Background and objectives: The prevention of obesity is a significant public health goal because obesity is associated with hyperlipidemia, metabolic syndrome, and type 2 diabetes. Previous animal studies show probiotic lactic acid bacteria derived from kimchi affected anti-obesity. However, only a few epidemiological studies have investigated the association between kimchi consumption and obesity. Therefore, this study aimed to examine the relationship between kimchi consumption and obesity in Korean adults.

Methods: Data was collected from 38 general hospitals and health examination centers from 2004 to 2013. A total of 119,224 participants (37,499 in men and 81,725 in women) aged 40 to 69 years were available for this cross-sectional study. Obese by body mass index (BMI, kg/m^2) was defined as 25≦BMI (class Ⅰ obese 25≦BMI<30 and class Ⅱ obese 30≦BMI), and abdominal obesity was defined as 90≦waist circumference (WC) in men and 85≦WC in women. The validated FFQ was used to assess kimchi consumption. Total kimchi included cabbage kimchi, radish kimchi, watery kimchi, and other kimchi. A multivariable logistic regression analysis model was used to estimate the odds ratio (OR) and 95% confidence interval (CI) of obesity according to kimchi consumption.

Results: The prevalence of obesity was 28.2% (35.9% in men and 24.6% in women) in this study. After controlling for potential confounders, women with higher cabbage kimchi consumption (≧150g/day) had 8% lower odds of class Ⅰ obese (OR: 0.922; 95% CI: 0.857-0.992) and 23% lower odds of class Ⅱ obese (OR: 0.774; 95% CI: 0.633-0.945) as compared with consumed<50g/day. In both men and women, participants who consumed radish kimchi≧median (25.0g/day in men, and 10.7g/day in women) were inversely associated with lower odds of abdominal obesity (OR: 0.915; 95% CI: 0.840-0.997 in men, and OR: 0.912; 95% CI: 0.863-0.963 in women) compared to non-consumers.

Conclusions: Consumption of total kimchi was not clearly shown to be associated with obesity and abdominal obesity. However, cabbage kimchi was associated with lower obesity prevalence in women, and radish kimchi was associated with a lower prevalence of abdominal obesity in both men and women.

Physical activity status and its associated factors among hypertensive patients in 3 counties of Guizhou Province

XiaoRong Ni[1], Rong Wang[1], Yi Liang[2]

1. GuiZhou Medical University (China), 2. Affiliated Hospital of GuiZhou Medical University (China)

Background and objective: To investigate the situation and influencing factors with hypertensive patients' physical activity in 3 counties of Guizhou Province.

Methods: With multi-stage random sampling, 2230 hypertensive patients with basic public health management and drug treatment were selected from residents of three counties and asked to fill in questionnaires on the assessment of physical activity and relevant factors.

Results: The proportion of physical activity meets standards was 37.0%. The results of logistic regression analysis showed that hypertensive patients with following characteristics were more likely to have physical activity behaviors: Living in a city or town (odds ratio [*OR*]=4.722, confidence interval [95% *CI*]:3.522~6.332), grade school culture degree(*OR*=1.587, 95% *CI*:1.247~2.019), Junior high school and above education level(*OR*=1.914, 95% *CI*:1.434~2.556), Non-farmers (*OR*=1.909, 95% *CI*:1.448~2.516), Central obesity (*OR*=1.284, 95% *CI*:1.009~1.632). The hypertensive patients with following characteristics were less likely to have physical activity behaviors: Han nationality (*OR*=0.606, 95% *CI*:0.486~0.755), The course of disease ranged from 5 years to 10 years (*OR*=0.714, 95% *CI*:0.587~0.869), Course of disease over 10 years (*OR*=0.603, 95% *CI*:0.420~0.865).

Conclusion: The physical activity in patients with hypertension in 3 counties of Guizhou Province is insufficient. Residence, education level, occupation, central obesity, nationality, course of disease are related to the physical activity.

Effects of Intermittent High-Dose Vitamin D Supplementation on Risk of Falls and Fractures: A Systematic Review and Meta-analysis

Seung-Kwon Myung[1], Heram Cho[2]

1. National Cancer Center Graduate School of Cancer Science and Policy (Korea), 2. Smith College (USA)

Background: Randomized controlled trials (RCTs) have reported controversial findings regarding the associations between intermittent high-dose vitamin D supplementation and the risk of falls and fractures in adults. This study aimed to investigate those associations by using a systematic review and meta-analysis.

Methods: We searched PubMed, EMBASE, and Cochrane Library from inception to May 25, 2022. Data were extracted for a random-effects meta-analysis to calculate a pooled relative risk (RR) with a 95% confidence interval (CI).

Results: Out of 527 articles, a total of 16 RCTs were included in the final analysis. In the meta-analysis of all the included RCTs, intermittent high-dose vitamin D supplementation showed no significant benefit in the prevention of falls or fractures (RR, 1.02 [95% CI, 0.92-1.13]; I2 = 53.8%; n = 16). In the subgroup meta-analysis by methodological quality assessed based on the Jadad scale, intermittent high-dose vitamin D supplementation showed an increased risk of falls and fractures (RR, 1.10 [95% CI 1.00-1.20]; I2 = 27.2%; n = 10) in high-quality RCTs. Publication bias was not observed in the Egger's test (P for bias = 0.35).

Conclusions: In this meta-analysis of RCTs, intermittent high-dose vitamin D supplementation had no preventive effect in the risk of falls and fractures and even showed a harmful effect in the high-quality trials. Therefore, an intermittent high-dose regimen of vitamin D supplements for the purpose of the prevention of falls and fractures in adults should be discouraged.

Diets poor or rich in unprocessed beef have similar effects on body weight homeostasis and body composition after rapid weight loss

Faidon Magkos[1], Sidse Rasmussen[1], Mads Hjorth[1], Sarah Asping[1], Maria Rosenkrans[1], Anders Sjödin[1], Arne Astrup[1], Nina Geiker[1]

1. University of Copenhagen (Denmark)

Background and objectives: The physiological effects of consuming different amounts of unprocessed red meat during weight loss maintenance are not known. We aimed to evaluate the effects of diets with small or large amounts of lean beef, consumed after successful weight loss, on body weight homeostasis and body composition.

Methods: In this randomized controlled trial, 108 adults with BMI 28-40 kg/m^2 (45 men/63 women) underwent an 8-week very-low-calorie diet (VLCD) phase, and those who lost at least 8% body weight (n=80) continued to a 12-week ad libitum diet phase while consuming a moderate-protein diet with 25 g beef/day (B25, n=45) or a high-protein diet with 150 g beef/day (B150, n=35).

Results: Among the 69 subjects who completed the entire study, weight loss during the VLCD phase averaged 12.5 kg (11.5, 13.5) in B25 and 13.1 kg (12.1, 14.1) in B150 (means with 95% confidence intervals). During the ad libitum diet phase, body weight decreased further in both B25 and B150 groups by -1.3 kg

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

(-2.4, -0.3) and by -1.1 kg (-2.2, -0.0), respectively; fat mass decreased by -2.4 kg (-3.2, -1.6) and by -3.0 kg (-3.9, -2.2), respectively, whereas lean mass increased by 1.1 kg (0.6, 1.7) and by 1.9 kg (1.3, 2.5), respectively. There were no significant differences between the two diet groups in these outcomes (all P>0.05). Intention-to-treat analysis with multiple imputation for dropouts (20 from B150 and 19 from B25) yielded similar results.

Conclusions: Diets with little or a lot of unprocessed red meat (lean beef) consumed ad libitum during the first 3 months after clinically significant rapid weight loss have similar effects on body weight and body composition.

Keywords: Obesity, weight maintenance, fat mass, lean mass, red meat

Conflict of Interest Disclosure: Dr. Geiker has received funding from various organizations to conduct studies relevant to the role of meat in the diet. The other authors report no conflicts of interest relevant to this abstract.

Therapeutic Approaches to Malnutrition Enteropathy (TAME): a randomised controlled trial in children with severe acute malnutrition in Zambia and Zimbabwe

Paul Kelly[1,2], Kanta Chandwe[2], Mutsa Bwakura-Dangarembizi[3], Beatrice Amadi[2], Gertrude Tawodzera[3], Simon Murch[4], Susan Hill[5], Raymond Playford[6], Kelley VanBuskirk[2], Andrew J Prendergast[1,3]

1. Queen Mary University of London (UK), 2. Tropical Gastroenterology & Nutrition group (Zambia), 3. Zvitambo Institute for Maternal and Child Health Research (Zimbabwe), 4. University of Warwick (UK), 5. Great Ormond Street Hospital (UK), 6. University of West London (UK)

Background: Severe Acute Malnutrition (SAM) carries high mortality when complicated by infection or metabolic derangements, which require inpatient management. As intestinal dysfunction (diarrhoea, microbial translocation, malabsorption) is a prominent feature of complicated SAM we set out to evaluate four novel interventions for intestinal dysfunction in children with complicated SAM.

Methods: Multi-arm, phase II, non-blinded randomised controlled trial in two hospitals in Lusaka, Zambia, and Harare, Zimbabwe. All children received inpatient standard care following WHO guidelines. Children were randomised to 14 days of i) oral or nasogastric bovine colostrum three times daily, ii) N-acetyl glucosamine three times daily, iii) budesonide three times daily (then tapered), iv) subcutaneous teduglutide once daily, or v) standard care only. The primary endpoint was a composite of faecal biomarkers (myeloperoxidase, neopterin and α_1-antitrypsin). Secondary endpoints were biomarkers of mucosal damage, inflammation, and microbial translocation; and clinical recovery, anthropometry, adverse events and mortality. A subgroup in Lusaka additionally underwent endoscopy for small intestinal biopsy. α for hypothesis testing was pre-specified at 0.1.

Results: Between May 2020 and April 2021, 125 children were randomised, 3 died, 3 withdrew, and 119 (95%) contributed endpoint data. The faecal biomarker score (mean at baseline 1.87) was reduced in the teduglutide group by 0.89 (95%CI -0.06, 1.85) compared with the standard care group (*P*=0.07 by ANCOVA). Teduglutide also led to a significant increase in crypt depth in mucosal biopsies compared to standard care (median 197mm (IQR 149,221) versus 151mm (IQR 136,162); P=0.02 across all groups). Budesonide reduced plasma C-reactive protein (CRP; mean reduction 5.2mg/L (95%CI 0.0, 10.5); P=0.05) and CD163 (mean reduction 405 ng/mL (95%CI 8,803); P=0.05) while colostrum and N-acetyl glucosamine had effects only on CRP (reductions 5.9mg/L (95%CI 0.6, 11; P=0.03) and 4.8mg/L (95%CI 0.3,10; P=0.07) respectively). Diarrhoea was reduced by 2.2 days (95%CI 0.9, 3.5: P=0.001) in the N-acetyl glucosamine group. Adverse Events were not significantly different between treatment arms.

Conclusions: All interventions were safe. Teduglutide led to significant reductions in markers of malnutrition enteropathy, and budesonide reduced systemic inflammation. Larger trials are warranted to establish clinical efficacy, optimal timing and duration of intervention during nutritional rehabilitation.

Optimising nutritional status in patients with chronic respiratory diseases through pulmonary rehabilitation to improve disease outcomes

Rita Caroline Isaac[1], Biswajit Paul[1], Paul Jebaraj[1], Jeyalakshmi S[1], Valsa Augustine[2], Rakesh Kumar S[1], Hilary Pinnock[3], David Weller[3]

1. Christian Medical College, Vellore, (India), 2. Schieffelin Institute of Health-Research and Leprosy Center, Karigiri, Vellore (India), 3. Usher Institute, The University of Edinburgh, Edinburgh, (UK)

Background and objectives: Chronic respiratory diseases (CRD) that include chronic obstructive pulmonary disease (COPD) and asthma with its associated fatigue, malnutrition, loss of muscle mass, reduced muscle strength and endurance and the resulting psychological effects adversely affects patient's health-related quality of life. Pulmonary rehabilitation (PR) includes assessment of nutrition status and interventions that will improve residual functionality in patients with CRD. The objectives of the study was to assess the feasibility of PR and improvement in functionality of CRD patients.

Methods: A pre-post quasi-experimental study assessed the feasibility of peripheral center based PR and its outcomes, offered at outreach centers close to their homes, promoted by peer volunteers and assisted by health professionals on 30

participants with CRD. After the written consent and optimising the medical treatment, the participants were assessed for their socio-demographic, medical and treatment history, endurance level, muscle strength, activities of daily living (ADL), haemoglobin level and BMI. For those with anaemia and abnormal BMI were assessed for dietary intake using 24 hours recall by the nutritionist. The components of PR included diet counselling, treatment of anaemia, changing physical activity habits, handgrip strength exercises, lower extremity strength training, breathing exercises to improve nutritional status, upper limb, lower limb and inspiratory muscle strength. Their rehabilitation activities were monitored by the trained peer volunteers.

Results: The median age of participants was 57.5(IQR=47.5-70.25);10% of them had mild to severe undernutrition, 37% had overweight and 13% were obese; 33.3% had anaemia. At the end of 8 weeks of training, aerobic capacity and endurance assessed by 6-minute walk test and endurance testing cycling time, hand-grip strength and percentage distribution of ADL improved significantly($p<0.01$); prevalence of anaemia reduced to 16.4% and BMI remained the same at the end of 6 months.

Conclusions: Pulmonary rehabilitation that paid special attention to nutritional status and muscle strengthening exercises can contribute significantly to reduce residual disability and improve functionality in patients with CRD

The Methods, Effectiveness, and Challenges of Nutrition Intervention Based on Digital Health

Ruixin Chi[1], Na Zhang[1], Guiyuan Shen[1], Guansheng Ma[1]

1. Peking University (China)

Background and objectives: Nutrition is one of the most critical factors in health management. Digital health provides new opportunities for nutrition education, dietary assessment, and management through online information delivery. With wide application, high convenience, and intense interaction, digital health-based dietary interventions are gradually playing a vital role in nutrition intervention. However, there is a lack of adequate review and evaluation. As a result, we tried to review the development of digital health intervention in nutrition.

Methods: We reviewed previous nutritional intervention studies using digital health methods through a literature review. Peer-reviewed published articles and grey literatures areliterature were all included. The quality of the literature was assessed according to guidelines on digital health by the CONSORT (Consolidated Standards of Reporting Trials) list.

Results: Digital nutritional interventions use mobile devices and self-reported data to collect participants' dietary status, rely on databases and algorithms to evaluate personal data, utilize online systems to transfer online information to provide nutrition and lifestyle education and to engage in discussion. It changes individual behavior and health outcomes by combining the above methods. In terms of the participants, interventions mainly focus on patients and young people. They always choose blank or usual care as a control. With the development, the number of participants is growing from only a few people to a sufficient scale. Meanwhile, the outcome indicators are not just usually compliance or behavioral indicators but disease-related outcome indicators, such as changes in blood biochemistry and imaging. Studies have demonstrated the feasibility of digital health intervention in nutrition. However, research design, intervention implementation, and scientific evaluation also have much room for improvement. Information security and health inequalities in this area should be given more attention. Therefore, it is necessary to carry out high-level scientific, normative and feasible dietary intervention research focus on more health problem and wider population.

Conclusions: Digital health has promising applications in nutrition and lifestyle interventions, but the quality of research needs to be strengthened, and the scope of its application should be promoted.

Changes in colon luminal environment induced mitochondrial dysfunction of epithelial cells in obese mice

Thomas Guerbette[1], Martin Beaumont[2], Mireille Andriamihaja[3], Gwénaëlle Randuineau[1], Régis Janvier[1], Patricia Leroyer[1], Olivier Loréal[1], Gaëlle Boudry[1], Annaïg Lan[1,3]

1. Institut NuMeCan (France), 2. GenPhySE (France), 3. UMR PNCA (France)

Background and objectives: Obesity and overweight are characterized by a systemic low-grade inflammation that has been associated with disturbances of intestinal homeostasis and dysbiosis. Energy metabolism, in particular through mitochondria, plays a central role in intestinal epithelial homeostasis. In addition, dietary modulations of the luminal environment may impact mitochondrial function. The aim of this study was to evaluate whether consumption of an obesogenic diet, also called western diet (WD), alters mitochondrial function of colonic epithelial cells (CEC) in mice.

Methods: Male C57Bl/6J were fed a control diet (CTRL, 10% kcal from fat) or a WD (58% kcal from fat and drink water supplemented with fructose and sucrose at 42 g/L). After 22 weeks, CEC were isolated to assess mitochondrial function by Seahorse® technology while colonic content was collected to characterize microbiota, through 16S DNA analysis, and

intestinal metabolites, via nuclear magnetic resonance and a methylene blue-based assay for sulfides.

Results: WD mice developed obesity associated with hepatic steatosis and systemic endotoxemia (LPS-BP: 535.8±38.5 vs 668.7±39.7 ng/mL, P<0.05). Analysis of CEC bioenergetics revealed a mitochondrial dysfunction marked by decreased basal (61.0±10.5 vs 31.2±5.5 pmol O_2/min/DNA, P<0.05) and maximal respirations (87.5±15.0 vs 44.1±9.9 pmol O_2/min/DNA, P<0.05) as well as lower respiration linked to ATP production (35.4±8.0 vs 18.8±2.9 pmol O_2/min/DNA, P<0.05). Yet, WD consumption did not alter gene and protein expressions of mitochondrial respiration chain complexes, and mitochondrial dynamics was not affected. The colonic metabolome analysis showed that consumption of a WD induced an increase in bile acid concentrations in WD mice, associated with an increase in the abundance of Desulfovibrionaceae and especially Bilophila, a known H_2S producer. Besides, sulfide concentration was markedly increased in colon content of WD mice (5.9±1.7 vs 31.74±10.5 µM/mg of content, P<0.01).

Conclusions: These results suggest that changes in the luminal environment induced by WD consumption disrupted the mitochondrial respiratory chain, potentially through deleterious effects of H_2S. This mitochondrial dysfunction could promote the loss of intestinal homeostasis or even increase susceptibility to intestinal inflammation.

PAB(T4)-206
Effect of consumption of fish rich in n-3 polyunsaturated fatty acids on treatment response in patients with rheumatoid arthritis

Olga Amengual[1], Masato Tarumi[1], Yuichiro Fujieda[1], Ryo Hisada[1], Michihito Kono[1], Masaru Kato[1], Tatsuya Atsumi[1]

1. Hokkaido University, Faculty of Medicine and Graduate School of Medicine (Japan)

Background and objectives: Rheumatoid arthritis (RA) is a systemic autoimmune disease caused by an inflammatory process triggered by environmental factors in genetically predisposed individuals. The use of targeted therapies has transformed the treatment of RA and resulted in a good clinical response, but not in all the patients. Consumption of fish rich in n-3 polyunsaturated fatty acids (PUFA) has been reported to have a favourable effect on RA incidence and disease activity. However, the effect of n-3 PUFA-rich fish on the response to targeted therapies in RA patients has not been elucidated. This study aimed to investigate the relationship between n-3 PUFA-rich fish consumption and response to targeted therapies in RA patients.

Methods: The study is a cross-sectional study of RA patients receiving targeted therapies at Hokkaido University Hospital. On the day of study entry, patients were invited to complete a brief self-administered dietary history questionnaire and a detailed fish intake frequency questionnaire (DFFQ). Fatty and non-fatty fish intake scores were calculated using a mathematical formula based on the intake of each of the fish included in the DFFQ. Alcohol consumption, smoking, educational level and employment status were also recorded, and disease activity was assessed by rheumatologists. Demographic, clinical/laboratory data were retrospectively extracted from medical records. Patients were classified as responders or non-responders using the disease activity score, DAS28-ESR.

Results: A total of 102 RA patients, 84 women, median age of 66 yrs (Q1-3, 56-73) were included. Ninety-one patients were on biologic agents and 11 on Janus kinase inhibitors. Seventy-six patients were responders to treatment. Ninety-eight % of patients reported having consumed fish rich in n-3 PUFA in the last month, 49% less than once a week, and 49% at least once a week. Patients who responded to treatment had higher n-3 PUFA-rich fish intake scores compared to those in the non-responder group (Mann-Whitney U test, p=0.02). Multivariate logistic regression analysis showed that higher n-3 PUFA-rich fish intake scores were associated with treatment response (p=0.03, OR: 1.12, 95% CI: 1.02-1.25).

Conclusion: Consumption of n-3 PUFA-rich fish is associated with treatment response in RA patients receiving targeted therapies.

Keywords: Rheumatoid arthritis, fish consumption, targeted therapy, n-3 PUFA, DAS28

PAB(T4)-207
Additive effect of common obesity-related SNP variants in admixed Brazilian population: 2015 ISA-Nutrition study.

Jaqueline Lopes Pereira[1], Camila Alves Souza[2], Julia Pavan Soler[2], Marcelo Macedo Rogero[1], Flavia Mori Sarti[3], Regina Mara Fisberg[1]

1. School of Public Health - University of Sao Paulo (Brazil), 2. Institute of Mathematics and Statistics - University of São Paulo (Brazil), 3. School of Arts, Sciences and Humanities - University of Sao Paulo (Brazil)

Background and objectives: Large-scale genome-wide association studies (GWAS) identified loci associated with obesity, however, most evidence refers to populations of European or Asian ancestry. Considering the importance of diversity and the participation of multi-ethnic groups in GWAS, we aimed to identify loci associated with obesity in admixed Brazilian population from Sao Paulo city.

Methods: The analyses included 841 free-living individuals aged 12 years or more of the cross-sectional population-based Health Survey of Sao Paulo with Focus on Nutrition (2015 ISA-Nutrition). Obesity was defined according to BMI cutoffs. Genotyping was obtained from blood using Axiom PMR Array, resulting in 731,392 high-performing markers, after quality control pruning. Population structure and global ancestry were accessed through principal component analysis, comparing data

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

with 1000 Genomes Project phase 3 (1KGP). A list of 1,500 markers previously associated with obesity-related traits in other GWAS reported by NHGRI-EBI GWAS Catalog was selected to perform initial evaluation of possible markers associated with obesity in ISA-Nutrition sample. We performed a logistic regression model with obesity as dependent variable, adjusted by sex, age group, interaction sex-age group, marital status, plasma C-reactive protein levels, presence of diabetes, hypertension, dyslipidemia, and the two first principal components of global ancestry, assuming an additive effect of the markers.

Results: The population included 49.7% of women, 29.7% adolescents, 34.5% adults and 35.8% older adults (mean age=47y; min.=12y; max=93y) with 22.8% prevalence of obesity. The mean ancestry proportion was: 53% European, 23% African, 23% Native American, and 1% Asian (East and South). There were 14 obesity-related candidate SNP that reached significance (P<0.01). Eleven SNP were previously associated with obesity-related traits in a study evaluating Hispanic children from Houston, TX, USA. The rs1993709 (OR-AG/AA=1.77, OR-GG/AA=3.15) and rs1514177 (OR-CG/CC=0.616, OR-GG/CC= 0.379) were previously associated with obesity and BMI in other studies with European populations, the rs259067 (OR-TG/GG= 0.618, OR-TT/GG= 0.382) was associated with obesity in East Asians, and the rs1421085 in gene FTO (OR-CT/TT=0.558, OR-CC/TT= 0.312) was associated with obesity and obesity-related traits in studies with diverse populations.

Conclusions: The findings provide an entry point to characterize common obesity loci that may be ancestry-specific in the Brazilian population.

Differences of different energy calculation formulas and the relationship between actual intake and clinical outcomes in critical patients with ventilator

Peichuan Tsai[1], Peirong Li[1]

1. Tungs' Taichung MetroHarbor Hospital (Taiwan)

Background and objectives: If the critical ill patients with ventilator fail to provide adequate nutritional intake in time, it would induce the loss of lean body mass and prolong the recovery time. Excessive caloric intake will increase consumption of oxygen and production of carbon dioxide. It also leads to difficult weaning from ventilator. However, the current clinical ways of evaluating caloric requirement were not consistent. It is quite important for how to conveniently and accurately assess the caloric requirement of critically ill patients with ventilator. The purposes of this study were to assess the differences between current caloric supply and the calculation result of Penn State equation (PSU), and to investigate the relationship between intakes and patients' clinical outcomes.

Methods: This was a retrospectively observational study. The medical records of patients with mechanical ventilation at the surgical intensive care unit (SICU) were reviewed. We collected patients' demographic characteristics, anthropometric measurements, ICU length of stay, ventilator days, and 28-day survival situation.

Results: Caloric requirements calculated using the PSU for ICU patients were not significantly different from the simple weight-based equations of ASPEN recommended. The average number of days for patients to reach their caloric goals, intakes up to 70% of the requirement, was only 1.5±1.6 days in the second to seventh day after admission to the ICU. Correlation analysis showed that caloric intake was not significantly associated with clinical outcomes. On the other hand, protein intake was only significantly correlated with the ventilator days. For every 1-gram increase in protein intake, the ventilator days decreased by 0.27±0.13 days (p<0.05).Although there was no statistically significant correlation between protein intake and ICU length of stay or 28-day survival rate, there was a trend for a decrease in ICU length of stay with each additional 1 gram of protein (-0.28±0.14 days, p=0.055).

Conclusions: The estimation of caloric needs by simple weight-based equations for ICU patients was similar to the PSU. Within one week of ICU admission, increasing protein intake might have a trend to improve clinical outcomes in the setting of calorie deficit.

Keywords: Ventilated critical patient, energy calculated formula, protein intake, clinical outcome

PAB(T4)-209
Impact of dietary counselling on dietary and plasma advanced glycated end products levels: A randomized controlled trial

Peichuan Tsai[1], Peirong Li[1]

1. Jung Eun Kim[1], Jasmine Hui Min Low[1]

Background and objectives: Advanced glycated end products (AGEs) are a complex group of compounds that are developed by non-enzymatic reactions between reducing sugar and amino acids in proteins and other macromolecules. They can be obtained exogenously from diet or formed endogenously within the body and greater levels found in older adults in particular. Previous research revealed that dietary and plasma AGEs levels are significantly associated with age-related diseases risk. Dietary counselling is one of an effective dietary strategy to attenuate an age-related disease risk while its effect on the modulation of dietary and plasma AGEs levels has not been well investigated. Therefore, this study aimed to assess the impact of dietary counselling on dietary and plasma AGEs levels in older adults through a randomized controlled trial (RCT).

Methods: This was a 12-week, parallel design, RCT where 39 older women (aged above 60 y) in Singapore were randomized

in which the intervention group received 12-week dietary counselling while the control group did not receive dietary counselling. The counselling covered various topics on food proportioning, food label reading, cooking methods and several age-related diseases conditions. N-carboxymethyl-lysine (CML) is a well characterized and most prevalent AGEs and dietary CML level was estimated using previous published databases and plasma CML level was analyzed using a high performance liquid chromatography.

Results: There was no significant difference and change in dietary CML levels between intervention (week 0: 5.6 mg/d ± 2.6; week 12: 5.5 mg/d ± 3.0) and control group (week 0: 5.8 mg/d ± 2.8; week 12: 5.8 mg/d ± 2.9). However, control group increased plasma CML level (week 0: 184.3 ng/ml ± 19; week 12: 292.1 ng/ml ± 27) while intervention group decreased plasma CML level (week 0: 166.3 ng/ml ± 17; week 12: 120.0 ng/ml ± 15) after intervention and there was a significant difference in plasma CML levels between groups at week 12.

Conclusions: The provision of dietary counselling may be a viable nutritional strategy in lowering age-related disease risk by modulating plasma AGEs levels.

The relationship between the distinction of nutritional supply to critically ill patients in different divisions and clinical outcomes

Peirong Li[1], Shungsheng Tsou[1], Xiaoyin Huang[1]

1. Tungs' Taichung MetroHarbor Hospital (Taiwan)

Background and objectives: The strategy of nutritional intervention was correlated with clinical outcomes in critically ill patients. Previous studies had found that not all critical patients improved the outcome after increasing caloric intake. In the acute phase of critical ill, the critical patients produced energy by catabolism to supply the energy expenditure. The debt of energy was the amount of energy supply. However, the difference of catabolism was existed between the different diseases. The purpose of this study was to retrospectively investigate whether the pattern of calorie and protein supply associated with clinical outcomes between medical and surgical intensive care unit.

