obesity during COVID-19 pandemic

Harshi Gunawardena[1], Hiruni Dias[1], Madushika Siriwardena[1]

1. Wayamba University of Sri Lanka (Sri Lanka)

Background and objectives: Adults were more prone to experience the shifts in their lifestyle patterns leading to excess weight gain during the *COVID-19* pandemic. Following a weight management intervention through lifestyle modification was quite challenging with the lock down and social distancing. Therefore, this study was conducted with the objective of investigating the effect of online weight management intervention during the *COVID-19* pandemic.

Methods: A randomized controlled study was conducted for fifteen weeks (t=15 weeks) with 40 (n=40) obese adults. Obese individuals were randomly allocated either to receive online weight management intervention (treatment group; n=20) or general weight management education for obesity management (control group; n=20). The online weight management intervention package consisted of short motivational messages, text messages, web posts and blog articles related to diet and physical activity modification and online structured counseling sessions on diet and physical activity modification by a registered dietitian. Body weight, waist and hip circumferences, physical activity level, and dietary intake of both groups were measured at the baseline (t=0 weeks) and end (t=15 weeks) of the intervention.

Results: Weight and waist circumference of the treatment group was significantly reduced $P < 0.05$) at the end compared to the baseline. There were no any significant reductions of weight and waist circumference observed in the control group. Further, obese adults who received online weight management intervention showed significant $P < 0.05$) reductions in their weight and waist circumferences compared to group who received the general lifestyle management education. Total

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

energy intake, energy from carbohydrates and fat were significantly *P* <0.05) reduced in the treatment group.

Conclusions: According to the findings, it can be concluded that the online weight management intervention was effective in reducing the weight and waist circumference of the obese individuals and dietary modifications may have contributed to the improvements.

Snacking is not associated with BMI in those with a healthy dietary pattern: ZOE Health study in 683,472 participants

Kate M Bermingham[1], Anna May[2], Joan Capdevila[2], Christina Hu[2], Emily Leeming[1], Rachel Gibson[1], Jonathan Wolf[2], George Hadjigeorgiou[2], Tim D Spector[1], Sarah E Berry[1]

1. Kings College London, London (UK), 2. Zoe Ltd, London (UK)

Background and objectives: Snacking accounts for 20-25% of daily energy intake, making it a key determinant of dietary quality. However, whether the snacking 'event' itself (multiple eating events and extended eating periods) or the poor dietary quality of snacks is associated with unfavourable health outcomes is unknown. Here we explore the association between snacking patterns, body composition and diet quality.

Methods: Diet data (food frequency questionnaire (FFQ)) and baseline characteristics (sex, age, socio-economic status (SES) and body mass index (BMI)) were analysed from 683,472 participants of the ZOE Health smartphone app. Self-reported daily snacking frequency (eating events between main meals) and diet quality (Diet Quality Score (DQS)) was assessed. The relationship between snacking frequency, diet quality and BMI (linear regression analysis adjusted for age, sex, eating window and SES) was investigated and post-hoc analysis carried out in age-matched subgroups.

Results: Average daily snack intakes in consumers was 1.89 portions (95% CI 1.88-1.89) (total cohort; 1.65 (95% CI 1.65-1.66)); 12% of participants did not snack, 36% consumed 1 snack/d, 34% 2 snacks/d and 18% > 2 snacks/d (frequent snackers). Frequent snackers versus non-snackers had a higher proportion of females (72% *vs* 58%), were younger (mean±SD) (47±14y *vs* 58±13y), had higher BMI (26.7±5.0kg/m^2 *vs* 25.8±4.3kg/m^2) and lower diet quality (9.9±2.0 *vs* 11.6±1.6), p<0.001 for all. There was a significant interaction between snacking and diet quality for BMI, p<0.001. Snacking frequency was not associated with BMI for those with a high diet quality (DQS>12). However, frequent snackers with low diet quality (DQS<10) had higher BMI versus non-snackers (difference; 1.07kg/m^2, p<0.01) (age-matched). Frequent snackers with high diet quality ate less unhealthy (crisps, fizzy drinks, sweets) and more healthy (fruits) snack foods compared to frequent snackers with low diet quality (p<0.001 for all).

Conclusions: High diet quality may negate the unfavourable relationship between snacking and bodyweight. However, further studies are needed to disentangle health effects of snacking events (frequency) from snacking quality (food) and dietary patterns.

Impact of probiotic consumption under the weight loss program on gut microbiota composition

Adela Penesova[1], Libusa Kubanova[2,1], Ivan Hric[2], Katarina Soltys[3], Jana Babjakova[4], Andrea Havranova[1], Zofia Radikova[1], Viktor Bielik[2]

1. Institute of Clinical and Translational Research, Biomedical Research Center, Slovak Academy of Sciences (Slovakia), 2. Department of Biological and Medical Science, Faculty of Physical Education and Sport, Comenius University, Bratislava (Slovakia), 3. Department of Microbiology and Virology, Faculty of Natural Sciences, Comenius University, Bratislava (Slovakia), 4. Institute of Hygiene, Medical Faculty, Comenius University, Bratislava (Slovakia)

Background and objectives: Obesity has been associated with structural and functional changes in the gut microbiota. Manipulatation with gut microbiota using probiotics have been shown to improve gut integrity, and restore the microbial shifts characteristic of obesity. Traditional probiotic products are fermented dairy products. Bryndza is a traditional Slovak fermented sheep's cheese. Most Bryndza microbiots are lactic acid bacteria. Therefore the aim of our study was to study the effect of short-term weight loss programs with Bryndza cheese consumption on the structure of the gut microbiota, and body composition in middle-aged women.

Methods: We conducted a randomized, controlled, 4-week intervention study involving 22 women with elevated body fat percentage (more than 25). Each participant individually received detailed instructions and advice on lifestyle changes, a personalized nutrition plan and a physical activity plan. Subjects were randomly assigned to a control or intervention group according to diet. The intervention group consisted of 13 participants whose diet contained 30 g of Bryndza cheese per day (WLPB). The control group consisted of nine participants without regular consumption of Bryndza cheese (WLP).

Results: Both interventions lead to a significant and favorable change of BMI (p<0.001), body fat (p<0.01), waist

circumference (p<0.01). Moreover, the relative abundance of *Erysipelotrichales* significantly increased in both groups. The higher abundance of order Erysipelotrichales was measured within the groups (WLPB-pre vs. WLPB-post; p=0.001; WLP-pre vs. WLP-post; p=0.027). Family Lachnospiraceae decreased in the WLPB group (p=0.006). However, the relative abundance of lactic acid bacteria (*Lactobacillales*, *Streptococcaceae*, *Lactococcus* and *Streptococcus*) significantly increased only in the WLPB group. Furthermore, short-chain fatty acid producers *Phascolarctobacterium* and *Butyricimonas* increased significantly in the WLPB group.

Conclusions: A short-term weight loss program combined with Bryndza cheese consumption improves body composition and increases the abundance of lactic acid bacteria and short-chain fatty acid producers in middle-aged women. Additional randomized placebo-controlled trials will help develop clinical guidelines for the use of probiotic therapy in obesity.

Untargeted multi-platform metabolomics identifies prognostic biomarkers for weight loss success on a New Nordic Diet

Kristina Pigsborg[1], Bekzod Khakimov[1], Søren Balling Engelsen[1], Faidon Magkos[1], Mads Fiil Hjorth[2], Lars Ove Dragsted[1]

1. University of Copenhagen (Denmark), 2. Healthy Weight Centre, Novo Nordisk Foundation (Denmark)

Background and objectives: Several randomized controlled trials have compared specific diets for treating overweight and obesity, but all have failed to provide an average efficacy above 10%. Consequently, different individuals will likely have success with different diets. The purpose of precision nutrition is to provide targeted diet plans for the individual or for groups with a similar metabolic profile. The current study aims to utilize explainable artificial intelligence to build a model that can predict whether a subject will have a successful weight loss eating a New Nordic diet and to understand the interaction within the model.

Methods: Ninety-one subjects completed a weight-loss study following a New Nordic diet for 26 weeks. Based on the subjects' weight loss during the intervention period, we classified the responder as having lost ≧5% of their initial body weight (n=46) and non-responders as having lost <2% of their initial body weight (n=21). Clinical baseline data were combined with baseline urine and plasma untargeted metabolomics data obtained from the two platforms nuclear magnetic resonance and liquid chromatography-mass spectrometry for better coverage of the metabolomes. The different metabolomics data sets were preprocessed individually and concatenated afterward, resulting in a final data set including 2766 features. We employed QLattice® to develop a predictive model of weight loss responders and non-responders. The QLattice® is a symbolic regression and a method within machine learning that attempts to explain a target variable Y by multiple input variables X using a mathematical expression containing a set of basic functions.

Results: Besides age (P=0.009; responders: 47.3±13.0 years vs. non-responders: 39.4±11.0 years), all other classical clinical baseline measures showed no difference. The final model contained two features, feature X and feature Y. The model can be described as logreg(−0.013×compX−0.048×compY+9.4). The model performed robustly from the training (ROC-AUC 0.88) to the test set (ROC-AUC 0.81).

Conclusions: From this study, we were able to identify a two-feature model that is able to predict whether a subject with overweight or obesity is likely to successfully achieve a weight loss by eating a New Nordic Diet.

Association between body composition by deuterium oxide dilution technique and anthropometric measurement in neurologically impaired patients

Wirada Sakamornchai[1], Oraporn Dumrongwongsiri[1], Jeeraparn Phosuwattanakul[1], Sirinapa Siwarom[1]

1. Ramathibodi hospital, Mahidol university (Thailand)

Background and objectives: Neurologically impaired (NI) pediatric patients are at risk of malnutrition which impacts their health and quality of life. Accurate nutrition assessment is important to guide appropriate nutritional support. There are some limitations in application of conventional nutrition assessment methods among NI patients. Determining body composition requires more complex equipments and cannot be routinely performed. This study was conducted to evaluate the associations between anthropometric parameters used in clinical practice and body composition assessed by deuterium (D^2O) dilution technique in NI patients.

Methods: This cross-sectional study enrolled severe NI patients (GMFCS IV-V) aged 1-20 years who were depended on home enteral nutrition for at least 3 months. After obtaining informed consent, baseline characteristics were recorded. Anthropometric measurements including weight, length, mid upper arm circumference (MUAC), and skinfold thickness (SFT) were performed. Weight and length were calculated to Z-score according to WHO growth standard. MUAC and SFT were used to calculated arm muscle area and body fat mass (FM) using predictive equation. Body composition is determined by D_2O

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

dilution technique (reference method) following the International Atomic Energy Agency (IAEA) protocol.

Results: Thirty patients (60% male) were enrolled. The mean (SD) age is 6.90 (4.08) years. One third of patients had BMI-for-age z-score between -2SD to 2SD. Body composition analysis shows mean percentage of total body water (TBW), FM and fat free mass (FFM) are 48.55% (11.00), 36.69% (14.79) and 62.82% (14.21), respectively. Mean percentage of FM from predictive equation is higher than reference method (mean difference 8.82% [4.75, 12.91]; p <0.001). Multivariate regression analysis shows that the factors associated with FM are age (β=0.1 [0.06,0.13]; p <0.001), BMI (β=1.07 [0.04, 1.74]; p =0.002), MUAC (β=-0.81 [-1.55,-0.07]; p <0.001), and triceps SFT (β=0.57 [0.17,0.96]; p <0.001). TBW is associated with age (β=0.07 [0.05, 0.10]; p <0.001) and MUAC (β=0.33 [0.10,0.56]; p =0.004).

Conclusion: Despite enteral nutrition support, most of the NI children were malnourished. Our study shows associations between some anthropometric parameters (including BMI, MUAC and SFT) with FM and TBW assessed by reference method. These findings should be further evaluated and applied to predict the body composition of NI patients in clinical practice.

Enhanced leptin-induced TFF3 expression and EGFR transactivation directs occurrence of neoplasia in stomach of dietary fat-induced obese mice.

Kyoko Inagaki-Ohara[1]

1. Prefectural University of Hiroshima (Japan)

Background and objectives: Obesity is a risk factor for gastric malignancies and tumors. However, the occurrence and mechanisms of neoplasia induced by high-fat diet (HFD) remain unclear. We have reported that HFD induces excess gastric leptin and its signaling, resulting in intestinal metaplasia, precancerous lesions of the stomach. In this study, we investigated the effect of gastric leptin signaling in intestinal metaplasia to clarify the mechanism of gastric neoplasia by HFD ingestion.

Methods: C57BL/6J or gastrointestinal epithelial cell-specific leptin receptor (LepR) conditional knockout (T3b-LepR cKO) mice were fed a high-fat diet (HFD) or control diet. The mice were euthanized by isoflurane inhalation, followed by surgical removal of the tissues for analyses of pathological changes, mRNA and protein expressions. COS-7 cells were transfected with plasmids expressing LepR and EGFR. The cells were then stimulated in presence or absence of recombinant rleptin or rTFF3.

Results: HFD induced leptin signaling, which in turn, accelerates the pathogenesis in the gastric mucosa along with extopic TFF3 expression and EGFR transactivation with the activation of STAT3, Akt, and ERK1/2. T3b-LepR cKO mice exhibited a suppressed elevation of leptin, TFF3, and phosphorylated EGFR in the stomach. Leptin promoted TFF3 expression in LepR-transfected COS-7 cells via STAT3, ERK1/2, and Akt phosphorylation. Additionally, in the LepR and EGFR co-transfected cells, these proteins were phosphorylated to a greater degree than that in LepR-transfected COS-7 cells along with augmented EGFR transactivation. Leptin induced TFF3 expression was greatly suppressed by PI3K inhibitor, LY294002. Furthermore, exogenous TFF3 treatment strongly phosphorylated EGFR in the EGFR-transfected COS cells.

Conclusions: These data suggest a novel LepR-signaling pathway that transactivates EGFR and leads to TFF3 expression via PI3K-Akt signaling. Notably, this promotes neoplastic transformation in the stomach. Therefore, this study shed light on the identification of new therapeutic targets for the treatment of precancerous symptoms in stomach and colorectal cancer.

Conflict of Interest Disclosure: There are no conflicts of interest to declare.

Reduction in anaemia through daily supplementation of Iron Folic Acid Supplementation for 90 days amongst rural adolescent girls in India

Aakriti Gupta[1,3], Harshpal Singh Sachdev[2], Umesh Kapil[1], Ravindra Mohan Pandey[1], Lakshmy Ramakrishnan[1]

1. All India Institute of Medical Sciences, New Delhi (India), 2. Sitaram Bhartia Institute of Science and Research (India), 3. Lady Irwin College, Delhi University (India)

Background and objectives: Anaemia is a major public health problem (40%) amongst adolescent girls in India. The current ongoing weekly iron folic acid (IFA) supplementation program has witnessed a slow decline in anaemia prevalence over the past decades. World Health Organization in 2016 recommended daily IFA supplementation containing 30-60 mg elemental iron for 3 consecutive months as a public health intervention in menstruating girls residing in high anaemia burden settings. Hence, the present study was conducted to understand the impact of daily IFA supplementation on anaemia amongst rural adolescent girls in India.

Methods: A community-based cluster-randomized trial was conducted and Baseline and the mid-term assessments were done using the cluster-sampling techniques. A total of 264 adolescent girls in the age group of 12–19 years with mild and moderate anaemia were selected from government schools of rural Ballabgarh block, Haryana, India. IFA Supplementation containing 60 mg elemental iron and 500mcg folic acid was administered daily under supervision for 90 days. Hemoglobin, serum ferritin, and vitamin B_{12} levels were assessed at baseline and endline.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Results: A total of 62 adolescent girls completed 90 doses of daily supplementation. The hemoglobin status of 67.5% participants improved to normal, post intervention with mean hemoglobin increase of 1.6 ± 1.2 g/dL. Adolescent girls with moderate anaemia (1.8 ± 1.2 g/dL) had higher increase in the mean hemoglobin levels as compared to mild anemic participants (1.0 ± 0.8 g/dL). Moderate anaemia reduced in 50.5% girls, however, hemoglobin status did not improve in 21.9% girls. Ferritin levels increased by 18.8 ± 35.0 ng/mL and completely alleviated in all girls post intervention.

Conclusions: Daily supplementation of IFA for 90 days reduced the overall proportion of anaemia by 67.5% and eliminated iron deficiency. Considering the operational feasibility and the effectiveness of the intervention, daily supplementation of IFA containing 60 mg elemental iron and 500mcg folic acid may be an effective strategy to reduce anemia amongst adolescent girls.

Acceptability and efficacy of Fish Surimi peptide in moderately acute malnourished children: a randomized clinical trial

Md Iqbal Hossain[1], SM Rafiqul Islam[1], Azharul Islam Khan[1], Sharika Nuzhat[1], Tahmeed Ahmed[1], Shugo Watabe[2]

1. icddr,b (Bangladesh), 2. Kitasato University School of Marine Biosciences (Japan)

Background & Objectives: Fish-Surimi-peptide, a low-cost long self-lived food-product from fish consisting of all essential-amino-acids, could be an attractive-alternative to supply fish-protein in children's diet. This study aimed to assess the acceptability and efficacy of Fish-Surimi-peptide in 2-5 years old children with moderate-acute-malnutrition (MAM).

Methods: In 34 MAM-children an acceptability study was completed by a randomly-blinded study with cross-over design. Children received Fish-Surimi-peptide (5g/lunch and 5g/supper) mixed meal in one day and the same meal on other day without any Fish-Surimi-peptide. We observed the completeness and eagerness of eating and any possible side effect. Following that, a pilot randomized intervention study was conducted in 75 MAM-children. Intervention group received two weeks' supply of Fish-Surimi-peptide @ 10g/day as take-home ration for three months. The control group received dietary advice in place of Fish-Surimi-peptide.

Results: In the acceptability-study 44% were female-children, their mean±SD age was 38.4±9.4 months and weight-for-height z-score (WHZ) was -2.13±0.76. Total feeding-time, amount of food eaten and number of food-refusals during lunch and supper together was found similar in Fish-Surimi added and non-added group respectively. Score in Hedonic scale (dislike extremely=0 to like extremely=5) by mother on test of food given to children was 3.9±0.2 vs. 4.0±0.2 (p=0.317) and on overall-acceptance (including the texture, smell, and appearance) of food was 3.9±0.2 vs. 4.0±0.2 (p=0.317) for Fish-Surimi added and non-added group respectively. No adverse event was observed in any group during the study period. All baseline characteristics of the children enrolled in efficacy-trial were similar between the intervention and control groups. On enrollment their mean±SD age was 38.4±9.5 vs. 37.1±10.8 months, and WHZ was -2.39±0.26 vs. -2.31±0.33. Over three months study period the improvement of anthropometric parameters was observed in positive trend in Fish-Surimi intervention group. Particularly, the height increment (cm) of 1.5±0.7 vs. 1.3±0.6 (p=0.042) and improvement of total protein (g/liter) of 2.87±5.28 vs. 0.26±4.12, p=0.038) were noticeable.

Conclusions: Fish-Surimi-peptide has been found to be a well-accepted safe supplementary food and showed a positive trend in the improvement of growth in Bangladeshi malnourished-children. This should be tested by larger randomized multicounty community level intervention-trial in undernourished or stunted children.

The Factors Associated to Severity Level in Women with Systemic Lupus Erythematosus at Indonesia Lupus Foundation

Iin Fatmawati Fatmawati[1], Dhea Putri Septiyani[2], Avliya Quratul Marjan[3], Ibnu Malkan Ilmi[4], Ikha Deviyanti Puspita[5]

1. Universitas Pembangunan Nasional Veteran Jakarta (Indonesia),
2. Universitas Pembangunan Nasional Veteran Jakarta (Indonesia),
3. Universitas Pembangunan Nasional Veteran Jakarta (Indonesia),
4. Universitas Pembangunan Nasional Veteran Jakarta (Indonesia),
5. Universitas Pembangunan Nasional Veteran Jakarta (Indonesia)

Background and objectives: Systemic lupus erythematosis is a chronic inflammatory disease because of an immune system error that causes the immune system to attack the body's own tissues and organs. Seveity of systemic lupus erythematosis is divided into 3 levels, there is mild, moderate and severe, which is seen based on the severity - the symptoms that appear. Several causes of inflammation in systemic lupus erythematosis patients was eaten foods high in saturated fat, depression, and sleep quality. The aimed of this study is to analyze the correlation between saturated fatty acid intake, depression, and sleep quality with severity level of women with Systemic Lupus Erythematosis patients in Indonesia Lupus Foundation.