Methods: This was a retrospectively observational study. The medical records of patients who had been admitted to an intensive care unit for more than 72 hours were reviewed. The inclusion criteria of this study for patients included those who were 20 years or older, and those who had been admitted to intensive care unit for more than 72 hours, the exclusion criteria were that they received neither enteral nor parenteral nutrition. Their demographic characteristics, anthropometric measurements, nutrient-related data form enteral, parenteral, or intravenous, laboratory data and several clinical outcomes were collected.

Results: There was no significant difference in baseline information and biochemical profile between the two groups except that white blood cells in medical patients was significantly higher than that in surgical patients (14.8±8.3 vs. 11.2±5.5 x10^3 cells/mm^3, p=0.001). There were no significant associations of caloric or protein intake with clinical outcomes either in all patients or when patients were classified as medical or surgical patients. Disease severity, by contrast, significantly associated with clinical outcomes. The patients were further divided into two groups according to disease severity, Apache Ⅱ score 14 points. It was found that the calorie intake of patients with a score of ≦14 might correlated with the length of stay (LOS), but which still no statistically significant difference (p=0.057).

Conclusions: Disease severity was still the most important factor to influence clinical outcomes. The correlation between caloric intake and LOS seemed to have a trend in patients with lower disease severity.

Effect of daily supplementation with spirulina fortified cereals on the body composition of people living with HIV/AIDS in Chad

Alain Nahaskida[1,2], Abdelsalam Tidjani[3], Mahamat Bechir[2], Himeda Makhlouf[2], Ndokain Jonathan[2], Stefaan De Henauw[1], Souheila Abbeddou[1]

1. University of Ghent (Belgium), 2. Direction de la Nutrition et des Technologies Alimentaires (Chad), 3. University of N'Djamena (Chad)

Background: Nutritional status of people living with HIV/AIDS (PLHA) in low- and middle-income countries remains a major determinant of mortality, poor response to antiretroviral therapy (ART), and higher dropout rates. Protein supplementation is a promising strategy for restoring fat-free mass (FFM) and reducing weight loss in PLHIV. Our objective was to assess, among PLHA receiving ART, the effectiveness of supplementation with spirulina-fortified or unfortified millet flour on changes in weight, and in FFM and fat mass (FM).

Methods: In an interventional randomized controlled trial, 345 adults living with HIV/AIDS, who attended the Hôpital du jour, N'Djamena and just started ART were enrolled. Participants were assigned randomly to receive one of the nutritional treatments for a period of six months: 1) standard care only, ART and nutritional counseling (Control); 2) daily 500 g of unfortified millet flour and standard care (Millet); and 3) daily 500 g of spirulina-fortified millet flour and standard care (Spirulina). At baseline and endline, weight and height were measured. Body composition was assessed using the deuterium dilution method.

Analysis of co-variance was used to compare the difference between groups. Differences were considered significant at $p<0.05$.

Results: 345 adults (33.2 ± 7.7 years of age) were enrolled and 295 completed the study. At baseline, 16.5% of participants were underweight (body weight index, BMI<18.5 kg/m^2<) and 79.4% had low to severely-low CD4. Weight increased in all groups (mean ± SD; 3.41 ± 4.17 kg). Weight gain was significantly higher in spirulina (4.74 ± 0.41 kg) than in millet (3.63 ± 0.44 kg) and control (1.91 ± 0.36 kg) groups ($p<0.0001$). Change in FFM was significantly greater in spirulina (6.02 ± 0.69 kg) compared to millet (3.06 ± 0.52 kg) and control (1.07 ± 0.84 kg). Proportion of FM (%FM) was lowest in the spirulina group (25.1% vs. 27.6% and 28.0% in control and millet groups respectively, $p=0.003$).

Conclusion: In food insecure settings, spirulina-fortified cereal flour increased weight with a body composition favoring FFM and a lower %FM. Further analyses will assess the effects on the immune response to ART.

Association of dietary patterns with overweight/obesity in school-aged children in Hebei

Yu Lu[1], Jinxin Guo[1], Hongmei Xue[1]

1. Hebei University (China)

Objective: To summarize the dietary patterns, analyze the current situation of obesity, and explore the relationship between dietary patterns and overweight/obesity in children aged 7-16 years in Hebei.

Methods: A total of 1085 children aged from 7 to 16 years old were enrolled in Hebei. Data on socio-demographic, dietary and lifestyle factors were collected by questionnaires. The dietary patterns of children were identified by factor analysis, and the population differences of overweight/obesity status of children were analyzed by chi-square test. The height and weight, waist circumference and hip circumference of children were measured on site to calculate body mass index (BMI), and then determine their overweight/obesity status. Logistic regression models were performed to evaluate the association between dietary patterns and children overweight/obesity.

Results: A total of 574 boys (52.90%) and 511 girls (47.10%) were included in this study. The overweight rate of children was 11.22%, the obesity rate was 8.02%, and the combined rate of overweight and obesity was 17.60%. Three dietary patterns of children in Hebei were identified: pattern 1 mainly includes beverages, ice cream, and western fast food; pattern 2 was beans, whole grains, dairy products as the main food; and pattern 3 was consisted of vegetables and fruits. After adjusting for gender, age, parental education, household income, energy intake, energy expenditure from moderate to high intensity physical activity, and pubertal development level, it was found that the higher pattern 2 score, the lower risk of developing overweight and obesity in children (OR: 0.58, 95% CI: 0.32-0.91); pattern 1 and pattern 3 may not be associated with overweight and obesity.

Conclusion: Children in Hebei are seriously overweight and obese. Thus, increasing food intake of legumes, whole grains, dairy products may be useful for improving overweight and obesity.

Keywords: Dietary patterns, Obesity, Nutrition, School-children

PAB(T4)-213
Effect of intake order of staple food, main dish, and side dish on postprandial blood glucose level in healthy young individuals

Ayumi Suda[1], Shunsuke Higaki[2], Yukiko Sumida[3], Tomohisa Koyama[3], Tomoko Asai[4], Yuichiro Takei[3], Reiko Inai[4], Tatsuhiro Matsuo[5]

1. Shitennoji University (Japan), 2. Hokkaido Bunkyo University (Japan), 3. University of Kochi (Japan), 4. Nara Women's University (Japan), 5. Kagawa University (Japan)

Background and objectives: Recently, dietary methods that consider the intake order of dishes have attracted attention in suppressing postprandial hyperglycemia and weight gain. On the other hand, the triangular eating (TE) method, in which staple foods, main dishes, and side dishes are eaten alternatively has long been established in Japan. In this study, we comprehensively investigated the effects of the intake order of staple food, main dish, and side dish on the increase in postprandial blood glucose levels. We also compared the effects of TE on postprandial blood glucose levels.

Methods: Seven healthy women participated in this study. The order of intake of the test meals was as follows: RMV: staple food (boiled rice), main dish (ginger grilled pork meat), and side dish (vegetable salad), RVM, MRV, MVR, VRM, and VMR. Regarding TE, the participants were randomly and alternately allowed to eat meat, vegetables, and rice in small amounts. Participants visited the laboratory at 9:00 on seven different days and consumed one of the seven test meals. Following blood collection, participants consumed one of the seven test meals, and the start of the test meal intake was considered 0 min. Blood was then collected again at 30, 60, 90, and 120 min to measure glucose levels. The area under the blood glucose concentration−time curve (AUC) between 0 and 120 min was calculated using the trapezoidal rule.

Results: The postprandial blood glucose level at 30 min of meal VRM increased similarly to that of meals RMV and RVM. At 120 min, postprandial glucose level was significantly higher in

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

meal VRM than in meals RMV, RVM, MRV, and TE. However, meal VMR, another vegetable-first meal, suppressed postprandial blood glucose levels and the AUC compared with meal VRM. The AUC was lower in meals MVR and MRV than in other meals, and the effect was stronger with meal MVR. In contrast, meal TE had little suppressing effect on postprandial blood glucose levels and the AUC.

Conclusion: These results suggest that the suppressing effect of postprandial hyperglycemia was greater for dietary protein than for dietary fiber. However, further detailed research may be needed.

Keywords: Intake order, rice, meat, vegetables, blood glucose

Effects of weight loss intervention program between diabetes referral patients and volunteers at a community hospital

Hsiao Chien Chen[1], Wei Lin[1], Chiao Yun Liu[1], Cheng Che Chen[1]

1. National Taiwan University Hospital Hsin-Chu Branch (Taiwan)

Background and Objectives: Lifestyle modifications can help weight control. Weight loss can also help delay pre-diabetes, and help diabetics control sugar. The aim of this study was to compare the effects of weight loss programs between referring diabetic patients and volunteers at outpatient clinics of a community hospital.

Methods: The subjects were adults with BMI ≧ 24 and referred from diabetes clinics or voluntarily enrolled. Weight loss intervention programs were held in the summer of 2018 and 2019, and each program contained four 50-min sessions of nutrition education and 50-min exercise courses. A total of 27 cases were participated, including 17 diabetic patients and 10 volunteers. Demographic data, height, weight, BMI and health information were collected before and after intervention.

Results: The average age was 51.7 years old and there was no significant difference in gender and age distribution between two groups. The average weights of the diabetes referral group before and after intervention were 81.5 and 80.1kg (-1.5kg; -1.8%). The average weight changes of the volunteers decreased from 77.1 to 73.9 kg (-3.3kg; -4.3%). There was no significant difference of weight loss between two groups. Linear regression analysis indicated that gender and age were not correlated to weight changes. All participants with higher body mass index before intervention had significant weight loss after intervention (p<0.01).

Conclusions: Although the weight loss program at community hospitals is beneficial to those with heavier weight, it is not effective for involuntary diabetes referral cases. Due to the small sample size and short-term intervention, it is difficult to receive obviously differences on weight changes. More study with large scale is needed through group intervention in the future.

Keywords: Weight loss program, lifestyle modifications, voluntarily enrolled

Personalized Nutrition Management and Information Provision for Autistic Children : Exploratory Clinical Research for Innovative Digital Platform

Hyejin Park[1], Minkyo Cha[1], Seungyeon Lee[1], Jinhyung Lee[1], Gyeongjun Park[1], Jiyoung Kim[1]

1. Seoul National University (Korea)

Background and Objectives: Considering personalized nutrition, people have different physiological and environmental complexities, and their dietary habits are different, so even if they eat the same food, their responses are very different. Previous researches have shown that children with autism spectrum disorder (ASD) have eating problems and therefore the quality and variety of diet they eat are generally lower than those of their normally developing peers. We developed a web/app-based personalized nutrition prediction model for ASD children and their caregivers, and performed the exploratory clinical basic research to investigate its effectiveness.

Methods: For application of personalized nutrition for children with ASD, the selection of biomarkers and nutrients to apply were reviewed in depth. Twenty children aged 3-5 years based on Autism Diagnostic Observation Schedule and K-Childhood Autism Rating Scale-2 and their 20 caregivers were participated in the study. Social Communication Questionnaire, K-Vineland-II, K-Parenting Stress Index-4 were observed for autism symptoms, and blood, genetics, and intestinal microbiota were examined for autistic children. Their caregivers recorded daily breakfast, lunch, dinner, snacks, nutritional supplements, etc. of autistic children for 6 weeks using the developed web/app tool. The first two weeks of the dietary data of children with ASD was observed followed by the four weeks, based on dietary, blood, and intestinal microbiome data, providing personalized nutrition counseling at weekly intervals to the caregivers. At the end of the study, the autism symptom, blood nutrients, and intestinal microbiome of the children with ASD were re-examined, and the caregiver satisfaction on the personalized nutritional prediction model was evaluated.

Results: By using the personalized nutrition prediction model, it was confirmed whether it could help improve diet diversity, intake of major nutrients for neurobehavioral development, diversity of intestinal microbiome, blood levels of nutrients, and autistic symptoms. Satisfaction with personalized nutrition management and information provision model was also investigated for caregivers.

Conclusions: Individualized nutritional interventions and appropriate supplementation using an innovative personalized nutrition digital platform can play an important role in ASD management.

Validation of a dietary pattern approach with risk of obesity in Korean adults: the Korea National Health and Nutrition Examination Survey

Jiyoung Hwang[1], Hyesook Kim[1], Oran Kwon[1]

1. Seoul National University (Korea)

Background and Objectives: Few studies have examined the multifaceted aspects of dietary patterns for their effects on obesity. The objective of this study is to identify the dietary patterns associated with the risk of obesity among Korean adults using data from the Korean National Health and Nutrition Examination Survey (KNHANES, 2015-2018) and for validation data (KNHANES, 2019-2020), a nationally representative cross-sectional survey.

Methods: A total of 20,500 adults (8,744 men and 11,756 women) aged 19-64 years participated in the Korea National Health and Nutrition Examination Survey (KNHANES) 2015-2018. A 24-h recalls for nutrient intakes was collected and dietary patterns were derived using Reduced Rank Regression (RRR). In this study, BMI and waist circumference were selected as the intermediate response variables based on the associations with obesity. Obesity in Korean adults is defined as body mass index ≧25 kg/m^2, and as waist circumference ≧90 cm for men and ≧85 cm for women. Associations were assessed by logistic regression with adjustment for confounding factors.

Results: All of energy and nutrient intakes of dietary pattern, characterized by high intakes of refined white rice, kimchi and salted vegetables, and low intakes of fruits, poultrys, eggs, milk and dairy products, and nuts significantly increased as the from quintile one to quintile five. After controlling for potential confounders, total subjects in the highest quintile of patten 1 scores had a greater risk of obesity (odds ratio = 1.30; 95% confidence interval = 1.15-1.48; p<0.01), in comparison to those from the lowest quintile. Moreover, verifying validity was confirmed by applying the same dietary pattern score to the validation dataset consisting of other subjects. Significant associations were observed for either men or women.

Conclusions: Adherence to a dietary pattern characterized high intakes of refined white rice, kimchi and salted vegetables, and low intakes of fruits, poultrys, eggs, milk and dairy products, and nuts is associated with a higher risk of obesity.

Keywords: Dietary pattern, Korean adults, Obesity, Reduced rank regression, Odds ratio

Evaluation of CKD Patients' Satisfaction in CKD Comprehensive Care Clinic, Fort Nawamintharachini Hospital

Kanokporn Wonganankit[1], Jatuphat Punjamat[1], Siripak Trakanant[1], Ittarom Jiwpraditkul[1], Raweewan Lappichetpaiboon[1]

1. Fort Nawamintharachini Hospital (Thailand)

Background and Objectives: Comprehensive care in chronic kidney disease (CKD) patients can prevent renal function decline and delay the progression of the disease, our team developed CKD clinic program with multidisciplinary team including nutritionist, physiotherapist, doctor, nurse, and pharmacist, which was for educational purposes not only medication but also diet and exercise intervention. Our program was empowering patients to get the information for lifestyle modification. One key to successful treatment is patients' satisfaction which contributes to patients' engagement, thus we aimed to study the CKD patients' satisfaction who attended in our clinic.

Methods: A cross-sectional study was conducted in 34 CKD patients (stage 3a-4) who attended in our clinic from December 2021- August 2022. The satisfaction was scored and described into four aspects: overall of our program, service, health professional staffs and other comment. We evaluated satisfaction level and also measured renal function before and after attending in this clinic.

Results: Most of CKD patients were male (76.5%), CKD stage 3a (58.5%), with mean age 67 years old. 50% of CKD patients felt very satisfied, 30% neutral, and 20% extremely satisfied. Most of patients thought that our clinic was useful and wanted to attend continuously. The average of GFR improved after attending to clinic 3.2 ml/min/1.73m^2.

Conclusions: CKD patients satisfied to attend in multidisciplinary care CKD clinic which contributed more knowledge and prevented renal function decline.

Association of diet quality and risk of overall hypertension and three hypertension phenotypes-isolated systolic hypertension, isolated diastolic hypertension, and systolic-diastolic hypertension

Jeeyoung Kim[1], Hyesook Kim[1], Seungyoun Jung[1]

1. Ewha Womans University (Korea)

Background and Objectives: Increasing evidence indicates that hypertension, which causes approximately half of cardiovascular deaths, is a heterogeneous disease. Isolated systolic hypertension (ISH), isolated diastolic hypertension (IDH), or systolic and diastolic hypertension (SDH) are major subtypes of hypertension reported to have varied population distribution, risk factors, incidence, and cardiovascular sequelae. However, little is known whether diet, a well-known risk factor for hypertension, has differential influences on ISH, IDH, and SDH risk. We evaluated associations between diet quality and the risk of overall hypertension and ISH, IDH, and SDH.

Methods: We analyzed a nationally representative cross-sectional data of 34,855 Korean adults aged ≧19 in the Korea National Health and Nutrition Examination Survey (2014–2020). Korean diet quality was evaluated using the Korean Healthy Eating Index (KHEI) based on a 24-hour dietary recall. Following the 2017 American College of Cardiology/American Heart Association and 2018 Korean Society of Hypertension guidelines, participants were defined to have hypertension (systolic blood pressure (SBP) ≧ 130 mmHg or diastolic blood pressure (DBP)≧80 mmHg or using hypertensive drugs), ISH (SBP ≧ 130 mmHg and DBP<80 mmHg), IDH (SBP<130 mmHg and DBP ≧ 80 mmHg), and SDH (SBP ≧ 130 mmHg and DBP ≧ 80 mmHg). Multivariate logistic regression analysis was used to examine the association between KHEI and risk of hypertension and its subtypes.

Results: A greater KHEI was significantly associated with lower risk of overall hypertension (P-trend: <0.001). Multivariable-adjusted odds ratios (ORs) (95% confidence intervals [CIs]) comparing in the highest to the lowest quintiles of KHEI were 0.79 (0.72-0.86). This inverse association was consistently observed irrespective of hypertension subtypes defined as ISH, IDH, and SDH. The multivariable-adjusted OR (95% CIs) comparing extreme quintiles of KHEI were 0.84 (0.71-0.99) for ISH, 0.85 (0.76-0.96) for IDH, and 0.74 (0.66-0.85) for SDH (all P-trend: ≦ 0.03).

Conclusions: In this first analyses of diet quality and hypertension subtypes in Korean, those adhering to dietary guideline for Koreans were at lower risk of hypertension regardless of its phenotype, which may reflect pleiotropic etiologic involvement of healthy diet preventing hypertension. Large-scale, prospective study is required to replicate these findings.

High sucrose diet-induced abnormal lipid metabolism in mice is related to the dysbiosis of gut microbiota

Yiying Fu[1], Yuki Araki[1], Fumiaki Hanzawa[2], Naomichi Nishimura[3], Saiko Ikeda[2], Satoshi Mochizuki[4], Hiroaki Oda[1]

1. Nagoya University (Japan), 2. Nagoya University of Arts and Sciences (Japan), 3. Shizuoka University (Japan), 4. Oita University (Japan)

Background and Objectives: The metabolic syndrome has become a problem all over the world. As a cause of metabolic syndrome, a high sucrose diet has received highly attention recently. In human, a high sucrose diet is thought to cause fatty liver and obesity. In rats, a high sucrose diet caused fatty liver and hyperlipidemia but did not cause obesity. However, a high sucrose diet caused obesity in mice. In order to find out the differences among species, we examined the effect of high sucrose diet in mice. Based on previous research on rats, high sucrose diet-induced metabolic disorder was related to the changed gut microbiome. In this research, the relationship between cecum microbiome and high sucrose induced abnormal lipid metabolism in mice was also examined.

Methods: First, to determine the phenotypes of different mouse strains, C57BL/6N, C3H/HeJ, DBA2, ICR and ddY mice were fed with a high sucrose diet for 28 days. Next, to determine the relationship between high sucrose diet induced abnormal lipid metabolism and the change in gut microbiome, C57BL/6N mice were fed with a high sucrose diet and 4 types of antibiotics for 28 days. Liver was collected to analyze the quantity of mRNA by real-time PCR. The content of cecum was collected for the analysis of gut microbiome.

Results: A high sucrose diet increased body weight and liver weight in C57BL/6N mice, and induced fatty liver in C57BL/6N, C3H/HeJ, DBA2 and ICR mice, but did not induce hyperlipidemia in all strains of mice. A high sucrose diet changed the composition of gut microbiome and short chain fatty acids in C57BL/6N mice. Antibiotics treatment suppressed the fatty liver, body weight gain and fatty acids synthesis induced by a high sucrose diet.

Conclusion: A high sucrose diet caused obesity and fatty liver in some strains of mice, but did not cause hyperlipidemia. Excess sucrose induced abnormal lipid metabolism through the change in gut microbiome in both rats and mice. It is possible that abnormal lipid metabolism induced by a high sucrose diet in human is also related to the dysbiosis of gut microbiome.

Anemia and body mass index are associated with the prognosis of Guillain-Barré syndrome: an observational study in Bangladesh

Zhahirul Islam[1], Israt Jahan[1], Yameen Hamid[1], Ismat Jahan Upama[1], Imran Hasan[1], Ananna Rahman[1], Shoma Hayat[1], Nowshin Papri[1], Gulshan Ara[1]

1. icddr,b, Dhaka, Bangladesh (Bangladesh)

Background and Objectives: Host nutritional status has effects on immune response that are implicated in the pathogenesis of autoimmune diseases including Guillain-Barré syndrome (GBS). We examined the association of nutritional and socio-economic status with disease progression and outcome of GBS in Bangladesh.

Methods: A total of 147 GBS patients were enrolled in this observational study in Bangladesh. Socio-demographic information was collected using a standard questionnaire and baseline anthropometric measurement such as body mass index (BMI), waist circumference (WC), hip circumference (HC) and mid-upper arm circumference (MUAC) were measured. GBS severity and prognosis were assessed by GBS disability score (GBS-DS). Routine blood parameters were measured using automated analyser. Logistic regression was performed to see the association between nutritional status, socio-economic status, disease severity and outcome.

Results: The median (IQR) age of the patients was 35 (20) years with male predominance (70%). The median (IQR) of BMI, WC, HC and MUAC were 23.3 (5.8), 82.0 cm (18), 88.5 cm (16) and 26.0 cm (4.9), respectively. More than 70% patients belonged to poor and middle-wealth socio-economic quintiles. Majority (98%) of the households used improved water source, mostly from own tube well (48%), followed by piped water supply (36%). Almost 90% GBS patients used good sanitation facilities. Around 44% GBS patients was underweight (BMI<18.5) and overweight/obese (BMI>25 to 29.9/ 30-39.9), which was associated with increasing disease severity (OR: 0.324, 95% CI: 0.10-1.0, *P*: 0.048). Increased haemoglobin was associated with lower risk of developing severe disease (OR: 0.61, 95% CI: 0.23-0.90, *P*: 0.01) and significantly associated with good outcome (GBS-DS<3) at 4 weeks (OR: 1.46, 95% CI: 1.06-1.63 *P*: 0.02) and 26 weeks (OR: 1.37, 95% CI: 1.07-1.8, *P*: 0.03). Decreased WBC (OR: 0.76, 95% CI: 0.68-0.89, *P*<0.05) was associated with long-term prognosis.

Conclusion: Anemia and underweight/overweight/obese patients with GBS are significantly associated with increased risk of disease severity and clinical prognosis. However, further large-scale studies are required to confirm the findings.

The association between Metabolic Syndrome and Chinese Healthy Eating Index in a community population of Shanghai

Shaojie Liu[1], Bo Chen[1], Yingnan Jia[1]

1. Fudan University (China)

Objective: To research the association between Metabolic Syndrome (MS) and Chinese Healthy Eating Index (CHEI), and identify the benefit or adverse diets of MS in a community population of Shanghai.

Methods: According to the included and excluded criteria, the data of 4 856 subjects from a community of Shanghai was collected by interview, and calculated the total CHEI score and its component score based on the frequency of food consumption. Physical examination and blood biochemical tests were used to diagnose the MS. The logistic regression model was used to analyze the relationship between MS or relative indexes and the total CHEI score or its component score.

Results: The study showed the overall prevalence of MS was 24.71%. There were significant differences in aspects of age, BMI, waist circumference, fasting blood glucose, triglycerides, total cholesterol, systolic blood pressure, diastolic blood pressure, glycated hemoglobin, high-density lipoprotein and energy intake between MS group and controls (*P*<0.05). After adjusting for potential confounders, the higher score of total CHEI score, the lower risk of central obesity, increased diastolic blood pressure, increased glycated hemoglobin, hyperglycemic and MS (*P*<0.05). The increased components score of potatoes, milk, beans, dark vegetables, fruits, oil and sodium reduced risks of obesity, hypertension, hyperglycemia, dyslipidemia and MS, respectively (*P*<0.05).

Conclusion: The healthy diet quality (CHEI score more than 80) and increased intake of specific dietary components (potatoes, milk, beans, dark vegetables, fruits) were reducing the risk of MS effectively.

Nutrition intervention for bariatric surgery patients by using social network service

Ya Ting Huang[1], Pei Fen Lee[1], Shu Chen Wei[1], Weu Wang[1]

1. Taipei Medical University Hospital (Taiwan)

Background: In Taiwan, the prevalence of obesity is rapidly increasing, and now it rise to 23.9%. Bariatric surgery is the most effective treatment to morbid obesity. The nutrition status will change due to the surgery, patients should have access to a comprehensive nutrition and dietetic assessment. The knowledge about food choices will influence their long term nutrition status.

Method: After nutrition consultation clinic to teach bariatric surgery patients how to eat, 997 patients will come back to nutrition consultation clinic for every 3 months, 626 patients after the nutrition consultation clinic, will added social network service to trace their diet, patients will measured body composition every 3 months and one year. Data analysis use SPSS 22. Result: Female 1035 and male 588, age 36.1±9.7 years old, Body mass index 40.4±6.6 %, body fat before intervention is 52.4±18 kg, one year body fat is 27.2±10.6 kg; body fat after intervention is 53.1±13.6, one year body fat is 26.2±10.4 kg

Conclusion: Nutrition is important for patients after bariatric surgery, use social network service could have a better intervention, help patient become heathier.

Keywords: Nutrition intervention, Bariatric surgery, social network service

The association between screen time and physical activity on mental health among preschool children: a cross-sectional design from Gui Zhou province during COVID-19 pandemic

Rong wang[1], Rong Xiao Ni, Yi Liang[2]

1. GuiZhou Medical University (China), 2. Affiliated Hospital of Guizhou Medical University (China)

Background and objectives: Preschool children are in the period of forming healthy personality, their mental health (MH) and behavioral health are the most critical factor of psychological development. This study aimed to investigate the relationship of physical activity (PA) and screen time (ST) with preschooler's MH outcomes.

Methods: The study was a cross-sectional design. 19015 parents/carers completed an online questionnaire on behalf of their child (aged 3-7 years old) in Gui Zhou province, China during 2019-2021. The parent version of the Strengths and Difficulties Questionnaire (SDQ) was selected to measured children's mental health. PA patterns were divided as three groups: total activity, Moderate to Vigorous Physical Activity (MVPA) and outdoor activity. PA time was divided as four categories, which were demonstrated as below 1 hour per day, 1-2 hour per day and beyond 2 hours per day. Similarly, ST time was performed to below 2 hours per day, 2-4 hours per day and beyond 4 hour per day. Multiple logistic regression analysis examined the association between PA and ST with MH.

Results: For five subscales of SDQ score, the emotional symptoms were the most common problems in children's mental health compared other subscales, inversely, Peer problems were the least problematic subscale. Multiple logistic regression analysis showed ST time more than 2 hours was associated with higher scores on SDQ, and preschooler who spent beyond 4 hours per day on screen time have higher risk of mental disorder than screen time on 2-4 hours per day. Higher level of total physical activity were associated with lower scores on SDQ. Moreover, only residence, CHSQ, annul average per capital income and whether affected by COVID-19 in other collected information have effect on SDQ score.

Conclusions: Both ST and PA time were independently associated with children's mental health, and less ST and more PA time are good for MT.

Keywords: Mental health, physical activity, screen time, Strengths and Difficulties Questionnaire, preschool children

Associations between Perceptions of Attractive Body, BMI, and eating habits among Young Women with and without Children in Japan

Kana Takahashi[1], Akari Tsuchiya[1], Fumi Hayashi[1], Yukari Takemi[1]

1. Kagawa Nutrition University (Japan)

Background and objectives: Thinness among young women is one of the critical health issues in Japan. To avoid unnecessary dieting, a proper perception of body image relative to Body Mass Index (BMI) is important. Furthermore, satisfaction with one's body image may also lead to higher self-esteem and remove the motivation for unnecessary dieting. This study aimed to determine the associations between perceptions of attractive body, BMI, dietary attitudes, and eating habits among young women with and without children in Japan.

Methods: We conducted a cross-sectional online survey in September 2021. The participants were 433 women aged 20–39 years in Japan. Perceptions of an attractive body was measured using the Physical Self-Perception Profile (Japanese version), and categorized into three groups based on distribution. The physical and cognitive variables were BMI, body shape perception, and misperception. Eating attitudes were measured using the Dietary

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Consciousness Scale, which analyzes the importance and precedence of diet. Eating habits were measured by frequency of intake of meals that included dishes with grains, fish or meat, and vegetables and the frequency of consumption of 18 food groups. The association between the three groups by attractive body score and the total score of recommended food groups intake was examined using analysis of covariance adjusted for age and financial and time constraints.

Results: Women with higher attractive body scores, with or without children, had significantly higher percentages of "thinness" (with children: 38.3%, without children: 41.1%) than lower attractive body score groups. Women with children had higher attractive body scores, regarded diets as important, and showed higher intake frequency of meals that included grains, fish or meat, and vegetables. In addition, women with higher attractive body scores had a higher total score (adjusted mean: 34.2±1.9) of recommended food groups intake (middle: 32.5±1.7, lower: 28.2±1.7).

Conclusions: These results indicate that women, with or without children, who had higher attractive body scores were underweight, but eating better. In the future, we would like to clarify not only the frequency, but also the amount of food intake among women who have higher attractive body scores.

Keywords: Perceptions of attractive body, BMI, eating habits, young women, Japan

PAB(T5)-2
Is maternal perception of their own body size and that of their children related to nutritional status?

Gloria Ethel Otoo[1], Afi Nelly-Flore Eze[1], Seth Adu-Afarwuah[1]

1. University of Ghana (Ghana)

Background and objectives: The Greater Accra Region has one of the highest prevalence of overweight or obesity in Ghana. A mother's bias about her own weight and that of her children may influence dietary practices and subsequent nutritional status. This study aimed to investigate whether maternal perception of their own body size and that of their children is related to their actual body sizes.

Methods: This cross-sectional study involved 229 mothers (≧18 years) of children 6-59 months old selected from creches in the Accra Metropolitan Area. The weight and height of mothers and children were measured, mothers' BMI and children's BMI z-scores were calculated, and appropriate WHO cut-offs were used to categorize the mothers and children as underweight, normal weight, overweight, or obese. Body size perception was evaluated according to Bush's body size images and a validated 7-image toddler silhouette. The agreement between maternal perceived and actual body sizes was assessed using kappa statistics. Logistic regression was used to determine the predictors of overweight/obesity among mothers and children.

Results: The mean ± SD age of the women and children was 33±7 years and 35±14 months, respectively. The prevalence of overweight or obesity was 62% and 1% among the mothers and children, respectively. There was no agreement between mothers' perceived own body size and the measured BMI category and between mother-perceived child body size and the measured BMI z-score category. An estimated 60% of mothers preferred a larger body size for themselves with only a third (35%) preferring a smaller body size. Only 12% of mothers preferred a larger body size for their children, compared to 23% who preferred a smaller child size. Significant predictors of overweight/obesity among women were age ≦28 years (OR=2.22, p=0.01), inaccurate body size perception (OR=1.84, p=0.03) and preference for large body size (OR=1.80, p=0.04). Significant predictors of overweight among children were food insecurity (OR=3.33, p=0.04) and mother's inaccurate body size perception (OR=14.70, p<0.0001).

Conclusion: Body size perception may be important for weight control. Interventions to increase awareness of the negative health consequences of large body size could contribute to reducing overweight or obesity in this population.

PAB(T5)-3
The Effect of Short-term Free Distribution of the Nutrient Rich Baby Food (KOKO Plus) on Mothers' Subsequent Purchasing Behavior: Experimental Evidence from Ghana

Satoru Okonogi[1], Reginald Adjetey Annan[2], Charles Apprey[2], Takeshi Sakurai[1]

1. The University of Tokyo (Japan), 2. Kwame Nkrumah University of Science and Technology (Ghana)

Background and objectives: Market-based approach for improving infant nutrition is currently emphasized in developing countries because of its potential sustainability. In this approach, mothers are expected to buy nutritionally enhanced complementary food products. However, since efficacy of such products is mothers' important concern, they would not be willing to purchase them without being convinced. We hypothesized that learning effect through free distribution of Koko Plus gives mothers the chance to learn its efficacy and induce demand for it. Therefore, the study tested this hypothesis.

Methods: The balanced panel data used for this study were from our own surveys conducted in August and November-December 2021 in Ghana, consisting of 379 mother-child pairs with baseline ages of children ranging from 6 to 20 months. We used the Becker-DeGroot-Marschak mechanism to elicit mothers' willingness-to-pay (WTP) for KOKO Plus. There were 4 treatment arms: (1) free distribution of KOKO Plus for one month, (2) free distribution for two months, (3) free distribution

for three months, and (4) control. Twelve Child Welfare Clinics were randomly assigned to one of the four study arms. Linear regression model was used to assess the effects of the free distribution on mother's WTP and demand for KOKO Plus.

Results: After controlling for pre-intervention status of the outcome variables, mothers who received one-month free distribution had higher WTP for 10 packages of KOKO Plus (β= 0.76 GHS; 95% CI: 0.19, 1.32) and bought more KOKO Plus in the past one month (β= 2.96 packages; 95% CI: 1.40, 4.52) than the control group. However, there were no statistically significant differences between the control group and the other treatment groups.

Conclusions: One-month free distribution of KOKO Plus significantly increased mothers' demand. This result indicates the short-term free distribution can induce the learning effect for product efficacy. However, longer free distribution did not have the effects. This may be because long-term free distribution makes beneficiaries acclimatized to being free.

Keywords: Market-based approach, Free distribution, Complementary food, Willingness-to-pay, Ghana

Conflict of Interest Disclosure: This study was funded by the Ajinomoto Foundation.

PAB(T5)-4
Behavior Change Communication improves breast milk intake measured by the Dose-to-Mother Deuterium Oxide Dilution among infants aged 4-5 months in rural Senegal

Ousmane Diongue[1], Pape Sitor Ndour[1], Adama Diouf[1], Abdou Badiane[1], Mane Hélène Faye[1], Mbeugué Thiam[1], Papa Mamadou Dit Doudou Sylla[1], Olouwafemi Mistourath Mama[1], Momar El Hadji Thiam[2], Nicole Idohou Dossou[1]

1. Cheikh Anta Diop University of Dakar (Senegal), 2. Conseil National de Dévelopement de la Nutrition (Senegal)

Background and objectives: Breastfeeding promotion is widely recognized as one of the most cost-effective investments to promote optimal child health, growth and development. Several studies have shown that breastfeeding education and counselling interventions have a significant impact on improving breastfeeding practices, including exclusive breastfeeding (EBF) rates and breastfeeding duration. However, very few studies have assessed the association between participation of breastfeeding counselling session and infant milk intake. This study aimed to investigate the association between infants' breast milk intake and mothers' participation in behavior change communication provided by the Nutrition Enhancement Program (NEP) and other associated factors.

Methods: A comparative cross-sectional study was conducted in 12 local communities in rural Senegal, six of which were located in the NEP area and the remaining, in the non-intervention area. Breast milk intake and EBF were measured using the deuterium oxide dose-to-mother dilution technique in 140 mother-infant pairs aged 4-5 months. Mothers' knowledge and practices on IYCF were assessed by questionnaire and nutritional status of mothers and infants was measured by anthropometry. Student's t-test, ANOVA and chi-square test were used to compare means and percentages. A mixed model linear regression was performed to identify factors associated with breast milk intake.

Results: Daily breast milk intake was significantly higher in infants from the NEP area (994.7 ±197.3 g/d), compared to those from the non-NEP area (913.6 ± 222.8 g/d), p=0.023. Participation in behavior change communication activities is associated with a higher infants breast milk consumption of 80.0 g/d compared to those whose mothers did not participated (p=0.013). Non-exclusively breastfed infants consumed 74.4 g/d less milk than exclusively breastfed infants (p=0.035). Giving infants porridge reduced their breast milk intake by 182.6 g/d (p<0.001). Stunted and wasted infants had a lower breast milk intake of 119.6 g/d (p=0.023) and 199.4 g/d (p<0.001) respectively, compared to infants with normal nutritional status.

Conclusions: Breastfeeding education and counselling received by mothers through the NEP's Behavior Change Communication intervention has contributed to improve infant milk intake in rural Senegal. Strengthening these activities could have an impact on reducing stunting and wasting in young children.

Keywords: Breast Milk Intake, Deuterium oxide dilution, Behavior change communication, Senegal

Conflict of Interest Disclosure: The authors declare that they have no conflicts of interest.

Further Collaborators: This study was conducted within the framework of the interregional project INT6058 of International Atomic Energy Agency (IAEA) and support by the Conseil National de Développement de la Nutrition (CNDN) of Senegal and UNICEF who have funded all the operational costs of the study.

Complementary feeding practices and nutritional status of infants and children aged 6-23 months in Nyeri County, Kenya.

Lydiah Asiko Omondi[1], Anselimo Makokha[2], Joseph Mutai[3]

1. Karatina University (Kenya), 2. Jomo Kenyatta University of Agriculture and Technology (Kenya), 3. Kenya Medical Research Institute (Kenya)

ABSTRACT

Complementary feeding practices and nutritional status of infants and children aged 6-23 months in Nyeri County, Kenya.

[1]Lydiah Asiko*,[2] Anselimo Makokha[3] Joseph Mutai

[3]Kenya Medical Research Institute, P.O. Box 54840 00200, Nairobi, Kenya.

Background and Objectives: Malnutrition remains a public health problem among children in most of the countries in Sub-Sahara Africa. It contributes to high morbidity and mortality of these children. One of the main causes of the high prevalence of malnutrition is poor complementary feeding practices. The objective of this study was to evaluate complementary feeding practices, and the nutrition status of children aged 6-23 months attending child clinics in Nyeri County-Kenya.

Methods: This prospective comparative study followed up 380 mother-child pairs. A nutrition education package was provided to participants from the intervention group and followed up for 3 months. Consecutive sampling was used to recruit the participants' at each clinic until the required sample size was realized. Pre-tested and structured questionnaires was used to collect baseline data for indicators of meal frequency, dietary diversity and acceptable diet as per World Health Organization (WHO) Global Strategy for Infant and Young Child Feeding recommendations. Three indices of nutritional status of children (wasting, stunting and under-weight) were expressed as standard deviation units from the median for the child growth standards recommended by WHO.

Results: Despite food availability, about one-third (32%) of the children 6-23 months received less than the threshold of minimum dietary diversity that is 4 out of the identified 7 food groups. Approximately one out of five children (21%) had minimum acceptable diet. The proportion of children whose weight-for-age below minus two standard deviations (-2 SD) and above two standard deviations (+2 SD) was 2% and about 6% respectively.

Conclusions: Child-feeding practices was sub-optimal with evidence of low acceptable diet and dietary diversity. Approximately one out of ten children was malnourished.

Investigation of food diversity of children under five in Mzimba, Malawi

Daisaku Urabe[1], Sakuma Yamamoto[1], Motoi Adachi[1], Sakiko Hamanaka[2], Yu Sato[2]

1. St.Mary's Hospital (Japan), 2. NGO:ISAPH (International Support and partnership for Health) (Japan)

Background and Objectives: In Malawi, a lot of foods and many varieties of foods are available at markets. However, more than a half of children under five were malnourished. This gap between high availability of foods and a high appearance rate of child malnutrition suggested that foods at markets were not reaching children properly. In order to know the real food-intake of children under 5 and their food procurement processes, we conducted an HDDS (Household Dietary Diversity Score; developed by United Nations) survey by using a 24-hour recall method.

Method: We selected 151 children under 5 years of age randomly in Manyamula, Mzimba, Malawi. Of them, 24 children were age 0-5 months, 51 were 6-23 months, and 76 were 24-59 months. Then we conducted home-visits to those target children and collected information from their mothers about what foods their children had eaten and how those foods were acquired. We simultaneously measured the children's height and weight. For this survey, we got ethical permission from the ethical committee of local government and informed consents from each household.

Results: Among 16 food groups, the only 5 food groups were eaten by nearly 100% of the target children and only 3 food groups were eaten by 50%. The remaining 8 food groups such as fish, animal meats, dairy products and vitamin A rich food groups were hardly eaten by any of them. In their daily lives, village people seldom procure foods for their meals from the market. They do not try new foods. Their foods were mainly supplied by their own agricultural products.

Consideration: Village people were mainly getting foods from their own agricultural products and not procuring them from the market. It seemed quite difficult to go to the market because of social and geographical difficulties. Vitamin A rich foods were not eaten because they are not produced in the area. They hardly eat house-farmed poultry because house animals are treated not as food stuffs but treasures or emergency foods. These social and cultural problems were disturbing food availability, accessibility and utilization, resulting in poor food diversity.

Keywords: Food diversity, Subsistent agriculture, Food culture, Food availability, Food utilization

Infant and Young Child Caregiving Practices: Prevalence, Determinants, and Small Doable Actions in Ntcheu and Balaka districts, Malawi

Lupafya Phindile[2], Natalie Roschnik[1], Nkhonjera Jean[3], Stein Danielle[4], Dee Jupp5, Brenda Phiri[6], Aulo Gelli[7], Melissa Gladstone[8], Julia Weatherson[9]

1. Save the Children (Malawi), 2. Save the Children (France), 3. Save the Children (Malawi), 4. Empatika (South Africa), 5. Empatika (UK), 6. Save the Children (Malawi), 7. IFPRI (USA), 8. University of Liverpool (UK), 9. Save the Children (Cambodia)

Background and objectives: One in three children under five years is chronically malnourished and two thirds are anaemic in Malawi. A range of factors have been associated with malnutrition (low birth weight, poor dietary diversity, frequent disease, low use of health and nutrition services, poverty, food insecurity, gender inequality), however there is little in-depth evidence on the context specific determinants of under-five caregiving behaviours and which small doable behaviours to prioritise and promote at scale. This mixed method research

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

answers these questions to guide scale up of Malawi's nutrition and early child development intervention package.

Methods: The presentation will draw on qualitative and quantitative research: 1) an Immersion Research using the Reality Check Approach (RCA) and Human-Centred Design in 12 households to understand current practices, determinants and test small doable actions; 2) a large household survey of around 3,000 mother and child pairs to assess coverage of recommended behaviours. Both methods are centred around Nurturing Care behaviours for optimal child growth and development.

Results: The findings (available in July 2022) will provide deep insight into current context specific caregiving behaviours across the nurturing care framework in these two districts of Malawi. They will include prevalence and coverage data of recommended caregiving practices, qualitative descriptions of the factors influencing those behaviours and a list of tested priority "small doable actions" to promote through existing community platforms (mother support groups, preschools, etc).

Conclusions: This presentation is unique because it combines findings from ethnographic (immersion) research, people centered design and quantitative methodologies to identify scalable behaviour change solutions to improve nutrition and early child development. These findings will help the government of Malawi scale up their integrated Nutrition and Early Child Development intervention package (supported by the World Bank Investing in Early Years programme). The innovative mixed research method to identify and prioritise small doable behaviours is relevant globally.

Nutritional guidance to infant and young child caregivers in the context of public health facilities in Peru

Rosario Bartolini[1], Cecilia Goya[1], Paula Griffiths[2], Nervo Verdezoto[3], Rebecca Pradeilles[2], Emma Haycraft[2], Emily K Rousham[2], Hilary Marian Creed-Kanashiro[1]

1. Instituto de Investigación Nutricional (Peru), 2. Loughborough University (UK), 3. Cardiff University (UK)

Background and objectives: The PERUSANO project aimed to develop new culturally appropriate interventions and actions to reduce the risk of micronutrient deficiencies and overweight/obesity in infants and young children (IYC) aged 6–23-months. We aimed to identify socio-cultural and environmental influences on IYC feeding practices to inform co-designed interventions. This study aimed to present qualitative findings from health centres (HC) to aid the development of appropriate health provider and policy nutrition intervention strategies.

Methods: This qualitative study was conducted in two low-income periurban areas between November 2019 and August 2020. We conducted interviews with 10 healthcare professionals (HP) and observations of 36 well baby consultations and 4 waiting areas of HCs to understand consultation routines relating to IYC feeding practices. The data were transcribed and analyzed using a grounded approach.

Results: IYC health services take place in a tense environment with limited space, high demand, crowding, long waiting times and restless children. The HP focus on nutritional assessment with anthropometric measurements, hemoglobin screening and asking about dietary practices and iron supplementation. Messages for anemia control predominate including recommendations for animal source foods and iron supplements and there is little focus on the prevention of overweight and obesity. Individual needs of children and concerns expressed by the caregivers about children's poor appetite are not addressed. Expository, unidirectional counselling predominates, without the use of educational support materials. A lack of cultural sensitivity and a judgmental attitude prevails. Marked competition between attending to the caregiver/child and completing the registration of various forms as required by the health system in the short time available was observed.

Conclusions: Nutritional guidance for caregivers occurs within a context that limits optimal counselling at the environmental, structural, attitudinal, and procedural levels. There is a need to promote behavior change for optimum IYC feeding practices and not only to provide information. Education and communication materials need to be adjusted to facilitate counselling in the conditions and limitations within which care is provided and to cover the changing nutritional challenges faced by infants in this context including risk for overweight and obesity.

What kind of "fish-based meals" do preschoolers eat at nursery schools? Based on Analysis of School Lunch Menus of 24 Nursery Schools

Haruko Sakai[1], Tomomi Ainuki[1]

1. Tokyo Kasei Gakuin University (Japan)

Background and objectives: N-3 polyunsaturated fatty acids, which are abundant in fish, have been shown to be beneficial not only in the prevention of lifestyle-related diseases but also in child development. Our goal is to develop an early childhood version of a nutrition education program based on the concept of "the relationship between fish, humans, and the environment

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

in Japan. Accordingly, the objective of this study was to obtain the data of what kind of "fish-based meals" preschoolers eat at nursery schools.

Methods: In June 2019, we collected the data on the 12 menus at 24 nursery schools in the same corporation. The main analysis were the kind, cooking method, and portion sizes of fish dishes.

Results: We collected data from 269 menus. Many types of fish were used for staples, main dishes, side dishes, and soups. In the main dish, fish dishes accounted for 93 of 245 dishes (38.0%), less than meat dishes. Twenty-nine different types of seafood were used, with white salmon being the most common, followed by pacific cod. The average portion size per person was 44g for white salmon and 51g for pacific cod. The weight of the fish main dish ranged from 30 to 50 grams per serving. The only fish dish with a head and tail was wakasagi fritters. Grilled fish dishes were the most common cooking method, followed by fried and simmered dishes. In the side dishes, 15 different types of fish were used, appearing in 83 of the 269 menus. The most frequently appearing fish types were grilled chikuwa and bonito flakes, followed by dried young sardines and canned tuna.

Conclusions: Salmon, dried shirasu (dried young sardines), and bonito flakes are proposed as subjects for the food education program, based on fish dishes that are familiar to Japanese preschooler.

Keywords: Preschooler, nursery school, nutrition education, fish dishes

Exploring resilience mechanisms against acute malnutrition in children under five in the health zone of Kalemie 2020: a qualitative study

Benito Kazenza[1], Didier Sashila[1], Marc Bosonkie[1], Paulin Mutombo[1]

1. University (Democratic Republic of the Congo)

Background: Despite several interventions implemented in the nutrition field, acute malnutrition among children under five years remains a very serious public health problem in the Kalemie Health zone in the Democratic Republic of Congo (DRC). This study aimed to explore the individual and community resilience mechanisms of acute malnutrition to contribute to the improvement of the health status of children under five. **Methods**: A case study using a qualitative approach was undertaken from December 1 to 31, 2020 in the Kalemie health zone. Both households with an acute malnutrition child and households without an acute malnutrition child were selected to participate. The key informants (community leaders, health care providers, and NGO partners) were approached. Four FGDs with mothers and twenty-four in-depth interviews were conducted and data were analyzed using inductive techniques. The triangulation method was applied. **Results**: A total of sixty-four people took part in the study, including forty during the FGDs and twenty-four during the interviews. The household sensitization on infant and young child food (IYCF), the small business activities, agriculture, food imports, fishing, the household livestock, the establishment of cooperatives through humanitarian aid to meet needs were the main resilience mechanisms identified to fight against acute malnutrition. **Conclusions**: Community and individual resilience capacities through sensitization of target groups effectively prevent malnutrition in children under 5 years old.

PAB(T5)-11
Effect of a mobile health education intervention on nutritional status of children under-5: a quasi-experimental study

Sam Newton[1], Princess Ruhama Acheampong[1], Easmon Otupiri[1], Ellis Owusu-Dabo[1]

1. Kwame Nkrumah University of Science and Technology (Ghana)

Background and objectives: Despite several interventions implemented by Ghana's Ministry of Health, malnutrition remain high in rural Ghana. Innovative approaches involving the use of mobile technology for improving the nutritional status of children remains a grey area. This study aimed to assess the effect of a theory-driven mobile health intervention on the nutritional status of children under-5 in rural communities of the Ashanti Region.

Methods: We conducted a quasi-experimental pre-post study with a non-randomly assigned control group. A total of 648 caregivers were interviewed; 324 assigned to the intervention group and 324 in the control group. For 6 months, caregivers in the intervention group received bi-weekly voice short message service (SMS) on nutrition-related messages based on the Health Belief Model (HBM). The treatment effect was examined using Difference-in-Difference (DiD) analyses. Nutritional status was assessed through anthropometry. Data was analysed using Stata version 16.

Results: The prevalence of wasting was 7.54%, underweight, 11.67% and stunting, 19.67% at baseline. The multivariate logistic regression analyses showed that gender of child (aOR=0.31; 95% CI: 0.36-0.82), age of child (aOR=3 .48, CI: 3.48, 95% CI: 1.11-10.89), caregiver's knowledge on child nutrition (aOR=0.31; 95% CI: 0.12-0.81) and ability of caregiver to read and write (aOR= 3.48; 95% CI: 1.54-9.53) were significantly associated with malnutrition in children under-5. Overall, there was a statistically significant reduction of wasting, underweight and stunting of 26.8% (Diff-in-diff=-0.268; t= 5.47; p<0.001) observed after the 6-month period. **Conclusion**: Mobile phones can serve as effective tools to increase the level of knowledge of caregivers and further improve the nutritional status of children under-5 in rural communities.

PAB(T5)-12
Impact of Differences in Involvement of Childcare Workers on Food Education to Know the "Blessing of Nature" in Early Childhood

Mika Tominaga[1]

1. Osaka Ohtani University (Japan)

Background and objectives: In Japan, "the Basic Law on Food Education" (2005) indicates the significance of consumption and production in harmony with the blessings of nature and the environment. To understand the "blessing of nature," food education has been implemented in childcare settings. However, it does not specifically state what should be implemented, and childcare workers only understand the phrase "blessing of nature."[1] Therefore, food education with the theme of "photosynthesis" was implemented. As a result, there were cases where children made remarks about the "blessing of nature," and cases where they did not. Thus, this study aimed to compare the two circumstances and clarify how the involvement of childcare workers affected children's remarks.

Methods: From 2019 to 2021, food education with the theme of "photosynthesis," which involves the entire process from growing food to consuming food, was implemented on 54 kindergarten children aged four–five years. Children's remarks and appearances were recorded based on childcare records and guardian questionnaires. We compared how differences in the involvement of childcare workers affected children's food education activities.

Results: In cases where childcare workers understood that children would independently realize the objective of food education as being the "blessing of nature," children made remarks about the blessing of nature. In cases where childcare workers did not understand that childcare workers were observed to have taught the blessing of nature to children in words, and the children made few remarks about the blessing of nature.

Conclusions: It is important for children to independently perform activities in order to make food education, which includes learning about the "blessing of nature," successful in childcare settings. It is important for all childcare workers and guardians dealing with children to understand the objective of food education and get involved by empathizing with the fact that children will learn about the blessings of nature with real feelings involved, such as being marveled or touched, instead of teaching the "blessing of nature" in words.

PAB(T5)-13
Effectiveness of a Family-based Cluster Randomized Intervention Delivered through School Health Nurses on Reducing Intake of Discretionary Foods and Drinks in Schoolchildren

Sidse Marie Sidenius Bestle[1], *Anne Dahl Lassen*[1], *Anja Pia Biltoft-Jensen*[1], *Bodil Just Christensen*[1], *Jeppe Matthiessen*[1], *Ellen Trolle*[1]

1. Technical University of Denmark (Denmark)

Background and objective: The intake of sugar-rich discretionary foods and drinks, such as sweets, cake, ice cream, and sodas, is much higher than recommended among Danish children. Public health interventions have focused on promoting healthy food, with less attention on discretionary choices. Strategies to limit the intake of discretionary foods and drinks among children are therefore needed. The objective of this study was to test the effectiveness of an intervention with focus on discretionary choices.

Methods: The "real-life" trial "Are You too Sweet" tested a range of knowledge- and behavioral capability-building components and strategies for reducing consumption of discretionary foods and drinks among school starters, 5-7 y. The trial was conducted as a two-arm, parallel, cluster-randomized controlled trial, running for 3.5-months in the period from October 2020 until March 2021. The intervention was delivered to participating families through collaboration with the local school health nurse in a Danish municipality (Hvidovre). The intervention entailed multiple components developed based on Social Cognitive Theory (SCT) and consisted of a sugar-rich food screener, extended consultation at the school health nurse, an online Facebook group and a take-home box. The take-home box contained a card game connected with a digital learning universe with a Sweet-monster-avatar, a portion guide with stickers, a children's book and an inspiration booklet. The intervention group was compared to a control group receiving standard care from the school health nurse.

Results: A total of 153 children and their parent's accepted the invitation to participate, and 148 completed the dietary record according to the protocol (n intervention group= 93, n control group=55). Preliminary results show that children in the intervention group reduced their intake of discretionary foods and drinks by weight by 30% compared to children in the control group (p=0.01) during the intervention. No change in intake of energy or food sub-groups were detected compared to the control group.

Conclusion: Results indicate that delivering messages through school health nurses might be an effective way to provide families with tools and knowledge to restrict the intake of discretionary foods and drinks among schoolchildren. Effective tools for behaviour changes are further worth illuminating.

Relationship between eating behavior during snack time and sports activities among elementary school children

Michiko Kikukawa[1], Ayana Nakazuru[1], Kayo Koizumi[2]

1.Japan Women's College of Physical Education Graduate School (Japan), 2. Japan Women's College of Physical Education (Japan)

Background and objectives: Elementary school students who learn sports have a clearer purpose of eating than those who do not learn sports, which indicates a relationship between sports lessons and eating behavior. However, it has not yet been verified how "food-related factors," "personal factors," and "environmental factors" of eating behavior are related to snacking among these students. Therefore, this study aimed to clarify the factors related to eating behavior during snack time among elementary school students who learn sports.

Methods: The subjects were students from 3rd grade to 6th grade of an elementary school (n = 1096). The survey used an anonymous self-administered questionnaire. The response rate was 96.0%. Items included attributes of participants, items related to actual situation of each lesson and actual situation of snacking, and factors influencing eating behavior. Participants were divided into two groups: those with a sense of purpose for snacking (conscious group) and those without a sense of purpose for snacking (unconscious group). The analysis was performed using crosstab and χ^2 test.

Results: Boys in 3rd and 4th grades who learn sports were conscious and related to "what to do if a snack that they had never eaten" was served (p = 0.002). Boys in 5th and 6th grades were more conscious of sports lessons and concerned about what is written on bags and boxes and the names of snacks, than the others. Among girls, learning sports was not associated with eating behavior regardless of their grade and awareness of snacking.