Methods: This study is a quantitative study using a cross-sectional design. The sample is women aged 15-45 years as many as 40 patients. The sampling technique in this study used

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

purposive sampling. The data used are primary data taken using the Mex–Sledai Questionnaire, Semi Quantitavtive - Food Frequency Questionnaire, Beck's Depression Inventory, and Pittsburgh Sleep Quality Index. Analysis of the correlation was done by using the chi square test.

Results: The results showed that 57.5% of the samples had severe conditions. Moreover, 78.2% of them had a high intake of saturated fat, 52.1% had moderate depression, and 95.6% had poor sleep quality. There is a relationship between saturated fat intake (p=0.039), depression (p=0.006), and sleep quality (p=0.000) with the severity level of the patient.

Conclusions: There was a significant correlation (p<0.05) between saturated fatty acid intake, depression, and sleep quality with severity level on systemic lupus erythematosus patients in Indonesia Lupus Foundation.

Keywords: Depression, saturated fatty acid intake, severity level of systemic lupus erythematosus, sleep quality

Effect of maternal dietary diversity during lactation on risk of atopic dermatitis via gut microbiome

Linh Ba Phuong Huynh[1], Nam Nhat Nguyen[1], Hsien Yu Fan[2], Shih Yi Huang[1], Yang Ching Chen[1,2]

1. Taipei Medical University (Taiwan), 2. Taipei Medical University Hospital (Taiwan)

Background and objectives: The maternal diet during pregnancy and lactation plays an essential part in modulating the mother's intestinal flora from which it is transferred to the infant in many ways. In addition, current evidence supports that infant intestinal microbiota contributes to atopic dermatitis in early life. This study aimed to explore the prospective association between maternal diet diversity during lactation and the risk of atopic dermatitis through the gut microbiome in early childhood.

Methods: We included 60 mother-infant pairs from the Taipei Maternal Infant Nutrition Cohort Study, Taiwan from 2018 to 2021. Dietary diversity was assessed by using a 24 hours dietary recall method for 3 days during lactation and FAO's Minimum Dietary Diversity for Women index. Stool samples were collected from the infants at 2 months. Microbiota analyses were performed using 16S rRNA gene amplicon sequencing. Children's atopic dermatitis was assessed by pediatricians at 0, 4, and 12 months of age.

Results: Twenty-seven percent of women had low dietary diversity during lactation. Among 60 infants, the number of infants with atopic dermatitis at the time points 0 months, 4 months, and 12 months of age were 1, 3, and 8, respectively. During lactation, high or low maternal dietary diversity affected the alpha diversity of the infant's gut microbiome. Principal coordinate analysis ordination revealed that the infant gut microbiome clustered differently for high and low maternal dietary diversity during lactation (p<0.05). The linear discriminant analysis effect size and feature selection identified 5 and 6 taxa from both the low and high maternal dietary diversity groups. Among the 11 abundant taxa, we observed that two taxa have an association with the risk of atopic dermatitis among infants at 12 months of age, including *Eggerthellaceae* and *Clostridia_Family_XI* (p<0.05).

Conclusions: There were significant differences in the microbiota composition between infants from mothers who had high or low dietary diversity during lactation. Through two taxa of gut microbiomes of infants including *Eggerthellaceae* and *Clostridia_Family_XI*, maternal dietary diversity can potentially contribute to the risk of atopic dermatitis.

Keywords: maternal diet diversity, lactation, infant gut microbiome, infant atopic dermatitis

Adherence to Dietary Quality Indices Is Associated with Lower Risk of Cardiovascular Disease risk factors and Graft Function Deterioration in Taiwanese Renal Transplant Recipients

Te Chih Wong[1], I Hsin Lin[2,3], Tuyen Van Duong[3], Shih Wei Nien[2,3], I Hsin Tseng[2], Hsu Han Wang[2], Yang Jen Chiang[2], Shwu Huey Yang[3,4]

1. Chinese Culture University (Taiwan), 2. Linkou Chang Gung Memorial Hospital (Taiwan), 3. Taipei Medical University (Taiwan), 4. Taipei Medical University Hospital (Taiwan)

Background and objective: The Alternative Healthy Eating Index (AHEI) is used to examine dietary quality. The AHEI and its updated version, AHEI-2010, are based on the American Dietary Guidelines. AHEI-Taiwan was modified from AHEI according to Taiwan's dietary recommendations. This study is aimed to investigate the association between dietary quality indices and both cardiovascular disease (CVD) and chronic kidney disease (CKD) risk in renal transplant recipients (RTRs).

Methods: This prospective study recruited RTRs aged >18 years with a functioning allograft and without any acute rejection in the past 3 months from September 2016 to June 2018. Dietary quality indices were calculated using 3-day dietary records, and calculated scores were divided into quartiles. Laboratory data were collected from medical record; CKD was defined as an estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73 m^2. Lipid profile include total cholesterol (TC), low lipoprotein cholesterol (LDL-C), high lipoprotein cholesterol and triglyceride were based on the National Cholesterol Education Program in Adult Treatment Panel III guidelines. Logistic regression analysis was performed to analyze the associations.

Results: This study included 102 RTRs. The RTRs with higher AHEI-Taiwan, and AHEI-2010 scores were older and had higher eGFRs; RTRs with higher AHEI-Taiwan scores had lower TC and LDL-C. After adjusted age, gender, energy intake and

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

comorbidity index, the highest quartiles of the AHEI-Taiwan, and AHEI-2010 had 90% (odds ratio [OR] = 0.10; 95% confidence interval [CI] = 0.03–0.43, p < 0.01), and 85% (OR = 0.15; 95% CI = 0.04–0.57, p < 0.01) lower risk of CKD, respectively. The highest quartiles of the AHEI-Taiwan had 82% (OR = 0.18; CI = 0.05–0.71, p < 0.05) lower risk of high TC, and 89% (OR = 0.11; CI = 0.03–0.50, p < 0.01) lower risk of high LDL-C, respectively.

Conclusion: Healthy dietary quality, especially AHEI-Taiwan which based on Taiwanese dietary recommendation was associated with decreased risk of both CVD and CKD risk in the Taiwan RTRs.

Keywords: dietary quality, eating index, renal transplant recipients, chronic kidney disease, cardiovascular disease

OAB(T4)4-7

Nutritional risk index and risk factors for graft function in renal transplant patients

Nguyen Thu Ha[1,2], Poh Bee Koon[2], Zulfitri Azuan Mat Daud[3], Rozita Mohd[2], Ruzita Abd Talib[2], Ho Trung Hieu[1]

1. 108 Military Central Hospital (Viet Nam), 2. University Kebangsaan Malaysia (Malaysia), 3. Universiti Putra Malaysia (Malaysia)

Introduction and objectives: Poor nutritional status has been associated with worse clinical outcomes and heightened mortality in kidney transplant (KTx) recipients. However, the risk of malnutrition and graft function following KTx is unclear. The present study sought to determine the association between nutritional status and graft function and its risk factors among 12-month KTx patients.

Methods: A longitudinal study was conducted among 75 KTx recipients at a hospital in Vietnam. Anthropometric, hemoglobin, serum albumin, glucose, triglyceride, HDL and serum creatine were obtained on the discharge day (T0) and after 12 months post-transplant (T12). The risk of malnutrition was assessed by nutritional risk index score (NRI). Kidney function was evaluated based on the estimated glomerular filtration rate (eGFR).

Results: At T0, 68.9% of the patients had no risk of malnutrition (A), 29.5% had mild and moderate malnutrition (B), and 1.6% were severely malnourished (C). The distribution of nutritional status was significantly changed (McNemar test, p<0.05) after 12 months post-KTx to 85.1%, 15.9%, and 0% for categories A, B and C, respectively. Prevalence of anemia decreased significantly from 77.1% at T0 to 16.7% at T12 (McNemar test, p<0.001). Cox proportional hazards found anemia (HR 0.24, 95%CI 0.14 - 0.40), low albumin (HR 0.01, 95%CI 0.03 - 0.07), BMI (HR 0.86, 95%CI 0.77 - 0.97), and risk of malnutrition (HR 0.41, 95%CI 0.24 - 0.70) were associated with decreased eGFR, while blood level of tacrolimus (HR 1.22, 95%CI 1.11 - 1.33) was associated with increased eGFR. Multilinear regression model found that 34.2% of variance change in eGFR mean was explained by gender, white blood cells, anemia, risk of malnutrition and length of stay (R^2 0.342), whereby eGFR = 87.63 - 0.35 male + 0.21 white blood cell count (G/L) + 0.14 risk of malnutrition – 0.33 anemia – 0.32 length of stay (day).

Conclusion: Nutritional status improved significantly at 12 months post-transplant compared to the baseline. Several independent risk factors, including male, anemia, low albumin, risk of malnutrition, and length of stay, led to a decrease in kidney function. Providing nutrition counselling to improve these factors among transplant patients may reduce the risk and improve graft survival.

Keywords: Graft function, Nutritional Risk Index, Renal transplant, Vietnam

Metabolic syndrome and plasma levels of amyloid-β, total-tau and neurofilament light chain: The Rotterdam study

Tosca O.E. de Crom[1], Mohsen Ghanbari[1], M. Arfan Ikram[1], Trudy Voortman[1,2]

1. Erasmus University Medical Center Rotterdam (Netherlands), 2. Wageningen University & Research (Netherlands)

Background and objectives: Components of metabolic syndrome have been suggested to increase the risk of Alzheimer's disease (AD), but pathways underlying this remain incompletely understood. Plasma levels of amyloid-β (Aβ), total-tau and neurofilament light chain (NfL) reflect AD-associated neuropathological features: Plasma Aβ levels are increased in the early stages of AD, while decreased levels are seen in the prodromal AD phase due to deposition. Plasma levels of total-tau and NfL reflect axonal damage and are often elevated before AD onset. We investigated the association of the individual components of metabolic syndrome with circulating plasma levels of Aβ, total-tau and NfL.

Methods: Between 2002 and 2005, metabolic syndrome components and plasma Aβ-40, Aβ-42, total-tau and NfL levels were measured in 4,871 participants (mean age 72 years, 57% women) from the population-based Rotterdam Study. Components of metabolic syndrome included: waist circumference, fasting serum triglycerides, HDL cholesterol and glucose, and systolic and diastolic blood pressure. Associations between these components and AD-related plasma markers were determined using multiple linear regression models.

Results: Serum triglycerides were associated with higher $\log_2$ Aβ-42 plasma levels (mean difference per standard deviation (SD) increase [95% CI]: 0.03 [0.01;0.06]), whereas serum HDL cholesterol was linked to lower plasma levels of $\log_2$ Aβ-40 (mean difference per SD increase [95% CI]: -0.06 [-0.08;-0.03]). No link was observed for other components of metabolic syndrome with Aβ-40 or Aβ-42. Waist circumference was associated with higher $\log_2$ total-tau and lower $\log_2$NfL plasma levels (mean difference per SD increase [95% (CI)]: 0.08 [0.04;0.11] for total-tau and -0.18 [-0.21;-0.16] for NfL). Systolic blood pressure was linked to higher $\log_2$ NfL plasma levels (mean difference per SD increase [95% CI]: 0.05 [0.02;0.08]), while

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

diastolic blood pressure was associated with lower log_2 plasma levels of total-tau and NfL (mean difference per SD increase [95% CI]: -0.04 [0.08;-0.01], for total-tau and -0.04 [-0.07;-0.02] for NfL). Other components of metabolic syndrome were not associated with total-tau or NfL.

Conclusions: Our findings suggest a link of serum triglycerides and HDL cholesterol with plasma levels of Aβ, while abdominal fat and blood pressure may contribute to the risk of AD though axonal damage.

Recurrent Western dieting alters brain homeostasis and regulation of food intake via persistent changes in the gut microbiota–host symbiosis

Melanie Fouesnard[1,2], Alexandre Benani[3], Selma Ben-Fradj [3], Gaëlle Champeil-Potokar[4], Isabelle Denis[4], Véronique Douard[2], Gaelle Boudry[1]

1. Institut NUMECAN INRAE, INSERM, Univ Rennes (France), 2. Insitut Micalis INRAE AgroParistech University Paris Saclay (France), 3. Centre des Sciences du Gout et de l'Alimentation INRAE CNRS (France), 4. UMR914 PNCA INRAE AgroParistech (France)

Background and objectives: Alternating periods of excessive and restrained eating, a dieting behavior that also occurs in normal weight individuals, is a risk factor for the development of excess weight gain and food intake dysregulation such as binge eating. We tested the hypothesis that recurrent exposure to palatable food (HFS) alters food intake regulation by changing either or both intestinal microbiota and brain homeostasis in mouse.

Methods: C57BL/6 mice underwent 3 cycles of 1 week of HFS (45% kcal from fat and 18% from sucrose) exposure separated by 2 weeks of chow diet exposure (CYCL group) or staid under chow diet (CTRL group). Food intake was precisely monitored after each dietary change to identify potential binge eating episodes as well as daily with body weight. Expression levels of inflammation- and reward-related genes were evaluated in the striatum, hypothalamus and brainstem before the 3rd HFS introduction and in CTRL mice. Cecal samples were collected to analyze microbiota composition through 16S DNA sequencing. Then, cecal samples from CYCL and CTRL mice were transplanted into naive recipient mice kept on chow diet or submitted to HFS to investigate whether differences in food intake behavior and central markers of inflammation and reward could be transmitted via the gut microbiota.

Results: Recurrent HFS exposures increased energy intake specifically during the first hours following HFS re-introduction. Inflammatory state in brain areas involved in food intake regulation was lower after recurrent exposure to HFS, either under chow or in response to HFS, while expression of reward-related genes was enhanced. Recurrent exposures to HFS induced changes in gut microbiota composition and metabolic activities which persisted even after the mice had returned to standard chow diet. Gut microbiota transfer from CYCL mice to naive recipient mice changed their feeding behavior on HFS, which becomes very similar to that of donor mice.

Conclusions: Our data demonstrate that altered gut microbiota contributes to the escalating consumption of palatable diet in the context of recurrent exposure to HFS. Worse still, altered gut microbiota likely participates to the relapse into overeating during dietary management of obesity, and likely explains failure in the obesity therapy.

Nutrient-dense vegan food for dysphagia patients using 3D printing

Satheeshkanth S S M[1], Mohammed A Bareen[1], Jatindra K Sahu[1]

1. IIT DELHI (India)

Background and objective: Dysphagia is a common problem in the elderly. And this is of particular significance in Japan, which has the world's largest elderly population. Dysphagia can lead to significant malnutrition and dehydration because it interferes with the voluntary process of safe feeding. To combat malnutrition caused by this illness, palatable meals with a pleasing texture that can also be easily swallowed must be created. 3D food printing is a potentially useful method for generating safe and high-quality food with established applications. Current research aims to explore the effect of 3D printing parameter settings and the very nutritious chia seed flour on the production of commercially viable transitional plant-based protein foods.

Methods: Pretreated horse gram flour and chia (Salvia hispanica L.) seed flour were blended in different combinations to produce 3D printable formulations with varying functionalities. The rheological behavior of the printing features of the composite formulations was investigated, as were the textural, functional, and morphological properties of the 3D printed structures. Moreover, the IDDSI tests for Level 6 and 7 dysgraphia food were performed to evaluate the 3D printed products for commercial viability, and the results were validated with instrumental analytical results.

Results: Analyzing the effect of chia seed flour addition and printing parameters revealed that 10% CSF incorporation, 0.8 mm nozzle diameter, 12 mm/s printing speed, 0.6 mm layer height, and 25% infill produce desirable 3D printed constructs in terms of better shape accuracy with and good stability. Furthermore, these conditions were conducive to the creation of 3D printed structures with decreased hardness and increased cohesion, which is desirable in dysphagia foods. In addition,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

using a combination of microwave heating and freeze drying to post-process these 3D structures resulted in a more appealing texture and 3D printed transitional food.

Conclusions: The findings of the printing performance, texture profile, and IDDSI tests revealed that the addition of CSF acted as a unique textural modifier and flow enhancer. The printing accuracy and post-printing stability of the constructs were impacted by the extrusion rate. As a result, our research paves the path for the use of CSF as a novel functional hydrocolloid in the development of nutrient-dense vegan transitional dysphagia food.

Longer-term mixed nut consumption improves brain and peripheral vascular function, and memory: Results of a randomized, controlled crossover trial in older adults.

Kevin Nijssen[1], Ronald Mensink[1], Peter Joris[1]

1. Maastricht University (Netherlands)

Background and objectives: Effects on vascular function may contribute to the beneficial effects of nut consumption on age-related cognitive decline. Therefore, we examined the longer-term effects of mixed nuts on both brain and peripheral vascular function that may underlie cognitive benefits among older adults.

Methods: Twenty-eight healthy individuals (age: 65±3 years; BMI: 27.9±2.3 kg/m^2) were included in a randomized, single-blinded, cross-over trial with a 16-week intervention (60 g/d mixed nuts: 15 g of walnuts, pistachio, cashew, and hazelnuts) and control period (no nuts), separated by an 8-week wash-out period. Participants followed the Dutch food-based dietary guidelines. At the end of each period, cerebral blood flow (CBF) - a marker of brain vascular function - was quantified using arterial spin labeling MRI, while peripheral vascular function was assessed by using validated markers of endothelial function, arterial stiffness, and microvascular structure. Furthermore, cognitive performance was assessed in the domains of memory, executive function, and psychomotor speed.

Results: Body weight and composition did not change during the whole study. Regional CBF was higher in three brain clusters that were located in the right frontal and parietal lobe (Δ5.0±6.5 mL/100g/min; P<0.001), left frontal lobe (Δ5.4±7.1 mL/100g/min; P<0.001), and bilateral prefrontal cortex (Δ5.6±6.6 mL/100g/min; P<0.001). Mixed nut consumption also improved endothelial function as the carotid artery response to a cold pressor test (Δ0.7 PP; 95%CI: 0.2 to 1.2; P=0.007) and brachial-artery flow-mediated vasodilation (Δ1.6 PP; 95%CI: 1.0 to 2.2; P<0.001) were higher. Furthermore, beneficial effects were observed on arterial stiffness and microvascular function, as the carotid-to-femoral pulse wave velocity was lower (Δ-0.6 m/s; 95%CI: -1.1 to -0.1; P=0.032) and retinal arteriolar calibers were higher (Δ2 µm; 95%CI: 0 to 3; P=0.037). Finally, memory was beneficially affected given the improved performance on the paired association learning (Δ-4 errors; 95%CI: -8 to 0; P=0.045) and verbal word recognition (Δ1 correct; 95%CI: 0 to 2; P=0.035) tasks. However, psychomotor speed and executive function did not change.

Conclusions: Longer-term mixed nut consumption on top of a recommended diet significantly improved both brain and peripheral vascular function, which may underlie observed beneficial effects on cognitive performance in older adults.

Dietary intake, malnutrition and hospital readmission among old adults; Randomized controlled intervention

Olof Gudny Geirsdottir[1], Gudmundur Gaukur Vigfusson[1], Berglind Soffia Blondal[1], Palmi V Jonsson[1,2], Alfons Ramel[1]

1. University of Iceland (Iceland), 2. Landspitali University Hospital (Iceland)

Background and objectives: Protein energy malnutrition (PEM) among older adults is undeniably a challenging problem as the world population ages. PEM refers to a nutritional deficiency that is commonly due to inadequate dietary intake among older adults, which has often been associated with age- or disease-related changes such as reduced appetite, physical mobility, and/or acute illness. Specific aims were 1) to explore the differences in dietary intake between the groups which received either 6-month multi-component nutrition therapy or standard care after hospital discharge, 2) to determine the prevalence of PEM according to the Global Leadership Initiative on Malnutrition (GLIM) criteria after discharge, 3) to investigate if 6-month-multi component nutrition therapy impacts hospital readmission and, or length of stay.