Conclusions: Among boys, snacking was associated with sports lessons and a sense of purpose in snacking. "Food-related factors (food experience)" and "individual factors (inter-individual factors)" of 3rd and 4th graders and "environmental factors (information environment)" of 5th and 6th graders were related to sports lessons and eating behavior. Among girls, sports lessons and eating behavior were not related regardless of whether there was a sense of purpose for sports lessons and snack intake.

The effectiveness of a non-face-to-face cooking program to enhance self-esteem in elementary school students

Tatsuaki Sakamoto[1], Yuka Miyake[1], Miho Sakai[1], Yukina Kikunaga[1], Haruna Matsumoto[1], Kouhei Hosoda[2]

1.Prefectural University of Kumamoto (Japan), 2. Jin-ai University (Japan)

Background and objectives: Japanese children have lower self-esteem than children in other countries. Longitudinal studies have shown that low self-esteem in childhood can lead to negative outcomes such as depression, suicidal thoughts, and risky behaviors like smoking. However, recent cross-sectional studies have shown that increased cooking experience is associated with improved self-esteem. Therefore, we have been experimenting with a cooking experience program to enhance self-esteem. This study aims to determine the effectiveness of a non-face-to-face cooking program that can be implemented during the COVID-19 pandemic period with the aim of enhancing self-esteem among elementary school students.

Methods: This research used a quasi-experimental design. The intervention was conducted from July to September 2021 once a week for a total of five sessions among fourth- through sixth-graders. The intervention group (24 participants) received cooking videos and ingredients with feedback on their efforts. The control group (29 participants) received only ingredients and paper recipes. To evaluate self-esteem, we used a scale whose reliability and validity were confirmed by previous studies (score range: 8–32 points).

Results: The results of the post-program questionnaire were not available for one participant each in the intervention and control groups. There was no difference between groups in gender, grade, or self-esteem before participation. The median self-esteem score (25th, 75th percentile) increased significantly in the intervention group from 23.0 (21.0, 25.0) before to 25.0 (20.0, 28.0) after program participation ($P < 0.05$), and there was a significant difference in the amount of change between groups ($P < 0.05$). The frequency of receiving praise from family members also increased significantly only in the intervention group.

Conclusions: This program may promote good communication among family members and enhance self-esteem through cooking experience.

Effects of dietary experiences in elementary school on interest in nutrition education and subsequent attitudes toward healthy eating habits in adulthood

Tomohiro Suzuki[1]

1. Tokyo Future University (Japan)

Background and Objectives: Healthy eating habits are important for good mental and physical health. To promote nutrition education for adopting healthy eating habits, the factors that encourage healthy eating habits must be identified. Therefore, this study investigated the effects of dietary experiences in elementary school on interest in nutrition education and subsequent attitudes toward healthy eating habits in adulthood.

Methods: Data from The Survey of Attitude toward Shokuiku, 2019, Ministry of Agriculture, Forestry and Fisheries in Japan provided by the Social Science Japan Data Archive, Center for Social Research and Data Archives, Institute of Social Science, The University of Tokyo was used for this secondary analysis. Participants comprised 1721 adults aged 20–90 years (759 men, 962 women, mean age = 56.13, *SD* = 17.53). The survey items used for the analysis pertained to the present degree of interest in nutrition education and attitudes toward healthy eating habits. Furthermore, 13 items assessing the degree of eating behaviors in elementary school have also been used for the analysis. For example, eating meals at regular times at home, expressing appreciation for foods and people who provide or produce them before and after a meal at home, and listening to or receiving food guidance from teachers at school.

Results: The correlation analysis showed that helping prepare the meal and cleaning up after at home, and having conversations with family members about food during meals at home had a positive effect on interest in nutrition education. Additionally, helping prepare the meal and cleaning up after at home had a positive effect on attitudes toward healthy eating habits.

Conclusions: This study provides some insight into the aspects of dietary experiences that are most effective in childhood. The results of this study suggest that food experiences within the home are important, and proactive involvement in food preparation is significant. Interestingly, including seasonal ingredients is an important factor. Future studies should explore the effects of these experiences in detail.

Keyword: nutrition education, eating habits, dietary experiences, elementary school, retrospective research

PAB(T5)-17
Changes in elementary school children after a two-year nutrition education intervention that encourages home cooking experience

Atsuko Sawamura[1,2], Miho Kogirima[1], Misaki Kamon[3], Yuko S Yoshimoto[4], Miki Yachiku[5], Kayoko Mori[6], Akiko Ootsuki[6], Tomoko Koda[1]

1. Doshisha Women's College of Liberal Arts (Japan), 2. Kyoto College of Nutritional & Medical Sciences (Japan), 3. Yabu City Board of Education (Japan), 4. Kyoto Prefectural University (Japan), 5. Sakai Municipal Niwashirodai Junior High School (Japan), 6. Doshisha elementary school (Japan)

Background and objectives: In a cross-sectional study of children, it was reported that cooking experience affects dietary concept and self-esteem. However, there are only a few reports on interventions. In this study, we conducted a two-year nutrition education intervention to encourage home cooking and examined changes in dietary concept, self-esteem, and evaluation of breakfast dietary balance with increased cooking experience.

Methods: A self-administered questionnaire was administered before and after the intervention to 327 elementary school children aged 9-12 years during 2016-2019. The data of 202 participants (61.8%) who responded validly both before and after the intervention were analyzed. The intervention involved distributing and explaining the workbook that was designed to encourage children to cook at home. In the questionnaire, cooking experience was classified into five subcategories: frequency of cooking, self-efficacy in cooking, cooking technique, dietary planning, and hygiene management; dietary concept was classified into one subcategory; self-esteem was classified into three subcategories: self-evaluation and self-acceptance, self in relationship, and self-assertion and self-determination. Three or more items were set for each subcategory, and the options were scored to calculate the mean score for each subcategory. We assessed what foods and dishes the children ate for breakfast. We used the "Breakfast dietary Balance Score" and rated one point for each of the six categories of food consumed. The participants were divided into two groups according to the change in the mean score of the cooking experience category (Decrease and Low maintenance group; DL and Increase and High maintenance group; IH).

Results: Of the respondents, 80.6% of the boys and 73.4% of the girls were in the IH group. The results of the pre-post comparison showed that both DL and IH girls had a lower dietary concept and self-esteem ($p<0.05$). The analysis of covariance showed that IH was higher than DL for both sexes in dietary concept and two subcategories of self-esteem ($p<0.05$). The breakfast dietary balance scores were significantly higher for girls ($p<0.05$).

Conclusions: Cooking experience could lead to desirable changes in dietary concept, self-esteem, and breakfast dietary balance scores.

PAB(T5)-18
Factor Structure of Enjoyable Eating in Schoolchildren

Ryosuke Inukai[1]

1. Nagoya University of Arts and Sciences (Japan)

Background and Objectives: To realize “enjoyable eating (EE)” that is unique to oneself throughout life, it is necessary to clarify the factors that influence EE in schoolchildren, which strongly affects the way they will eat for the rest of their lives. The purpose of this study was to qualitatively clarify the factor structure of EE in schoolchildren.

Methods: A hypothetical model of EE was developed and an interview guide was developed based on the model. Using the developed guide, individual semi-structured life story interviews were conducted with 12 fourth-year students (6 men and 6 women) enrolled in the School of Nutrition and Dietetics at N University from August 2020 to August 2021, with each interview lasting approximately 1 hour. The interviews were recorded and transcribed verbatim, and the variables of EE were extracted from the transcripts and embedded in the hypothetical model in order to examine the factors of EE in schoolchildren.

Results: The initial hypothetical model of EE was developed from the following concepts: 1. diet-related behavior, 2. taste and affective factors, 3. personal factors that influence eating behavior (personal factors), and 4. other influencing factors. The hypothetical model was then reconstructed by embedding the extracted variables into the model. It was found that EE is formed by 2. taste and affective factors, 3. personal factors, and the availability of 4. other influencing factors, as well as by practicing 1. diet related-behavior. In schoolchildren, “school” was the key word because school influences 3. personal factors, and as a result, the approach to EE changes. This cycle is repeated, and one's own style of EE is established.

Conclusion: It is clear that schoolchildren are more strongly influenced by 4. other influencing factors than by 3. personal factors. We believe that is because schoolchildren are strongly influenced by school and family members who prepare food for them. However, the importance of 3. personal factors that demonstrate initiative and individuality was also confirmed. We believe that EE in schoolchildren means that they can develop their independence in the environment that surrounds them and exercise their own individuality in terms of eating habits.

Creating a system for evaluating Shokuiku (food and nutrition education) in Japanese schools

Akemi Nakanishi[1], Kumi Eto[1], Mieko Kanbe[2], Takayo Inayama[3], Tatsuaki Sakamoto[4], Tomomi Ainuki[5], Rie Akamatsu[6]

1. Kagawa Nutrition University (Japan), 2. Kiryu University (Japan), 3. The University of Nagano (Japan), 4. Prefectural University of Kumamoto (Japan), 5. Tokyo Kasei Gakuin University (Japan), 6. Ochanomizu University (Japan)

Background and objectives: To promote Shokuiku(food and nutrition education) in schools, the Ministry of Education, Culture, Sports, Science and Technology (MEXT) prepared a "Guide to Teaching about Food" in 2007 and revised in 2010, showing how to teach Shokuiku with the aim of forming desirable dietary habits in children. Using survey data conducted by the Nutrition Education Committee of the Japanese Society of Health Education and Promotion, this study compared the necessities for investigations and evaluations on Shokuiku in Japanese schools by the method of meal preparation.

Methods: From November 2018 to January 2019, we conducted an anonymous self-administered questionnaire survey on 262 nutrition teachers and school nutrition staff in Gunma, Tochigi, Chiba, Saitama, and Hiroshima prefectures in Japan (valid response rate: 37.4%). We compared the implementation status of investigations and evaluations on Shokuiku according to the meal preparation method using Chi-square test or Fisher's exact probability test. In addition, we qualitatively analyzed free responses on "reasons why the system for evaluations of the Shokuiku plan is not established.”.

Results: Respondents in the school lunch center group were less likely to report the involvement of a president and a vice-president in evaluation of the Shokuiku plan than those in the onsite group. There were no significant differences between the groups in involvement of diet and nutrition teachers, nursing teachers, and teachers in charge of Shokuiku. As for reasons why the system is not established, seven categories, such as insufficient skills for investigation and evaluation, were extracted from the onsite group and 7 categories, such as difficulties of cooperation between the center and distributed schools, were extracted from the school lunch center group.

Conclusions: It was demonstrated that to investigate and evaluate in relation to food, it is necessary to (1) develop systems inside and outside school, (2) position food and nutrition education within the curriculum, (3) cooperate with managers and teaching and administrative staff, (4) secure time and labor for investigation and evaluation, and (5) construct tabulation systems.

Changes in food awareness and attitudes of Japanese first-year elementary school students who eat school lunches, as perceived by parents

Yuko Naruse[1], Naoko Hirota[2]

1. Matsumoto University (Japan), 2. The Graduate School of Matsumoto University (Japan)

Objective: School lunches in Japan not only have to meet the nutritional needs of children, but also is playing an important role in the development of a proper understanding and appropriate discernment of food in children. This study aimed to clarify changes in food awareness and attitudes of Japanese first-year elementary school students who eat school lunches.

Methods: A survey was conducted of 827 parents of children enrolled in 11 different elementary schools in Matsumoto City in Nagano Prefecture. The parents were asked to complete a questionnaire upon their child's enrollment in elementary school (April 2021) and at 2 months (June), 3 months (July), and 6 months (October) after the start of school lunch. The questionnaire from April and June were collected and 516 parents who answered both questionnaires were subject to analysis. As analysis, chi-squared tests were used. A p-value less than 0.05 was considered statistically significant.

Results: 424 (82.0% of valid answers, same hereafter) children had a strong or moderate interest in food upon enrollment. In June, 373 (73.0%) children talked about school lunches at home. The number of children who developed a strong interest in eating and food after starting to eat school lunches was 196 (38.3%) and 246 (48.0%) children talked more about food, 162 (31.6%) children had fewer expression of likes and dislikes of food, and 187 (36.5%) children had started to enjoy eating meals. Interest in food upon enrollment and the frequency of talking about food were not found to be associated with the presence or absence of experience of meals at nursery school or another institution. Significantly more children with an interest in food upon enrollment moved in the right direction in terms of interest in food, talking about food, food-related likes and dislikes, and enjoyment of eating in June.

Conclusions: School lunches appeared to be a major topic of interest among first-year elementary school students. School lunches had a considerable positive impact on children's food awareness and attitudes. This study was conducted with the aid of a grant from the Japan Dairy Association (J-milk).

Nutrition Education Methods for Students and Parents with Its Influence to The Vegetables, Fruits and Fish Consumption Behavior

Nur Intania Sofianita[1], Ali Khomsan[2], Ikeu Ekayanti[2], Budi Setiawan[2]

1. Pembangunan Nasional Veteran Jakarta University (Indonesia), 2. Bogor Agricultural University (Indonesia)

Background and Objectives: The behavior of consuming less vegetables, fruit and fish is still a nutritional problem in Indonesia. Vegetables and fruit are a source of vitamins, minerals and fiber that the body needs and fish is a source of protein containing omega 3 which is good for children's brain development. Efforts to increase consumption directly by providing vegetables, fruit and fish at home and providing nutrition education to increase knowledge, build positive attitudes and good consumption behavior in students, teachers and parents. This study aims to examine the effectiveness of the nutrition education method on students and parents and their effect on the consumption behavior of vegetables, fruit and fish.

Methods: The research method used a quasi-experimental pretest and posttest control group design. There are five study groups with a total sample of 85 students and 51 mothers. There are five study groups; (A) student group; parents with video; games, (B) student group with video; games, (C) student group with lecture; practice, (D) student group; parents with lecture; practice and, (E) control group students; parents, were not given any intervention. Nutrition education through lectures and videos is given four times in four weeks.

Result: The results of the N-gain score test show that nutrition education is quite effective in increasing knowledge in all nutrition education intervention groups, increasing respondents' attitudes is most effective in group (A), and quite effective in improving practice in group (D). The effectiveness of nutrition education on mother's knowledge, attitudes and practices showed that nutrition education was not effective in increasing knowledge because mother's knowledge was quite good before the intervention, but both methods were effective in improving mother's attitude, and the lecture method; practice was quite effective in improving mother's practice.

Conclusion: Nutrition education was quite effective in increasing knowledge in all study groups given the intervention compared to the control group. However, for improving practice, it was quite effective only in the student intervention group; parents in the lecture method; practice. Nutrition education involving parents had a significant effect on increasing knowledge, attitudes and practices of mothers in the intervention group compared to the control group.

Breakfast consumption and its relationship to knowledge, attitudes, self-efficacy and lifestyle factors among primary school students and junior high school students in Osaka: suggestions for future nutrition education

Naomi Hayami[1], Taro Nishi[1], Ashleigh Pencil[1], Shigekazu Ukawa[1], Hisayo Yokoyama[1], Katsushi Yoshita[1], Tomoe Fukumura[1]

1. Osaka Metropolitan University (Japan)

Background and objectives: One of the goals of the Fourth Basic Plan for the Promotion of Shokuiku in Japan is to decrease the percentage of citizens skipping breakfast. The goal is set as 0% for the students' age group. The aim of the study is to identify mutual/unique factors related to skipping breakfast and breakfast quality among primary school students (PSS) and junior high school students (JHSS) in Osaka, Japan in order to suggest a group-appropriate educational approach.

Methods: A self-administrated questionnaire survey was conducted from May to June in 2021. Participants were 427 students of the 5th grade and 6th grade from four public primary schools and 1282 students of the 7th and 8th grade from seven public junior high schools. Binary logistic regression analyses separated by PSS and JHSS were performed to calculate adjusted odds ratios for skipping breakfast and breakfast quality. Knowledge, attitudes, self-efficacy towards breakfast or healthy lifestyles and lifestyle factors were set as independent variables.

Results: The rate of breakfast skipping was 20.6% among PSS and 22.9% among JHSS. The rate of students who have a well-balanced breakfast regularly was 64.4% among PSS and 30.6% among JHSS. The logistic regression analysis indicated that, for skipping breakfast, late bedtime hour was a mutual factor among PSS and JHSS. Furthermore, lack of sleep was a negative factor in PSS and waking up late, not believing that breakfast can enhance concentration in the morning, negative attitude towards eating and low self-efficacy towards healthy lifestyle were the negative factors among JHSS. Regarding good breakfast quality, a good attitude towards a healthy lifestyle was the only positive factor among in PSS, and sleeping late, low self-efficacy towards menu planning of a well-balanced breakfast and self-efficacy towards cooking breakfast were the negative factors among JHSS.

Conclusions: Our findings suggest that future nutrition education needs to emphasize the importance of healthy lifestyle practices particularly sleeping habits to reduce skipping breakfast and to encourage a well-balanced breakfast for both PSS and JHSS. In addition, nutrition education should include activities to raise self-efficacy specifically towards diet quality to improve breakfast quality among JHSS.

Keyword: Skipping breakfast, Breakfast quality, Adolescents, Self-efficacy, Lifestyle

PAB(T5)-23

Dietary status of high school students, and effects of nutrition education on the status to the students.

Masako Kawanishi[1], Saki Yoshida[1], Rin-taro Yoshida[1], Tomoko Ojima[1], Mikiko Sekiya[1], Toshiyuki Kohri[2], Chiho Myojin[1]

1. Kindai University (Japan), 2. Konan Women's University (Japan)

Background and Objectives: The eating habits of high school students may have many problems due to changes in the individual living environment and further independence of a life style which is controlled by themselves. It is necessary to encourage young people such as high school students to acquire and practice healthy eating habits such as "having breakfast every day" and "increasing vegetable intake". We aim to characterize the diet status of high school students from Osaka, Japan, and to assess their association with nutrition knowledge, life style, physical and mental conditions, and consciousness and action on their diet.

Methods: In total, about 400 students (in 10 classes) aged 15–16 years in high school in Osaka, Japan, participated in the study. Internet questionnaires were distributed twice in all classes in August and November, 2019. A half of them (5 classes, intervention group) participated in nutrition education lessons twice and received some information on food and nutrition 4 times by e-mail. Another half of them (5 classes, non-intervention group) had no lessons.

Results: About 50% of the students sleep more than 6 hours during the night, which is about 10% less than the average. About 85% of them eat breakfast everyday but only 15% of them eat “full breakfast” (3 plates, staple food, main dish and side dish). Their average intake of vegetable is about 250g, which is 100g less than recommended amounts. After education, the intervention group had more knowledge about food and nutrition such as recommended amounts of vegetables, than the non-intervention group or than before the education, but their intake of vegetable after education was as the same as before the education. About 60% of them use their electronic device just before (less than 30 minutes) getting sleep. There is some relation between using electronic devices before bed time to the quality of their breakfast, that is, the longer the group used the electronic device before bed time, the less they tended to have a variety of food as their breakfast.

Conclusion: More approaches are needed in order to change their eating habits such as eating more vegetable.

Keyword: Dietary status, Eating habits, High school students, Nutrition education

DOI: 10.1159/000530786

PAB(T5)-24
Assessment of lifestyle and eating habits of school-refusing students in Japan

Asahi Tsuchimoto[1], Hiroko Inoue[2], Takako Kobayashi[3], Michiyo Sugiyama[4], Ayako Hashimoto[5], Reika Ogihara[1], Toko Nakano[1], Saki Hino[1], Noriko Kameyama[1], Toshiko Kuwano[1]

1. University of Shizuoka (Japan), 2. Toyo University (Japan), 3. GENKI-GAKUEN (Japan), 4. Kusanagi Ekimae Ladies Clinic (Japan), 5. Kyoto Women's University (Japan)

Background and objectives: The number of school-refusing students (SRS) in Japan is increasing annually. To better understand this trend and develop effective supportive measures for such students, we have surveyed the physical conditions, lifestyle, eating habits, and living environments of Japanese SRS.

Methods: The participants of the survey were students (*n*=119) aged 12–15 years (junior high school students) who refused school and participated in a consultation hosted by a free school in S city, S prefecture; students (*n*=143) attending K junior high school in M city, S prefecture; and their guardians. This study protocol was approved by the Research Ethics Review Board of the University of Shizuoka. The survey was conducted between May 2017 and October 2021 and collected data using physical measurements, a diet and lifestyle questionnaire, and a brief self-administered diet history questionnaire. Statistical analysis was performed using SPSS 27.0 J for Windows (IBM Japan) to compare the SRS and school-attending students (SAS). The significance level was set at $p < 5\%$.

Results: The mean ages of the participants were 13.4±0.8 years (SRS) and 13.3±0.9 years (SAS). There was no significant between-group difference in physical conditions such as height, weight, and BMI. However, the screen time (when using mobile phones and other devices) was significantly longer for SRS than for SAS ($p<0.001$). Moreover, many SRS had low levels of physical activity. As for breakfast, 80.4% of SAS answered that they “eat every day,” but only 40.8% of the SRS reported the same. SRS had significantly lower intakes of energy ($p<0.001$), protein ($p<0.001$), lipids ($p <0.01$), carbohydrates ($p<0.01$), vitamins, and minerals than the SAS. However, when adjusted for energy intake, no significant between-group difference was observed.

Conclusions: Our findings suggest that SRS may not be able to engage in enough physical activity or follow a sufficiently healthy diet and lifestyle to meet the requirements for the growth and development of junior high school students. Early intervention and support for the improvement of eating habits and lifestyle are, therefore, recommended.

Designing school-based nutrition education interventions using social and behavior change principles to improve dietary practices of adolescent girls in Ethiopia

Tamirat Walissa[2], Yonas Asrat[2], Abdulaziz Oumer[2], Sunny S. Kim[3], Tina G. Sanghvi[1]

1. FHI 360 (USA), 2. FHI 360 (Ethiopia), 3. International Food Policy Research Institute (USA)

Background and objectives: Large-scale interventions implemented through schools have the potential to reach over seventy percent of adolescent girls in Ethiopia. Promotion of healthy food consumption practices among adolescent girls should address their motivations, barriers, and influencing factors. We designed and facilitated the implementation of nutrition interventions delivered through government primary schools to improve the diet of adolescent girls. **Methods**: We applied the socio-ecological model of social and behavior change (SBC) to develop an effective strategy for adolescent nutrition in SNNP (Southern Nations, Nationalities and Peoples) (agrarian) and Somali (pastoralist) regions. Gaps in dietary practices, barriers and motivations, roles of influential persons, and channels of communication were identified. Context-specific intervention models were developed for each region using multiple sources of information and data. Interventions were implemented by school principals, supervisors, teachers, student leaders, community leaders and health extension workers. Program monitoring and participatory problem-solving sessions helped to adapt the interventions, and informed and refined the implementation process. **Results**: School teachers and parents had good knowledge about nutrition prior to interventions, but they were not addressing the drivers of adolescents' dietary behaviors. Interventions were developed to improve adolescent girls' knowledge, self-efficacy, social norms, and beliefs by engaging parents, teachers, and peers in interactive dialogue conducted through multiple existing school-based activities that were streamlined to easily integrate into existing events such as flag ceremonies, school clubs/peer to peer sessions, and classroom lessons. Hands-on, participatory, face to face communication aided by audiovisual materials were used. Student take-home materials were used to reach parents; contacts were expanded through parent-teacher meetings, health worker visits and community events to encourage parents to provide an enabling home food environment. Repeated training, supervision and monitoring were key to solving operational constraints. **Conclusions**: Social and behavior-change principles may be needed to design nutrition education activities for improving dietary practices of adolescent girls. Primary schools can be effective channels for scaling up interventions to improve adolescent nutrition.

Parent's level of education and dietary patterns among out of school adolescents in Ibadan Nigeria

Akinkunmi Paul Okekunle[1], Rashidat Abosede Adenekan[1], Folake Olukemi Samuel[1]

1. University of Ibadan (Nigeria)

Background and objectives: The importance of formal education and well-informed decision-making cannot be underscored in the health and wellbeing of populations. Access to quality education is limited in most low resource environments (particularly among adolescents), where school enrollment and drop-out rates are low and high, respectively. However, little is known about the significance of parents' level of education (PLE) in dietary patterns adherence (DPA) of out-of-school adolescents. This study aims to assess the relationship between PLE and DPA among out-of-school adolescents in Ibadan, Nigeria.

Methods: A cross-section of 190 out-of-school adolescents was identified in Ibadan, and information on age, last school enrollment, and PLE were collected via in-person interviews after due informed consent. Using a semi-quantitative food frequency questionnaire, respondents reported the frequency of food consumption, and principal component analysis was applied to identify two major dietary patterns ('unhealthy' and 'healthy'). A Chi-square test was applied to determine the relationship between PLE and DPA among out-of-school adolescents at P<0.05.

Results: Adolescents with strong adherence to the 'unhealthy' diet patterns were significantly higher (P=0.032) among those who reported having a father (62.3%) or mother (67.1%) with primary school education only compared to a similar population whose father (44.9%) or mother (37.8%) had at least a secondary school education. Contrariwise, the proportion of adolescents with adherence to 'healthy' diet patterns was significantly higher (P=0.017) among those with fathers (55.1%) or mothers (58.6%) who had at least a secondary school education compared with a similar population whose fathers (35.8%) or mother (38.0%) had a primary school education only.

Conclusion: PLE was associated with the DPA among out-of-school adolescents in this population. The importance of continuing parental education might be a promising soft target approach in promoting healthy dietary choices and managing the burden of malnutrition among adolescents from low-resource environments.

The effects of body image and media on dieting behaviors among Japanese adolescents: suggestions for an educational approach to improve their healthy eating habits.

Maho Matsuda[1], Ashleigh Pencil[1], Naomi Hayami[1]

1. Osaka City University (Japan)

Background and objectives: In Japan, dieting has become a serious health problem among girls and young females. It is important for adolescents to build a positive body image. However, such studies are limited in Japan. One of the factors influencing body image is media, a socio-cultural factor. It is recognized as the most influential sociocultural factor. The aim of this study was to examine the effects of media on body image and dieting and to suggest educational approaches to promote healthy eating habits among adolescents.

Methods: Anonymous self-administered questionnaires were administrated to the grade 7 students (n=552) attending three public junior high schools in Osaka Prefecture, Japan in February 2020. The number of valid answers was 375 (boys:181, girls:194). Participants completed a set of demographic questions (height and weight), media use, dieting, body image (perception, ideals, discrepancy), and socio-cultural influence (Sociocultural Attitudes Towards Appearance Questionnaire-4: SATAQ-4). A binomial logistic regression analysis was conducted as well as descriptive statistics and univariate analysis.

Results: Girls (47.0%) were more likely to diet than boys (22.5%) (p<0.001). Binominal logistic regression analysis showed that among girls, dieting was associated with perceiving themselves as being fat regardless of their actual body shapes (OR:95%CI; 2.895:1.292-6.485) and SATAQ4-Media-Pressure scores (1.119:1.025-1.222). There was no significant correlation between body image and dieting among girls. There were no significant factors related to dieting among boys.

Conclusions: This study reported high rates of dieting attempts among girls, which is consistent with other studies. Our findings suggest that nutrition education may have a positive impact among girls, teaching them not to think they are fat and not to internalize thin media-ideals, whereas further studies are needed to find any factors among boys. Being fat is likely to be portrayed negatively in the Japanese society. This may cause adolescents to attempt dieting though their body shapes are mostly standard or slim. Interestingly, understanding the "correct body image" was less important. Health/nutrition educators should remember this and need to teach about "healthy body" carefully. Future nutrition education programs should be more comprehensive, and must build media literacy towards thin-ideals and promote positive body perceptions.

Increasing speed while maintaining quality: Lessons learned in adapting adolescent nutrition social and behavior change communication materials from Ethiopia to Tanzania

Mariam Mwita[1], Lydia Clemmons[2], Joyceline Kaganda[1], Carolyn O'Donnell[3], Alex Rutto[1], Victoria Christian Marijani[1]

1. Save The Children International (Tanzania Office) (Tanzania), 2. The Manoff Group (USA), 3. Save The Children International (USA)

Background and Objectives: In Tanzania, where 14-18% of adolescents experience malnutrition (TDHS 2010, 2015), the evidence base on adolescent nutrition (AN) has been limited and few nutrition social and behavior change communication (SBCC) materials for adolescents exist. In 2019, Lishe Endelevu, a five-year activity funded by the US Agency for International Development (USAID), faced the challenge of ensuring the rapid implementation of nutrition SBCC programming to improve nutrition outcomes among adolescents in four regions of Tanzania. The Activity made the strategic decision to use the same priority behaviors and adapt evidence-based AN SBCC materials used by USAID/Empowering New Generations to Improve Nutrition and Economic Opportunities Activity in Ethiopia.