Methods: The HOMEFOOD study is a 6-month randomized controlled intervention. Total participants were 104 patients, aged 65 years or older at risk for malnutrition or malnourished according to nutritional screening and discharging from the hospital to independent living. Dietary intake at baseline (day before the discharge from the hospital), after 3-months and at 6-months was assessed using a 24-hour-dietary-recall interview. The prevalence of PEM was determined according to GLIM

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

criteria at baseline and after 6 months. Data on hospital readmissions and length of stay among participants were obtained from the Icelandic electronic hospital registry (SAGA).

Results: Energy and protein intake 3- and 6 months after hospital discharge were significantly higher in the intervention group ($p<0.001$, $p<0.001$, respectively). At baseline 30 (58%) patients in the control group and 34 (65%) patients in the intervention group were malnourished according to GLIM criteria. However, 6 months after discharge, 9 participants (17%) were malnourished in the intervention group according to GLIM criteria, compared to 38 participants (73%) in the control group. 6-month multi-component nutrition therapy did not have any impact on hospital readmission and/or length of stay.

Conclusions: 6-month-multi-component nutrition therapy impacts energy- and protein intake and decrease risk of malnourishment according to GLIM criteria. However, 6-month multi-component nutrition therapy does not affect hospital readmission and/or length of stay.

Lifestyle-based risk prediction models for colorectal cancer in a European population: a systematic review and meta-analyses

Elly Mertens[1], Maria Keuchkarian[2], Chiara Colizzi[1], Maria Salve Vasquez[3], James Cottam[1], José Luis Peñalvo[1]

1. Institute of Tropical Medicine (Belgium), 2. Ghent University (Belgium), 3. Sciensano (Belgium)

Background: Colorectal cancer (CRC) is the second leading prevalent cancer in Europe, of which one-fifth is attributable to unhealthy lifestyle, including high body mass index (BMI). Risk models identifying high-risk groups based on lifestyle may support improved prevention through motivating lifestyle change.

Objectives: To provide an overview of risk models of primary CRC based on lifestyle data and developed and/or validated for a European population, including a summary of the effect size of common lifestyle factors.

Methods: A systematic review was conducted in PubMed and Web of Science. Included were risk models for CRC (i) based on lifestyle, (ii) developed and/or validated in an adult asymptomatic European population, (iii) reported the estimates with uncertainty measure for the predictors included. The model-specific effect sizes of lifestyle factors included in at least five risk models were summarized into a weighted average and 95% confidence interval (CI) using inverse-variance random-effects meta-analyses.

Results: A total of 17 risk models for CRC (reported in 12 studies) were eligible, of which nine were validated in an European population but developed elsewhere, mostly US. Pooled effect sizes for common lifestyle factors were found to be of similar strength, with for ever smoker a pooled RR of 1.22 (95%CI: 1.15, 1.29), for high alcohol consumption of 1.14 (95%CI: 1.08, 1.20), and for being physically active of 0.87 (95%CI: 0.82, 0.93), and for BMI of 1.13 (95%CI: 1.10, 1.16) for overweight and of 1.32 (95%CI: 1.20, 1.44) for obesity, based on twelve, nine, six, eight and ten, respectively, model-specific effect sizes. Diet-related lifestyle predictors were: consumption of meat (with two models total, two red and two processed meat) and vegetables (four models), amongst others: dairy and multivitamins (each in two models), and calcium, sugar and confectionary and dark bread (each in one model).

Conclusions: Lifestyle was identified as a significant predictor in multiple risk prediction models for CRC. Early identification of high-risk groups based on lifestyle data would therefore offer the potential to encourage participation in lifestyle and screening programmes, and subsequently reduce the CRC burden.

Dietary patterns underlying biological mechanisms and breast cancer survival: Evidence from a prospective cohort study

Carlota Castro-Espin[1,2], Catalina Bonet[1], Laure Dossus[3], Antonio Agudo[1,2]

1. Catalan Institute of Oncology (ICO) (Spain), 2. Institute of Biomedical Research of Bellvitge (IDIBELL) (Spain), 3. International Agency for Research on Cancer (IARC) (France)

Background and objectives: A number of dietary patterns have recently emerged in nutritional research aimed at assessing the biological mechanisms underlying diet-cancer associations, probably due to synergistic or additive effects of dietary components. In part, because of advances in treatment, the number of breast cancer survivors has increased, and they may not die from the disease but from other causes. We aimed to examine associations between pre-diagnosis dietary patterns underlying biological mechanisms presumably related to breast carcinogenesis (insulin-resistance, low-grade chronic inflammation, and estrogen metabolism) and breast cancer survival.

Methods: The diabetes risk reduction diet [DRRD], the inflammatory score of diet [ISD], and the estrogen-related dietary pattern [ERDP], were calculated using dietary data from the European Prospective Investigation into Cancer and Nutrition (EPIC) study. We examined the associations between these patterns and overall and specific mortality among 13,270 breast cancer survivors during a mean follow-up of 8 years. Adjusted Cox regression analyses were used to estimate the association between dietary patterns and overall mortality, and

the associations with breast cancer-specific mortality were based on competing risk models.

Results: Adherence to DRRD score was associated with 22% lower overall mortality (HR HR_{Q4vsQ1}=0.78; 95%CI 0.68-0.90) and an 8% decrease per one standard deviation increase in the score (HR=0.92; 95%CI 0.87-0.96). High DRRD score (low-risk diet for diabetes) combined with low ISD (anti-inflammatory diet) using the median as cut-off points to dichotomise each score, was associated with lower overall mortality (HR=0.83; 95%CI 0.73-0.93) compared to low-DRRD-high-ISD (high-risk diet for diabetes, pro-inflammatory diet). The ERDP did not show a clear association with mortality. None of the dietary patterns were associated with breast cancer-specific mortality. Higher DRRD and higher ISD were inversely and positively associated, respectively, with mortality among postmenopausal breast cancer cases, those presenting healthy weight, physically inactive, and with progesterone receptor-positive (PR+) tumours, despite no significant heterogeneity by subgroups.

Conclusions: Greater adherence to DRRD score, corresponding with a low-insulin-resistance diet, was associated with better overall survival among breast cancer survivors. This effect was more pronounced in combination with anti-inflammatory diet, suggesting that following these dietary patterns pre-diagnosis may be important for breast cancer survivors.

Undetected hypertension: prevalence and association with age, gender and dietary pattern among healthy urban adults in Delhi

Harmeet Kaur[1], Bani Tamber Aeri[1]

1. Institute of Home Economics, University of Delhi (India)

Background and Objective: High blood pressure is a classical feature of the cardiometabolic syndrome and it is seen that almost one-third of hypertensive patients have metabolic syndrome. It is reported that as high as 50% of the people with diabetes remain undetected in India. The present study was planned to assess the prevalence of undetected hypertension among apparently healthy urban adults and its association with gender, age and dietary pattern.

Methods: The study was conducted among 400 healthy urban adults comprising of 200 vegetarians (VS) and 200 non-vegetarian subjects (NVS) as per the operational definitions for the present study. SBP and DBP measurements were taken using a digital OMRON Blood Pressure Monitor (HEM:8712 OMRON Corporation, Japan). Hypertension was defined based on JNC 7(2003) defining criteria.Data on the socio-demographic profile, anthropometric measurements, were collected using standardized tools and techniques. Data were analyzed using SPSS version 25.

Results: The study results highlight that 26.75% were hypertensives and 46.5% of the subjects were found to be prehypertensives thus highlighting the substantial burden of undiagnosed hypertension. The prevalence of undiagnosed hypertension was 27.97% and 25.6% among males and females respectively. Considering the dietary pattern, it was seen that non-vegetarian males (NVM) had a significantly higher prevalence of undiagnosed hypertension (34%) than vegetarian males (VM,21.9%, p=0.001*). Almost an equal number of vegetarian females (VF) and non-vegetarian females (NVF) were noted to be hypertensives (26% and 25.2% respectively, p=0.271). The prevalence of hypertension was significantly higher among the subjects who were >45 years (34.28%) of age than those less than 45 years (22.69%, p =0.002*). Results of multiple regression analysis depicted that SBP was significantly associated with age (**p=0.001*), gender (p=0.017*) and diet (p=0.024*) while there were no significant associations found between DBP with these variables.**

Conclusion: The study highlights the importance of timely screening of the population to prevent and manage hypertension efficiently and prevent further complications related to elevated blood pressure

Personalised dietary advice delivered using a metabotype approach improves lipid profile: a randomized controlled trial

Elaine Hillesheim[1], Geetha Priya Sundaramoorthy[1], Xiaofei Yin[1], Lorraine Brennan[1]

1. University College Dublin (Ireland)

Background and objectives: Metabotypes are groups of individuals with similarities in their metabolic profile and have been associated with diet-related diseases and responses to dietary interventions. However, its effectiveness to deliver personalised dietary advice has not been tested in an intervention. Our previous work developed a framework to deliver personalised dietary advice based on metabotypes, with individuals being classified using four biomarkers (triacylglycerol, HDL-cholesterol, total cholesterol, glucose). The objective of this study is to examine the effectiveness of the metabotype approach at improving metabolic health biomarkers compared to population-level dietary advice.

Methods: A randomized single-blind controlled trial was performed with 107 healthy adults (Ethics approval LS-19-98-Brennan). Participants received dietary advice based on the metabotype approach or generic healthy eating guidelines.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Blood biomarkers, anthropometry and blood pressure were assessed pre and post 12-week intervention. Targeted metabolomic analysis of plasma was performed using UHPLC-MS/MS. One-way analysis of variance was performed on metabolomic data at baseline to assess differences across metabotypes. Comparison between study groups post-intervention was performed on an intention-to-treat basis by general linear models adjusted for measurement at baseline.

Results: Following the intervention, individuals receiving advice based on their metabotype group had significantly lower concentrations of triacylglycerol (0.5±0.4 vs 0.7±0.6 mmol/L), total cholesterol (4.9±1.0 vs 5.5±1.3 mmol/L) and LDL-cholesterol (3.8±1.1 vs 4.2±1.3 mmol/L) compared to the control group (all $p<0.05$ between groups). No significance was observed for anthropometry, blood pressure and glucose. Examination of the metabotypes revealed distinct metabolic profiles for each metabotype as baseline. Metabotype 3 was characterised by the highest mean total cholesterol (5.7±1.0 mmol/L), triacylglycerol (1.2±0.5 mmol/L) and glucose (4.9±0.5 mmol/L) and the highest levels of leucine and isoleucine (branched-chain amino acids) and a-aminoadipic acid (FDR<0.05). Metabotype 1 had the highest mean HDL-cholesterol (2.2±0.4 mmol/L). Metabotype 2 had the lowest mean total cholesterol (4.4±0.9 mmol/L) and the lowest levels of phosphatidylcholines and sphingomyelins.

Conclusions: Our metabotype approach classifies individuals into distinct and meaningful metabolic profiles. Personalised dietary advice delivered using the metabotype approach is more effective than population-level dietary advice at improving metabolic health biomarkers, in particular their lipid profile. Future analysis will elucidate changes in diet quality.

OAB(T4)6-4

Temporal trend of macronutrient intakes and physical activity level among lipid-lowering medication users and nonusers in the US: NHANES 2007-2018

Nobuhisa Morimoto[1], Sadaharu Asami[1], Kevin Y Urayama[1]

1. St Lukes International University (Japan)

Background and objectives: Previous studies indicated a clear benefit of saturated fat intake reduction and regular physical activity in decreasing cardiovascular disease (CVD) risk. Statin use is also an approach to reducing CVD risk. While statin prescription substantially increased over time, the adherence to healthful lifestyle habits may be suboptimal. We examined the temporal trend of macronutrient intakes and physical activity level among lipid-lowering medication (LLM) users and non-users in the U.S.

Methods: We used data on non-pregnant adult participants aged 40 years or older at the time of enrollment in the National Health and Nutrition Examination Survey (NHANES) 2007-2018. We divided participants into three groups: no dyslipidemia (non-DLP), non-users with dyslipidemia (non-LLM), and LLM users (LLM). To estimate the nutrient intakes in each survey cycle, we fitted generalized linear models with log-link function and gamma distribution, treating nutrient intakes as a continuous outcome variable, with adjustment for age category, gender, race/ethnicity, education level, poverty, and diabetes mellitus. The models included survey cycle to evaluate the temporal trend of the nutrient intakes. Also, temporal trends in the proportion of individuals meeting the recommended level of physical activity were examined in the three groups using logistic regression.

Results: Among 20,417 eligible participants, 28.4% were LLM users and 21.6% were non-users with dyslipidemia. Total caloric intake showed an increasing trend among the LLM group. Total fat and saturated fat intake showed an increasing trend in all three groups mainly for more recent years. The proportion of individuals meeting the recommended physical activity level increased in the non-DLP group while such trend was absent in the LLM and non-LLM groups.

Conclusions: LLM users showed a trend of increasing total caloric and fat intake in more recent years, which may be concerning. The proportion of physically active individuals increased over time in the non-DLP group only. More efforts are needed to improve the lifestyle habits of LLM users.

Effect of milk and soy milk consumption on blood lipids and blood calcium concentration among individuals with metabolic syndrome

Chatrapa Hudthagosol[1], Suwimol Sapwarobol[2], Maneerat Techavichian[1], Yanisa Thapcharoen[1], Promluck Sanporkar[1]

1. Mahidol University (Thailand), 2. Chulalongkorn University (Thailand)

Metabolic syndrome is a group of interconnected metabolic risk factors that increase the risk for developing cardiovascular disease, type 2 diabetes, obesity, and all-cause mortality. Some studies have shown that consuming soy product could decrease lipid profile since soy contains beneficial components such as isoflavones, polyphenols, and other phytonutrients. The current study aimed to comprehensively evaluate the potential effects of milk and soy milk consumption on cardiometabolic risk factors and blood calcium concentration on metabolic syndrome adults. Seventy participants with metabolic syndrome were randomized in 4 groups: group 1 received cow milk daily, group 2 soy milk with milk powder, group 3 high calcium soy milk, plain, no sugar added, and group 4 high calcium soy milk, multigrain, no sugar added. Groups 1

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

and 2 consumed 500 ml of milk daily, while groups 3 and 4 consumed 460 ml of milk daily. Milk and soy milk were consumed twice daily 15-30 minutes before breakfast and dinner for 8 weeks. Blood serum lipid and blood calcium concentration was determined at weeks 0, 4 and 8. One way repeated measures ANOVA and Friedman two-way analysis of variance were used to analyze the differences within each group. One way ANOVA and Kruskal-Wallis test were used to analyze the differences between groups, and statistical significance was defined at p-value <0.05. The results of within-group comparisons revealed that all 4 types of milk significantly raised HDL-cholesterol at week 8. For soy milk with milk powder and high calcium soy milk, plain, no sugar added, significantly reduced LDL- cholesterol. The between-group comparisons showed that LDL-cholesterol for the high calcium soy milk, plain, no sugar added group was significantly lower those for that in the cow milk and high calcium soy milk, multigrain, no sugar added group. Blood calcium concentration was significantly increased in all groups except soy milk with milk powder group. Therefore, consuming cow and soy milk and could improve serum lipid profile and blood calcium concentration.

Human DNA methylation trajectories of the postprandial metabolic response to food

Ricardo Costeira[1], Lidia Daimiel Ruiz[2], Lucy Sinke[3], Colette Christiansen[1], Bastiaan Heijmans[3], Eline Slagboom[3], Melanie Waldenberger[4,5], Sarah Berry[1], José M Ordovás[2,6,7], Jordana T Bell[1]

1. King's College London (UK), 2. IMDEA Food (Spain), 3. Leiden University Medical Center (Netherlands), 4. German Research Center for Environmental Health (Helmholtz Zentrum München) (Germany), 5. German Research Center for Cardiovascular Disease (DZHK) (Germany), 6. Tufts University (USA), 7. University Camilo José Cela (Spain)

Background and objectives: Diet and postprandial markers of metabolic flexibility are major determinants of cardiometabolic health. The postprandial response is highly individualised, and molecular mechanisms underlying this variability are not well characterised. DNA methylation (DNAm) is a key regulator of gene function with potential to modulate the personalised metabolic responses after food intake. Within the JPI-DIMENSION consortium, we characterised human DNAm changes over the postprandial response, and explore their impacts on genes linked to metabolism and disease.

Methods: We profiled whole blood DNAm using the Infinium MethylationEPIC Kit in 360 samples from 120 individuals in the PREDICT1 study of postprandial metabolic responses in healthy individuals. Samples were profiled at baseline and after food intake, comparing changes in DNAm from fasting state (t_0) to peak glycemia (t_{30m}), and to peak lipemia (t_{4h}). Changes specific to peak lipemia were also explored in the baseline postprandial phase of the CORDIOPREV study, a randomized clinical trial involving patients with coronary disease. We profiled DNAm in 300 samples from 150 CORDIOPREV individuals at fasting and 4h. Changes in DNAm trajectory postprandially were tested in both samples at >756,000 CpG-sites genome-wide, using linear mixed-effects models adjusted for sex, age, BMI, smoking, blood cell composition, technical covariates, and family structure. Results are presented after multiple testing correction (FDR=10%).

Results: Overall, 19 differentially methylated positions (DMPs) showed postprandial trajectory changes in PREDICT1. The peak signal was in the *CAMTA1*ge ne, with decreased methylation at 30m after test meal (cg23021268; *b*=0.311±0.050, *p*=2.40E-08). PREDICT1 and CORVIOPREV meta-analysis identified 125 DMPs across 94 genes that changed postprandially at 4h, including in the cholesterol efflux gene *ABCG1*(cg27518648: *b*=0.078±0.016, *p*=1.11E-06). Pathway analysis identified enrichment in the PKA pathway, as well as in pathways of cardiac and metabolic signalling. Ongoing analysis include sex-specific components and transcriptomic profiling of 50 individuals of the PREDICT1 sample which link specific expression changes to DNAm trajectories.

Conclusions: In summary, we observe significant changes in DNAm levels at target genomic regions postprandially. Signals include both changes at peak glycemia and peak lipemia, and target metabolically relevant genes, with insights towards mechanisms mediating inter-individual variation in response to food.

Conflict of Interest Disclosure: Sarah Berry is a consultant for Zoe Global Ltd (associated with the PREDICT1 study).

OAB(T4)6-7

Nutrition and lifestyle behavioural changes in metabolic syndrome: Experience from a peer-led community-based intervention in Malaysia

Amutha Ramadas[1], Muhammad Daniel Azlan Mahadzir[1], Saleem Perwaiz Iqbal[1], Kia Fatt Quek[1], Khalid Abdul Kadir[1]

1. Monash University Malaysia (Malaysia)

Background and objectives: Peer-led programs benefit people with chronic diseases such as metabolic syndrome (MetS), which requires long-term intervention and social support. However, there is a lack of evidence on a peer-led behavioural change program to address the growing prevalence of MetS among Malaysians. This study aimed to develop a structured peer-led intervention for Malaysians with MetS addressing nutrition and lifestyle behavioural risk factors.

Methods: The study was conducted in three phases. Phase 1 included evidence synthesis and a cross-sectional study to identify modifiable risk factors for MetS in this population.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Subsequent Phase 2 focused on developing the community-specific peer-led intervention (PERSUADE), and the feasibility of PERSUADE was assessed in the third phase.