Methods: Key steps in the adaptation process included: Review the evidence base on adolescent nutrition in Tanzania and Ethiopia and prioritize nutrition behaviors. Procure copies of AN SBCC materials from Ethiopia and adapt them to the Tanzanian context Pretest the adapted materials with adolescent girls, mothers and fathers of adolescent girls, and teachers. Use the pretest findings to make further revisions to adjust to local Tanzanian context. Submit the materials and pretest report to government authorities for technical review. Incorporate technical review feedback to finalize the materials. Reproduce and disseminate the materials. Train teachers and community volunteers to use the materials. Monitor implementation and document lessons learned.

Results: In less than 2 years from adapting the set of 8 adolescent nutrition SBCC materials from Ethiopia to the Tanzania context, Lishe Endelevu reached 625 teachers and 3952 community health workers who in turn reached 100370 adolescents through 493 in-school nutrition clubs and an additional 72410 adolescents in out of school activities.

Conclusion: Programs can speed up implementation by obtaining existing evidence-based SBCC materials that have had success in other places and developed for similar audiences and contexts following a methodological process to adapt them to a different context. Pretesting materials with the intended audiences, soliciting reviews and feedback from technical experts, and ensuring careful revisions are critical steps in process to adapt materials from other programs.

High Fat, Salt and Sugar (HFSS) food consumption and television advertisements: an undesirable association

Shonima Venugopal[1], Vaibhavi Shinde[1], Uma Iyer[1]

1. The Maharaja Sayajirao University of Baroda (India)

Background and objectives: Easy availability and access to High Fat, Salt and Sugar (HFSS) food is a contributing factor to the increasing burden of childhood obesity. Television food advertisements play an important role in influencing children's choices of food consumption. The present study was planned with the objective to study the association between television food advertisements and consumption of HFSS foods by school age children.

Methods: A total of 378 students studying from 6th to 12th standard were enrolled from an English medium private school in Vadodara city, Gujarat, India and were asked to complete an online self-administered questionnaire related to HFSS food consumption and television advertisements.

Results: Around 70.6%, 81.7%, 71.9% and 83.3% of thin, normal weight, overweight and obese subjects reported HFSS food consumption in the previous 24 hours of the survey respectively. At least one HFSS food product was consumed in the previous 24 hours by 44.5% subjects and 24% subjects reported consumption of two HFSS food products. Around 66.8% of the school children reported that they get information about HFSS foods from television advertisements followed by friends (43.9%) and the internet (43.3%). When asked whether they like to try out the new food products shown in television advertisements, 59.3% subjects replied in the affirmative. Subjects (52.1%) reported trying out new food products shown in television advertisements within a period of one month. Majority (91.1%) subjects reported that they liked to consume HFSS food because they were tasty.

Conclusions: Children need to be sensitized about the ill effects of HFSS food consumption and encouraged to make healthy lifestyle choices. There is a need for implementation and enforcement of existing laws to regulate advertising of different HFSS food products which could help in reducing the intake of HFSS food products by children. Also, there is a need to encourage advertising of healthy foods. Using the medium of television for nutrition education and promoting healthy lifestyle behaviours could help in alleviating the problem of childhood obesity and its associated health risks.

Evaluation of nutrition education program for prevention of noncommunicable diseases: A case study of sugar intake

Chinatsu Tobari[1], Masako Takamasu[2]

1. University of Human Arts and Sciences (Japan), 2. Japan Women's University (Japan)

Background and objectives: This study aimed to implement a nutrition education program on sugar intake for university students in Malaysia to prevent noncommunicable diseases (NCDs) and conduct process, impact, and outcome evaluations of this program.

Methods: We conducted a nutrition education workshop that involved 102 students at Universiti Teknologi MARA (UiTM) who responded to a preworkshop survey. The results were analyzed before and after the workshop. A pre- and postworkshop comparison was conducted for 61 students who participated in the postworkshop survey.

Results: The nutrition education workshop was successful overall. More than 80% of the students were glad that they attended the workshop. Subsequently, they expressed a positive view of the nutrition education program and practiced what they had learned. Comparison of the pre- and postnutritional education program data showed improvement in students' knowledge regarding sugar consumption students demonstrated self-efficacy in selecting beverages with little sugar and a high degree of self-awareness by being careful about consuming large amounts of sugar. Furthermore, students demonstrated improvement in behaviors by eating breakfast regularly; skipping breakfast was identified as a preimplementation problem. Moreover, students reduced consumption of sugar-sweetened beverages (SSB), and engaged in exercise. As an evaluation measure of outcomes, we focused on the intake frequency of SSB and sweets. For the daily intake frequency of SSB, the number of people who answered “more than three times” decreased significantly.

Conclusions: The implementation of the nutrition education program led to positive changes in the knowledge, attitudes, and behaviors of the participants regarding sugar intake. Thus, conducting a nutritional education program and follow-ups for university students with a focus on sugar intake is meaningful for NCD prevention, and the effectiveness of this program proves that it can be applied to all. Following the implementation of the nutrition education program, NCD prevention is expected to improve as university students spread information regarding the same and play the role of information disseminators in their hometowns.

The effects of the intervention by adding soy milk okara powder to the Young Woman

Masako Tsuji [1] , Marin Oozono[1], Suzuka Fukunaga[1], Hitomi Watanuki[1], Nao Tatemichi[1], Tomoko Yoshino[1], Yuuka Suzuki[1], Ayaka Nomura[1], Kazuya Hayashi[1]

1. Tokyo Kasei Gakuin University (Japan)

Background and objectives: Recently, the dietary fiber(DF) intake of Japanese people has been decreasing. The reason is the decrease in intake of cereals, potatoes, legumes, vegetables and fruits. According to the Dietary Reference for Japanese, 2020, the daily target amount of DF for women over the age of eighteen is 18.0g or more. However, the intake of women in their twenties is 14.6g. Therefore, we conducted a crossover randomized trial study using soy milk okara powder to investigate the relationship between increased DF intake and defecation status in young women. **Methods**: The participants were young women volunteers(University students) aged 20 to 23 years. Twenty-one participants were divided into two groups, an intervention group (A:n=11) and a control group(B:n=10). We conducted a 9-week crossover randomized trial with and without soy milk okara powder(SMOP) added to the soup(pre-test:1w, First test:3w, washout:1w, next test(Exchange intervention and control) :3w, post-test:1w). The intervention group consumed about 3.0 g of fiber from SMOP per day for 3weeks. **Results**: The mean energy during the intervention of A was 1430.7 ± 268.1 kcal, and the energy during the control was 1330.2 ± 279.4 kcal. And, the energy of B during control was 1543.6 ± 318.0 kcal, and the energy during intervention was 1478.9 ± 328.5 kcal. The energy intake during the intervention study of B showed high overall results. The dietary fiber intake fluctuations (intervention・control) of A were 14.7 ± 5.0 g and 8.7 ± 5.0 g. The fluctuations in the intake of B dietary fiber (control・intervention) were 11.5 ± 3.9 g and 13.3 ± 5.1 g. Defecation volume was higher than before the intervention(=pre trial), but there was no significant difference between the two groups due to this intervention. **Conclusions**: It was suggested that nutrition education is necessary to actively take in DF-rich diets such as okara and encourage proper dietary intake.

Is there a relationship between unexplained complaints and skipping breakfast?

Akiyo Shiohara[1]

1. Toyo University (Japan)

Objectives:

Breakfast skipping is reported to have significant effect on unexplained complaints, particularly in adolescents, when lifestyle factors such as dietary habits are considered. This report aims to investigate the relationship between dietary intake and unexplained complaints related to breakfast by using data from dietary-intake status and health surveys of female college students.

Methods:

Between 2017-2019,172 female college students were surveyed regarding their daily diet, fats, carbohydrates, potassium, calcium, magnesium, iron, dietary fiber and salt. The data regarding food groups, habitual meal times, height, weight and Body mass index (BMI) were determined using a semi-quantitative food intake-frequency survey method (FFQW82). Additionally, the completed questionnaires of 114 individuals related to 24 unexplained complaints acquired in the spring of the same year were linked by ID and analyzed. The subjects were divided into a breakfast-skipping group (n=70) with a breakfast intake of <200 kcal, and a breakfast feeding group (n=102). A Mann-Whitney U test with a significance probability of <5% was used to compare the groups.

Results:

The energy and nutrient intake significantly differed between the groups when fat intake was excluded. The breakfast-skipping group had a higher cereal energy ratio and consumed less fish, soy products, and vegetables. Consequently, the intake of potassium, calcium, and magnesium in the breakfast-skipping group was reduced by nearly half. Moreover, each nutrient intake was below the reference ranges in both groups, and 18.8% of the breakfast-skipping group was classified as underweight based on BMI. Furthermore, there was no significant correlation between the frequency of unexplained complaints and nutrient intake, physique, or other factors.

Conclusions:

This study was unable to establish a significant correlation between dietary intake and unexplained complaints. While the relationship between diet and depression has been established, further focus is needed on the relationship between intake status and unexplained complaints.

Awareness and consumption of event foods among university students in Kochi Prefecture

Yuko Araki[1], Hitomi Takeichi[2], Ruriko Hibino[3]

1. Kochi Gakuen University (Japan), 2. Kochi Gakuen University (Japan), 3. Kochi Gakuen University (Japan)

Background and purpose: Japanese food culture is characterized by the four seasons and geographical diversity, and is linked to traditional regional events and manners. The world-class characteristics of Japan's food culture have been gradually disappearing in recent years, due to the growing trend toward nuclear families, the weakening of regional ties, and the diversification of food. The purpose of this study was to investigate the awareness and consumption of traditional Japanese foods among university students and to examine the transmission of food culture. **Method**: A questionnaire survey was conducted among 75 university students in Kochi Prefecture. They were asked about their consumption of New Year's dishes (ozoni, osechi, toso sake, and Sawachi cuisine), their recognition of and experience with annual event foods, and their awareness of event foods. **Result**: New Year's dishes were *ozone* (93.2%), *osechi* (83.8%), Sawachi cuisine (60.8%), and *toso-shu* (8.1%). *Kamaboko* (fish cake) had the highest consumption rate at 77.3%, followed by *kuromame* (black soybeans) and herring egg. Vegetable dishes such as *nishime* and *namasu* were consumed by 17.3% and 25.3% of the respondents, respectively. Among the foods eaten for the five festivals, chirashizushi and *somen noodles* were eaten by 91.9% and 90.5% of the respondents, respectively, on Doll festival and Star festival. The edible chrysanthemum dish for Chrysanthemum Festival was quite low in both recognition and eating experience. Event foods were viewed by 87.8% of the respondents as a way to feel the seasons, 79.7% as a way to pass on culture, and 54.5% as a way to enjoy. There was a high level of awareness of the importance of passing on food events (91.9%). **Conclusion**: It was suggested that although the younger generation has a high awareness of the need to pass on food culture, they have little experience with food culture, so it is necessary to provide them with places and opportunities to learn about local foods and culture and gain experience in eating them.

Examination of nutrition education for collegiate athletes based on food education in home economics

Mizuho Adachi[1]

1. Nippon Sport Science University (Japan)

Background and objectives: The Basic Act on *Shokuiku* (Food and Nutrition Education) (2005) was enacted, and based on the Fourth Basic Plan for the Promotion of Shokuiku (2021), *Shokuiku* is being promoted in Japan. The government course [curriculum] guidelines were announced in 2017 for elementary and junior high schools and in 2018 for high schools. In the new curriculum guidelines, home economics should be considered to contribute to the enhancement of *Shokuiku*. Various issues have been reported regarding the food knowledge and eating habits of collegiate athletes. The purpose of this study was to examine the nutrition education necessary for collegiate athletes based on food education in home economics in elementary school, junior high school, and high school.

Methods: First, we investigated the learning objectives and content regarding food education in the curriculum guidelines for home economics at elementary, junior high, and high schools. Next, we investigated whether the issues and goals of the Fourth Basic Plan for the Promotion of Shokuiku are related to food education in the curricula. These results were compared with the content of nutrition education provided to collegiate athletes in eight sports discipline.

Results: In the curriculum guidelines for home economics, the systematization of food education among each school type was clarified, and the graduality was also recognized. Sports nutrition were listed as teaching items in high school. Among the goals in the the Fourth Basic Plan for the Promotion of Shokuiku , *shokuiku* promoted from the concept of "new normal" and sustainable food and nutrition, and nutrition education for prevention of lifestyle diseases were not specifically mentioned in the curricula. There were also not addressed in nutrition education for collegiate athletes.

Conclusions: Nutrition education for collegiate athletes should also take into account the perspective of *Shokuiku* that supports sustainable food and lifetime physical and mental health, which are not covered in home economics.

This study was conducted with academic research support from the Japan Dairy Association, the Milk Education Research Council

Keyword: collegiate athlete, home economics, nutrition education

Intervention study on health and dietary awareness among young women using the Line social media application

Makoto Ohtsuki[1]*, Ai Komada*[2]*, Hiromi Okada*[3]*, Kanako Furuta*[4]*, Yuki Aikawa*[2]*, Yoriko Umehara*[4]

1. Suzuka University of Medical Science (Japan), 2. Tsu City College (Japan), 3. Tsu Public Health Center (Japan), 4. Suzuka Junior College (Japan)

Background and objectives: Young women in Japan tend to be thin, and there is a need to educate them about the importance of healthy eating for their future health. We examined the impact of providing information using the social media application (app) “Line” to improve health awareness and dietary awareness among young Japanese women.

Methods: We conducted a randomized controlled trial to examine the effects of the intervention. Participants were from one university and two junior colleges in Mie Prefecture. The intervention period was from September to October 2019. Using Line, we delivered content regarding appropriate weight and dietary balance and the correct intake and intake method of nutrients (calcium, iron, vitamin C, dietary fiber, potassium, salt, fat, saturated fatty acids, protein, and carbohydrates). Content was delivered twice a week for 2 months, for a total of 18 times. Self-related health and dietary awareness were assessed using a questionnaire, and nutrient and food group intakes were assessed using a simple self-administered dietary history questionnaire. Intention-to-treat analysis was conducted among 51 participants in the intervention group and 52 young women in the control group. To confirm the effectiveness of the intervention, we used the Wilcoxon signed rank test for within-group comparisons of continuous variables, the Mann-Whitney U test for between-group comparisons, the McNemar test for within-group comparisons of categorical variables, and the $\chi 2$ test for between-group comparisons.

Results: Compared with the control group, subjective health perception and subjective dietary fiber intake worsened in the intervention group whereas consumption of potatoes and other vegetables as well as dietary fiber intake increased significantly. Additionally, beverage consumption decreased and use of seasoning and spices increased.

Conclusions: Our findings suggested that providing information on health and food via a social media app over a 6-week period may lead to changes in health awareness and dietary awareness among young women.

Keyword: Social media application, Intervention study, Health awareness, Dietary awareness, Young women

Effects on energy intake and expenditure of ingesting low-calorie artificially-sweetened beverages in free-living healthy young women

Mizuho Sawahara[1], Kentaro Yamanaka[1]

1. Showa Women's University (Japan)

Background and Objectives: Many studies have investigated the immediate (short-term) and habitual (long-term) effects of artificial sweeteners on appetite and energy intake. However, it is not unclear that the middle-term effects of artificial sweeteners on energy balance (intake and expenditure) during daily life. The purpose of this study is to examine the effects on the energy intake (EI) and energy expenditure (EE) of the day and the next day of ingesting low-calorie artificially-sweetened beverage (ASB) and sugar-sweetened beverage (SSB) in free-living healthy young women.

Methods: Ten healthy young women (21.9 ± 0.6 years old, BMI = 21.0 ± 2.6 kg/m²) participated in a single-blind, randomized trial of 3-days experimental sessions, in which they were free to behave and eat as normal and record their all food intake (mobile phone photographs and text messages) and physical activity (Actigraph, AMI). On the 2nd day of each session, they were asked to ingest a bottled beverage (500 mL) with either low-calorie artificial sweetener or sugar. From the food records and physical activity data, the amounts of EI and EE were estimated for each day, and calculated the amount of EI and EE changes on the 2nd and 3rd days form the 1st day.

Results: For the EI changes, there were no significant effect of beverage (ASB or SSB) and day (2nd or 3rd) and no interaction between them. On the other hand, for the EE changes, there were no significant effect of beverage and day (2nd or 3rd) but a significant interaction between them: EE decreased on the day after ASB ingestion while increased on the day after SSB ingestion.

Conclusions: Our results demonstrated that the participants may have unconsciously reduced the amount of physical activity on the day after the ASB ingestion but increased it on the day after the SSB ingestion. This suggests that the benefits of using artificial sweeteners to reduce EI may be diminished by compensatory EE reduction on the next day.

Keyword: low-calorie artificial sweetener, energy intake, energy expenditure

PAB(T5)-37
A randomized controlled trial of slow eating using a smartphone-based educational program on mindful eating among young Japanese females

Ayano Chiba[1,2], Nobuo Yoshiike[1]

1. Aomori University of Health and Welfare (Japan), 2. Aomori Chuo Junior College (Japan)

Background and objectives: Mindful Eating (ME) is the practice of being fully aware of the food being consumed and how one eats. One element of ME is to eat slowly. Education that targets chewing behaviors and eating rates has been conventionally conducted, such as eating slowly and chewing 30 times per bite. However, the effects of education interventions using ME have not been investigated. Therefore, this study aimed to generate two intervention programs (focusing on 1) ME and 2) slow eating), and clarify the effects of these programs on the eating rate.

Methods: A randomized controlled trial was conducted on 66 female university students. Participants were randomly divided into the ME intervention group and the mastication intervention group. Each group participated in an 8-week program. Web-based questionnaire surveys were conducted before (B_X), at the end (A_0), one month (A_1), and three months after the intervention (A_3) on items related to basic attributes, eating rate assessed by the newly developed smartphone-based self-check tool, eating style, Mindful Eating Questionnaire (MEQ), and subjective diet-related quality of life (SDQOL). Within-group and between-group comparisons were made for each endpoint. Those who changed from undesirable to desirable situations were classified as "success," while the rest were classified as “non-success.”

Results: In both groups, eating rates at A_0, A_1, and A_3 were significantly lower than at B_X ($p < 0.001$), suggesting sustained improvement in terms of slow eating after interventions. The percentage of “success” at the end of the study was significantly higher in the ME group than in the mastication group regarding some items of the MEQ; "awareness of physiological and psychological experiences" ($p = 0.002$) and "awareness of external cues" ($p = 0.048$). Meanwhile, the percentage of "success" was significantly higher in the mastication group than in the ME group regarding the chewing period per bite ($p = 0.036$) and the number of chews per bite ($p = 0.013$).

Conclusions: Compared to the educational program focused only on mastication, the program focusing on ME showed not only similar improvement in terms of slow eating but also preferable changes in some items of the MEQ.

Relationship of obesity with lifestyle and eating habits among Thai young adults

Minatsu Kobayashi[1], Paponpat Pattarathitwat[2], Apidech Pongprajakand[2], Sikaret Kongkaew[3]

1. Otsuma Women's University (Japan), 2. Rajamangala University of Technology Thanyaburi (Thailand), 3. Chiang Mai Rajabhat University (Thailand)

Background and objectives: In Thailand, the proportion of the obese population has increased due to the improving income levels and the consumption of a westernized diet. Although obesity is also prevalent among young adults, only a few studies have evaluated the body type and health risks in young adults using a small sample size. In this study, we aimed to examine the differences in biomarkers, lifestyles, eating habits, and interest in dieting associated with bodyweight classification among young Thai adults; the survey was conducted over several years to obtain a sample size that is larger than that in previous studies.

Methods: The survey was administered to Thai university students residing in suburban Bangkok (Thanyaburi) and suburban Chiang Mai from 2017 to 2020 regarding their lifestyle and eating habits, using physical measurements and a questionnaire. A total of 207 male students and 507 female students were classified as “underweight,” “average weight,” “overweight,” or “obese” according to their BMI: these groups were compared in terms of their differences in biomarkers, lifestyle, and eating habits.

Results: Overall, 34.8% of men and 28.4% of women were overweight or obese. Students of both genders in the overweight and obese group had a higher body fat percentage and systolic/diastolic blood pressure (all P<0.0001). Overweight and obese group students were more interested in dieting (men: P=0.0007, women: P<0.0001), and most of them reported that they have dieted in the past (P=0.222, P<0.0001). Additionally, the obese group was more likely to report eating quickly (P=0.107, P=0.014).

Conclusions: The combined percentage of overweight or obese young adults in the study was as high as the adult population of Thailand. The higher mean systolic and diastolic blood pressures in the overweight and obese groups indicated that it is essential to address hypertension, a lifestyle-related disease, as soon as possible to prevent the development of cardiovascular and cerebrovascular diseases. Many participants with obesity were not currently dieting yet had previously been on a diet. We suggest that continuous weight loss intervention programs should be proposed to such individuals to help them maintain an appropriate weight and body composition.

Keyword: Obesity, Body weight, Lifestyle, Eating habits, Thai young adults

Consumer perception on processed fruit peels as dietary additives: a preliminary study on minimising fruit wastes

Eridiong Ogbonna Onyenweaku[1,2], Hema Kesa[1]

1. University of Johannesburg (South Africa), 2. University of Calabar (Nigeria)

Background and Objectives: Research has shown the role of healthy diets in the prevention of both chronic and infectious diseases. With the current increase in the occurrence of non-communicable diseases (NCDs), people need to make healthy food choices. This study aimed at generating data on consumer fruit peel preferences, food choice motives and consumer perception of product quality to enable the design and production of acceptable processed fruit peel sprinkles which will be used as food additives. The objectives of this research include: to ascertain consumers' acceptance of new products (dried, powdered fruit peels) and to determine the most preferred fruits and flavours.

Methods: An online questionnaire was used for this cross-sectional survey carried out in South Africa. The questionnaire link was circulated in the different provinces for 4 weeks (June 2021); it was structured to gather socio-economic data, nutrition knowledge, overall perception/acceptance of processed fruit peel products by the respondents and factors that influence consumer choices. Descriptive statistics were used in the statistical analyses.

Results: The surveyed population consisted of 517 participants from the nine South African provinces with Gauteng, North West and KwaZulu-Natal accounting for over 70% responses. About 70% of the participants also had a tertiary education and most of the participants showed good nutrition knowledge (85%); they were aware that fruit peels contain useful micronutrients and antioxidants which promote good health and can also assist in weight loss (67%). ‘Sweetened' (36%) was the most suggested flavor for the proposed product, followed by ‘Natural' i.e. no flavor additives (24%) and ‘Chilli' (11%). About 90% of the participants were interested in learning how to process the fruit peels for consumption purposes.

Conclusion: Consumers showed keen interest in the consumption of processed fruit peels, with demand for citrus fruit peel products being the highest. Processing and consumption of fruit peels should be encouraged and promoted in order to strengthen the immune system especially during this pandemic, with the reduction of fruit wastes being a key target.

Relationship between milk intake behavior and health literacy during the adulthood - Current situation and issues in Japan and Korea-

Mie Imanaka[1], Kim Miok[2], Jiro Takeuchi[3], Shiori Fukuda[1], Hiroshi Tatano[1], Chie Kuwajima[4], Hiroko Sakamoto[5], Teruyo Miyagawa[6]

1. The University of Shimane (Japan), 2. Daegu Health College (Korea), 3. Hyogo College of Medicine (Japan), 4. Kyoto Koka Women's University (Japan), 5. Kyoto Kacho University (Japan), 6. NPO Zero-JI Club (Japan)

Background and objectives: Health literacy, defined as "an ability to inform health-related decisions" is one of the issues that attracts attention in the field of health education. The health literacy of Japanese people is known to be lower than that of European and other Asian nations. Insufficient calcium intake is a health issue that can affect elderly persons. Milk intake is one of the primary sources of calcium in the adulthood. We aimed to explore the relationship between milk intake behavior and health literacy and identify the differences in the relationship between Japan and Korea.

Methods: This was a cross-sectional study performed as an international joint research in Japan and Korea. The study period was April 2019 to March 2020. The participants were adults over the age of 18 in Kyoto, Shiga, and Shimane, Japan, and in Daegu, Korea. We distributed the modified Health Literacy Survey (m-HLS-14) and Brief-type Self-administered Diet History Questionnaire (BDHQ) among all the participants. We employed correlation coefficient to explore the factors related to milk intake behavior. Test and analyses were performed using JMP14 software.

Results: The number of participants were 464 in Japan and 76 in Korea (response rate 64.4%). The participants who answered that they drink milk every day and their age factors correlated negatively in Japan (r= -0.22; p< 0.0001) and in Korea (r= -0.32; p= 0.005). And the participants who answered that they drink milk every day and their gender difference factors correlated positively in Japan (r= 0.03; p= 0.53) and in Korea (r= 0.08; p= 0.50). The participants who answered that they drink milk every day and Body Mass Index factors correlated negatively in Japan (r= -0.06; p= 0.27) and correlated positively in Korea (r= 0.02; p= 0.86). In the item about an ability to inform health-related decisions, the number of the participants who answered that they would not do anything is 100 (23.9%) in Japan and 15 (19.7%) in Korea.

Conclusions: Milk intake behavior correlated with increasing ages in both of Japan and Korea. We need to develop health literacy to obtain essential nutrients for during the adulthood.

Keyword: milk intake behavior, health literacy, adulthood, Japan and Korea

Joint Activities by Universities for the Improvement of Improving Lifestyle Habits of Community-residing Adults: Influence of the Number of Times Participating on Food Preferences and Lifestyle Improvement

Yoshie Tanaka[1], Masayo Oumi<[2], Yasuko Sakaida[3], Tatsuya Tagawa[4], Toshiyuki Tsujisawa[5], Hisako Hikiji[5], Atsuko Nakamichi[5], Etsuko Teshima[6], Aiko Ishii[7], Atsumi Nagata[7]

1. Fukuoka Woman's University (Japan), 2. Nakamura Gakuen University (Japan), 3. University of Nagasaki (Japan), 4. Fukuoka International University of Health and Welfare (Japan), 5. Kyushu Dental University (Japan), 6. eatas Co.,Ltd. (Japan), 7. Seinan Jo Gakuin University (Japan)

Background and objectives: A joint project for improving the lifestyle habits of local residents in Kitakyushu City, Fukuoka, Japan was implemented in 2014. The activities of this project consisted of extension lectures for lifestyle-related diseases alongside a meal prepared considering the characteristics of the disease. While promoting dietary education activities for local residents, students were also encouraged to positively engage in the activities as a type of participatory education.

Methods: The project was carried out for six years from 2014 to 2019. More than 90% of the participants were over the age of 60, and the number of participants gradually increased during the project period. To assess the program, we used the results of a questionnaire to examine the effects of different numbers of time participating in this course on food preferences and lifestyle-related improvement.

Results: A total of 1,516 valid responses were collected. The respondents were divided into 4 groups according to the number of times they participated in the course (out of a possible 23)—1 time (15.1%), 2 to 5 times (46.6%), 6 to 9 times (28.8%), and 10 or more times (9.5%). The group with 10 or more participations had a higher percentage of respondents who answered "very healthy" than the other groups, and the percentage of people practicing healthy eating habits was also high in this group. In addition, more than 80% of the participants were repeaters.

Conclusions: This project helped participants interact and raise awareness of health promotion. Because several individuals have participated in multiple activities within this project, their degree of understanding of the lectures was high and their lifestyles were improved. This project has proved to be effective and engaging. Future research is needed to create health awareness and improve lifestyles in the local community.

Meal preparation characteristics of Japanese elderly people: A preliminary study of the elderly living alone.

Megumi Togawa[1], Fumi Hayashi[1], Yukari Takemi[1]

1. Kagawa Nutrition University (Japan)

Background and Objectives: Weight loss and poor-quality diets are some of the factors associated with frailty in the elderly. Consuming a variety of foods is essential for a balanced diet. Food intake requires skills in food preparation, such as cooking. Women are more skilled in meal preparation, while men face challenges due to social norms. This study aimed to clarify the characteristics of meal preparation among Japanese elderly who consume a variety of foods.

Methods: The participants were 133 community-dwelling elderly adults aged 62-88 living alone in City A, Saitama Prefecture. Participants photographed and recorded all food and drinks they ate for three non-consecutive days in September 2013. A total of 7,035 dishes and foods were observed. These were divided into the following four categories: ″ homemade, ″ ″ re-cooked dishes bought outside,″ ″ prepared outside the home,″ and ″ eating out.″ Cooking methods were classified into 20 patterns based on previous studies. Participants were grouped according to the Dietary Variety Score (DVS), a 10-point scale, one of the indicators of diversity of food intake among the elderly in Japan: low DVS group (3 points or less) and high DVS group (4 points or more). Unpaired t-test and Mann-Whitney's U-test were performed by gender and DVS group.

Results: Women had more dishes per person per day ($p=0.010$) and were ¨homemade¨ ($p<0.001$) than men. For men, the high DVS group ate more dishes per person per day than the low DVS group (19.76 ± 3.9 vs. 15.35 ± 4.2, $p<0.001$). The number of ¨homemade¨ dishes were higher in the men high DVS group than the men low DVS group (17.27 ± 2.5 vs. 12.36 ± 2.6, $p<0.001$). No significant differences were found among women between DVS groups. The most frequently occurring homemade cooking methods for both men and women were marinated and salads for vegetables and grilling or stew for seafood and meat. There were no differences in frequent cooking methods between the two genders.

Conclusions: The men high DVS group had more homemade meals than the low DVS group. Cooking methods did not differ between genders.

Aim to Provide Meals for Events at a Nursing Home During the COVID-19 Pandemic Situation

Kyoko Bessho[1], Fukuko Kinoshita[2], Miyuki Sunaga[3]

1. Otsuma Women's University (Japan), 2. Nursing Home Green Hill (Japan), 3. Seitoku University (Japan)

Background and objectives: A nursing home in Japan provides event meals in addition to regular meals in order to increase the satisfaction of residents. Unlike the regular meal basis, when serving meals, it is best to have a buffet style for the residents and nursing home staff. It allows comfortable conversations over a wonderful buffet style meal. However, it changed the style of how people eat during the COVID-19 pandemic. We must practice social distancing and keep quiet while eating. So, we plan to conduct a good dining event. It will help create good conversations and provide enjoyable meals for everyone.

Methods: When serving meals, we observe the residents and how they eat their food. We think of ways to make meals more exciting and appealing to them. We usually serve a set meal (rice or bread, main dish, side dish and soup). Moreover, we plan to eat quietly instead of buffet style with a good ambiance for a better dining experience.

Results: We had no choice but to use disposable containers because of the COVID-19 pandemic situation. Shokado bento boxes (Japanese traditional style lunch box) are sometimes served at event meals. They are served in a disposable shokado bento containers. The residents enjoyed their meal.The fish will be cooked on the spot. It was grilled in shichirin (portable brazier) and served. We usually use fish fillets, but we used a whole one for the event meals. It is better to grill a whole fish than fillet. The fragrance of the whole fish is appetizing. Residents who find it difficult to swallow can eat the fish while being careful. We devised a way to make the food more appetizing and fragrant.

Conclusions: A silent eating style would continue for a while in the COVID-19 pandemic situation. We would devise a good ambiance for people to enjoy during their meals while having good conversation with others. The measurement of meal satisfaction of residents is necessary. For care home residents, mealtimes can be even more important.

Keyword: Nursing home, Event meals, COVID-19, Satisfaction of residents, Silent eating

PAB(T5)-44
The importance of instructions on proper hydration during cheerleading practices

Ayana Nakazuru[1], Michiko Kikukawa[1], Yuka Yamada[1], Kayo Koizumi[2], Akane Miura[2]

1. Japan Women's College of Physical Education graduate school (Japan), 2. Japan Women's College of Physical Education (Japan)

Background and objectives: In Japan, the Heat Illness Prevention Guidebook contains hydration guidelines formulated by the Japan Sports Association. The guidelines are not provided on the website of the Foundation of Japan Cheerleading Association. In contrast, hydration guidelines are provided on the websites of several other sporting associations in Japan. There have been situations where coaches of high-performance clubs have concentrated on technical guidance, but not on sufficient hydration. This study explored the relationship between hydration instructions and cheerleading performance.

Methods: In this study, 116 coaches of junior schools, junior high schools, high schools, and universities that entered the 2021 Kanto cheerleading competition were enrolled. The coaches completed a questionnaire-based survey that elicited responses concerning practice environment, length of practice, hydration guidance information and type of hydration fluid. The high-performance group included teams that qualified for the semifinals of the Japan Championships in the division1 free-acting category of the 2016–2021 Kanto cheerleading competition (HHG: junior high schools, high schools, and high-performance group (n=11); HJG: junior high-performance group(n=2)). Other teams comprised the low-performance group (LHG: junior high schools, high schools, and low-performance group (n=21); LJG: junior low-performance group (n=5)). In the analysis, the questions were cross-aggregated using competitive power for each school type, and the χ^2 test was performed.

Results: The coaches of the junior schools provided instructions on proper hydration techniques regardless of their performance group. On the other hand, HHG coaches did not usually provide proper hydration instructions, compared with LHG coaches (p=0.044). HHG coaches were significantly less likely to provide instructions concerning daily oral ingestion of NaCl (p=0.05) and carbohydrate (p=0.049). LJG coaches were significantly more likely to provide instructions to ingest carbohydrate based on the length of the exercise (p=0.008). Regardless of school type and performance, coaches did not measure the weight of the athletes before and after practice to ensure proper hydration during practice, and did not recognize the types of fluid ingested.

Conclusions: HJG and LJG coaches instructed their athletes on proper hydration techniques. LHG coaches were better than HHG coaches in delivering instructions on hydration techniques.

Associations of a balanced diet combining staple food, main dish, and side dish and with eating behavioral outcome expectations and self-efficacy in adolescent and young adult athletes.

Emi Nakazaki[1,4], Tomoko Takabatake[2,4], Takayo Inayama[3], Yasuo Katsuki[1,2]

1. Hokuriku Institute of Wellness and Sports Science (Japan), 2. Yawata Medical Center (Japan), 3. The University of Nagano (Japan), 4. Graduate School of Health and Nutrition Sciences, The University of Nagano (Japan)

Background and objectives: In Japan, a healthy dietary balance is recommended to eating balanced diet with staple food, main dish and side dish. It is also important for athletes with high physical activity levels to take such a recommended dietary behavior. This study identified balanced dietary behaviors and related predisposing factors that should be focused on as pre-assessment items when implementing nutrition education for adolescent and young adult athletes at the national competition level.

Methods: The participants were adolescents and young adults designated as candidates for the 2016-2020 National Sports Festival and targeted for nutrition education support (14-18 years: 104 males, 43 females; 19-28 years: 15 males, 19 females). A self-administered questionnaire was used to assess frequency of intake of staple foods, main dishes, and side dishes, outcome expectations (OE) and self-efficacy (SE) for eating behaviors, and other health behaviors. In the analysis, the dependent variable was defined as eating a combination of staple meal, main dish, and side dish at least twice a day (favorable level), the independent variables were OE, SE, and health behaviors, and the adjustment variables were sex and age. A series of binary logistic regression analysis were performed to calculate adjusted odds ratios (AORs) and 95% confidence intervals (CIs).

Results: One hundred and seven respondents (59.1%) met the favorable level. Taking this balanced dietary behavior was significantly associated with OE (AOR = 2.63, 95% CI: 1.05-6.59) and SE (AOR = 2.55, 95% CI: 1.30-5.02) of " eating a enough staple meal (rice)", OE (AOR = 3.55, 95% CI: 1.61-7.83) and SE (AOR = 2.47, 95% CI: 1.28-4.77) of "eating a complete meal with staple food, main dish and side dish at every meal", OE (AOR = 2.82, 95% CI: 1.46-5.46) and SE (AOR = 3.13, 95% CI: 1.58-6.19) of "eating a side dish with every meal". It also showed an association with weight measurement habits (AOR = 2.09, 95% CI: 1.09-4.00).

Conclusion: In nutrition education for the athlete during adolescence and young adulthood, goal setting that encourages staple food and side dish intake behaviors may be effective.

Keyword: adolescence and young adults, athletes, Japanese-style diet, staple food, side dishes

PAB(T5)-46
Relationship between cooking techniques and refrigerator foods among female college athletes living alone

yuka yamada[1], Ayana Nakazuru[1], Michiko Kikukawa[1], Kayo Koizumi[2]

1. Japan Women's College of Physical Education graduate school (Japan), 2. Japan Women's College of Physical Education (Japan)

Background and objectives: For each residence, correlations between total refrigerated foods and cooking techniques were analyzed. College students living alone have difficulty enriching their meals. Female college athletes living alone spend longer on sports, thus cook less. However, cooking skills can help prepare quicker low-priced, nutritionally balanced meals, thus reducing refrigerated food loss. Therefore, we clarified the relationship between refrigerated food and cooking techniques of female college athletes.

Methods: Participants were all J university students (n=294) receiving introductory nutrition. We conducted a survey using Google Forms; subsequently, 112 respondents were examined. Questions were regarding living style, exercise habits, refrigerated foods (37 kinds of vegetables, 46 kinds of seasonings, 15 kinds of foods other than seasonings and vegetables), cooking techniques, and knowledge of sustainable development goals. To clarify living-alone characteristics, the chi-square test was performed after cross-tabulation of living style and each question item. Living style results were as follows: living alone, (n=13); living with family, (n=74); and living in a dormitory, (n=25). One-way ANOVA was performed for lifestyle and refrigerator capacity analyses.

Results: The refrigerator's capacity was not significantly different for those living alone (190.4±136.6 L) and living in a dormitory but was significantly smaller among those living at home (p<0.001). Considering refrigerated foods, 23/37 of vegetables (62.2%), 24/46 of seasonings (53.2%), and 2/15 of seasonings and non-vegetables (13.3%) were present. There was no significant difference between the three groups regarding spoiled or expired food, except tofu. All people living alone answered that there were no spoiled vegetables (p=0.002). This study revealed that those with cooking skills know the relationship between food and seasonings. For those living alone, great cooking ability positively correlated with the presence of refrigerated vegetables (r=0.204 ns), seasonings (r=0.412 ns), and non-vegetables/seasonings (r=0.563, p<0.05).

Conclusions: Female college athletes living alone or in dormitories have a smaller refrigerator capacity. However, they store about half the amount of food as those living with families. Those living alone did not have spoiled vegetables, and those with high cooking skills stored numerous foods. Therefore, female college athletes could reduce food loss by improving their cooking skills.

Keyword: food loss, refrigerator, college student-athlete living alone, cooking skill

PAB(T5)-47
A study on food education for female college athletes using “Edo Tokyo traditional vegetables"

Kayo Koizumi[1], Naoko Yamada[2], Kazuo Tsujimoto[3], Norimichi Kurosawa[3]

1. Japan Women's College of Physical Education (Japan), 2. Nippon Sports Science University (Japan), 3. General incorporated association ChefooDo (Japan)

Background and objectives: At 212.1g/day, Japanese women in their 20s consume fewer vegetables than other age groups. While food education is conducted targeting all generations, there is little data regarding the vegetable intake of female college athletes. "Edo Tokyo traditional vegetables" has been a success in Tokyo's vegetable culture since the Edo period. This study examined whether there is a relationship between the experience of eating "Edo Tokyo traditional vegetables," and the vegetable eating habit.

Methods: The study participants were 44 female college athletes enrolled in March 2021. As part of their food education, the participants ate lunch containing “Edo Tokyo traditional vegetables,” attended a lecture on it, and answered various questions. A French chef devised and cooked their lunch according to a Japanese food guide: the grain dishes were 2.5 SV, vegetable dishes were 4 SV, and the fish and meat dishes were 2 SV. The study analyzed cross-aggregated questions using the relationship between likes and dislikes regarding vegetables, vegetable intake habits, participation in food education, and the χ^2 test.

Results: All those interested in food were vegetable lovers (LVG n=36), while the percentage of vegetable haters (HVG n=8) was 37.5% (p= 0.004). There was a significant difference in food education participation (p=0.013), with many LVG participants, but only two HVG participants. While all participants attempted to consume vegetables (p=0.818), the percentage of eating vegetables more than once a day was different, with LVG at 72.2% compared to HVG at 0.0% (p<0.001). There were few leftovers of the radish boiled in red wine, and stir-fried meat and burdock, with some 95% of respondents wanting to eat it again; 55.2% of the marinated vegetables became leftovers, and 37.9% of participants wanted to eat them again.

Conclusions: The study found that a taste for vegetables is associated with interest in food and participation in food education, but not with the willingness to eat vegetables. Even if they do not actively encourage vegetable intake, novel foods may encourage better food practices by eating in the usual way of cooking.

FFQ for Food consumption pattern among pre diabetic women in a rural community of north India

Puneet Misra[1], Shashi Kant[1], Priyanka Kardam[1]

1. All India Institute of Medical sciences, New Delhi (India)

Background and Objectives Non communicable diseases are on increase in India mainly attributable to improper diet and life styles. People are moving away from traditional diet towards more refined diet. This nutrition transition is largely responsible for various life styles related non communicable diseases. The study aimed at describing the food consumption patterns in a sample of pre diabetic women residing in rural area of north India. **Methods** A cross sectional study was done in the field practice area of All India Institute of Medical Sciences, New Delhi. A pre validated, pretested, 29 item, food frequency questionnaire was applied to assess the food consumption pattern of 116 participants. **Results** The mean age of the participants was 47 years with a standard deviation of 7.5 years. Whole wheat flour was consumed by all participants. Refined flour, rice and broken wheat and bread was reported to be consumed occasionally by most of the participants. Buffalo milk was reported to be consumed daily by more than 80 percent of the participants, Chicken, egg, fish and other animal products like mutton and pork etc were reported to be consumed never by most of the participants. **Conclusion** Food frequency questionnaire could be a simple way to know about preferred consumption pattern. Based on preferred or consumed food items, proper diet chart can be prepared which is best suited for the community based on their dietary habits. Based on this nutritional and health education material for the community or individual can be developed and all this material along with results of this study can be utilized to prepare these charts for rural north India to deal with non communicable diseases through right kind of dietary practices

Do people with hypertension or diabetes change their processed food consumption behaviour?

Ali Ahsan[1], Abu Abdullah Mohammad Hanif[1], Mokbul Hossain[1], Fahmida Akter[1], Abu Ahmed Shamim[1], Mehedi Hasan[1], Md Showkat Ali Khan[1], S M Mustafizur Rahman[2], Malay Kanti Mridha[1]

1. BRAC James P Grant School of Public Health, BRAC University (Bangladesh), 2. Institute of Public Health Nutrition (Bangladesh)

Background and objectives: In Bangladesh, morbidities and mortalities related to non-communicable diseases (NCD) have increased several folds during the recent decades. Dietary management of a patient with hypertension or diabetes is important for the prevention of complications and maintenance of a healthy life. In this study, we aimed to understand whether people with diabetes and hypertension change processed food consumption practices. Methods: We analyzed data from Bangladesh Food Security and Nutrition Surveillance round 2018-19. In this study, data were collected from 82 randomly selected clusters covering rural, non-slum urban, and slums areas in all eight administrative divisions of Bangladesh. We interviewed 20-59 years old women and men about their diabetes and hypertension status. Processed foods comprised savory and fried snacks, sugary snacks and sugar-sweetened beverages. The weighted prevalence of self-reported hypertension and diabetes was estimated. Two-sided t-test was done to see the statistical significance of the mean differences in the weekly frequency of consumption of processed foods. Results: A total of 9986 adults aged 20-59 years were included in this analysis. The weighted prevalence of self-reported hypertension was 16.3% (95% CI: 14.7, 18.1) and self-reported diabetes was 4.9% (95% CI: 4.0, 5.9). The mean weekly frequency of consumption of savory and fried snacks, sugary snacks and sugar-sweetened beverages among hypertensives were 2.91, 5.17 and 13.38 times, respectively. The mean weekly frequency of consumption of savory and fried snacks was lower among known hypertensives compared people who were normotensive or did not know their status. The mean weekly frequencies of consumption of savory and fried snacks, sugary snacks and sugar sweetened beverages among diabetics were 2.91, 6.28 and 13.38 times, respectively. The weekly frequency of consumption of savory and fried snacks and sugar sweetened beverages were lower in known diabetics but the weekly frequency of consumption of sweet snacks was higher. **Conclusions**: Processed food consumption practices of known diabetics and hypertensives were different from people without diabetes or hypertension but still harmful. The Ministry of Health and Family Welfare in Bangladesh should consider this while designing and implementing health programs for diabetics and hypertensives.

Evaluation of nutrient intakes, dietary practices, and interests of nutrition education among Japanese collegiate baseball players

Ryosuke Haruna[1], Tatsuo Doi[2], Shingo Otsuki[3], Shinya Yasumoto[2], Kazuma Nishiwaki[2], Hitoshi Watanabe[1], Mio Yasuda[1], Nobuko Hongu[4]

1. Osaka City University (Japan), 2. Dynamic Sports Medicine Institute (Japan), 3. Osaka Sangyo University (Japan), 4. Osaka Metropolitan University (Japan)

Background and objectives: Collegiate athletes believe that good nutrition will improve their performance. Recently, more attention has been devoted to the nutritional intake of collegiate baseball players. Some studies have addressed the need for the development and implementation of nutrition education program for these athletes. This study aimed to evaluate the nutrient intakes, dietary practices, and interests of receiving nutrition education lessons among collegiate baseball players.

Methods: Forty-seven Japanese male baseball players (age, 20.7±1.4years; height, 173.1±4.9cm; body weight, 69.6±7.5kg, BMI 23.2±1.9kg/m^2) participated voluntarily in this study. Nutrient intakes were determined by Food Frequency Questionnaire. All participants answered dietary practice questions (e.g., nutritional supplements usage, interests of particular nutrients, etc.). They were also asked to give the researchers their feedbacks about the nutrition educations lessons they have received for the 3-month. Readiness to improve dietary practice was measured using one question with five response options that corresponded with the stage of change construct of the Transtheoretical Model of Behavior change.

Results: Average daily energy, protein, fat, and carbohydrate consumptions were 3042±792kcal, 127±43g, 96±25g, 399±113g, respectively. The dietary assessment showed an adequate intake of calories, vitamins, and mineral, except for calcium (742.3±319.1mg) and dietary fiber (14.1±4.9g), for which most of the participants did not reach the recommendations. Sixty-two% of players regularly consumed nutritional supplements, such as protein powder, branched-chain amino acids. After receiving the nutrition lessons, more than 85% of players responded that they were interested in learning about sports nutrition. Younger college students (i.e., freshman, sophomore), particularly for those living away from the family home were interested in learning about food preparations, cooking, and grocery shopping. Readiness to change their dietary behavior (Contemplation and preparation stages) was observed more than 54% of players. Increase muscle strength and body size, and recovery strategies were the reasons for their food choices.

Conclusions: Collegiates baseball players had lower calcium and dietary fiber than recommended levels. The results of this study suggest that collegiate baseball players could benefits from basic nutrition education. Successful sport nutrition program requires an understanding of the needs and various life factors faced by collegiate athletes.

PAB(T5)-51
Nutritional status and protein supplement use in collegiate male lacrosse athletes

Kayana Matsumoto[1], Ryosuke Haruna[2], Nobuko Hongu[1], Katsushi Yoshita[1]

1. Osaka Metropolitan University (Japan), 2. Osaka City University (Japan)

Background and objectives: A proper diet enhances an athlete's overall health status. It has been reported that many athletes had inadequate energy intake and nutrient needs. However, dietary intakes and supplement use in Japanese collegiate male lacrosse athletes remains largely unexplored.The aim of this study was to evaluate the body composition, dietary intake, and use of protein supplements of Japanese collegiate male lacrosse athletes.

Methods: Twenty-nine male lacrosse athletes (mean ± SD; age:20.97±0.90 y; height:172.2 ± 4.5cm; body mass:66.8 ± 5.8 kg; %body fat:14.5 ± 4.1%) participated in the study. Body composition was measured through multifrequency bioelectrical impedance analysis (InBody 770). Food intakeswere analyzed through four-day food records (three practice days and one day off from practice). Athletes were asked to take pictures of the foods, beverages and supplements, reporting names of foods, brand name of all dietary supplement products and sending these to a project dietitian. Daily average values were calculated for total energy, protein, carbohydrate, and fat intakes and compared to theDietary Reference Intakes for Japanese – physical activity level III (Ministry of Health, Labour and Welfare, 2020). All participants answered a questionnaire about their use of nutritional/protein supplements and interests of learning about balanced diets.

Results: Analysis of food intakes between practice days and off days shows significant more intakes of energy and carbohydrate during practice days ($p<0.005$). However, the athletes consumed significantly less than recommended values for energy (2384±387 kcal vs. 3050 kcal) and carbohydrates (338±76g vs. 381g) ($p<0.005$). Athletes consumed significantly more protein than recommended (78±12g vs. 65g) from food items ($p<0.001$), which was not included their intake of protein supplements (approximately 20g/day). All athletes reported habitual protein supplements use (>2days/week over the past year). 76% of the collegiate male lacrosse athletes were interested in learning about balanced diets.

Conclusions: Results of the study suggest that collegiate athletes had insufficient total energy and carbohydrate intakes but consumed more protein than recommended. The athletes could benefit from basic nutrition education that promotes a

PAB(T5)-52
How do para-athletes perceive their diet and dietitians? a pilot study based on interview survey

Hisayo Yokoyama[1], Miwako Deguchi[1], Nobuko Hongu[1]

1. Osaka Metropolitan University (Japan)

Background and objectives: Nutritional support for para-athletes (PAs) lags athletes without disabilities. At present, there is very little guideline that dietitians can refer to when supporting them. In addition, various dietary problems caused by individually different types of disabilities make nutritional support for them difficult. The aim of the study was to elucidate how PAs perceive their diet and dietitians and explore clues for effective measures that would help them practice evidence-based sports nutrition.

Methods: Six active elite PAs (30 – 70 yrs., 4 males) with lower-limb disabilities who participated in the international wheelchair sports competitions (tennis, softball and table tennis, with 2 – 26 years of player history), and a female boccia trainer without physical disability were surveyed through semi-structured interviews on the ideal diet for improving competitive performance, evaluation of their typical diets, and role of the dietitian as a supporter. Responses obtained from participants were analyzed using quantitative content analysis by language analysis software (NTT Data Mathematical Systems, Tokyo, Japan).

Results: There are differences in the ideal diet based on the characteristics of the sport, but most participants believed that a nutritionally well-balanced diet with abundant vegetable was ideal for improving competitive performance. PAs who use wheelchair daily pay attention to their total calorie intake, because gaining weight is a critical issue for operating their wheelchair and transferring themselves into their wheelchair. Despite their high competition levels, none of them received routine dietary advice from dietitians. Some participants did not even feel the need to engage with dietitians.

Conclusions: Even for para-athletes at a high level of competition, the "ideal diet" they consider is not always the optimal diet for improving their competitive performance. In addition, there are various barriers to practice their optimal diet due to disability characteristics. Dietitians need to understand these barriers, their worries and conflicts and to act to help them practice sports nutrition. Thus, there remains a lot of room for providing nutritional supports for PAs. This is a truly new field of study how qualified nutritionists, medical and exercise practitioners in para-sports can support PAs by “power of nutrition”.

Qualitative research on the support required to promote physical activity among people with visual impairments

Wakako Tatsuta[1], Erika Yamanaka[2], Takayo Inayama[3]

1. Nihon University (Japan), 2. General Incorporated Association H&H (Japan), 3. The University of Nagano (Japan)

Background and objectives: People with visual impairments are at a higher risk of chronic diseases compared to those who are non-visually impaired. Hence, it is important for them to make efforts to improve their health. It has been reported that few people who are visually impaired achieve the recommended amount of physical activity (PA), a pillar of health promotion. Hence, combined efforts are required to promote PA among them. The purpose of this study is to summarize the implementation to promote PA and the support they considered necessary in terms at the level of intrapersonal, interpersonal, and community factors, and to identify these characteristics among people with visual impairments. Methods: Ten people with visual impairments in their 30s~50s living in Japan participated in focus group interviews in September 2021.The interview items were: ① how PA would be secured and ② support required to perform PA. The transcripts was transcribed verbatim and written data was delimited for each single content. For each piece of delimited information, the content was summarized in concise and appropriate codes. Categories were created based on the codes collected for similar content. Results: ① Devices for the implementation of PA were grouped into nine categories. Of these, six items corresponded to intrapersonal factors, two to interpersonal factors, and one to community factors. ② Support required for the implementation of PA was grouped into 15 categories. Of these, one item corresponded to intrapersonal factors, three to interpersonal factors, seven to community factors, and four to access to information. Conclusions: Many items from the “intrapersonal level” were mentioned for innovations towards the implementation of PA. In addition, many items from the “community levels and access to information” were mentioned for necessary support. The results suggest the importance of creating a community where individuals can share their innovations and skills and the creation and dissemination of a guide for sports facility staff. In addition, health promotion programs are required to provide the necessary information.

Keyword: Visual impairment, physical activity, intrapersonal factors, environmental factors, health promotion

PAB(T5)-54
Examination of a cooking education program for nutrition and home economics student teachers

Natsuhi Hirata[1], Junko Ishida[1]

1. Kinjo Gakuin University (Japan)

Background and objectives: Poor culinary skills are often a source of anxiety for students who aspire to become nutrition and home economics teachers. This study was thus conducted to examine the effectiveness of a program designed to improve the home cooking skills of students who are preparing to become nutrition and home economics teachers.

Methods: The participants consisted of 24 second-year teacher trainee students studying nutrition and home economics in a women's university. They participated in this program during 2021-2022, with prior consent. A flipped learning program was conducted on “Cooking sardine kabayaki” based on Japanese junior high school home economics textbooks. The practical training contents and cooking video were shown to the students one week in advance, and the cooking practice was conducted on the same day of the training. A questionnaire was administered to the participants “before” and “after” they watched a video on teaching cooking to students who aspire to be nutrition and home economics teachers. In addition to the “experience of handling sardines in the past” before the training, the participants were asked about their “level of confidence in teaching others” before and after the training. After the training, they were also following: “How many times have you watched the flipped learning video” and “What are your impressions of the video”. The analysis was conducted using SPSS 26.0 for the quantitative survey and KH coder for the qualitative survey.

Results: The average age of the respondents was 20.1±0.9years. Only two students answered “I can teach others on cooking practices” prior to the survey. After the flipped learning program, 12 more students responded that they felt confident about educating others on cooking practices ($p<0.05$). Those who responded, “cannot teach” tended to watch more videos than those who responded, “can teach”. Many participants have commented that they felt positive about the training, including that it gave them confidence in their ability to teach. This program thus provided participants with confidence in their ability to teach others.

Conclusions: This program is considered useful for participants.

Keyword: flipped learning, nutrition student teachers, home economics student teachers, cooking practice

PAB(T5)-55
Correlation between holding chopsticks correctly and consumption of fish dishes among childcare students

Chuhwa Cho[1], Kayo Koizumi[2]

1. International Pacific University (Japan), 2. Japan Women's College of Physical Education (Japan)

Background and objectives: Since ancient times, the appropriate use of chopsticks has been part of a dietary etiquette in Japan, and its knowledge is an important theme of dietary education. Okayama prefecture, connected with the Seto Inland Sea, specializes in many local fish and shellfish dishes; for this reason, students who could hold chopsticks correctly were believed to consume fish items frequently. This study aimed to investigate the correlation between the correct manner of holding chopsticks and the intake of fish dishes among childcare students.

Methods: The study included 234 first to fourth grade students enrolled in a nursery school in Okayama prefecture. A questionnaire method was employed to examine how chopsticks were held and how fish dishes were consumed. We asked the students to choose the appropriate method to hold chopsticks from the question items created using figures in the survey form. The frequency of fish consumption included the intake of fish dishes for a week. Accordingly, 10 items were evaluated on a 5-point scale to gauge what type of dietary form was common when consuming fish. Using the SPSS Statistics Version23 (manufactured by IBM), cross tabulation was performed on how to hold chopsticks and the consumption of fish items, and analyzed using the χ-square test.