Results: The overall prevalence of MetS was 32.2% (*N*=481). Low physical activity (OR=4.76, 95%CI=1.49-15.26) and quick finishing of meals (OR=2.17, 95%CI=1.02-4.60) were mostly associated with increased odds of MetS. These findings and the outcomes of evidence synthesis were amalgamated with existing guidelines to result in a 12-weeks PERSUADE program. Four peer groups comprising 48 peers (median age=46 years) participated in PERSUADE. Although there were significant overall increases in total carbohydrate intake and glycemic load (both p <0.001), we noted significant reductions in the intakes of total energy and fat (both p <0.001). Physical activity (total METS/week) also showed a significant improvement (p <0.001). Overall, significant but marginal improvements in anthropometric and vital metabolic parameters were observed. More than 81% of the peers attended all sessions, with high satisfaction with the content (93.3%). More than two-thirds of the peers were satisfied with peer leadership. Content satisfaction was correlated with reduction in body fat content (r=0.348, p=0.015) and triglyceride (r=0.431, p=0.002). Peer leadership, however, was only correlated with a reduction in triglyceride (r=0.363, p=0.011).

Conclusions: This was the first of such efforts to develop and test the feasibility of a community-based peer-led intervention for MetS in the country. PERSUADE supported the adoption of the peer-based framework though there is a need to assess the long-term impact of such interventions in local community settings. Findings from this study also set the direction for other researchers to develop various other intervention models in Malaysia.

OAB(T5)1-1

Effects of video-based health education on birth outcomes and anemia status of mothers in Dirashe District South Ethiopia: cluster randomized controlled trial

Wanzahun Godana Boynito[1,2], Kidus Temesgen[1], Yordanos Gizachew[1], Godana Yaya[1], Tsegaye Yohanis[1], Stefaan De Henauw[2], Souheila Abbeddou[2]

1. Arba Minch University (Ethiopia), 2. Ghent University (Belgium)

Background and objective: Maternal undernutrition during pregnancy is associated with poor birth outcomes. Guidelines on recommended nutritional and health practices are designed and implemented in low and middle income countries through perinatal community services. However, coverage and adherence are suboptimal. Behavior change communication (BCC) during pregnancy using videos can overcome the limitations of coherence of messages delivered by the health extension workers (HEW) and might increase the coverage of- and the adherence to the video-based BCC. This study aims to assess the effects of video-based BCC on anemia status of pregnant women and birth outcomes.

Methods: This cluster randomized controlled trial was conducted in rural communities of Dirashe District, Southern Ethiopia. **Pregnant women** from 16 communities were included in their first trimester (n=596) and were assigned to receive either standard BCC messages by HEW (Control, eight communities) or via videos projected at the household during the six-month intervention till delivery (VideoHealth). There were ten videos covering maternal and infant nutrition and health. Groups were compared for birth outcomes and maternal anemia using analysis of co-variance.

Results: At baseline, women were (mean ± SD) 25.1±5.4 years of age, 46.3% did not have any formal education and 6.7% had hemoglobin concentration (Hb) < 11.0 g/dL. From all pregnancies, 6.2%, 2.2% and 17.9% ended in miscarriage, preterm birth and still birth respectively. Maternal Hb near delivery was12.9±0.06 g/dL and 13.1±0.07 g/dL in Control and VideoHealth groups, respectively (p=0.003). Mean birth weight was 3004 ±440 g in Control group and 3191±490 g in VideoHealth group (p=0.027). One-in-five women used maternity waiting homes and 70.6% of births were attended by skilled health personnel in the VideoHealth group *vs.* one-in-ten (p=0.002) and 50.2% (p=0.001) in the Control group.

Conclusions and Implications: Video-based BCC improved the utilization of maternity waiting homes and institutional delivery. It has also significantly increased birth weight and maternal Hb near delivery. Additional analyses will assess the effectiveness of the intervention to increase adherence to the recommended care during pregnancy.

Effect of maternal mentoring program on improving iron and folic acid intake among Indonesian pregnant women: cluster randomized trial

Yhona Paratmanitya[1], Siti Helmyati[2], Detty Siti Nurdiati[2], Hamam Hadi[1]

1. The University of Alma Ata (Indonesia), 2. Universitas Gadjah Mada (Indonesia)

Background and objectives: Anemia is major nutritional problem in Indonesia. Based on Indonesian Basic Health Survey 2018 the prevalence of pregnancy anemia is 48,9%. The mentoring program for mothers that has been carried out since

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

the preconception period is expected to improve the iron status of the mother during pregnancy. The present study aims to determine the effect of a mentoring program since preconception period on the iron and folic acid intake among pregnant women in Bantul, Indonesia.

Methods: This cluster randomized controlled trial was conducted in Sedayu, Pleret, and Pajangan subdistricts of the Bantul District. A total of 128 clusters divided into 61 clusters per treatment arm. At the baseline, there were 322 samples, of which 205 were later confirmed pregnant and 194 were admitted to the end of the study. The intervention group received mentoring program, while the control group only received usual services from the Public Health Center. The mentoring program consist of health education, monitoring, and text-messages reminder. Mentoring was carried out from the preconception period, then followed up to 12 weeks of gestation. Iron and folic acid intake were measured twice, in the preconception period and between 13-16 weeks of gestation by using Semi Quantitative Food Frequency Questionnaire. Statistical test using T-test and Mann-Whitney test, with statistical significance at α=0.05.

Results: The results showed that in the intervention group, the mean intake of iron increased by 1.64 mg/day (p=0.001) while folic acid intake increased by 39.48 mcg/day (p=0.003). At the cluster level, respondents in the intervention group on average consumed 10 iron tablets more than the control group, but the difference was not statistically significant (34,57±15,11 vs 24,13±13,42; p=0,069).

Conclusions: Mentoring program since the preconception period can have positive impact on the iron and folic acid intake in pregnancy. This program can be suggested to be implemented in the other areas that still need improvement in iron and folic acid consumption.

Learning to respond to social norms to improve maternal and child nutrition

Neha Jhaveri[1], Katherine Dickin[1]

1. USAID Advancing Nutrition (USA)

Background and objectives: Food choices and child feeding practices are deeply embedded in gender, social and cultural norms. These social norms influence the meaning and value of food, as well as roles and expectations for each person.

Through this session, participants will do the following: Identify social norms relevant to behaviors to improve women's and children's diets.

Summarize evidence on effectiveness of social norms-focused interventions on nutrition outcomes.

Describe approaches to foster social norms that support recommended nutrition outcomes.

Access resources to understand and respond to social norms.

Methods: A systematic review collected what is known about social norms and nutrition and then identified gaps and implications for program and research on social norms and women's diets. Searches included PubMed, Scopus, Web of Science, and CINAHL, and unpublished reports through USAID's Clearinghouse and program listservs. The findings from the systematic review informed development of a step-by-step program guide, based on the findings, helps practitioners understand and respond to social norms to improve women's and children's diets. Programs in northern Ghana and in Niger are refining the guide based on user testing.

Results: The literature documents that social norms influence what food, how much food, and how children are fed. Norms also influence what food, how much, and when women can or cannot eat. Although women are usually tasked with food preparation and feeding, cultural norms in many contexts limit decision-making on food allocation or the ability to go against elders. The review found a growing trend among programs to include strategies to address social and cultural norms in nutrition and evidence for positive change, although the evidence is still limited. Norms-focused approaches combine community engagement and innovative media, reaching multiple family members or whole communities.

Conclusions: Nutrition practitioners can improve outcomes by responding to underlying social norms, whether positive or harmful. Local input and partnerships are key for considering social norms within broader cultural contexts and avoiding stigma or over-simplification.

Women's and family members' experience of participating in a practical demonstration based maternal nutrition education intervention: Qualitative evidence from rural Bangladesh.

Neeloy Ashraful Alam[1], Morseda Chowdhury[2], Michael J Dibley[1], Camille Raynes-Greenow[1]

1. The University of Sydney (Australia), 2. BRAC, (Bangladesh)

Background and objectives: Maternal under-nutrition is widely prevalent in South Asia, including Bangladesh. Undernutrition is associated with an inadequate food intake but choosing appropriate amounts of different foods is crucial. We developed a nutrition behaviour change communication to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

promote a balanced diet in pregnancy in rural Bangladesh and tested the impact with a cluster randomized controlled trial. The nutrition education was delivered through practical demonstrations of a balanced plate with appropriate portion sizes. As part of the evaluation, we conducted qualitative assessments to examine the barriers and coping strategies to adhere to the intervention from the perspectives of women, families and providers.

Methods: We conducted in-depth interviews (n=24) with pregnant women, recently-delivered women, and husbands; focus groups with mothers-in-law (n=7), and key-informant interviews (n=6) with community health workers who provided the nutrition education intervention.

Results: We revealed differences in experience reported by women, mothers-in-law and husbands regarding participating in the intervention. Pregnant women experienced visual presentation effective in recalling messages and easy to apply in practice. They often needed to borrow certain food items to make the balanced plate which supported a culture of food sharing. Some mothers-in-law found the messages contradictory to their traditional knowledge but accepted them considering the wellbeing of an unborn grandchild. Husbands felt the practical demonstration of portion seizes as an innovative and unconventional approach to nutrition education and were attracted to participate. Health workers regarded the intervention as an expansion of opportunity to engage with the community and use their professional training and everyday experience to educate their local community. Dominant barriers to complying with the intervention included financial constraints and scarcity of animal source foods. To cope with the additional costs for pregnant women's balanced diet, families often adjusted the budget or sourced freely available or cheaper local alternative produce.

Conclusions: Maternal nutrition intervention through practical demonstration of portion sizes has potential for high uptake and adherence. Interventions should utilize local food culture, and engage families and community health workers to mobilise social support to create an enabling environment to bring changes in dietary habits to optimise maternal nutrition.

Insights from community health workers on persuasive counseling of family members to improve maternal nutrition and breastfeeding behaviors in rural Bangladesh

Gargi Wable Grandner[1,2], Kathleen M Rasmussen[2], Katherine L Dickin[2], Purnima Menon[3], Tiffany Yeh[4], John Hoddinott[2]

1. The George Washington University (USA), 2. Cornell University (USA), 3. International Food Policy Research Institute (India), 4. University of North Carolina (USA)

Background and objectives: Community health workers (CHWs) increasingly provide nutrition education and counseling to childbearing women and their families to improve adoption of recommended maternal and child nutrition behaviors. Little is known about CHWs' first-hand experiences garnering family support for improving nutrition practices in low-resource settings. Using focused ethnography, we aimed to draw insights from CHWs on strategies they employed to persuade family members to support recommendations on maternal diet, rest, and breastfeeding in a behavior change communication intervention in rural Bangladesh.

Methods: We interviewed 35 CHWs providing at-home nutrition education and counseling to rural pregnant women and their families in seven 'Alive & Thrive' intervention sites across two resource-poor districts in northern Bangladesh. In-depth probing focused on how CHWs addressed beliefs around maternal diet, rest, and breastfeeding, cultural food practices during pregnancy and postpartum, and lack of family support. Thematic coding based on Fisher's narrative paradigm revealed strategic use of three rhetorical principles by CHWs: *ethos* (credibility), *pathos* (emotion) and *logos* (logic).

Results: In addition to pregnant women, all CHWs reported educating male and female adults during home visits. CHWs selectively targeted husbands and mothers-in-law for counseling given their influence on behavioral adoption as food procurers and family health and nutrition advisors, respectively. Several CHWS identified the cultural belief of restricting gestational food intake and rest to avoid cesarean delivery as an important challenge. CHWs reported that families were motivated to support maternal food intake and breastfeeding when they heard about benefits like improved fetal growth and child intelligence while improved maternal health was the least motivating outcome, even among mothers. Logically coherent messaging resonated well with husbands, while empathetic counseling was additionally required for mothers. Mothers-in-law were most intransigent but were persuaded via emotional appeals. Persuasion on maternal rest was most effort-intensive, resulting in contextually appealing but scientifically inaccurate messaging ('mother rests, baby rests').

Conclusions: Our study demonstrates that CHWs can offer important insights on context-relevant, feasible counseling strategies to improve family support and uptake of nutrition recommendations. It also identifies need for focused CHW training and monitoring to address persuasive but scientifically-flawed counseling narratives.

Usage of Local Traditional Food for Food Education at Kindergarten to Improve Students' Food Literacy

Katsura Omori[1], Yu Inoue[1], Hiromi Okuyama[2]

1. Yamagata University (Japan), 2. Yamagata University Kindergarten (Japan)

Background and objectives: In Japan, the Basic Act on *Shokuiku* (Food and Nutrition Education) was established in 2005, and food education has been promoted nationwide for all ages. Food literacy including knowledge and skills regarding healthy eating is significant for lifelong well-being and it can begin to be taught at young age. At the same time, usage of local traditional food as learning subjects would support not only local agriculture but also sustainable food systems in our society. The objective of this research is to evaluate the effects of food education that utilizes local traditional food in order to enhance young children's food literacy.

Methods: The participants were thirty students aged 5-6 years old. We selected a famous local traditional food, green soybeans (*Edamame*), as a learning subject. Our food education program was implemented at a local kindergarten from June to October, 2021 in Yamagata prefecture, Japan. The program contained four lessons in which students learned about soybeans' nutrition and various products made from it. Students also participated in preparing and eating green soybeans together. For assessment of this program, we prepared quizzes and investigated how the students' understandings about soybeans changed after learning. We also asked the students' parents to answer a questionnaire about daily meal preparation at home.

Results: After our program, the percentage of the students who could correctly answer the quiz about the nutritional characteristics of soybeans increased from 10.0% to 60.0%. Also, their knowledge about its growing processes and soybeans-derived products improved. These results suggested that their food literacy improved through our program. From the questionnaire it was found that more than 90% of the parents used local farmers' markets to buy food for family meals.

Conclusions: Agricultural areas like Yamagata prefecture may have many resources and advantages when it comes to teaching children about healthy and sustainable eating by way of locally grown fresh food. It can be expected that food education at kindergarten could enhance young children's food literacy more effectively by integrating it with family eating habits at home.

Indonesian Adolescent Girls Are Aware of the Importance of Healthy Eating and Physical Activities but Having Limited Knowledge on Balanced Diet

Marini Amalia Mansur[1], Rahayu Indriasari[1], Muhammad Rachmat[1]

1. Hasanuddin University (Indonesia)

Background and Objectives: Adolescent girls in Indonesia are facing various nutritional problems, such as anemia and unhealthy eating habits. This is often driven by inadequate knowledge and misconception about health and nutrition. Our study aims to explore Indonesian adolescent girls' perspectives on general health, nutrition, and balanced diet.

Methods: This study is part of a larger study to develop nutrition education apps to prevent anemia among adolescent girls from low-mid social-economic. A Qualitative approach using Focus Group Discussion (FGD) was applied to explore perceptions of 23 adolescent girls. FGD was conducted in three batches with 7-8 participants in each FGD. Each FGD was recorded upon the permission of participants and transcribed verbatim, then analyzed using thematic analysis.

Results: Adolescent girls revealed that health is an essential aspect of their lives and perceived health as an investment for their future. Health is perceived as an asset for the future to prevent non-communicable diseases in later life and to generate a better generation. Furthermore, they define maintaining healthy eating and physical activities as an effort that can be performed to achieve a healthy life. Although adolescent girls are aware of the benefit of healthy eating and physical activities on health, they have an uncomprehensive understanding of healthy eating and balanced diet. When asked about healthy foods, adolescent girls mentioned fruits and vegetables along with high-priced foods such as milk and meat as healthy foods. Empat Sehat Lima Sempurna (Four Healthy Five Perfect), previous Indonesian dietary guidelines, was mentioned as definition of healthy eating. On the other hand, no one of the adolescents identified Gizi Seimbang (Balanced Diet), the current Indonesian dietary guidelines which developed based on the nutritional needs of each age group, as healthy eating. In addition, adolescents are facing several barriers in developing a healthy lifestyle, such as skipping meals due to poor time management, picky eating habits, peer influence, food availability and affordability, and sedentary habit.

Conclusion: Our study highlights the urgency of nutrition education for adolescent girls, specifically on the promotion of balanced diet and affordable healthy foods. Moreover, it should also cover practical and barriers management aspects.

Nutrient Quality of School Meals and their Contribution to RDAs of Children, Multi Sectoral Approaches for Sustainable School Feeding Programmes in Uganda

Robert RF Fungo[1,2]

1. Makerere University (Uganda), 2. International Center for Tropical Agriculture (Uganda)

Background and objectives: School going children face a complicated period of growth and development, which remarkably affects their health and productivity. Out of the 15 million children in Uganda, about 12 million suffer from malnutrition with 29% being stunted and 11% underweight. Government nutrition interventions have limited focus on school feeding.

Methods: This study documented the various school feeding programmes, the successes and challenges experienced in implementing the programmes. Four levels of assessment were conducted and included: I conducting 11 key informant interviews, II conducting 45 focus group discussions III carrying out indicator-based observation evaluation of facilitates and IV evaluating the nutritional quality of school meals among 225 school going children.

Results: Two forms of feeding programmes: parent led and home grown, school feeding programmes were implemented concurrently. This is possible through the financial and in-kind contributions made by parents. In some districts, school feeding is enforced through local government ordinances. All students benefitted from the existing school feeding programmes. Parents with children in secondary schools had less difficult in making contribution towards school feeding. About 90% of the learners ate food items from 2-4 food groups (cereals, pulses and legumes, vegetables and bulbs). Children in all categories of schools were supplied with sub optimal daily nutrients (energy, proteins, vitamin A and iron) from school meals. Nationally, school children were only accessing 28% of their energy needs, 64% proteins requirements and 42% of iron requirements. School meals provide about 40 to more than 100% vitamin A requirements about 40-62% of iron requirements and about 30% daily energy requirements.

Conclusions: In order to improve school feeding in the country there is need to enhance coordination and stakeholder engagement; improve the nutrient content of school meals and engage stakeholders to change their attitudes and practices toward healthy eating. The current school feeding and nutrition guidelines need to be reviewed holistically using multi-sectoral approaches. There is need to strengthen local and community focused school feeding, including establishment of local committees and implementing school feeding where appropriate.

Agricultural based projects in conjunction with nutrition education enhance dietary diversity of women and children in Tanzania

Joyce Kinabo[1], Peter Mamiro[1], Theresia Jumbe[1], Akwilina Mwanri[1], Lufingo Mwakatobe[1], Abdalla Hussein[2], Augustine Malero[2], Abbas Ismail[2]

1. Sokoine University of Agriculture (Tanzania), 2. University of Dodoma (Tanzania)

Background and objective: Agricultural programmes have traditionally focused on increasing the availability of food rather than promoting consumption and improving nutrition status. This study examined the effect of nutrition sensitive interventions on dietary diversity of women and children. It hypothesized that agriculture can improve diets of women and children through vegetables and chicken production for household consumption if coupled with nutrition education.

Methods: A cluster randomised study design involving 1762 households evaluated the effect of nutrition education, chicken and vegetable production on consumption. Study villages were allocated to three treatment arms namely, vegetable + chicken, chicken only and Control. The vegetable + chicken villages obtained improved chickens and a package of nutrition education to promote behaviour change and resources for household vegetable production. The chicken only villages obtained improved chickens without a package of nutrition-sensitive interventions, and the Control villages did not receive any of the treatments. Data were collected from central semi-arid, eastern sub-humid and southern highlands agro-ecological zones using mobile devices on ODK system.

Results: The mean general nutrition knowledge score at endline was 2.1 for the control, 3.0 for chicken only and 3.1 for vegetable + chicken ($p<0.0001$) treatment arms. Mean household dietary diversity score at endline was 5.6 compared to 5.2 at baseline. Household dietary diversity score (HDDS) was significantly higher in chicken only ($\beta=0.3274$, $p=0.0278$) and vegetable + chicken ($\beta=0.3434$, $p=0.0193$) treatment arms compared to the Control treatment arm. The increased HDDS was significantly associated with zones ($p=0.0239$) and ownership of improved chickens ($p=0.0002$). Women's dietary diversity score at endline was higher in chicken only and vegetable + chicken treatment arms compared to the Control treatment arm. Consumption of more than four food groups among children increased from 48% at baseline to 75% at endline contributed by cereals, oils and fats, fruits, vegetables, chicken meat and eggs.