Results: Approximately 60% of respondents followed the correct method of holding chopsticks. No association was found between how the participants held their chopsticks and the consumption of fish dishes.

Conclusions: Although there was no association between how to the chopsticks were held and the consumption of fish dishes, the manner in which childcare students involved in children's dietary education learn to hold chopsticks correctly influences culture. The percentage of people who consumed fish dishes such as sashimi and sushi, which can be obtained anywhere in the country, was higher than those who consumed rose sushi and mamakari, which are local dishes.

The relationship between food and nutrition education provided by nutrition teachers and students' eating habits

Miyuki Akamatsu[1], Eiko Murai[2], Mihoko Nagashima[2], Naomi Aiba[3]

1. Kagawa Board of Education (Japan), 2. Japanese Association for Dietetic Research and Education (Japan), 3. Kanagawa Institute of Technology (Japan)

Background and objectives: In Japan, the assignment of nutrition teachers to elementary and junior high schools began in 2005 against the backdrop of the Nutrition Education Basic Law. We conducted this study to understand the current status of nutrition education promotion in schools and students' dietary habits and to clarify the results of the assignment of nutrition teachers.

Methods: A self-administered questionnaire survey was conducted on the content of nutrition education implemented in elementary schools to which nutrition teachers belong and in one class of the sixth grade of elementary school, resulting in 1,373 schools with nutrition teachers. Student responses were averaged for each school and used as school data. Statistical analysis was conducted using the Mann-Whitney U test and the Kruskal-Wallis test.

Results: We classified the food-related instructions into three categories: academic subjects, mealtime instruction, and information provision. Children who received a combination of the three types of instruction were more aware of the importance of breakfast consumption and the inheritance of local cuisine than those who received only one kind of instruction (p=0.015 and p=0.006) and who received information provision (p=0.022 and p=0.018). The children's breakfast intake and efforts to pass on local cuisine were higher in the combination of three types (p=0.018 and p=0.013) than in a kind of instructions, and breakfast intake was higher than information provision alone (p=0.050). Children's perception of the importance of breakfast consumption was influenced by lunchtime instruction (p=0.009), and the inheritance of local cuisine was influenced by the school subjects and lunchtime instruction (p=0.002 and p=0.009). The children's efforts in passing on local cuisine were affected by the teaching of subjects (p=0.001).

Conclusion: It was considered adequate to combine academic subjects and mealtime instruction and information provision to increase students' breakfast intake and raise their awareness of the importance and inheritance of local cuisine in elementary school.

Survey on Current Status of Education and Academic-Industrial Partnerships at Dietitian Training Universities in Vietnam Second report: Consideration of industry-academia collaboration in the food service field

Yoshiyuki Takato[1], Haruna Ubukata[1], Chi Kim Nguyen[1], Huy Do Nguyen[2,3], Nhung Thi Hong Hoang[2], Chi Thi Quynh Vu[4], Chi Thi Quynh Nguyen, Hiromi Ishida[5]

1. SHIDAX CORPORATION (Japan), 2. National Institute of nutrition (Viet Nam), 3. Thanh Dong University (Viet Nam), 4. Dong A University (Viet Nam), 5. Kagawa Nutrition University (Japan)

Background and Objectives: This is the second report following a survey of the current state of the educational environment and academic–industrial partnerships at dietitian training universities in Vietnam. Based on the current situation of academic–industrial partnerships in the field of food service at dietitian training universities, we considered how Japan might contribute to training dietitians in Vietnam.

Methods: TThe survey was targeted to 20 universities that have, or are planning to offer, dietitian training courses in Vietnam. The content of the survey included the educational curriculum, educational status, and current situation of academic–industrial partnerships. In February 2022, a joint briefing session was held online with the National Institute of Nutrition in Vietnam and a questionnaire was sent out. The respondents were department chairs of each university and full-time faculty members.

Results: Responses were received from 18 universities (90% response rate), including 12 of the 13 existing universities and 6 of the 7 universities scheduled to open. Among the 12 existing universities, only 5 (42%) had educational programs related to the management of food service facilities, and few provided training in cooking or education on food service management or quality management. Ten universities currently have partnerships with corporations, and 7 of them are collaborating with overseas partners. Regarding expectations for academic–industrial partnerships with Japan, the most frequent responses were “human resource development of students through internships and studying abroad” and “investment in educational facilities and food service facilities” (16 universities, 89%). As many as 14 schools (78%) chose the responses “research activities” and “education on nutrition and diet”.

Conclusions: More than half of Vietnam's dietitian training universities are promoting academic–industrial partnerships, and there are high expectations for these partnerships, especially those with Japan, including financial support for human resource development and capital investment. At present, many of the universities do not offer education on the management of food service facilities; thus, it is necessary to consider providing educational programs on food service operations at facilities such as hospitals and corporate cafeterias as part of Japan's contribution to training dietitians in Vietnam.

PAB(T5)-58

Survey on the Current Status of Education and Academic–Industrial Partnerships at Dietitian Training Universities in Vietnam First Report: Current Status of Education at Dietitian Training Universities in Vietnam

Huy Do Nguyen[1,2], Nhung Thi Hong Hoang[1], Yoshiyuki Takato[3], Haruna Ubukata[3], Chi Kim Nguyen[3], Chi Thi Quynh Vu[4], Chi Thi Quynh Nguyen, Hiromi Ishida[5]

1. National Institute of nutrition (Viet Nam), 2. Thanh Dong University (Viet Nam), 3. SHIDAX CORPORATION (Japan), 4. Dong A University (Viet Nam), 5. Kagawa Nutrition University (Japan)

Background and Objectives: In Vietnam, four-year nutrition courses were approved in 2012 and the health occupation "Dietitian" was born in 2017. In 2020, the Ministry of Health issued a notification regarding nutritional management at hospitals, and the legal system has been developed so that dieticians play an active role in society. We have investigated the current state of the educational environment and academic–industrial partnerships at dietitian training universities and examined how the Japanese food service industry can contribute to training dietitians in Vietnam. This first report focuses on the current state of the educational environment at dietitian training universities in Vietnam.

Methods: The survey was targeted to 20 universities that have, or are planning to offer, dietitian training courses in Vietnam. The content of the survey included the educational curriculum, educational status, and current situation of academic–industrial partnerships. In February 2022, a joint briefing session was held online with the National Institute of Nutrition in Vietnam and the questionnaire was sent out. The respondents were the department chairs of each university and full-time faculty members.

Results: Responses were received from 18 universities (90% response rate), including 12 of the 13 existing universities and 6 of the 7 that are scheduled to open. Regarding the fields on which education is focused, "clinical nutrition" and "public health" were reported by 18 universities, "school meals" by 16 universities, and "food service management" by 13 universities. Regarding the facilities and equipment, only 10 universities had test kitchens, and only 1 university had training rooms for school meals. Regarding out-of-school training destinations, "medical facilities" were reported by 17 universities, "public health centers" by 14 universities, while both "welfare facilities" and "companies" were reported by 7 universities. There was a tendency towards few opportunities to learn about food service management and mass food preparation in practice.

Conclusions: The findings of this survey suggest that dietitian training universities in Vietnam are currently focusing on the training of dietitians who are expected to play an active role in public health and medical settings.

The consciousness of the salt intake of the women's students of the Japanese administrative dietitian training university

Tomomi Tsukaguchi[1], Ayu Sato[1], Satomi Ishii[1]

1. Rakuno Gakuen University (Japan)

Background and Objectives: The daily salt intake says that less that 5g are desirable in WHO. However, there are many daily salt intakes of Japanese. Therefore we examined the recognition of the intake salt of the student of the university (A student of the fourth grade) which trained an administrative dietitian. **Methods**: The subjects of we study was women's students at Hokkaido in Japan. The investigation method askes it for an answer, using the question vote that we made (20 questions). The surveys were conducted in April and May 2021 (immediately after entering and advancing to the next yare). The method of analysis was to divide the students into three groups of "adequate" "excessive" and "insufficient" in terms of their perception of their usual salt intake at different by the year and to compare the results among the groups. The χ^2 test was used for the analysis (p=0.05). **Results**: The total number of students analyzed was 140 (36 first year students, 38 second year students, 34 third year students and 32 fourth year students). Regarding their perception of their usual salt intake, in the first year students answered 61.1%"adequate", 38.9% "excessive" and no one "deficiency". In the second yare students answered 26.3% "adequate", 73.3% "excessive" and no one "deficiency". In the third yare students answered 17.6% "adequate", 79.4% "excessive" and 2.9% "deficiency". In the fourth year students answered 28.1% "adequate", 68.1% "excessive" and 3.1% "deficiency". More than half of the first-year students answered adequate". More than half of the students in the second year and above students answered "excessive". Significant differences (p=0.003) were found, indicating that there were differences in salt intake awareness by different by the year of student. **Conclusions**: In Japan, there are many seasoning, salt intakes from a processed food. We guessed, the first yare students the knowledge for the meal was poor. We hypothesized, but in the second year student and above answered "excessive" because they understood the criteria for salt intake and the difficulty of controlling salt intake.

The result of the survey of students on the off-campus dietician training practicums during COVID-19 pandemic period (Food Service Management)

Hiromi Ikeda Katsuragi[1]

1. Nihon University (Japan)

Background and objectives: To obtain a dietitian license, Students (Survey group of total 85 students; Male18, Female 67) went to an off-campus training from July 2021 to February 2022 during the COVID-19 pandemic period. There was food service facility (nursery centers, elementary and junior high school, facilities for elderly, company canteen) and hospitals for off-campus training. The purpose of this report is to obtain information from student's aspect and off campus facilities' supervisor aspect about student's anxiety before going to food service facility training including the feedback from student and evaluation form each facility's supervisor after training.

Methods: Before going to the off-campus training, student would conduct a web survey in July 2021. Then, after the off-campus training finished students would answer their feedback the self-assessment the handbook. The evaluation of off campus facilities' supervisor would be submitted on a paper basis. The data would collect and analyze for further use.

Results: Before the off-campus training start, the students had 5.0 ± 5.8 factors of anxiety (out of 13 factors). The 7 majors factor that students were worried about were "lack of knowledge and skills", " not to cause any inconvenience ", "What kind of training will be done", "communication ability", " challenges ", and " Is greetings and wording appropriate?". The self-evaluation after the off-campus training finished was 4.4 points ± 0.7 points (out of 5 points) for the students. The evaluation of the off-campus facility's supervisor was 4.0 ± 0.8 points. From result of the after-training survey, we could notice the significant differences between students and supervisor in aspect of placing the importance on evaluative factors. The list of evaluation factors below was higher from the supervisor's point of view than the students. It is that "Greeting / wording", "Communication, working manner and cooperative attitude", "Actively engaged in", "A sense of responsibility", "Training goal".

Conclusions: Improving knowledge and skills of students to reach the facility supervisor expectation, we will deepen the cooperation among teachers in charge of all subjects such as cooking to share the same goal. Also encouraging all faculty staff and students exchange greetings daily.

PAB(T5)-61
Tips of a skilled movement for peeling a whole apple with a kitchen knife

Kumiko Akiyama[1], Kentaro Yamanaka[1]

1. Showa Women's University (Japan)

Background and objectives: By clarifying the tips of kitchen knife manipulation, it will be possible to effectively teach to improve the kitchen knife skill. Therefore, we investigate the biomechanical features of the movement of peeling a whole apple with a kitchen knife.

Methods: We first assessed the movements of peeling a whole apple with a kitchen knife in 70 female university students. Then, we selected 3 skilled and 3 unskilled students for our main experiment. In the main experiment, we recorded kinematic data using a 3D motion capture (VICON) while the 6 students peeled a whole apple with a kitchen knife, and compared the biomechanical features of the movements of the participants.

Results: We found three differences in knife manipulation between the two groups: 1) Skilled students held the knife at about 45 degrees from the horizontal plane while unskilled students held it more horizontally. 2) Skilled students moved their right thumb in advance to lead the knife while unskilled students moved their right thumbs synchronously with the knife. 3) Skilled students held a space between their right thumb and knife while unskilled students put their right thumbs on the knife blade. In addition, skilled students and unskilled but relatively efficient students held the knife blade between their thumbs and index fingers while unskilled but relatively inefficient students held the knife with their index fingers extended on the dull edge.

Conclusions: We suggest that analysis of these biomechanical features is important for teaching the proper way to peel a whole apple with a kitchen knife.

Keyword: motor skill, kitchen knife, peeling apples

PAB(T5)-62
Assessment of upper arm muscle activity between instructor and student using surface electromyography

Kimie Nakajima[1], Takeshi Sato[2], Mizuki Nakajima[2], Miyu Kayama[3], Kenichi Egawa[1]

1. Tokyo Kasei Gakuin University (Japan), 2. Jissen Women's University, Institute for Research Initiatives (Japan), 3. Junior College of Kiryu (Japan)

Background and objectives : Specialists in nutrition are now expected to play a variety of roles in various fields. In university

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

nutrition education, there are four fields of study, such as "Clinical Nutrition," "Nutrition Education and Community Nutrition Care," "Sports Nutrition," and "Food Service," which are designed to provide basic knowledge of "human nutrition" as well as a variety of activities as a dietitian. However, there were not enough data about posture and setup while whole cooking. This study aims to assess muscle activity compare both instructor and student during various tasks in a kitchen. Methods : This study was demonstrated the different mass cooking of school lunch as a task simultaneously regular meals and allergy-friendly meals by both instructor and student. Surface EMG signals were recorded at a sampling frequency of 500 Hz using a sEMG system (Polymate A108, Japan), right and left both radial muscles and biceps brachii muscle. Results : Both participants completed the experimental procedures two different mass cooking of school lunch. There were significant differences while cooking time and integrated EMG by far the faster and the smaller in instructor.

Conclusions: This study has assessed the different of cooking skill between instructor and novice student. It was considered that to practice of cooking to get occupational skill.

Keyword: EMG, Cooking skill, professional experience

Enhancing healthy-eating concept in Hospital staff, from environmental protection to food safety education.

Chia-Tzu Lin[1], Chia-Tzu IIN[1]

1. Changhua Christian Hospital, Changhua, Taiwan (Taiwan)

Background and objectives: Diet is related to environmental protection and food safety, in order to enhance the healthy food concept of hospital staff, our study is to help staff implement low-carbon diets, reducing the use of disposable tableware, and understand food safety through meal supply and education activities, so as to achieve environmentally friendly and healthy eating.

Methods: In the meal serving segment, 70% of the 16 dishes in the staff cafeteria are vegetable dishes, and all food are seasonal; In order to encourage staff to bring their own tableware, a deduction of 3 NT dollars is used as a reward method to reduce the use of disposable tableware. In the education section, an staff cooking competition was held on The theme of healthy cooking on World Chef's Day, and food safety knowledge videos and games were conducted on World Food Safety Day to promote the healthy food concept of employees.

Results: About 300 employees participate in low-carbon catering every day, and the number of people who get a 3NT discount with self-prepared tableware has increased from 1,000 people in year 2017 to 1400 people in year 2020 per monthly. As of year 2020, the use of disposable tableware has been reduced by 64,000, equivalent to 4.4 seats Taipei 101 altitude, which is the tallest building in Taiwan. During the educational activity, 400 employees watched the food safety video, 350 employees answered correctly, and the satisfaction of the activity reached 90%.

Conclusions: Diet is closely related to environmental protection and food safety. Dietitians can build a healthy food concept for hospital staff through meal design and educational activities.

Keyword: healthy-eating concept, low-carbon diets, education, food safety, disposable tableware

PAB(T5)-64
The Salt Remaining Rate of vegetables Due to Salt-rubbing

Ayako Shimizu[1], Tomomi Asano[1]

1. Kinjo Gakuin University (Japan)

Background and objectives: Salt reduction is important for preventing various diseases; thus, awareness of our salt intake is essential for our health.

Salt is used not only for seasoning food but also for food preparation, such as removing water from food by making use of the increase in osmotic pressure.

Not all of the salt used in the preparation process is ingested, but it is not clear how much salt remains in the food that has been prepared using salt.

In this study, salt-rubbing, a typical vegetable preparation treatment, was performed to determine the residual salt in foods after preparation.

Methods: The samples were daikon radishes, carrots, and cabbage, which are often served raw.

The shredded samples were salted by adding 1% salt, the vegetables were squeezed after 20 or 120 minutes of leaving, and the salinity of the squeezed juice was measured.

Results: The amount of water released from each sample after salting and squeezing was approximately 40%, 20%, and 15% of the pre-treatment sample weight for daikon, carrot, and cabbage, respectively.

The percentage of salt remaining in each sample was approximately 45%, 60%, and 60%, respectively, with no significant difference between 20 and 120 minutes of exposure.

Conclusions: The water content squeezed out was highest in daikon, followed by carrots and cabbage.

The amount of salt eluted was expected to increase with the amount of water released.

For the same vegetables, a correlation was observed between the amount of water released and the residual salt, where the quantity of water released was correlated negatively with the residual salt.

However, a comparison between vegetable types showed that cabbage had the lowest amount of dehydration, yet its

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

residual salt level was similar to that of carrots, indicating that the amount of residual salt also depends on the type of vegetable.

No significant difference was observed between 20 minutes and 120 minutes of leaving time, indicating that leaving time is not related to the residual salt amount.

Keyword: salt, salt-rubbing, vegetables

PAB(T5)-65
A mixed-methods study to explore salt preferences, procurement, and utilization practices among local households to inform a trial of multiply-fortified salt in Punjab, India

Bidhi L Singh[1], Mona Duggal[1], Neha Singh[1], Manpreet Kaur[1], Preetika Sharma[1], Reena Das[1], Yvonne E Goh[2,3], Mari S Manger[2,3], Kenneth H Brown[2,4], Christine M McDonald[2,3]

1. Post Graduate Institute of Medical Education and Research (PGIMER), Chandigarh (India), 2. University of California, San Francisco (USA), 3. International Zinc Nutrition Consultative Group (USA), 4. University of California, Davis (USA)

Background and objectives: Context-specific information on salt preferences, procurement, and utilization is important to plan and implement salt fortification interventions effectively. The current study explored these practices among non-pregnant women of reproductive age (NPWRA) in Punjab, India, to inform the design of an upcoming trial of multiply-fortified salt (MFS) in this area.

Methods: Data were collected between December 2020 - February 2021 using semi-structured questionnaires administered to 100 NPWRA across 11 villages in the Mohali district and eight focus group discussions (FGD) (4 among NPWRA 18-40 y; 4 among women >50 y). FGDs were conducted in Punjabi and transcribed verbatim. Descriptive statistics were used to summarize the quantitative data, and FGD transcripts were coded with Dedoose software and analysed using thematic analysis.

Results: Ninety-six (96%) of the women used Tata iodized salt and rest 4% used patanjali iodized salt and crystal iodized salt for food preparation and seasoning. NPWRA described Tata iodized salt as having good quality and taste, reasonable price, white color, and free-flowing texture. Black and pink salt were also used in smaller quantities to enhance the flavor of fruits and salads immediately before consumption. Nearly half of the women reported seasoning food at the table, and among these women 74% used a different type of salt than used for coking, primarily black salt (77%). Ninety-eight (98%) women procured salt monthly from local markets and corner shops in their village or adjacent villages. Most women (62%) procured 1kg of salt every month and stored it (87%) in plastic containers. Less than one-quarter of NPWRA reported sharing salt, and FGDs revealed that women believed sharing salt with family was acceptable but not with neighbours as this brought bad luck.

Conclusion: The current study has confirmed that refined, iodized salt is widely used and will be an appropriate vehicle to evaluate in the upcoming MFS trial. Educational messaging throughout the trial will emphasize the need to use the MFS salt for all discretionary purposes including flavouring fruits and salads and discourage salt sharing with family members who live outside the index Household.

Changes in the Vitamin C Content of Vegetables Due to Salt-rubbing

Tomomi Asano[1], Ayako Shimizu[1]

1. Kinjo Gakuin University (Japan)

Background and objectives: A discrepancy between the calculated nutritional value using the standard tables of food composition and the actual measured nutritional value of cooked meal has been noted. This is because the loss or increase of nutrients during the cooking process is not considered. Although there have been reports of nutrient comparisons before and after cooking, changes in water-soluble nutrients are expected to occur even during non-heat cooking, such as cutting, soaking, and pressing. In this study, we focused on vitamin C among water-soluble vitamins and revealed the changes in the vitamin C content of vegetables before and after salt-rubbing, which is a type of non-heat cooking.

Methods: The samples were daikon radish, carrot, and cabbage, which are often served raw. The shredded samples were rubbed with 1% salt, and left to stand for 20 min, after which the water that released from the vegetables was squeezed out. The vitamin C content in the samples before and after salt-rubbing as well as in the squeezed water was determined using the hydrazine-HPLC (High Performance Liquid Chromatography) method.

Results: The weight of each sample after salt-rubbing and squeezing treatment was approximately 60%, 70%, and 80% of the pretreatment sample weight for daikon radish, carrot, and cabbage, respectively. The residual rate of vitamin C in each sample after treatment was approximately 75% for daikon radish and 90% for carrot and cabbage.

Conclusions: Water release by salt-rubbing and squeezing was the highest in daikon radish, followed by carrots and cabbage. Vitamin C, a water-soluble vitamin, was predicted to be lost following water release. However, the residual rate of vitamin C was the lowest in daikon radish, but was comparable in carrot and cabbage. The results suggested that the loss of vitamin C in vegetables due to salt-rubbing depends on the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

amount of released water as well as differences in cellular tissue structure and interaction with the contained nutrients.

Effect of dietary education on Japanese workers for 3 weeks using table top memo

Satomi Maruyama[1], Ichizo Morita[2]

1. Kinjo Gakuin University (Japan), 2. Japanese Red Cross Toyota College of Nursing (Japan)

Background and objectives: In Japan dietitians manage the nutrition and health of workers at lunch using dietary guidance media. The purpose of this study was to clarify the effectiveness of dietary education using table top memos for three weeks.

Methods: This study was a cross sectional study. We conducted 150 employees who usually ate the lunch in the employee canteen of one company in July 2017. First of all we conducted a survey of the habitual food intake of the subject over the past month using a brief type self administered diet history questionnaire and discovered that many subjects had an excessive salt intake. We created four types of table top memos for salt reduction education and placed them on the table in the employee canteen for seventeen consecutive weekdays based on the results. We taught that reducing salt like not drink udon and ramen soup in the tabletop memos. The questionnaire was conducted using a self administered questionnaire after three weeks dietary education using table top memos. The number of subjects analyzed was 137 excluding invalid answers. There were two categories depending on whether the answer to the question was yes or no.

Results: The ratio of subjects who Table top memos affected their eating habits was 62.5% and 28.1% respectively among 112 subjects who can incorporate by table top memo and 25 who cannot incorporate. There was a significant difference between these categories.

Conclusions: Three weeks of dietary education using table top memo could be an opportunity to improve the diet of workers. There are two points to improve the educational effect. One is to ensure that workers read the tabletop memos and the other is to make the content interesting and be able to incorporate the educational content into your daily life the workers.

Nutritional evaluation for High protein CHANKO and Traditional CHANKO

Miyu Kayama[1], Kimie Nakajima[1], Mizuki Nakajima[3], Takeshi Sato[3], Yousuke Takeishi[2]

1. Junior College of Kiryu (Japan), 2. Kyushu Institute of Information Sciences (Japan), 3. Jissen Women's University (Japan)

Background and objectives: The sumo is traditional and popular culture in Japan. It was the classic sport that occurred from human competition in strength and scuffle. Due to the hitting the whole body and contact to wrestle with competition partner, the body weight has bigger is an advantage. It was served during sumo tournaments is made exclusively with chicken, the idea being that a wrestler should always be on two legs like a chicken, not all fours. However, there was not enough data to investigate nutrition evaluation of Chanko. Therefore, the purpose of this study nutritional evaluation of CHANKO which contains a lot of protein that was the source of muscle, and NORMAL CHANKO which was previously cooked by athletes.

Methods:It was selected Kyushu Institute of Information Science as a famous college sports club in Sumo. CHANKO by college club sports cooking were polytheism divisions, washing vegetables, cutting vegetables, seasoning of the chicken meat dumpling, work out mince as dumpling, and to put food into a big-hot caldron. High-protein CHANKO contains soy milk, Koya tofu, sesame seeds, and pork. It was performed nutritional evaluation by commercial software by Kenpakusha, Japan.

Results:There were 26 items as food into the caldron, minced chicken meat, rice wine, egg, soy sauce, Chinese cabbage, frying tofu, sprout, hypsizigus mamoreus, enoki mushroom and seasoning. It was cooking the standard quantity as a stew before 100 for 20 Sumo players. High-protein CHANKO of PFC is 19:24:57, Traditional CHANKO of PFC is 16:31:53.

Conclusions:CHANKO was a healthy diet because of rich volume of vegetables, low carbohydrate. Due to the calorie intake, there were a lot of using sesame oil for mice addition as a connection and improved flavor. High protein CHANKO was suitable for athletes. It was considered that in case of weight-limited competition, CHANKO has possibility low calorie diet food both a small amount of oil and chicken breast. The reason for gaining weight was eaten a lot of white rice. It was showed well-balanced meals for sports nutrition to adequate personal conditions.

Traditional food intake affecting dietary diversity of a deep rural community in KwaZulu-Natal, South Africa

Jandri Barnard[1], Susanna Kassier[1]

1. University of KwaZulu-Natal (South Africa)

Background and Objectives: The Zulu people are the largest ethnic group (77.8%) in South Africa with an estimated 10 – 12 million people living predominantly in the province of KwaZulu-Natal. Traditional heritage foods that are consumed by Zulus, but also other ethnic groups, includes: ujeqe (steamed bread), samp and beans, phutu porridge (classified within the starch food group), amasi (fermented cow's milk), amadumbe (root crop similar to sweet potato) and imifino (wild edible greens including morogo or spinach leaves).

This study aimed to determine by self-reported food intake questionnaires the dietary intake patterns and diversity among adults residing in a deep rural community in KwaZulu-Natal, South Africa.

Methods: Participants were conveniently sampled with door-to-door visits within the Umzinyathi District – one of the most underdeveloped rural areas of KwaZulu-Natal (KZN), South Africa, consisting predominantly of Zulu people. Trained fieldworkers administered 24 hour recall to determine dietary diversity and dietary patterns (per consumption of 12 food groups), as well as anthropometric measurements.

Results: The black African study sample (N = 150) were predominantly female (83.3%). Primary food group consumption indicated dietary pattern intake of mainly cereals (97.3%), sweets (94.6%), miscellaneous items (93.3%) and oils and fats (81.3%) predominantly. Although 70% of participants reported daily vegetable consumption, the dietary pattern was limited to tomatoes and onions. This was followed by an intake of flesh and organ meats (40%) and fruit (36.6%). Dietary patterns indicated that nearly 56.6% consumed 4 – 6 different food groups, while 14.6% consumed 10 – 12 food groups. In this rural area traditional food consumption included jeqe (steamed bread), samp (dried corn kernels that have been stamped and chopped), organ meats and indigenous vegetables like amadumbe tubers and amaranth (wild spinach).

Conclusion: According to the self reported food intake questionnaire the dietary pattern intake of this rural community indicates a lack of dietary diversity from limited food intake and availability within the area.

It is suggested that regular food education to be done at nearby clinics to educate patients on changes to their dietary pattern to include more diverse, healthy food groups and starting a vegetable garden.