Conclusion: Both crop and livestock projects improved consumption of diversified diets for women and children more with nutrition education intervention than on their own. Clearly, development of agricultural interventions needs to incorporate nutrition considerations in the planning and implementation of activities to ensure improved agricultural productivity and nutrition.

OAB(T5)2-4

Fruit and vegetable consumption practices among Pacific and New Zealand European women with different body composition profiles

Rozanne Kruger[1], Amy Richter[1]

1. Massey University (New Zealand)

Background and objectives: Obesity is a major health concern in New Zealand (NZ) and is closely related with diet. Current fruit and vegetable consumption practices of NZ women are unclear. This study investigated fruit and vegetable intake and consumption patterns of Pacific and NZ European (NZE) women with different body composition profiles.

Methods: Women (142 Pacific; 161 NZE) living in Auckland were recruited. Fruit and vegetable intake were isolated from 5-day Food Records and 7-day Dietary Diversity Questionnaires. Anthropometric measures and Dual X-Ray Absorptiometry were used to assess body composition. Spearman's rho correlation coefficients and multiple linear regressions were used to analyse the relationship of fruit and vegetable serves and body composition, and to analyse predictors of body composition.

Results: Combined daily median fruit and vegetable serves differed significantly between normal BMI women (Pacific: 3.24 (2.33, 4.26) and NZE: 4.70 (3.71, 6.35). Among obese BMI women, NZE ate significantly more servings of vegetables (2.81 (1.77, 3.93) than Pacific (1.92 (1.35, 3.27). Combined daily- and vegetable servings, adjusted for age and ethnicity, were inversely correlated with BMI (-0.15, -0.16) and BF% (-0.21, -0.20) respectively, particularly for green (-0.14, -0.18) and yellow Vitamin-A-rich (-0.12, -0.14) and cruciferous (-0.13, -0.18) vegetables. Every one serve (75g) of vegetables predicted a 0.65kg/m^2 reduction in BMI and 1.16% reduction in BF% for women combined (P<0.01). Most women did not consume recommended fruit and vegetables servings, independently of ethnicity, BMI or BF%. NZE consumed significantly more yellow vitamin-A-rich and cruciferous vegetables; Pacific consumed more starchy vegetables. Pacific women consumed the highest servings later in the day (Lunch, Afternoon tea, Dinner) than NZE (Breakfast, Lunch, Dinner) (P<0.01). Most consumed vegetables and fruit were carrots, onions, lettuce, tomatoes and potatoes, and bananas and apples. No differences in energy or nutrient intakes were observed between BMI and BF% groups within ethnicities. However, comparatively, women with normal BF% had increased total carbohydrate and total sugar intakes from fruit and vegetables.

Keywords: Fruit and vegetable recommendations, Diversity, Serves, Meal timing, Nutrient intakes

Conclusion: Daily serves of fruit and vegetables were significantly correlated with body composition despite low overall intake. Pacific and NZE women had significantly different fruit and vegetable intakes and consumption patterns.

OAB(T5)2-5

Achieving a Planetary Health Diet: 'Veggie Monday' School Lunch and the Potential of School Lunch in Japan

Satomi Mizuguchi[1], Yuko Teshima[2,3]

1. Fukushima Prefectural Futaba Mirai Junior High School (Japan), 2. Sanyu Consultants Inc. (Japan), 3. Department of Community and Global Health, Graduate School of Medicine, The University of Tokyo (Japan)

Background and objectives: The aim of school lunch in Japan is not limited to the maintenance and improvement of health. It also includes many elements such as the formation of desirable eating habits, an understanding of traditional food culture, the development of attitudes that contribute to environmental preservation, and a correct understanding of food production, consumption, and distribution. In addition, after the EAT-Lancet Commission Report "Food in the Anthropocene", a Great Food Transformation is required to simultaneously achieve human and planetary health through food systems. We report practical activities through the regular provision of vegetarian meals in school lunch programs in Japan. Vegetarian school lunches are not simply a denial of meat-eating, but also a menu that incorporates many elements, such as helping students overcome their dislike of vegetables and maintaining their health, reviewing the good qualities of Japanese food, gaining knowledge of global food issues, and deepening their understanding of food distribution.

Methods: In line with the global Meat Free Monday movement, vegetarian lunches have been offered at school lunches in public junior high schools in Fukushima Prefecture every Monday since 2019. By implementing nutrition education in conjunction with the provision of vegetarian school lunches, the program aims to deepen students' understanding of sustainable diets and encourage behavioral change.

Results: By implementing vegetarian school lunches on a regular basis, students and parents were able to understand the purpose of implementing the menu. Over 79.9% of the total number of students responded: "very concerned/concerned about food and the environment" on the eating habits questionnaire. Behavioral changes were observed, such as students themselves conducting leftover food surveys and showing appreciation for food. However, the percentage of students with obesity levels of 20% or higher remained unchanged at 16.4%, and it is necessary to promote nutrition education that also involves families.

Conclusions: Regular vegetarian lunches can be provided in school lunch programs, and when combined with nutrition education, students can become more concerned not only about their own health issues but also about global environmental issues.

Assessment of consumer's knowledge, perception and behavior regarding food labels

Aliya Nazhat[1], Mahpara Safdar[1], Faisal Shahzad[2], Hajra Ahmad[1], Zaheer Ahmed[1], Asma Afreen[1]

1. Allama Iqbal Open University Islamabad (Pakistan), 2. University of Engineering and Technology Taxila (Pakistan)

Background and objective: Food label is an effective communication tool. It attracts consumers to select nutritionally appropriate food, and food makers can promote and share elementary information. The aim of this cross-sectional study was to assess consumers' knowledge, perception, and behavior regarding food labels in Mirpur A.K, Pakistan.

Methods: Data was collected from 384 consumers between the ages of 20 and 60 years, comprising both genders. A random sampling technique and a structured questionnaire were used for data collection. The reliability and validity of the questionnaire were assessed using Keiser Meyer Olkin (KMO), the Bartlett's test of Sphericity and Cronbach's Alpha coefficient. Descriptive statistics, Pearson's correlation, and linear multiple regression was used for data analysis.

Results: The results showed that more than half of consumers knew about food labels, half of consumers perceived that reading the food labels is always important, while 24% of consumers always, 18.5% often, and 42.2% sometimes read food labels. *Knowledge*: a sizable portion of consumers had knowledge of brand name and dates, and mostly consumers knew about sugar-free products, ingredients list, calories, fat, vitamins and minerals. *Perception*: more than half of the consumers' perceived that taste and price are always important when buying food. *Behavior*: most consumers always check the expiry date. The Pearson's correlation coefficient is significant at 0.01 and a moderate negative correlation exists between consumer knowledge with perception and behavior, while a moderate positive relationship exists between perceptions with behavior. Multiple regression analysis contributed significantly at $p<0.05$ and eight predicated variables explained 46.1% variation with dependent variables consumers' knowledge, 20.0% variation with consumers' perception and 32.1% variation in consumers' behavior regarding food labels.

Conclusion: The study concluded that mostly consumers have knowledge about brand name, dates, sugar-free products, ingredients list, fat, vitamins, and minerals. Most consumers perceived that price and taste are important and mostly consumers read price and recipe information, difficulty in sub type of fat, serving size, sodium, and CHO. The suggestions for manufacturers to use simple language for consumers and for health professionals and the government to conduct awareness programs regarding food labels.

Teaching activities continued at pre-schools during the COVID-19 pandemic: The case in Subang, West Java, Indonesia

Avita Aliza Usfar[1], Ju Lan Phan[1]

1. Dakra Consultant (Indonesia)

Background and objectives: The objectives of the study were to assess learning implementation by teachers of pre-school students during the COVID-19 pandemic, including whether nutrition related topics were taught, and anthropometric measurements were assessed. The study was conducted in Subang district, West Java province, Indonesia.

Methods: Google online survey platform was used to collect the data in September 2021. Questions related to September 2020 was asked retrospectively.

Results: 139 teachers responded to the questionnaire. In September 2020, 42% of the learning process was organized online, 18% offline (students came to school), and 40% combination of the two methods. In September 2021, 98% were offline. We categorized the learning implementation into four online and three offline channels, namely using Whatsapp, zoom, Google meet, video call, Facebook messenger, attendance by the students, home visit by the teacher, and school visit by the parents. Information from teachers to students were delivered via social media, home visit, or at school. Majority of the teachers used Whatsapp for delivering materials and communication with parents by forming Whatsapp group. Parents played a role in facilitating their children using the social media for online learning. The home visit can be private tutoring for one student or for several students who gathered in one house. The offline method at school was implemented following the government's health protocol. Assignments in the form of videos or pictures were commonly submitted via Whatsapp. Combination of channels were used by the teachers. Dissemination of nutrition topics such as food and washing hands were taught throughout these two time periods. Monitoring of weight and height of the students were commonly done through the village health post (*Posyandu*). Teachers who conducted anthropometric measurements decreased from September 2020 to September 2021 (97% to 83% respectively for weight and 96% to 83% respectively for height).

Conclusions: Teachers implemented various channels to disseminate information to students and parents, adapting to the pandemic. Dissemination of nutrition information continued despite of the limitations.

Dietary diversity modification through school-based nutrition education among Bangladeshi adolescent girls: a cluster randomized controlled trial

Zannatun Nyma[1,2], Mahfuzur Rahman[1], Subhasish Das[1], Md Ashraful Alam[1], Enamul Haque[1], Tahmeed Ahmed[1]

1. icddr,b (Bangladesh), 2. Shiga University of Medical Science (SUMS) (Japan)

Background and objective: Adolescents gain up to 50% of their final adult weight, 20% or more than that of their adult height and 50% of their adult skeletal mass; of this entire growth, most is achieved during the early adolescence. Adolescence is the last opportunity to intervene and break the vicious cycle of inter-generational malnutrition. Previous studies revealed that nutrient inadequacy and inadequate dietary diversity are the major causes of adolescent malnutrition. We aimed to measure the efficacy of school-based nutrition education on dietary diversity of the adolescent girls in Bangladesh.

Methods: A matched, pair-cluster randomized controlled trial was conducted from July 2019 to September 2020. Randomization was done to select intervention and control schools. There were 300 participants (150 in intervention and 150 in control arm) at baseline. We randomly selected our study participants from grade six, seven and eight of each school. Our intervention components included parents' meeting, eight nutrition education sessions, and distribution of information, education and communication materials. An hour-long nutrition education session was provided using audio-visual techniques in a class of intervention school once in a week by trained staff for two months. We calculated mean dietary diversity score of adolescent girls at baseline and at endline.

Results: Mean age of the adolescent girls were 12.31 years and 12.49 years in control and intervention arms respectively. Percentages of consumption of organ meat, vitamin A rich fruits and vegetables, legumes, nuts and seeds were higher in intervention arm than in control arm at end-line. Mean dietary diversity score remained unchanged in control arm 5.55 (95% CI: 5.34 - 5.76) at baseline and 5.32 (95% CI: 5.11 - 5.54) at endline. After intervention, mean dietary diversity increased from 4.89 (95% CI: 4.67-5.10) at baseline to this mean was 5.66 (95% CI: 5.43-5.88) at endline. Result from difference-in-difference analysis revealed that the mean dietary diversity was likely to increase by 1 unit due to intervention.

Conclusion: The study has clearly demonstrated the feasibility of the school-based nutrition education intervention for improving dietary diversity of adolescent girls and so, the intervention should be re-tested on a larger scale.

Should food literacy be a matter of concern among women in a university community in Nigeria?

Motunrayo Funke Olumakaiye[1], Bolanle Rachael Popoola[1], Victor O Olayemi[1]

1. Obafemi Awolowo University (Nigeria)

Background and objectives: Food literacy is a set of skills and attributes that help people with the daily preparation of healthy, tasty, and affordable meals for themselves and their families. Food literacy could impact healthy food provision within the households. The study investigated the level of food literacy using five domains; nutrition knowledge, meal preparation skills, ability to plan daily meals, ability to practice healthy eating and ability to select healthy foods.

Methods: The cross-sectional study was conducted among 203 non-academic female staff of Obafemi Awolowo University, Ile – Ife, Nigeria. Data were collected using a stratified random sampling technique with a well-structured questionnaire. Descriptive and inferential analyses were done using percentages, mean and standard deviation and Pearson's correlation and Chi-square.

Results: The mean age was 45.38 ± 10.98, and 83.7% were married, with a mean household size of 5.12 ± 1.65. About half of the women (55.7%) were rated high in the ability to plan daily meals. Only 41.9%, 18.7%, 36.0% and 39.9% were rated high in nutrition knowledge, food preparation skills, ability to practice healthy eating, and ability to select healthy foods, respectively. The cumulative food literacy score showed that 19.2% of the respondents were rated high and low. Food preparation skills ($r = 0.294$, $p<0.01$), daily meal planning ($r = 0.202$, $p<0.01$), and ability to select healthy food ($r = 0.206$, $p<0.01$) had a positive and significant relationship with nutrition knowledge. The household type also had a positive and significant relationship ($\chi^2= 55.511$, $p<0.001$) with food literacy. Households with more members were thrice more likely to have low food literacy (OR =3.34, 95% CI (0.62-2.75).

Conclusion: Food literacy was low among the women in the study area. Food literacy promotes personal health and well-being and is associated with a healthier diet. A food literacy programme should be established in the university community to provide nutrition education for healthy living.

Food choice motivators and food literacy in relation to diet quality in Japanese adults aged 19–80 years: a nationwide cross-sectional study

Kentaro Murakami[1], Nana Shinozaki[1], Xiaoyi Yuan[2], Ryoko Tajima[2], Mai Matsumoto[2], Shizuko Masayasu[3], Tracy A McCaffrey[4], Barbara E Livingstone[5], Satoshi Sasaki[1]

1. University of Tokyo (Japan), 2. National Institute of Biomedical Innovation, Health and Nutrition (Japan), 3. Ikurien-Naka (Japan), 4. Monash University (Australia), 5. Ulster University (UK)

Background and objectives: Little is known about how motivators of food choice, as well as food literacy, are related to food consumption in free-living settings. We cross-sectionally examined the associations of food choice motivators and food literacy with diet quality in a nationwide sample of 2231 Japanese adults aged 19–80 years.

Methods: We assessed eight food choice motivators (accessibility, convenience, health/weight control, tradition, sensory appeal, organic, comfort, and safety, using a 25-item scale) and food literacy characterized by nutrition knowledge (using a validated 143-item questionnaire), cooking and food skills (using 14-item and 19-item scales, respectively), and eight eating behaviors (hunger, food responsiveness, emotional overeating, enjoyment of food, satiety responsiveness, emotional undereating, food fussiness, and slowness in eating, using the 35-item Adult Eating Behavior Questionnaire). Dietary information was collected using a validated brief-type diet history questionnaire, and diet quality was assessed using the Healthy Eating Index-2015 (HEI-2015). All the variables were included into a sex-specific multiple linear regression model simultaneously, as well as age, body mass index (based on self-reported weight and height), and the ratio of energy intake to estimated energy requirement. The variance inflation factor scores for any variable in any model (range: 1.11–3.91) were within acceptable limits (<10), suggesting that multicollinearity was not an issue. Regression coefficients (β) were calculated as the change of the HEI-2015 with 1-SD increase of each variable.

Results: The mean (± SD) HEI-2015 was 55.5 ± 6.5 for males (*n* 1068) and 57.2 ± 6.6 for females (*n* 1163). HEI-2015 was positively associated (P <0.01) with food choice motivators of health/weight control (β: 0.82) and organic (β: 0.82), nutrition knowledge (β: 0.49), and slowness in eating (β: 0.52) and inversely with food fussiness (β: −1.17). In females, HEI-2015 quality was positively associated (P <0.05) with food choice motivators of health/weight control (β: 0.79) and safety (β: 0.54), nutrition knowledge (β: 0.44), and cooking skills (β: 0.67) and inversely with a food choice motivator of accessibility (β: −0.43), emotional overeating (β: −0.42), and food fussiness (β: −0.47).

Conclusions: These findings would provide a basis for developing more targeted and effective strategies for healthy eating.

OAB(T5)3-5

Assessment and modification of food and physical activity environment (FPAE) of Workplaces as a part of a Workplace Wellness Programme (WWP)

Paromita Banerjee[1], Bhanuprakash Gee Reddy[1], SubbaRao Maruthi Gavaravarapu[1]

1. Indian Council of Medical Research-National Institute of Nutrition (India)

Background and objectives: The workstyle of Information Technology (IT) employees in India is dominantly sedentary and exposes them to obesogenic environment, contributing to the growing rate of Non-Communicable Diseases (NCDs). The workplace environment influences physical, mental and social well-being of employees and potentially impacts their health-related behaviour. Turning workplaces into effective locations through Workplace Wellness Programs (WWPs) can contribute in prevention of NCD risk factors. The objective of this study was to assess the food and physical activity environment (FPAE) of the workplaces and to modify it by implementation of a flexible and strategic WWP model.

Methods: The FPAE of the workplaces was evaluated using a 36-item checklist developed by modifying and contextualising the guidelines issued by WHO and Food Safety and Standard Authority of India (FSSAI). Ground Truthing - a systematic on-field surveying method - was used to assess the availability, promotion of healthy food items, presence and utilisation of physical activity facilities, strategies for creating stress-free environment. The FPAE of three IT companies of varied sizes [Big-(A), medium-(B), small-(C)] located in Hyderabad, the IT hub of India were assessed. A multi-component WWP model with interventions at individual, interpersonal and organisation levels was developed and implemented. At organisational level, modification of FPAE was attempted to create an enabling environment for promoting healthy lifestyles.

Results: On the 36-point checklist, company A, B, C scored 21, 12 and 7 respectively. Ground truthing revealed healthy foods were neither available nor primed in the cafeterias of the companies. Physical activity facilities were not uniform in all companies. Even in places where they were available, they were under-utilized. Voluntary participation in the intervention program was 13.4%. FPAE modifications introduced were - replacing beverage vending machines with healthier options, priming healthy foods in cafeterias, promoting stair usage instead of elevators, post-lunch walk breaks. Positive motivation and active involvement of employees and management was observed resulting in minor changes in BMI and triglyceride levels of the employees.

Conclusion: The WWP modifying the FPAE along with health education at employee level resulted in healthy behaviour changes at the workplaces.

Empowering communities to transition to healthier, more diverse diets – insights from Turkana County

Francis Odhiambo Oduor[1,2], Irmgard Jordan[1], Céline Termote[1]

1. Alliance of Bioversity International & CIAT (Kenya), 2. University of Nairobi (Kenya)

Background and objectives: Participatory approaches, described as a group of approaches or methods that enables rural people to analyze their resources/assets, share and enhance their knowledge enabling them to plan and act on their own development/future are gaining importance in many disciplines including nutrition sensitive agricultural programming. The integrated community-based approach for farm, market and diet diversify was first conceptualized and tested in the Humid tropics of Western Kenya. The present project aims to pilot – test the approach in a contextually different Turkana County in Kenya, an area inhabited by transhumance pastoralists and characterized by high temperatures, unreliable and erratic rainfall and frequent droughts.

Methods: The study was conducted within the framework of a cluster – randomized control study design. From the 17 communities sampled for the baseline survey, 10 community groups (382 households) were randomized to receive treatment delivered in two phases: a) participatory intervention co-creation phase implemented through six community workshops in each of the communities resulting in the development of community action plans (CAP) for farm and diet diversity, and b) participatory intervention implementation and monitoring phase where the communities implemented interventions and received nutrition counseling as outlined in the action plans with targeted technical support.

Results: At baseline, only 5% of the households surveyed had kitchen gardens. During the CAP co-creation phase all 10 community groups decided to go for kitchen gardening. Additionally, 4 and 2 communities respectively implemented village savings and loaning (VSL), and poultry rearing. Monitoring reveals 100% adoption rates of kitchen gardening among the group members, but low adoption of poultry rearing (22%). The number of indirect beneficiaries with kitchen gardens also increased. A total of KES. 600,880 ($ 5,500) was saved in the VSL activities and 194 households benefited from loans extended to them as start up for small businesses and paying children's school fees.

Conclusion: Evidence from project monitoring shows that it is quite likely the project had a positive impact on the diets, incomes and livelihoods of the communities which demonstrates that the approach can equally work in difficult contexts such as Turkana. An endline evaluation is planned to take place in the coming weeks.

Keywords: participatory approaches, Turkana, diet diversity, farm diversity

The role of gender on the food environment in Ghana in relation to households food acquisition and consumption

Vivian Ayamah[1], Charles Apprey[1]

1. Kwame Nkrumah University of Science And Technology (Ghana)

Background and Objectives: Gender dynamics play a significant role in household food security and consumption. The main objective of this study was to determine food acquisition and consumption differences between households where a man or woman is in charge of food acquisition. The study also sought to determine the gender roles within food value chains of six major food commodities to determine where gender-specific policies can target.

Methods: A household food frequency questionnaire was used to assess the food consumption patterns in households and obtain information on household food sourcing. On the food value chain, six commonly consumed foods, three health-promoting foods, and three non-health promoting foods were used in the study to know their wholesale and retail patterns by the gender groups. The snowball and purposive sampling techniques were used to identify food retailers and wholesalers of the six identified food commodities. Two communities were selected; one rural and one urban community. Household members above 18 years who were knowledgeable about household food consumption were selected for the study.

Results: Poverty was higher in female-headed households compared to male-headed households. The findings reflected that 63% of the total female respondents reported low risk but vulnerable which is similar to that of the male where the majority, 62.7% of the total male respondent were low risk but vulnerable as well. For Lived Poverty Index (LPI), female respondents had the highest deprivation level due to poverty 40.32% while the male was 27.41. Generally, women recorded the highest 99% seldom consumption of obesogenic promoting foods compared to men with 95.6% in seldom consumption of unhealthy food. The findings on the food chain value depicted that on a scale of 50 to 70%, 55.8% of the respondent said more men are into the production of food commodities compared to women whereas 29.9% of respondents said 50 to 70% of producers are women.

Conclusion: It is necessary that we do not overlook the important role gender plays in the food chain value, household food acquisition, and consumption based on the findings from the study.

Empowerment Model in Randomized Control Trial to Increase Vegetable Intake and Achieve Glycemic Control in Indonesian Adults with Type 2 Diabetes Mellitus

Shot Yen Tan[1], Endang S Basuki[2], Min Kyaw Htet[1,3], Umi Fahmida[1]

1. Southeast Asian Ministers of Education Organization-Regional Centre for Food and Nutrition (SEAMEO-RECFON), Jakarta, (Indonesia), 2. Department of Public Health, Faculty of Medicine, University of Indonesia (Indonesia), 3. Sydney School of Public Health, Sydney Medical School, The University of Sydney, Sydney NSW 2006 (Australia)

Background and objectives: Life style changes, particularly in dietary patterns have contributed a great deal to the incidence and risks of type 2 diabetes mellitus. There are barriers in consuming vegetables, i.e. non-existing habit, taste and servings, besides cognitive aspects on carbohydrate choices and food preparation techniques. Mediating variables that impede or facilitate self-dietary care of diabetes may include the level of social support, the degree of self-efficacy and the individual's time management skills. Facilitating behavioural change from non-adherence to adherence is essential. A coaching approach can be used to encourage positive choices, develop self-sufficiency and assist people in identifying and overcoming barriers. The study aims to investigate the effectiveness of The Empowerment Model to enhance vegetable intake in adults with type 2 diabetes mellitus to achieve glycemic control.

Methods: This is a 12-week mixed methods research, applying both quantitative and qualitative data in a single study. Qualitative study was embedded within quantitative methodology which was a two-arm non blinding randomised controlled trial. Individuals with known type 2 diabetes and poor glycemic control (HbA1c ≧8 g%) were eligible and a total of 84 subjects were recruited. Assigned by clustered randomisation, subjects in the intervention group (n=41) received weekly coaching using The Empowerment Model module and the control group (n=40) followed the conventional diet according to the guidelines of Indonesian Society of Endocrinology.

Results: There was significant difference in change of vegetable intake of the intervention group compared to the control group ($p<0.001$). HbA1c decreased significantly in the intervention group compared to the control group ($p=0.009$). Fasting blood glucose, post prandial blood glucose in the intervention group decreased significantly along with bodyweight, waist circumference, and total cholesterol. Qualitative study demonstrated that health provider's positive attitudes defined subjects' attitudes in creating adherence during coaching sessions with the presence of encouragement and acknowledgment, learned lessons, process honoring, buddy's involvement, confidence and self-regulation, also outreaching ability being role model to enrol others in consuming more vegetables.

Conclusions: The Empowerment Model improved vegetable intake and the intervention significantly reduced HbA1c.

Keywords: The Empowerment Model, Type 2 DIabetes Mellitus, Vegetable, Glycemic control, Indonesia

The nutritional intervention of counseling and cooking assistance on hypertensive patients

Rany Adelina[1,2]

1. Undergraduate Program in Applied Nutrition and Dietetics, Department of Nutrition, Politeknik Kesehatan Kementerian Kesehatan Malang (Indonesia), 2. Center of excellence for local-based material science and technology for non-communicable diseases, Politeknik Kesehatan Kementerian Kesehatan Malang, Ministry of Health (Indonesia)

Background and objective: Nutritional recommendations for people with hypertension set by WHO include limiting sodium/salt intake to achieve or maintain normal blood pressure; consume adequate amounts of carbohydrates from nutrient-dense foods such as vegetables, fruits, whole grains, and legumes; and consume enough fiber. The purpose of this study was to determine the effectiveness of the intervention to reduce salt intake in hypertensive patients.

Method: The design of this study was a quasi-experimental study using a control-treatment group comparison. The research location is in the Kendalkerep Health Center area of Malang city, carried out in July - October 2019. The total participants were 100 people with hypertension (50 people in the treatment group, 50 people in the control group). Participants come from various ethnic groups and socio-demographic backgrounds. The intervention was carried out by providing nutritional counseling, physical activity, and cooking assistance to patients and families with hypertension. The results measured were blood pressure and four days (4-d) food records (3 normal days and 1 holiday/weekend) for 24 hours. Processing of statistical analysis using the Independent T-test, Wilcoxon Mann Whithney, and Logistics Regression.

Results: The average respondent was 66 years old, female, married status, Javanese ethnicity, elementary school education level, does not have a job, and income is below the minimum wage. From the results of BMI and abdominal circumference measurements, most of the respondents were overweight. The results of blood pressure showed a decrease after the intervention was given.

Conclusion: There is a significant difference in blood pressure before and after treatment. However, there was no difference in anthropometric status and salt intake. There is a significant difference in blood pressure before and after treatment. However, there was no difference in anthropometric status and salt intake.

Keywords: nutritional intervention, counselling, high blood pressure

Conflict of Interest Disclosure: The authors declare that there is no conflict of interest.

Food culture as a key component to understanding sustainable diets and building food systems resilience for times of concomitant crises: an example from three distinct regions in Chile

Rebecca Kanter[1], Mariana León V[1].

1. University of Chile (Chile)

Background and objectives: Together with ongoing climate change, Chile has experienced a 2019 social crisis that destroyed supermarkets; and the COVID-19 pandemic that has negatively affected livelihoods. Sustainable diets are: culturally acceptable; protective of the natural environment; physically and economically accessible; and nutritionally adequate. To assess sustainable diets as a potential solution for food systems resilience in times of concomitant crises, an understanding of present-day food culture is imperative. The study objectives were to describe traditional – culturally relevant – Chilean culinary preparations in three distinct geographic areas; to understand the sustainability of said preparations and; to develop nutrition education interventions to promote healthy and sustainable diets in Chile.

Methods: The study was conducted in the north (Arica-Parinacota), center (Metropolitan) and south (La Araucania) of Chile; with participants from 5 age- and ethnic- groups (25-45 y, 46-65 y, >65y, first nations or not). Key informant interviews (n = 15) included free-listing traditional culinary preparations and direct observations of cooking traditional recipes. Focus groups (n = 27) examined dietary frequency, taste preferences, and ingredient access of traditional culinary preparations. Semi-structured interviews (n = 80) assessed how participants perceived sustainability of 25 preparations still consumed and liked to inform educational recipe books for nutrition interventions (n = 11) that included short surveys (n = 232); and one electronic informative recipe book.

Results: Across regions, key informants free-listed 262 traditional culinary preparations. The focus groups confirmed that the traditional culinary preparations most consumed and liked vary regionally. Chileans interviewed in distinct regions perceive sustainable diets differently, especially about environmental impact, and economic access; that resulted in 9 sustainable recipes per region for nutrition interventions. Across interventions, >84% liked all recipes and >90% were willing to learn how to cook them. The COVID-19 pandemic elucidated the utility of an electronic nutrition education recipe book on sustainable diets to adapt to crisis.

Conclusions: Geographic context is inextricably linked to food culture that affects how adults perceive sustainable diets. Traditional culinary preparations are a means to operationalize food culture into practice through the promotion of sustainable diets for both human and planetary health, especially in times of crisis.

OAB(T5)4-4

Changes in mealtime behaviours following Taste Education intervention: Focusing on children with and without neurodevelopmental disorders and their families. A randomized controlled trial

Anna S Olafsdottir[1], Sigrun Thorsteinsdottir[1]

1. University of Iceland (Iceland)

Background and objectives: Mealtime behaviour problems frequently occur among families of children who display fussy eating behaviours, resulting in a low-variety diet and adverse health-related outcomes, including poorer nutrition profiles, and parental worries or stress. This is especially true for children with neurodevelopmental disorders (ND), such as Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD). Creating easy-to-use tools for parents to deal with their children's difficult mealtime behaviours, is of high importance as negative experiences and parents' unwitting communication and own behaviours, may exacerbate problematic eating behaviours in their children. The aim was to investigate a parenting-education component in Taste Education food-based intervention, and whether these methods would be effective in reducing problematic mealtime behaviours in children with and without ND. This intervention has in former publications shown effective in decreasing fussy eating and increasing food variety among children.

Methods: To investigate the effect of Taste Education on changes in problematic mealtime behaviours, 81 children with ND (*n* = 33), and without (*n* = 48), aged 8–12 years, and their parents, participated in a 7-week food intervention. Children were matched on age, ND, and sex, and randomized into Immediate-intervention and Delayed-intervention groups. The study comprised two parts, i.e., a) two parenting-education sessions, 2 hours each, and b) six kitchen sessions, 90 min each. Collaborative parent/child sessions included sensory-based games, in-class hands-on training, food-based exercises at home, food preparation and easy cooking. Parents completed the Meals in Our Household questionnaire (MiOH). After adjusting for baseline measures, repeated-measures analysis-of-variance with time-points, and condition as factors (Immediate intervention and Delayed intervention), were used to examine changes in MiOH-scores with robust linear mixed-model fitted.

Results: Superior results were identified for Intervention compared to waiting on the four subscales analysed i.e., 1) structure of family meals, 2) problematic child mealtime behaviours (frequency and magnitude), 3) use of food as reward,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

4) parental concern about child diet, with stable effects through six-months follow-up. There were non-significant differences between children with and without ND.

Conclusion: The Taste Education program shows promise as a simple, non-invasive way to improve problematic mealtime behaviours in children in the long-term.

OAB(T5)4-5

Education, work and food culture practices at the "Ponta Norte Agroecological Fair" in the city of Brasília (Brazil)

Fernando Bomfim Mariana[1]

1. UNB University (Brazil)

Background and objectives: The "Ponta Norte Agroecological Fair" is one of the most importante street fair in Brasília (capital city of Brazil) - a weekly space for rural agricultural producers and segments of organized civil society that meets each other to exchange and sell healthy foods without the use of pesticides. The objectives of this research work focus on the analysis of the transformation and diversification of dietary habits of the inhabitants of the city of Brasília, as well as the new conceptions of nutrition disseminated by rural workers. During the covid-19 pandemic, the street fair was responsible for the direct supply of healthy food in the Asa Norte neighborhood (city of Brasília).

Methods: The methodology used for the research was focused on monitoring the weekly debates that take place at the "Ponta Norte Agroecological Fair" on topics related to nutrition sciences. Through "registration diaries", testimonies from the street fair participants were gathered about their work (rural agricultural producers) and consumption (residents who buy food at the fair) dynamics. During the covid-19 pandemic, virtual communication was used through social networks.

Results: The results obtained were compiled through the publication of campaigns for healthy eating, audiovisual records of the street fair and technical reports - in addition to the evaluation of the space for integration between education, work and renewed forms of food culture in Brazil. The publicity of the positive impacts of the street fair is carried out through social networks (@pontanorte) and by the actions of local community associations.

Conclusions: The preliminary conclusions of this work - started in December 2019 - reveal the enormous contribution of the "Ponta Norte Agroecological Fair" in guaranteeing the food security of the Brazilian population. During more than two years of existence of this space for exchanging knowledge on healthy nutrition, we can say that the "Ponta Norte Agroecological Fair" contributes not only to the food reeducation of the community, but also proposes a critical reflection on the inseparability between the valorization of workers rural areas and an emancipatory conception of nutrition Science – beside good health and happiness for future generations.

OAB(T5)4-6

An evaluation of nutrition, culinary, and production interventions on the consumption of African Indigenous Vegetables in Western Kenya.

Emily Merchant[1], Martins Odendo[2], Norah Maiyo[3], Ramu Govindasamy[1], Xenia Morin[1], James E. Simon[1], Daniel Hoffman[1]

1. Rutgers University (USA), 2. Kenya Agricultural and Livestock Research Organization (Kenya), 3. Academic Model Providing Access to HealthCare (Kenya)

Background and objectives: Food security continues to worsen in sub-Saharan Africa. African Indigenous Vegetables (AIVs) are yet to be fully exploited to achieve food and nutritional security. The objective of this study was to evaluate the programmatic impact of AIV interventions on food security and diet quality.

Methods: Smallholder farmers (18 to 65 years) from five counties in Western Kenya were randomly assigned to one of four treatments: 1. control (Trans Nzoia County, n=61); 2. production intervention (PI), which addressed key bottlenecks such as cultural practices, improved technologies and seeds, integrated pest management, and irrigation and drought tolerance (Nandi and Kisumu County, n=64); 3. nutrition and culinary intervention (NCI), which addressed daily intake guidelines, recipe and meal preparation, nutrition for each AIV and bodily processes supported (Bungoma County, n=55); and 4. NCI and PI (Busia County, n=70). Quantitative baseline and endline surveys were administered in October 2016 and June to July 2019, respectively. The impact evaluation was analyzed by Household Hunger Scale (HHS), Women's Dietary Diversity Score (WDDS), AIV consumption frequency, and AIV market availability.

Results: Seasonal differences resulted in an overall decrease in WDDS, HHS, and consumption frequency between baseline and endline. Despite this, postintervention, households that received NCI and PI as well as households that received only NCI demonstrated a protective effect as measured by a higher WDDS and HHS relative to the control: WDDS 5.1 ± 1.8 and 4.9 ± 1.7 vs 4.2 ± 1.5, p=0.01; HHS 0.9 ± 1.5 and 0.8 ± 1.4 vs 0.3 ± 1.0, p=0.029. In addition, between baseline and endline, there was an overall increase in the percentage of respondents that reported an adequate supply of key AIVs, particularly for households that received PI. Furthermore, seasonal effects caused a reported shift in the primary location for purchasing AIVs from the village to the town market.

Conclusions: Nutrition and culinary intervention, particularly when coupled with production intervention, provided a protective effect against the seasonal decline of availability and subsequent consumption of AIVs. Applications of such

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

interventions have the potential to improve food security in rural Kenya.

Keywords: behavior change, healthy diets, indigenous vegetables, malnutrition, orphaned crops

Consumption of discretionary salt and bouillon cubes and related knowledge, attitudes & practices in Senegalese households

Saliou Diombo Kebe[1], Adama Diouf[1], Papa Mamadou Dit Doudou Sylla[1], Mbeugué Thiam[1], Ousseynou Baba Coly[2], Mane Hélène Faye[1], Abdou Badiane[1], Babou Diaham[1], Nicole Idohou Dossou[1]

1. Laboratoire de Recherche en Nutrition et Alimentation Humaine (LARNAH), 2. Université Cheikh Anta Diop (UCAD) (Senegal)

Background and Objectives: Excessive salt consumption contributes significantly to the development of non-communicable diseases (NCDs). Sodium intake is directly linked to high blood pressure (HBP), the most important risk factor of cardiovascular diseases and mortality worldwide. The WHO has set a target of reducing population salt consumption by 30% by 2020 to contain the prevalence of HBP. To reach this target, we should address the lack of scientific evidence in low-income countries such as Senegal. Monitoring of salt consumption and obtaining information on population habits are important steps in implementing policy and key strategies to reduce salt intake. This study aimed to assess discretionary salt intake and related consumption patterns of Senegalese populations in urban and rural area.

Methods: A cross-sectional study was conducted among 57 urban (Dakar) and 54 rural (Kaffrine) households. The quantities of discretionary salt and bouillons used in the meal's preparation, were accurately measured by direct weighing method. Contribution of bouillons to salt intake was determined using national manufacturing standard. Knowledge, attitudes and practices related to salt and bouillons consumption were collected using the WHO STEPS questionnaire.

Results: Overall, individual salt intake was estimated at 6.3 g/d and was significantly higher (P<0.01) in rural than in urban areas (10.2 vs. 4.6 g/day). The individual contribution of bouillons in salt intake was estimated at 2,9 g/day and 2 g/day respectively in rural and urban areas. Based on WHO recommendation, it appears that more than two thirds of households (66,7%) had high salt consumption (>5g/d/person), particularly in rural area (94%). Despite this, 82.9% of households thought they consumed the right amount of salt. Seventy percent (70%) of urban households considered that they were able to cook without bouillon, whereas only 30.2% accorded less importance to reducing their sodium intake.

Conclusion: Salt consumption is above the WHO recommendation, particularly in rural areas in Senegal, with a significant contribution of bouillons, and highlight the need to implement a policy reduction of salt consumption.

Keywords: Salt intake, Discretionary, Hypertension, Bouillons cubes, KAP

Biochemical components and sensory analysis of handmade stock and instant bonito-kelp stock in Japanese-style dishes

Yoko Okamoto[1], Kenji Tayama[2], Maki Suzuki[3], Hitomi Morihisa[3], Ayumi Furuta[3], Run Wang[3], Shota Tanimoto[3]

1. Hiroshima Shudo University, Former (Japan), 2. Hiroshima Shudo University (Japan), 3. Prefectural University of Hiroshima (Japan)

Background and objectives: The Japanese soup stock "dashi", which is beneficial to health, is part of the Japanese food culture. We prepared and studied "handmade bonito-kelp stock", "four different types of instant packet bonito-kelp stocks" and "instant granule bonito-kelp stock". Our aim was to differentiate the tastes of Japanese stock by examining various factors.

Methods: In Experiment 1, we analyzed handmade and instant packet stock, and in Experiment 2, we analyzed handmade and instant granule stock. Using an instrument in Experiment 1and 2, we examined analyzed the biochemical components in the stocks: free amino acids and nucleic acid compounds. We also investigated which stocks humans identified and preferred.

Results: Experiment 1 - The handmade stock and packet stocks all featured multiple tastes with different biochemical components, including aspartic acid, glutamic acid, inosine monophosphate and adenosine monophosphate. The concentrations of biochemical components differed between handmade stock and all four packet stocks. The handmade stock and packet stocks could easily be distinguished by the human volunteers. The handmade stock was significantly preferred compared to the four types of packet stocks. Experiment 2 - Our analysis showed that handmade and granule stocks had significantly different compositions of biochemical components. For illustration, the concentrations of aspartic acid and histidine were both higher in the handmade than in the granule stock. Instant granule stocks had markedly higher concentrations of glutamic acid and 5'-inosinic acid as compared with handmade stocks. In addition, the total number of free amino acids and nucleic acid compounds differed between the handmade and granule stocks: handmade stock had many types of components, whereas granule stock had only a few types. Japanese dishes prepared with handmade or granule bonito-kelp stocks could be discriminated from one another. Conclusions: These findings imply that the composition of biochemical components is more

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

complex in handmade stocks and instant packet stocks than in instant granule stocks. The number, types, and concentration of biocomponents contained in the stock accounts for the difference in tastes of "dashi".

Keywords: Handmade bonito-kelp stock, Instant packet bonito-kelp stock, Instant granule bonito-kelp stock, Biochemical component analysis, Sensory analysis

The integrated consumers' sustainable and healthy dietary behavior patterns among Japanese adults

Yui Kawasaki[1], Rie Akamatsu[1], Sayaka Nagao-Sato[1], Emi Yoshii[2]

1. Ochanomizu University (Japan), 2. The University of Nagano (Japan)

Background and objectives: Consumers are the driving force of food production and the direct cause of food waste. In the previous study, the authors developed the 30-item sustainable and healthy dietary behaviors (SHDBs) to comprehensively discuss multifaceted consumer food sustainability issues from food choice to disposal. This study aims to examine (1) the behavioral patterns of SHDBs and (2) independent predictors of each pattern.

Method: Five hundred and eight Japanese adults who took part in the self-administered cross-sectional questionnaire survey in December 2021 were included in the final sample of the present analysis. The principal component analysis was performed on the 30-item SHDBs. These items reported in the previous study composes of five scenes such as food choice (14 items, e.g., “I choose local products”), storing and preservation (3 items), cooking (6 items), consumption (2 items), and disposal (5 items, e.g., “I separate and recycle garbage”). Independent predictors of each component score were analyzed using multiple linear regression models, including demographics, psychological factors concerning SHDBs (pros and cons for the decisional balance of SHDBs and number of environmental issues of interest), and meal preparation habits.

Results: Participants' median age and BMI (25, 75%tile) were 41 (30, 50) and 21.0 (19.2, 24.0), respectively. Female were 51.0% (n=259). The following 5 SHDBs patterns and several independent predictors were identified ($p<0.05$, respectively): (1) “higher SHDBs” with male (β=-0.105), higher pros scores (β=0.134), and higher cooking frequency (β=0.443) and skill (β=0.244); (2) “lower cooking” with larger household size (β=0.102), higher age (β=0.112), household income (β=0.139), cooking frequency (β=0.268) and skill (β=0.256), and pros scores (β=0.243) and lower cons scores (β=-0.110); (3) “avoiding disposal” with higher pros scores (β=0.264), lower cons scores (β=-0.208), many numbers of environmental issues of interest (β=0.086), and higher cooking frequency (β=0.220) and skill (β=0.146); (4) “avoiding plastic products”, with higher age (β=0.130) and pros scores (β=0.138) and many numbers of environmental issues of interest (β=0.097); (5) “regarding expiry date highly” with lower age (β=-0.114), smaller household sizes (β=-0.130), and being in charge of food purchase (β=-0.136).

Conclusion: Our findings provide behavioral insight to develop strategies to promote consumers' SHDBs.

Dietary and environmental mediators of socioeconomic inequalities in child undernutrition in West Africa

Adeladza Kofi Amegah[1], Duah Dwomoh[2], Christian Sewor[1], Samuel Annim[3], Saverio Stranges[4], Ngianga-Bakwin Kandala[5]

1. University of Cape Coast (Ghana), 2. University of Ghana (Ghana), 3. Ghana Statistical Service (Ghana), 4. Western University (Canada), 5. University of Warwick (UK)

Background and objectives: A number of studies have investigated the association of socioeconomic status (SES) with child undernutrition in several regions including West Africa. However, to date no study has attempted to elaborate the possible pathways through which socioeconomic disadvantage leads to higher prevalence of child undernutrition. Document the level and trend of low birth weight (LBW), and child undernutrition in West Africa, and further establish the mediating role of dietary factors and household environmental quality in the association of SES with child undernutrition.

Methods: We analyze DHS and World Bank data for the period 1985 – 2019. Random effects model with Knapp–Hartung adjustment to the standard error (SE) was used to derive overall prevalence estimates. Fixed-effect OLS regression with cluster robust SE was used to conduct time trends analyses. 132,448 under-five children born within five years preceding the survey were investigated. Poisson regression with robust SE was used to estimate prevalence ratios and their corresponding 95% CI. Structural Equation Modelling was used to conduct the mediation analysis.

Results: We observed a decline in prevalence of stunting (β=-0.20%; 95%CI: -0.43%, 0.03%), log-wasting (β=-0.02%; 95%CI: -0.02%, -0.01%), log-underweight (β=-0.02%; 95%CI: -0.03%, -0.01%) and anemia (β=-0.44; 95%CI: -0.55%, -0.34%), and an increase in LBW (β=0.06%; 95% CI: -0.10%, 0.22%) in West Africa over the period. Pooled prevalence of stunting, wasting, underweight, anemia and LBW in WA for the period 1985-2019 was 26.1%, 16.4%, 22.7%, 76.2% and 11.3%, respectively. Minimum dietary diversity (MDD), minimum meal frequency (MMF), minimum acceptable diet (MAD), and HEQ mediated the association of low maternal education and poor household wealth with child undernutrition. Percentage mediation ranged from 20.3% to 26.6% for MDD, 6.4% to 14.2% for MMF, 24.2% to 33.5% for MAD, and 6.6% to 7.3% for HEQ.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: We provide the evidence base for assessing the effectiveness of national and regional interventions that have been implemented over the last four decades for tackling child undernutrition and LBW in West Africa. Evaluating existing interventions for effectiveness should be done through a socioeconomic lens if we are to address the high burden of child undernutrition in West Africa.

The Effect of Concurrent Anemia and Stunting on Cognitive Ability : A Longitudinal Study of Children in Indonesia

Avliya Quratul Marjan[1], Ratu Ayu Dewi Sartika[2], Iin Fatmawati Fatmawati[1], Sintha Fransiske Simanungkalit[1], Nur Intania Sofianita[1]

1. Universitas Pembangunan Nasional Veteran Jakarta (Indonesia), 2. Universitas Indonesia (Indonesia)

Background and objectives: Anemia and stunting are nutritional problems that affect the cognitive abilities of school aged children in Indonesia. Concurrent anemia and stunting conditions can occur due to the characteristics of the child, mother and family environment. This study aims to asses the impact of concurrent anemia and stunting on children's cognitive ability.

Methods: We use two wave (2000-2007) longitudinal data from Indonesia Family Life Survey (IFLS). The subject of the study were 568 children aged 3-5 years old in 2000. Anthropometric data and hemoglobin level were collected for children at 3-5 years of age. Cognitive ability was measured with Raven Progressive Matrices, collected for children at 10-12 years of age. We used one-way annova to measured the frequency and correlation of cognitive ability with concurrent anemia and stunting. We also build linear regression models for multivariate analysis.

Results: Cognitive ability score of children with concurrent anemia and stunting was 11.72±3.30 (95% CI=11.12-12.31). The prevalence of concurrent anemia and stunting in this study was 21.65%. Concurrent anemia and stunting in early childhood were associated with head circumference, animal protein consumption, maternal education, father and mother's occupation and region of residence. Based on multivariate analysis, children with concurrent anemia and stunting have the lowest cognitive abilities compared to other groups and were statistically signitificant (p=0.031) after adjusted with children, parents and household factors.

Conclusions: Concurrent anemia and stunting at 3-5 years of age will increase the risk of low cognitive ability at 10-12 years of age. Therefore, nutritional and public health intervention to prevent low cognitive abilities and concurrent anemia and stunting not only focus on 1000 days of life but include children up to 5 years or more.

Keywords: Concurrent anemia and stunting, Cognitive ability, Early childhood, Stunting

Micronutrient fortified milk consumption, vitamin D and socio-economic status in school age children in a rural region of Morocco

Kaoutar Benjeddou[1], Mehdi Azlaf[1], Naima Saeid[1], Hanane Bouijij[1], Noureddine El Haloui[1], Jaafar Heikel[2], Mohammed El Mzibri[1], Khalid El Kari[1], Hasnae Benkirane[1], Hassan Aguenaou[1]

1. Ibn Tofaïl University-CNESTEN, Joint Research Unit in Nutrition, Health and Environment, RDC-Nutrition AFRA/IAEA, Laboratory Biology and Health, 14000 Kenitra, (Morocco), 2. Mohammed 6 University of Health Sciences, Casablanca (Morocco)

Background and objective: Vitamin D deficiency is very common and affects about 50% of the world's population. The aim of this study is to determine the effect of micronutrient fortified milk consumption on vitamin D status among school age children.

Methods: Children aged 7 to 9 years participated in this double-blind longitudinal study were divided in 2 groups: a fortified group received daily 200mL of fortified UHT milk and a non-fortified group received 200mL of non-fortified UHT milk during 9 months. Socio-economic profile and anthropometric measurements were recorded. Blood samples were collected 3 times (at baseline, after 4 and 9 months).

Results: Our results showed that: 1- The majority of children's parents are illiterate, 72% of families consisted of 5 persons or more per household and 82.1% of families spent less than 120US$ per month for food; 2- 8.4% and 3.4% of children are stunted and underweight, respectively; 3- At baseline, 47.5% of the children had a 25(OH)D concentration <50nmol/L. 4- The consumption of fortified milk resulted a relative improvement in the prevalence of insufficiency of 64.2% after 9 months in the group consuming fortified milk compared to the group consuming non-fortified milk and the net gain improvement is 24.5% always favor the fortified group between the beginning and the end of the study.

Conclusion: The consumption of fortified milk has improved the vitamin D status and reduced its prevalence. It seems to be a good alternative for the improvement of vitamin D status among schoolchildren in Morocco.

School-based nutrition interventions had impacts on dietary diversity and meal frequency among adolescent girls in Ethiopia

Celeste Sununtnasuk[1], Sunny S. Kim[1], Hanna Berhane[2], Tamirat Walissa[3], Abdulaziz Oumer[3], Yonas Asrat[3], Tina Sanghvi[4], Purnima Menon[5]

1. International Food Policy Research Institute (USA), 2. Addis Continental Institute of Public Health (Ethiopia), 3. FHI Solutions (Ethiopia), 4. FHI Solutions (USA), 5. International Food Policy Research Institute (India)

Background and objectives: Adolescence is a critical period of physical and psychological development, especially for girls as poor nutrition can affect their well-being as well as the well-being of their children. In Ethiopia, where the population is very young, evidence on the nutrition of adolescent girls and their determinants is scant. We tested the impact of a package of nutrition interventions delivered primarily through schools and implemented by Alive & Thrive (A&T) on the diet of adolescent girls.

Methods: We used a cluster-randomized trial design, comparing 27 primary school clusters in A&T intervention areas to 27 control schools in the SNNP and Somali regions. We surveyed adolescent girls (n=536) aged 10–14 years and enrolled in primary school grades 4-8, following at least one school semester (approximately 4 months) of implementation in March-April 2021. Using linear regression models, we tested for differences between program groups on dietary diversity, meal frequency, and consumption of unhealthy foods. In adjusted models, we controlled for age, household food security and wealth, and region.

Results: Dietary diversity score (1.4 food groups) and minimum dietary diversity (OR: 5.2) improved among girls in A&T schools compared to those in control schools. Among the food groups, there was significantly higher consumption of 5 groups in A&T areas: pulses, meats, eggs, vitamin A-rich fruits and vegetables, and other fruits. There was also a significant impact on meal frequency of 0.9 meals/snacks in the previous 24 hours, with girls in A&T areas consuming 4.0 meals/snacks out of 6 eating times compared to 3.2 in control areas. There was no impact on consumption of sweets, baked sweets, sweetened beverages, and fried and salty foods among girls, but there was lower consumption of sweets in the previous 24 hours in A&T (14%) versus control areas (23%).

Conclusions: Integrating nutrition interventions into primary schools in Ethiopia was feasible and achieved a significant impact on girls' dietary diversity and meal frequency. Reinforcing messages about eating better and more often resulted in incremental behavior change related to dietary diversity and meal frequency; however, telling adolescents not to eat junk foods without changing their food environments may be less successful in curbing consumption.

What Japanese children eat in school lunches: findings from the National Health Nutrition Survey 2012-2019

Aya Fujiwara[1,2], Mai Matsumoto[1], Ryoko Tajima[1], Xiaoyi Yuan[1,2], Emiko Okada[1], Keiko Asakura[3], Hidemi Takimoto[1]

1. Department of Nutritional Epidemiology and Shokuiku, National Institutes of Biomedical Innovation (Japan), 2. Department of Social and Preventive Epidemiology, School of Public Health, University of Tokyo (Japan), 3. Department of Environmental and Occupational Health, School of Medicine, Toho University (Japan)

Background and objectives: To promote the healthy development of children and attain favourable dietary habits, Japanese elementary and junior high schools provide uniformed school lunches for which the School Lunch Nutritional Standards are established for energy and several nutrients rather than food groups. This study aimed to show an overview of dietary intake from school lunches based on a nationwide survey over multiple years.

Methods: Participants were 5,244 elementary school students aged 6-12 years (ESS) and 2,201 junior high school students aged 12-15 years (JHSS) who participated in the National Health and Nutrition Survey 2012-2019 and reported having school lunches on the survey day. Dietary intake was estimated by a one-day semi-weighed household dietary record. The intake from school lunches was estimated based on the menu from each school, including information on names and weights of the ingredients. We estimated mean intakes of energy, nutrients, and food groups from school lunches and their contribution to total daily intake.

Results: Participants took one-third of daily energy intake from school lunches irrespective of age group and survey year. Regarding ESS, the school lunches contributed more than 40% in VA, VB_2, and Ca for nutrients with the Standards and in VD, VB_{12}, pantothenic acid, K (except for 2012 and 2017), and P but SFA (except for 2017 and 2018) for nutrients without the Standards throughout survey years. A similar trend was observed in JHSS, except for K and SFA with 40% contribution in the 2012-2014 survey only. No nutrients contributed to less than 30% of daily intake, except for MUFA in JHSS. For food groups, the contribution was varied from 5% for confectioneries to 85% for milk in both age groups. More than 40% contribution was observed in potatoes, pulses, nuts/seeds, vegetables, mushrooms, seaweeds, fish/shellfish, and milk, but in noodles, other grains, sugar/sweetener, and fat/oil throughout survey years (with some exceptions).

Conclusions: This study clarified that school lunches were successively and substantially contributed to dietary intake in Japanese children, even for some nutrients and food groups without the Standards. The present findings provided future directions for the improvement of school lunches in Japan.

Public management and social control - How to measure the quality of school feeding menus

Rafaella Camargo[1], Semíramis Domene[1]

1. UNIFESP (Brazil)

Background and objectives: Food quality indices, based on food guides and nutritional recommendations, allow evaluating the quality of diet groups and individuals, to compose actions to prevent diseases and promote food and nutritional security. The use of demanded objects, objective location for each country, target audience. The Quality Indicator for School Feeding Menus - IQCAE was created to evaluate school feeding menus within the scope of the National School Feeding Program - PNAE, considered the largest and most comprehensive food and nutrition program in Brazil. The IQCAE is the only validated instrument available in Brazil; however, guidelines indicated in consensus among specialists and changes in the normative instruments of the PNAE demand their revision. The aim of this study is to review the IQCAE.

Methods: Methodological study of a quantitative nature, carried out in three stages. The first involved: analysis of the current instrument, consensus study on healthy eating among experts, current legislation and limitations found after validation of the instrument. In the second phase, collaborators from the workshop Sustainable and Healthy School Meals – British Council UK, participated in the review of the IQCAE. Finally, the new proposal was presented to the research group and will be validated.

Results: The new version of the IQCAE includes eight daily assessment components and four weekly assessment components. The daily assessment components are food groups such as cereals and tubers; legumes; vegetables; whole; eggs, birds and fish; and dairy products. These components score positively, while the supply of sweets and ultra-processed foods score negatively. The weekly evaluation components depend on the frequency with which these foods are offered during the week and are intended to inhibit or encourage the consumption of these items in school meals, such as regional sweets and processed foods, time compatibility with type of meal and sustainability components. such as regional foods, socio-biodiversity and red meats. The IQCAE generates a maximum daily score of 16 points and varies from 0 to 100 points per week.

Conclusions: The review of the IQCAE allows us to affirm that the instrument will promote the incorporation of advances in regulatory mechanisms for the management of school meals, and knowledge about the pattern of food consumption on health. The inclusion of sustainability components represents another relevant improvement to what contributes to healthy eating.

The distribution and healthiness of foods sold around urban and rural schools in Kenya.

Sharon Mugo[1], Caroline Karugu[1], Milka Wanjohi[1], Stefanie Vandevijere, Michelle Holdsworth, Amos Laar, Veronica Ojiambo[1], Gershim Asiki[1]

1. African Population Research Center (Kenya)

Background: Urbanization and globalization of food production and marketing are two important factors fuelling the rise in the prevalence of obesity and non-communicable diseases in LMICs. The availability of food retail outlets around schools has been shown to influence food choices among school children. We estimated the density of food retail outlets around schools and the availability of healthy and unhealthy food options sold in the retail outlets in Kenya.

Methodology: This was a cross-sectional study conducted in three Kenyan counties (Nairobi-urban, Mombasa-urban, and Baringo-rural) from July 2021 to August 2021. Through multi-stage and population proportionate sampling approach,500 schools were selected from the three counties each stratified into high and low socio-economic status based on poverty indices from the Kenya National Bureau of Statistics All the food retail outlets within a radius of 250 meters around each school was mapped and the characteristics of all the foods sold in them were collected. NOVA classification was used to classify the foods according to healthiness into four categories (ultra-processed, processed culinary ingredients, and unprocessed foods).

Results: A total of 7792 outlets were mapped around the schools with a density of 25 (1-110), 19(1-47), and 3(1-17) for Nairobi, Mombasa, and Baringo counties, respectively. The most common types of outlets in the three counties were vegetable food stands at (30.21%), shops (25.19%), kiosks (13.6%), local vendors (13.4)%, and restaurants (7.34%). According to the NOVA classification, the unprocessed/minimally processed food category was the most common, n=15,657, (71.59%), followed by ultra-processed foods n=5483, (25.1%), processed culinary ingredients n=565(2.6%), and processed foods n=166, (0.8%).

Conclusion: Retail food outlets are common around schools in Kenya with a higher density in urban than in rural counties. Most of the foods sold around schools are healthy but there was also a substantial proportion of unhealthy food options such as ultra-processed foods. There is a need to develop policies to regulate the zoning of food retail outlets around schools to prevent exposure to unhealthy food options.

Extensive advertising of unhealthy foods around primary and junior high schools in the Greater Accra Region, Ghana

Gideon Senyo Amevinya[1], Stefanie Vandevijvere[2], Bridget Kelly[3], Richmond Aryeetey[1], Wilhelmina Quarpong[4], Akua Tandoh[1], Kobby Mensah[1], Gershim Asiki[5], Michelle Holdsworth[6], Amos Laar[1]

1. University of Ghana (Ghana), 2. Sciensano (Belgium), 3. University of Wollongong (Australia), 4. Emory University (USA), 5. African Population and Health Research Center (Kenya), 6. Université de Montpellier (France)

Background and objectives: The advertising of energy-dense nutrient-poor food products is common in obesogenic food environments. The extent of advertising within surroundings where children live and play has the potential to influence their food choices. This study examined the extent and nature of advertising of foods, alcoholic and non-alcoholic beverages around selected schools in Ghana's most urbanized region, the Greater Accra region.

Methods: Basic schools (n =200) were selected using a multi-stage systematic sampling approach in six randomly selected districts of the Greater Accra region. This cross-sectional study assessed outdoor advertising around the selected schools using an adapted protocol from the International Network for Food and Obesity/Non-communicable Diseases Research, Monitoring and Action Support (INFORMAS). All outdoor advertisements (of food and non-food products)–within 250m road network distance from the entrance of all selected schools were photographed and geocoded. For each food advertisement, information was collected on the setting, type, and size of the advertisement, and promotional techniques used. All advertised food products were classified using the INFORMAS' as well as the NOVA food classification systems.

Results: A total of 5,887 advertisements were identified around the surveyed schools, 42% of which were for foods and beverages. Advertisements were most prevalent at food outlets (78% of all food advertisements) but also along roads, and on non-food structures. Overall, 70% of food advertisements featured non-core/unhealthy products, while 12% and 14% had core/healthy and miscellaneous (including soup cubes, seasonings, tea) products respectively. About 50% of the foods and beverages advertised were ultra-processed foods, 30% processed, 3% processed culinary ingredients, and 17% unprocessed or minimally processed foods. Sugar-sweetened beverages were the most advertised food product type (32%). Promotional characters were found on 14% of all food advertisements, most were cartoons/manufacturer's characters (69%). About 8% of all food advertisements had premium offers, including price discounts and gift/collectibles.

Conclusions: There is an abundance of unhealthy food advertisements around public basic schools in Accra. Policies and actions are needed to protect pupils from such marketing practices.

Periconceptional folic acid supplementation and the risks of small and large for gestational age at birth: the mediation effect of maternal homocysteine level during pregnancy

Qianling Zhou[1], Meijing An[1]

1. Peking University (China)

Background and objectives: Some studies have demonstrated the protective effects of periconceptional folic acid supplementation (FAS) on the occurrence of small for gestational age (SGA). However, the effect of periconceptional FAS on the occurrence of large for gestational age (LGA) is still unclear. Besides, homocysteine (Hcy) concentration during pregnancy has found to be associated with birth weight. This study aimed to explore the independent effects of periconceptional FAS on the risks of SGA and LGA, and to test the potential mediation role of maternal Hcy during pregnancy on the above associations where a significant effect existed.

Methods: A large-scale prospective birth cohort was conducted among pregnant women from June 2018 to August 2019. Periconceptional FAS was evaluated by a self-administered questionnaire in early pregnancy. Neonatal birth weight was measured at delivery in the hospital. Maternal serum Hcy concentrations were measured in early and late pregnancy as part of the routine prenatal care. Logistic regression analyses were performed to assess the associations between FAS during preconception and/or early pregnancy and the occurrence of SGA or LGA. A mediation model was constructed to determine the role of maternal Hcy on the above associations.

Results: FAS before pregnancy (risk ratios [RR]=0.819, 95% confidence interval [CI]: 0.672-1.000, *P*=0.05), during early pregnancy (RR=0.622, 95%CI: 0.451-0.858) and from pre-pregnancy to early pregnancy (RR=0.564, 95%CI: 0.371-0.857) were associated with lower risk of LGA. However, no significant association was found between periconceptional FAS and SGA birth. Maternal Hcy concentration in late pregnancy mediated the independent effects of maternal FAS during preconception and early pregnancy on the risks of LGA birth.

Conclusions: Periconceptional FAS was associated with lower risks of LGA, which may be mediated by the reduced serum Hcy concentration in late pregnancy. The recommendation of periconceptional FAS should be complied with to achieve the optimal fetal growth.

Identifying factors to address multiple forms of malnutrition in Peru: a cross-sectional study of mothers and infants in low-income urban areas

Edwige Landais[1], Rebecca Pradeilles[2], Rossina Pareja[3], Sabrina Eymard-Duvernay[1], Hilary M Creed-Kanashiro[3], Oonagh Markey[2], Michelle Holdsworth[1], Emily K Rousham[2]

1. French National Research Institute for Sustainable Development (IRD) (France), 2. Loughborough University (UK), 3. Instituto de Investigación Nutricional (Peru)

Background and objectives: Multiple forms of malnutrition coexist in Peru posing public health challenges. Hence, in order to identify opportunities for interventions, this study aimed to describe the coexisting forms of malnutrition at different levels: population, dyad (mother/infant) and individual (mother); and to investigate factors associated with coexisting forms of malnutrition at the dyad and individual levels.

Methods: A cross-sectional study was conducted amongst low-income urban mother-infant dyads (n=244) from Manchay (Lima) and Huánuco district (Huánuco) using a purposive quota sampling to recruit mothers with children 6-23 months. The main outcomes were dyad-level double burden of malnutrition (DBM) i.e., co-existence of maternal overweight/obesity and child anaemia and individual-level DBM in mothers i.e., co-existence of overweight/obesity and anaemia. Logistic regressions were performed to investigate socio-demographic and dietary factors associated with the DBM.

Results: Overall, 59.8% of mothers were overweight/obese and 34.0% were anaemic. Two maternal dietary clusters were identified: "varied, high fat, high sugar" and "high potato, low fruit and vegetables (FV), low red meat". Among children, 8.4% were overweight/obese and 61.5% were anaemic. At the dyad-level, the prevalence of DBM was 36.3%. Factors positively associated with dyad-level DBM included maternal age (aOR/five years: 1.41 [1.15-1.73]), having at least two children under five (aOR=2.44 [1.23-4.84]) and maternal work (aOR=1.73 [0.96-3.12]), although the confidence intervals (CIs) straddled the null for the latter. Living in Huánuco was negatively associated with dyad-level DBM (aOR=0.42 [0.24-0.74]). At the individual level, the coexistence of overweight/obesity and anaemia was 19.9%. Factors positively associated with maternal DBM included maternal age (aOR/five years: 1.35 [1.07-1.71]), parity (aOR=1.28 [1.05-1.55]), maternal work (aOR=1.86 [0.84-3.68]) and the "high potato, low FV, low red meat" cluster (aOR=1.92 [0.97-3.82]), although the CIs straddled the null for occupation and diet.

Conclusions: One third of dyads and approximately a fifth of mothers had concurrent overweight/obesity and anaemia. Double-duty actions that tackle multiple forms of malnutrition at the individual and dyad level are needed in low-income urban areas of Peru. Interventions that promote nutrient-rich diverse diets should be implemented and especially targeted at working mothers and their offspring as well as women with at least two children under five.

The Effect of Breastfeeding to Accelerated Growth in Early Life : The Indonesia Family Life Survey 1997 and 2000

Firlia Ayu Arini[1], Endang Laksminingsih Achadi[2], Eflita Meiyetriani[3]

1. UPN Veteran Jakarta (Indonesia), 2. Faculty of Public Health, Universitas Indonesia (Indonesia), 3. SEAMEO RECFON, Universitas Indonesia (Indonesia)

Background and objectives: Accelerated growth in height and weight during early life is associated with the development of obesity and cardiovascular disease. Accelerated growth commonly occurs in malnourished children as a result of recovery from undernutrition. Some studies had found that breastfed infants who were born preterm or SGA at term had slower growth compared to non-breastfed children who had a higher risk for cardiovascular diseases. The purpose of this study was to investigate whether children who were not exclusively breastfed and experienced malnutrition in early life tend to have accelerated growth in height and weight.

Methods: We analyzed 3 years followed-up longitudinal study (1997-2000) from Indonesia Family Life Survey (IFLS). A total of 535 children aged 0 – 23 months in 1997 from 13 different provinces in Indonesia during the survey term were included in this study. Data on exclusive breastfeeding and mothers' characteristics were collected in 1997 and information on children's nutritional status was collected in both 1997 and 2000, to determine accelerated growth in height and weight. We divided children into 3 groups to compare the risk of accelerated growth between children with malnutrition in early life who were breastfed and non breastfed, compared to breastfed children without malnutrition occurrence. We used a multivariate-adjusted logistic regression model to estimate the odds ratio (OR) for accelerated growth among groups.

Results: The prevalence of accelerated growth in height and weight in non-breastfed malnourished children was 47,60% and 36,06%. The OR for accelerated growth in height of non-breastfed malnourished children was 8,41 (4,57-15,46) and the OR for accelerated growth in weight among them was 7,27 (3,67-14,40) compared with breastfed children, after adjusted with children's gender, mothers body mass index and education level.

Conclusions: Malnourished children who were not exclusively breastfed had a higher risk of accelerated growth in height and weight than breastfed children, many studies had

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

shown that accelerated growth in early life leads to metabolic syndrome in later life. Therefore, breastfeeding is a preventive strategy to protect the children, particularly those who were malnourished in early life, from the potential of accelerated growth that associated detrimental effects in adulthood.

University of Yaounde I (Cameroon), 6. Regional Hospital Limbe (Cameroon), 7. Helen Keller International (Senegal), 8. Helen Keller International (Kenya)

Background and objectives: Despite the high prevalence of moderate acute malnutrition (MAM) in Cameroon, there are limited national policy directives for its management. The study aimed to evaluate the effectiveness of a food voucher program (FVP) designed to treat MAM by supplementing usual diets, and examine the factors associated with dietary outcomes.

Methods: A longitudinal cohort study was carried out from March to August 2020 in the Kaele health district. Eligible children 6-59 months were identified through mass screening by community health workers (CHW) using mid-upper arm circumference (MUAC). Children identified with MAM (MUAC between 115 mm and 125 mm) were referred to health facilities for confirmed diagnosis and enrollment in the FVP. Study subjects were randomly selected using stratified sampling with probability proportional to the size of each health area. At enrollment and bi-weekly follow-up examinations, health agents provided caretakers a voucher to redeem for a pre-defined food basket (milk, eggs, fruits, vegetables, red millet flour, sugar and oil) from pre-selected local vendors. Complementary activities included discussions of recipes and child nutrition. Children's dietary intake was assessed at enrollment, then every two weeks until exit from the program upon a MUAC measure greater than 124 mm. Life table analysis was used to assess the cumulative probability of achieving the minimum dietary diversity (MDD) among children aged 6-23 months. Mixed effect logistic and linear regressions assessed factors associated with changes in MDD and dietary diversity score (DDS) among children 24-59 months of age.

Results: Among the 474 MAM children, the cumulative probability of meeting MDD increased from 19.9% at enrollment to 100% after 12 weeks, while mean DDS increased from 3.2 to 5.1 (95%CI: 4.6-5.7). Caregivers' perception of the safety of food items redeemed was positively associated with MDD increase (adjusted RR = 0.52; 95%CI: 0.30-0.82). Sharing of voucher foods with other family members was significantly associated with lower DDS (adjusted coef. = 0.33, p = 0.047).

Conclusion: The FVP was associated with improved dietary diversity of MAM children in the Far-North of Cameroon. Perceptions of food safety appears to influence dietary intake, even in contexts of high food insecurity.

Impact of Behavioural Change Communication on the Knowledge and Child Survival Practices of Mothers of Under-Five Children in South-West Nigeria

Bukola Olanike Bamisaye[1], Thomas Oladejo Adepoju[2]

1. The World Bank (Nigeria), 2. University of Ibadan (Nigeria)

Background and objective: Behavioural Change Communication (BCC) is useful in promoting positive health outcomes through several models. However, its potential in promoting Child Survival (CS) practices remains understudied. Furthermore, poor child survival practices among mothers of under-five children have greatly contributed to the leading causes of child deaths in Nigeria. The study was conducted to evaluate the impact of BCC on knowledge and child survival practices of mothers of under-five children in Southwestern, Nigeria.

Methods: Cluster randomized design involving a four-stage sampling technique was adopted to sample mother-child pairs from 654 households in Oyo, Ogun, and Ekiti States of Nigeria. The 654 (218 per state) were randomly assigned to the Experimental Group (EG) (327) and Control Group (CG) (327). The experimental group was exposed to six sessions of BCC and followed up using an inter-personal communication approach for six months. Pre-tested, interviewer-administered, semi-structured questionnaires containing 12-point knowledge and 13-point practice scales were used to assess mothers' knowledge and practices of CS. The CS components measured were newborn care, breastfeeding, complementary feeding, micronutrient supplementation, immunisation, management of sick children, and use of mosquito nets. Data were analysed using descriptive statistics and paired students' t-test at $\alpha_{0.05}$.

Results: Mean Ages of mothers and children were 31.19±6.1 years and 31.49±15.9 months respectively. Mothers' knowledge of CS components significantly increased from 4.5±3.0 at

baseline to 10.2±1.8 for EG and increased from 4.9±2.1 to 5.3±2.1 for CG. Mothers' practice of CS increased from 3.96±2.13 at baseline to 12.9±2.4 for EG and from 3.8±2.1 to 3.9±2.1 for CG. There was an improvement of 5.64±3.37 and 8.94±3.17 for mothers' knowledge and practices respectively. A large effect of BCC (0.74, 0.89) on the knowledge and practices of mothers of the under-five children was revealed in the study.

Conclusion: Behavioural change communication through interpersonal communication has improved mothers' child survival knowledge and practices and its use is thereby recommended for promoting child survival practices among mothers of under-five children.

Maternal factors and dietary diversity in relation with *stunting* among under-5 children: analysis of mother-child pair data of Indonesia basic health survey 2018

Qonita Rachmah[1], Zida Husnina[1], Sri Sumarmi[1], Soenarnatalina Melaniani[1], Kuntoro Kuntoro[1], Nunik Puspitasari[1], Agus Triwinarto[2], Nurillah Amaliah[2], Yurista Permanasari[2], Takashi Yamano[3]

1. Faculty of Public Health - Universitas Airlangga (Indonesia), 2. National Institute of Research and Development, Ministry of Health (Indonesia), 3. Asian Development Bank (Japan)

Background and objectives: Indonesia are now still suffering from high prevalence of child stunting. Maternal factors play a significant role in the prevention of stunting which need to be addressed. Additionally, dietary diversity also predicts the adequacy of nutrients that could prevent stunting. This study aims to understand the maternal factors and dietary diversity as a risk of child stunting in Indonesia.

Methods: A cross-sectional, secondary analysis using mother-child pair data from Indonesia health survey 2018 was done in this study with total sample of 73,691 paired data. Maternal characteristic collected by interviewing of structured questionnaire. Maternal height and mid-upper arm circumference (MUAC) were collected using direct measurement, while dietary diversity was measured based on the type of food group intake in the last 24 hours which consists of 9 food groups. Stunting was retrieved from Height-for-Age Z-score (HAZ) using WHO Anthropometry software based on direct measurement of length/height. Data then analyzed using logistic regression to get the magnitude of risk for each variable tested with significancy at $\alpha < 0.05$.

Results: Stunting prevalence was found at 27.4, significantly higher in boys. Maternal characteristic that correlated to stunting were mother's age *p*< 0.000; OR = 1.736; 95% CI 1.718 – 1.755), age of first pregnancy (*p*< 0.000; OR = 0.040; 95% CI 0.030 – 0.050), total parity (*p*<0.000; OR = 1.725; 95%CI 1.716 – 1.733), mother's education (*p*< 0.000; OR = 1.216; 95% CI 1.200 – 1.233), mother's working status (*p*< 0.000; OR = 1.898; 95% CI 0.891– 0.925), adherence of iron-folic acid (IFA) tablet consumption (*p*< 0.000; OR = 1.683; 95% CI 1.677 – 1.689), mother's stature (*p&lt* ;0.000; OR=6.31; 95% CI – 6.00 – 8.00), and mother's MUAC (*p*< 0.000; OR = 0.120; 95% CI 0.120 – 0.130). Dietary diversity was also significantly higher in non-stunted children compared to stunted children (p=0.031; OR = 1.646; 95% CI 1.641 – 1.650).

Conclusion: In conclusion, we found highest risk factor of stunting was mother short stature, working status and adherence to consume IFA. This study implies that prevention of stunting prevention should start as early as possible by preparing the nutritional status of childbearing age women or before pregnancy starts, as well as the need for monitoring IFA consumption compliance.

The impact of COVID-19 on vitamin A supplementation coverage among children aged 6-59 months in four countries in Sub-Saharan Africa

Melissa M. Baker[1], Amynah Janmohamed[1], Romance Dissieka[3], Fatou Ndiaye[6], Alkaya Kounta[5], Regina Khassanova[2], Cheick Barry[2], Koffi Landry Kouadio[3], Mohamed Lamine Fofana[4], Djeinam Toure[6]

1. Helen Keller International (Kenya), 2. Helen Keller International (Burkina Faso), 3. Helen Keller International (Cote d'Ivoire), 4. Helen Keller International (Guinea), 5. Helen Keller International (Mali), 6. Helen Keller International (Senegal)

Background and objectives: Vitamin A supplementation (VAS) for children aged 6-59 months occurs mainly during semi-annual health events in Sub-Saharan Africa (SSA). Infection prevention measures and community sensitization were integrated into campaigns during the COVID-19 pandemic to reduce risk of transmission and mitigate reticence to health service delivery at home. This study explored the impact of socio-demographic factors, COVID-19 concerns and behavioural modifications on VAS coverage in four countries in SSA.

Methods: Data from eight nationally-representative household post-event coverage surveys (n=~27,700) using a cross-sectional cluster study design and conducted in Burkina Faso, Côte d'Ivoire, Guinea and Mali were used to compare changes in VAS coverage between 2019 and 2020. Data were

collected from primary caregivers of children aged 6-59 months. Descriptive statistics and adjusted multi-variable logistic regression models examined the effects of rural vs. urban residence, child sex, child age, caregiver education, household wealth status, and levels of concern regarding COVID-19 on child VAS status.

Results: Between 2019 and 2020, VAS coverage increased in Burkina Faso (82.2% to 90.8%), Côte d'Ivoire (87.0% to 93.3%), and Mali (76.1% to 79.3%), and decreased in Guinea (86.0% to 82.3%). In the 2020 models, children living in rural areas had a higher likelihood of VAS compared to children in urban areas in Burkina Faso (aOR = 4.75; 95% CI: 3.52, 6.40), Côte d'Ivoire (aOR = 5.19; 95% CI: 3.10, 8.70) and Mali (aOR = 1.41; 95% CI: 1.15, 1.74). Children aged 12-59 months had a higher likelihood of VAS compared to children aged 6-11 months in Côte d'Ivoire (aOR = 1.67; 95% CI: 1.12, 2.48) and Mali (aOR = 1.74; 95% CI: 1.34, 2.26). A moderate to high level of concern regarding COVID-19 was associated with a lower likelihood of VAS in Côte d'Ivoire (aOR = 0.55; 95% CI: 0.37, 0.80).

Conclusions: The higher VAS coverage observed in 2020, as compared to pre-pandemic levels, in three of four countries suggests that COVID-19-related caregiver concerns and behavioural modifications may not have been limiting factors to uptake of VAS in some countries in SSA where campaigns incorporated measures to reduce risk and sensitize communities.

Impact of COVID-19 pandemic on children food security and nutrition: results of the 2021 Student Evaluation Survey conducted by the Mexican National System for the Integral Development of the Family

Karina Sanchez Bazan[1], Arturo Juarez[3], Catalina Torres[2], Uritzimar San Martin[2], Lina Pohl[1], Gustavo Olaiz[3]

1. Food and Agriculture Organization of the United Nations (Mexico), 2. National System for the Integral Development of the Family (SNDIF) (Mexico), 3. Center for Research in Policies, Population and Health of the Faculty of Medicine of the National Autonomous University of Mexico (CIPPS-UNAM) (Mexico)

Background and objectives: Mexico has been severely impacted by the COVID-19 pandemic. As of April 2022, 324,033 total deaths directly related have been reported. In 2021, the National System for the Integral Development of the Family (SNDIF), which is the government agency responsible for the implementation of Food Social Assistance Programs, studied the impacts of the pandemic in children's food security and nutrition through its Student Evaluation Survey (SES). The first SNDIF SES was conducted in 2018. Therefore, the 2021 SES has a baseline for comparison. The objective of the study is to determine if factors associated with the pandemic such as head of household illness and/or death and loss of employment or economic stability, modified the following indicators: a) growth, b) food security, and c) diet. It is expected that the evidence of this study will inform policy making.