The characteristic of Bhutan's dairy products in use cow and yak milk and rice in the meal

Satomi Ishii[1]

1. Rakuno Gakuen University (Japan)

Background and objectives Such food in the European region is said to be “wheat and meat ”. Mean while, Food in the Asian region is said “rice and fish” as its centerpiece. As for Bhutan, Located in the buffer zone in the East and Weat Eurasian. Rice and milk is the center of food. Bhutan's dairy products have been made from cow and yak milk. keep a cow in the low place, Yak is kept in the highlands above 3,000 m sea level. **Methods** In 2015 and 2018, Investigated and characteristic of the traditional cheese to make in Bhutan, and rice in the meal. Chemical composition and general mineral analysis of the cheese. **Results** A non-ripe type cow's milk made three kind of cheese called “datui”, “tyugo”, “thippa”. Datui and red pepper is large amount of rice are eaten every day . The amount of meat to eat is small, Cheese is important protein source. And yak in the area of high altitudes. The whole yak milk is fermented at first, then the milk fat called “gee” is removed, and finally the skimed milk with a reduced amount of lactose is processed. “Gee” is important energy taken, and add in tea. Consequently, such dairy products possible to be used even by lactose intolerance people and this technique is allow effective use of the milk. Bhutan's milk processing technique is said to have Tibetan origin. Dairy products of Bhutan and geographically distant Mongolia are different, but they have the same properties and similar amounts of energy. Yak skimed milk fermented cheese named “syorusei”, in casein squeeze up young aged in yak leather bag and after smoke dried from 3 month. The “syorusei” is not add salt but not corrupt .The four types of cheeses highest calorie content measured 403 kcal / 100 g is “syorusei”.In Bhutan, the homemade cheese and rice play important role in nutrition. **Conclusions** The increase in salt intake while enabling the eating of rice in large quantities. Bhutan's food centerpiece of “rice and milk”.

Acceptance of insects as food and its influencing factors in Malaysia

See Meng Lim[1], Chai Nei Thien[1], Bee Koon Poh[1], Abdoul Karim Toure[2]
1. Universiti Kebangsaan Malaysia (Malaysia), 2. Universiti Sains Islam Malaysia (Malaysia)

Background and objectives: Entomophagy (eating insects) is a traditional practice in many countries since prehistoric times. The concept of utilising insects as human food has gained massive attention recently due to their high nutritional values with low environmental impacts. However, the acceptance of eating insects as food in Malaysia is still unclear. Therefore, this study aimed to determine the acceptance of insects as food and its influencing factors among adults in Malaysia.

Methods: A cross-sectional online survey was conducted among 292 Malaysians aged 18 years and above from Klang Valley and Kuching. Information on insect-eating experience, general attitudes towards eating insects as food, and possible reasons for rejecting insects as food, were self-reported by the respondents. The Chi-square test of independence was used to compare the two locations. The Friedman test followed by a Wilcoxon signed-rank posthoc test was used to determine the main factors influencing the acceptance of insects as food.

Results: A total of 104 respondents (35.6%) reported that they had consumed insects previously, with sago worm, cricket and grasshopper being the top three highly consumed insects. Although one-third (30.1%) of the respondents reported that they accepted insects as food, only 18.2% of the respondents were willing to eat insects as food in their daily life. However, there was no significant difference between adults from Kuching and Klang Valley in terms of the acceptance and readiness towards insects as food. Insect texture, food safety issues and feelings of disgust were the main identified factors influencing the non-acceptance of insects as food.

Conclusions: The acceptance of insects as food among Malaysians are generally still low, with the main barriers being sensory attributes, food safety and aversion towards insects as food. Future studies should include interventions that consider these factors to better encourage more Malaysians to accept insects as food.

Analysis of trends in food and nutrition intake and eating habits of younger generation in modern Japan using quantification of the tendency toward the basic ”Washoku" pattern and "Japanese Dietary Pattern"

Sakura Kushiyama[1,2], Minako Saito[2], Misaki Fuchigami[2], Eriko Yokoyama[2], Noriko Homma[1], Akifumi Kushiyama[3], Michiko Minami[2]

1. National College of Nursing (Japan), 2. Tokyo Gakugei University (Japan), 3. Meiji Pharmaceutical University (Japan)

Background and objectives: With the modernization of food, dietary trends have changed drastically. Dietary trends in modern Japan have been analyzed through the National Health and Nutrition Survey by Ministry of Health, Labour and Welfare. Since this is a survey on all generations and requires time and effort to cooperate with the survey, it is possible that particularly young single-person households with mostly high school attendance or gainful employment rates were not included in the survey. Based on these facts, the following analysis was conducted to elucidate the overall dietary habits of the younger generation.

Methods: In this study, we made two types of analysis on the dietary contents of university students. As a duplicated diet method, we asked university students (n=26) to send us photographs of their meals for one week, based on which we cooked replicated meals. According to the replication, we analyzed the amount of food and nutrients consumed by the younger generation. In addition, as a 24-hour dietary recall method, we asked university students (n=1,324) recording the contents of their one-day meals. The students also responded to a questionnaire regarding their living environment and lifestyle.

Results: We have developed our own quantification to the tendency toward the basic *Washoku* pattern and “Japanese dietary pattern” regarding each of the dietary contents of university students. Both the duplicated diet method and the 24-hour dietary recall method showed that even they tended to have a more nutritionally balanced diet when they take the above two patterns of dietary contents. We were able to identify trends toward over- and under-intake of some nutrients in the diets of younger generation in contemporary Japan.

Conclusions: Although the dietary habits of the younger generation have been reported insufficient vegetable intake and calcium intake, and excessive fat intake in the analysis of the NHNS, furthermore, the actual dietary problems among the younger generation would be more serious. It is also suggested that although the younger generation has received food and nutrition education during school education, they are not yet able to put their knowledge of food and nutrients into actual practice in their diets.

Behavioral study of bakery users in special need

Yanjin Banzragchsuren Mogoi Nuden[1]

1. Endomed (Mongolia)

Health and food sectors in Mongolia are in the development stage comparatively with the world, diabetes is increasing dramatically as estimated by the survey ofInternational Diabetic Association. For instance the registered diabetic patients are increased from 97300 in 2017 to 129000 in 2022. Exercises and proper nutrition are crucial for diabetic patients as well, then these people needs to take attention in food. In Mongolia, there is a lack of bakery cook for people in special need, people do not know where they buy what kind of cakes and no information and knowledge in this regard. So information and knowledge is needed for those people who are in special needs.

In my research 30.7 percent of the participants are having with diabetes for 1-3 years after the diagnosis and 27.7 percent are having for 3-5 years respectfully.

It shows that for the last few years, diabetic illnesses are increased. Totally 279 survey participants out of 368 or 75.8 percent answered that they are in trouble when use products with sugar. But 176 participants out of 368 or 47.8 percent do not

substitude sugar when they are in trouble using sugar. In total 37.2 percent of participants seek sugar free cakes and cookies, 25.5 percent seek sometimes and 37.2 percent do not seek it. This shows that sugar free cakes and cookies are not readily available. It is evident by the answer that such products are seldom found by 54.9 percent of participants and not available by 45.1 percent of participants. Then no participant answered that it is available.Half of the participants or 52.2 percent do not have an advice in use of cakes and cookies from specialists and nutritionists and take carelessly for thier health. The survey target popluation is people in special need and the survey findings would be used to improve thier quality of life and maintain treatment results.

Effects of different drinks in divided diet on sensor glucose values after evening meal

Fumina Matsuzawa[1]*, Kaaya Wakabayashi*[1]*, Masayo Kuriyama*[1]*, Rumiko Sugimura*[1]

1. Rakuno Gakuen University (Japan)

Purpose: This study performed flash glucose monitoring (FGM) of the interstitial fluid after drinks were drunk as a divided meal to observe the sensor glucose value (SG value) and its area under the curve (AUC). It then compared the results of investigating effective methods of eating to suppress postprandial blood glucose elevation.

Methods: The subjects were 12 healthy women in their twenties and the study was performed according to the blood glucose level measurement protocol of the Japanese Association for the Study of Glycemic Index. The test meals were 350ml of Fanta (Coca-Cola Co., Ltd.) for group A for which sugar in the principal component, 200ml of milk (Megmilk Snow Brand Co., Ltd.) for group B for which protein- and lipids are the principal components, and 330ml of green smoothie (Kagome Co., Ltd.) for group C for which dietary fiber is the principal component. A crossover study was conducted in which subjects consumed a divided meal at 06:00 pm after three hours of fasting and a dinner at 09:00 pm. The measurements were taken with the subjects wearing the Free Style Libre (Abbott Japan LLC) with the values read and recorded. The AUC was then obtained using those measured values.

Results: Preprandial and maximim SG values were 78.8 mg/dl and 113.8 mg/dl respectively in the control group (no divided meal). The corresponding values for A, B and C were 77.6 and 110.5, 85.8 and 119.0, and 89.8 and 118.1 respectively. The maximum rate of change based on the time of dinner intake was 44.4% (45 min from the start of the meal) in the control group, followed by 42.5 (90) in A, 38.6 (60) in B, and 31.6 (90) in C. The AUC of the rate of change in SG values was lowest in C followed by the B, with A showing the highest value.

Discussion: Group A, which included the highest sugar content, had a high rate of change of SG values after the evening meal, which may have been influenced by the rapid rises and falls in SG values during divided food intake.

Questionnaire survey results on fish, calcium and protein intake

Naomi Katayama[1]

1. Nagoya Women's University (Japan)

Background and objectives: Since the calcium intake has not reached the target amount in the Japanese diet. It is also recommended to maintain protein intake from the viewpoint of preventing sarcopenia and frail in the elderly. Therefore, as a first step to understand the actual situation, this study conducted a questionnaire survey on the intake of fish rich in EPA and DHA and the intake of Ca and protein. **Method**: A questionnaire survey was conducted on 61 participants regarding the intake of fish, Ca and protein. The questionnaire method is self-administered, and I asked the 15 items. **Results**: The mean ± standard deviation of 61 participants (18 to 28 years old) was 21.1 ± 2.0 years of age, height of 158.4 ± 5.9 cm, and weight of 52.9 ± 7.1 kg. According to the results of the questionnaire survey, the average desired price for purchasing fish was 266 ± 162 Japanese yen (2.2±1.35 USD), the frequency of eating fish was most often 1 to 2 times a week at 41.0%, and the frequency of eating meat was most often 3 to 4 times a week at 67.2%. Eggs were most often eaten 3 to 4 times a week at 47.5%, and soy products were most often eaten 1 to 2 times a week at 34.4%. 83.6% answered yes to whether they like fish, 75.4% answered yes to know fish that can eat bones. And 82.0% answered yes to want to eat fish that can eat bones. 68.9% answered yes to whether they felt lack of calcium, and 95.1% answered yes to whether they wanted to take calcium positively. 32.8% of the respondents answered yes to whether they felt protein deficiency, 90.2% answered yes to whether they wanted to take protein positively. **Discussion**: Participants this time ate meat and eggs more often than fish and bean products in their daily lives. We believe that it is necessary to increase the consumption of fish in order to extend healthy life expectancy, so we would like to continue to recommend the consumption of fish.

PAB(T5)-76
Association between Food Intake Frequency and Food Procurement Methods at the Household Level, in Xaybouathong, Khammouane, Lao PDR

Yu Sato[1,2,4], Hisao Ando[1,2], Takaaki Ishizuka[1,2], Shinjiro Saeki[4], Miki Miyoshi[3], Eriko Kondo[5], Kenji Shinkai[5]

1. Non-Profit Organization ISAPH (Japan), 2. St. Mary's Hospital (Japan), 3. Graduate School of Health Sciences, Aomori University of Health and Welfare (Japan), 4. Non-Profit Organization Japan Edible Insect Science Lab (Japan), 5. The Ajinomoto Foundation (Japan)

Objective: Lao PDR has the high prevalence of stunting among children under five years of age among ASEAN countries, and ISAPH found in a previous study that one of the direct causes of this is the strongly biased dietary diversity of children. However, there is insufficient information on the background of the lack of diversity. Therefore, to analyze the bias in food intake from the perspective of access to food at the household level, we investigated the association between the way food is procured methods and food intake frequency.

Methods: In July 2017, all households with children under five years old were interviewed about the frequency of food intake and their procurement methods in three villages in Xaybouathong District, Khammouane Province, Central Laos. A total of 25 foods were selected through the discussions with health service professionals at the Xaybouthong hospital. This list was also constructed in terms of dietary diversity. Then, the respondents were asked about intake frequency. As for the procurement types, the respondents were instructed to select one option from four: 1. monetary purchase, 2. own production (cultivation/farming), 3. hunting/gathering, and 4. other.

Results: Valid responses were obtained from 209 of the 226 eligible households. Ninety percent of the households hunted and gathered bamboo shoots, frogs, small fish, crabs, and grasshoppers, while instant noodles, milk, soy milk, soybeans, and eggs were purchased with money. Onions, chickens, and ducks were procured through production by more than 70% of households. Procurement methods for the other 12 foods were diverse among the respondents. The top five foods that were eaten more than three times a week were bamboo shoots, onions, crab, eggs, and instant noodles, while the foods that were rarely eaten were soybeans, milk, duck, beef, and mango.

Conclusion: Although some foods have limited procurement methods, it is clear that people procure foods from a combination of these sources in the target areas. Some foods (e.g., soybeans and duck) were available through production or hunting and gathering but were consumed less, while some foods (e.g., instant noodles and eggs) were consumed frequently even if they had to be purchased with money. The residents may be SELECTING the foods they want to eat based on preferences, customs, or some other factors. Therefore, we must pay attention to not only food access but also other factors that influence the household's food choices that might cause low dietary diversity in children.

Keyword: Food Choice, Food Intake Frequency, Food Procurement Methods, Lao PDR, Rural Area

Current Dietary Practices in Rural Zambia A Day in the Dry Season in Kachenjera and Mwenbeshi, Lusaka Province

Mayumi Nakahira[1], Mari Toyooka[2], Yuriko Haito[3], Izumi Takahashi[4], Naoko Komenami[5]

1. Shiga Junior College (Japan), 2. Shiga Junior College (Japan), 3. Shiga Junior College (Japan), 4. Former Japan Overseas Cooperation Volunteers for JICA (Japan), 5. Kyoto Women's University (Japan)

Background and objectives: In Zambia, the undernourished population was 47.4% of the total population in 2014 and remains high. In rural areas, more than 65% of the working population is in agriculture and tends to be chronically undernourished. The aim of this study was to understand the actual dietary situation in rural areas of Chilanga in Lusaka Province, and to link this to support for healthy eating and improved nutrition among small farmers from the perspective of sustainability.

Methods: The study population consisted of 50 farmers living in two villages in Lusaka Province: Kachenjera and Mwembeshi. The study period was September 9-18, 2018, and involved physical measurements, daily dietary surveys using a combination of food records and photography, and interviews to investigate their living conditions.

Results: Mean BMI was 22.6 for 12 male participants and 26.7 for 38 female participants; the percentage of underweight individuals with a BMI under 18.5 was 2% and the percentage of obese individuals with a BMI over 25 was 48%. The staple food was nshima, which is made from corn flour, which was eaten for 5.7% of breakfasts, 89.4% of lunches, and 97.9% of dinners. The percentage of those missing meals was 25.5%. The percentage of respondents who ate no main dish at all in a day was 19.1%, and the percentage of respondents who ate no side dish was 25.5%. Munkoyo, a homemade fermented corn beverage, was consumed by 27.7% of respondents, for breakfast and by 36% for snacks. Because of its poor palatability, cold nshima tended to be undesirable and was discarded or fed to livestock.

Conclusions: The diet of the people in this region was biased toward the staple food and lacking in protein, vitamins, and minerals. We believe that reverting from corn-derived nshima to minor grains, which have been eaten for centuries, will improve the nutritional balance. Because many meals did not have all of a staple, main dish, and side dishes, and food is in short supply during the off-season in this region, nutrition education, food storage, and the use of leftover food should be studied in the field.

Keyword: Zambia, Healthy eating, Nutrition education, Food storage, Dietary bias

PAB(T5)-78
A Literature Review of the Nutrition Status and Dietary Practices of Ethnic Minority Groups (Indigenous People) in the Past Ten Years in China

Zeyuan Wang[1]

1. University of Toronto (Canada)

Background and Objectives: Indigenous food systems can affect multiple aspects of Indigenous people's health. In China, the government has declared that there are no Indigenous peoples in China and instead uses the term ethnic minority groups. No existing studies have broadly investigated or summarized the nutritional status and dietary practices of all 55 ethnic minority groups living in China. These 55 groups represent 8.89% of the total population in China.

Methods: To understand this critical issue, a systematic review was conducted. The selection criteria were that research publications should be about nutritional status or dietary practices among ethnic minority groups in China, specify the name of the ethnic minority group, and be published within the past ten years. For this literature review, 111 publications were selected. Linear regressions were applied to explore what factors can affect the total number of publications for an ethnic minority group.

Results: The literature review revealed five crucial findings. First, dietary intake data that represents the general people of an ethnic group is only available for 15 ethnic minority groups; there is data for only seven ethnic minority groups on both nutritional status (anthropometric and nutrients intake/deficiency) and dietary practices (dietary intake and dietary habits). Second, ethnic minority groups in China are suffering from double-burden malnutrition and consuming unhealthy diets. Their undernutrition rate has been decreasing while the overnutrition rate has been increasing in the past years. Third, among all selected publications, the most prevalent study populations are primary and middle school students. Fourth, ten ethnic minority groups with a total population of 845,420 are lacking data on both nutritional status and dietary practices. Fifth, generally, there were more publications about an ethnic minority group with a larger population or the group only inhabit in a specific region.

Conclusions: More national-level programs and timely surveillance is needed to monitor the nutritional status and dietary practices of ethnic minority groups in China. More studies involving maternal nutrition, targeting underrepresented ethnic minority groups and age groups, and exploring traditional food systems in China are also essential to better understand and address this issue.

Where do Inhabitants of the parish Kanyanya in Kampala, Uganda shop?

Andrea Fongar[1], Youri Dijkxhoorn[2], Nalweyiso Martha Dorcas[1], Beatrice Ekesa[1], Vincent Linderhof[2]

1. Bioversity International (Uganda), 2. Wageningen Economic Research, Wageningen University and Research (Netherlands)

Background and Objectives: As Africa is urbanizing, the urban population in Uganda increased from 7.4 million in 2014 to 9.4 million in 2017. Thus, the dietary aspiration of the African population is changing, and urban food systems have to evolve rapidly to address the new demand. This requires a deep understanding of the current food system. Where do people shop for their basic food items and does this change over time when they are informed about healthier food choices? We contribute to the literature by identifying the different used food retail sources of inhabitants of a low-income area in Africa and how these change over time.

Methods: Kanyana parish (Kawempe division, Kampala, Uganda) was selected, which has similar demographic characteristics to Kampala city. Respondents were interviewed twice, first in March-April (mid-COVID 19 look down) and in December 2021 (post COVID-19 look down). A seven-day households food consumption recall was administered, capturing food sources for each named food item. Additionally, three Focus Group Discussions (FGDs) with parish representatives (disaggregated into women, men and youth) were conducted to gather information around the used food sources in 2020 (pre-COVID-19).

Results: In total, 376 households were interviewed twice, while 85 inhabitants participated in the FGDs. Preliminary results indicate that six different food retail stores are used (markets, food vendors, kiosks, butchers, supermarkets, retail shops). In early 2021, 50% of households reported to source food from retail shops and 29% from the market. The market was used by slightly more households in December. While in 2020, food stalls (fixed stalls in residential areas) were reported to be the main food outlet used by the community to purchase their food items.

Conclusion: Traditional retail outlets are still the major food supplier in a low-income parish, although the magnitude and drivers like the availability of healthy food products are not yet clear. The next steps are to identify which food items are sourced at the different retail outlets and at the different time points, as well as to analyse usage patterns of the three groups of intervention (control group, flyer, flyer and text messages).

The impact of sensitization and capacity building on the utilization of indigenous foods in household nutrition in the upper east region, Ghana.

Rosemary Anderson Akolaa[1], Louis Kusi Frimpong[1], Michael k. Appiah[1], Andrews Adugudaa Akolaa[2], Valentine Adolsum Adolsum[3], Philip Teg-Nefaah Tabong[4]

1. University of Environment and Sustainable Development (Ghana), 2. Faculty of Management Studies, University of Professional Studies, Accra, Ghana (Ghana), 3. Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ), Ghana. (Ghana), 4. Department of Social and Behavioural Sciences, School of Public Health, University of Ghana, Legon. (Ghana)

Background and objective: Malnutrition is one of the debilitating health conditions that affect the fast-growing population in Africa. Global trends have revealed a persistent increase in malnutrition, with 121 countries being plagued by either one type or class of malnutrition. Statistics reveal that approximately 32% of global disease burdens have a direct relationship with malnutrition. In Ghana, numerous interventions have been implemented to improve the malnutrition situation. Though there have been observed improvements, malnutrition persists. Food insecurity, improper dieting, culture, and ignorance of the importance of indigenous food resources to sustainable nutrition among others primarily account for persistent malnutrition, especially in northern Ghana. Studies reveal that indigenous foods have the potential to contribute to addressing malnutrition in Africa. However, poor perceptions about indigenous foods limit their utilization. The absence of sensitization and capacity-building on the utilization of nutritious indigenous foods may increase the risk of malnutrition amongst household members. **Methods**: This study was conducted in three communities in the Upper East Region of Ghana, where under-nutrition is on the ascendancy. We explored the impact of sensitization and capacity-building of women on the usefulness of indigenous foods to combating malnutrition. The study was executed in two phases. The first phase involved sensitization and capacity-building events. The second phase involved an analysis of the narratives of twenty participants, using Interpretative Phenomenological Analysis to assess the impact. **Results**: The narratives from participants revealed an improvement in the health of their household members and were attributed to the insight and knowledge they gained during the sensitization and capacity-building events. Participants indicated that they now consume more indigenous foods than before. Participants' narratives revealed other benefits such as economic gains, positive psychological impact, and behavioral change. **Conclusion**: The sensitization and training programme organized was impactful, and the gains are sustainable. The breadth of the impact indicated that the programme touched on various dimensions of the wellbeing of participants, which is an indication that sensitization and capacity-building is one of the ways to encourage indigenous foods consumption, which is a sustainable way of combating malnutrition. Efforts should be made to maintain and improve these gains.

Food security awareness and attitude of food-supervisors in Albania

Shkurti Enkelejda[1], Shtiza Diamant[1]

1. University of Medicine (Albania)

Background Food is handled by numerous persons, thus rising the possibilities of food pollution because of inappropriate management. Intentional or accidental pollution of food through large scale fabrication might jeopardize the health of customers, and have very costly outcomes on a country. The aim of this study was to evaluate the food safety knowledge and attitudes among food- supervisors in Albania.

Methods The study was performed by means of a cross-sectional survey of 25 institutes using a questionnaire to 326 food-supervisors. The survey was arranged into five distinguishing parts to gather information on demographic features, workers' job contentment, knowledge on food security and food hygiene practices.

Results: The most of the food-supervisors were among 45-55 years (32 %). Female participants were (65%). In our survey, the food-supervisors were well-informed about sanitary practices, housework and sanitation processes. Nearly all of the food-supervisors were conscious of the overall sanitary practices in the work environment, such as hand wash (95 %), using gloves (70%), good cleaning of the devices (83%) and detergent usage (67%). About illness conduction, 76.2% of the food- supervisors did not recognize that Salmonella is a food borne pathogens and 66 % did not identify that hepatitis A is a food allowed pathogen. Logistic regression analysis indicated statistical significance ($p < 0.05$), for models in which the variable was the level of education.

Conclusions: Generally, the food-supervisors have satisfactory understanding in food security but this does not decode into stern sanitized practices through dealing out and controlling food products.

PAB(T5)-82
profiling of commercially produced complementary foods in three Southeast Asian and four West African contexts

Alissa Pries[1], Eleonora Bassetti[1], Asha Khosravi[1], Susannah H. Mayhew[2], Nadine Nasser[3], Anzelle Mulder[4], Jane Badham[4], Lara Sweet[4], Rachel Crossley[3], Elizabeth Zehner[1]

1. Helen Keller International (USA), 2. London School of Hygiene and Tropical Medicine (UK), 3. Access to Nutrition Initiative (UK), 4. JB Consultancy (South Africa)

Background and objectives: Commercially produced complementary foods (CPCFs) for infants and young children vary widely in quality, with some containing high levels of added salt or sugar. In 2019, the WHO Regional Office for Europe published a nutrient profiling model for CPCFs (WHO Europe CPCF NPM) for Member States to use to restrict inappropriate promotion of CPCF products in their countries. The WHO Europe CPCF NPM is one of the first NPMs developed specifically for CPCF products and its application to markets in other regions is a first step in enabling the validation and use of nutrient profiling for CPCFs globally. This study piloted the WHO Europe CPCF NPM in three South-East Asian and four West African contexts to assess the nutritional suitability of CPCFs in regions where markets for these products are rapidly expanding.

Methods: CPCF products were purchased in Cambodia (n=68), the Philippines (n=211), and Indonesia (n=211). Secondary datasets of CPCF label information were purchased for Burkina Faso (n=20), Cameroon (n=52), Ghana (n=127) and Nigeria (n=109). Using product label information, nutrient composition and content of CPCF were assessed against the WHO Europe CPCF NPM.

Results: The majority of CPCFs sold in both Southeast Asia and West Africa performed poorly in the WHO Europe CPCF NPM. Only 1.9% of products in Cameroon, 4.4% in Cambodia, 10.0% in Indonesia, 10.0% in Burkina Faso, 15.8% in Ghana, 20.2% in Nigeria, and 37.0% in the Philippines complied with WHO Europe NPM nutrient composition requirements. The presence of added sugar and sweeteners were particularly problematic. Fifteen percent of CPCF in Burkina Faso, 16.2% in Cambodia, 21.1% in Nigeria, 27.0% in Indonesia, 30.8% in Cameroon, 37.0% in Ghana, and 58.8% in the Philippines contained total sugar content levels that would require a 'high sugar' warning.

Conclusions: Most of the analyzed CPCF were not nutritionally suitable to be promoted for older infants and young children based on their nutrient profiles, with many containing high levels of sugar. It is crucial to introduce new policies, regulations, and product standards to limit the promotion of inappropriate CPCF in the South-East Asia and West Africa regions.

Keyword: nutrient profiling, complementary feeding, infants and young children, West Africa, Southeast Asia

PAB(T5)-83
Problems with labelling Foods with Function Claims

Kuniko Takahashi[1]

1. Gunma University (Japan)

Background Foods for Specified Health Uses (FOSHU) and Foods with Function Claims (FFC) are Foods with Health Claims that can be labeled with health functions. FOSHU began in 1991 and allows for the labeling of health functions that have been approved by the national government through individual review ("approved labeling"). The FFC was begun in 2015 as a simplified version of FOSHU, which allows food business operators to label health functions on their own responsibility. The health functions to be displayed are "Notified Labeling" and have not been approved by public authorities. Since FFC is easier to label than FOSHU, the number of FFC notifications has increased dramatically, while the number of applications for FOSHU has sharply declined. In addition, there are many health functions in the FFC labeling that are not permitted by FOSHU. I have investigated the problems with FFCs, which have been present since the inception in 2015, and have compared them with FOSHU based on public information on the website of the Consumer Affairs Agency.

Methods For FOSHU, I referred to the "List of permitted items of food for specified health use" (updated on December 22, 2021), and for FFC, we referred to the "Notification search site for food with functional claims" (updated on February 22, 2022).

ResultsThe number of permitted FOSHUs was 1,832 over 30 years, and the number of FFCs with notification acceptance was 5,080 over 7 years. The number of permitted FOSHU was 104, 93, 30, 39, 23, 8, and 16, and the number of FFC notifications received was 310, 620, 452, 690, 882, 1,067, and 1,059 from FY 2015 to FY 2021 (FY 2021 was mid-year). The health functions that can be labeled by the FFC are basically the expressions approved by FOSHU. However, there are some labels that do not fall under this category, such as "reduction of fatigue," "improvement of cognitive function and memory," and "reduction of stress“, as well as products that refer to "uric acid levels" and "liver function".

Conclusion FFC labeling may be misleading to consumers.

PAB(T5)-84
Front-of-pack warnings for commercial complementary foods available online in Chile, Brazil, Mexico, United Arab Emirates and the United Kingdom

Alissa Madeline Pries[1]*, Asha Khosravi*[1]*, Eleonora Bassetti*[1]

1. Helen Keller International (USA)

Background and objectives: Commercially produced complementary foods (CPCFs) can provide energy and nutrients for infants and young children during a critical period of development. However, some CPCFs contain inappropriate levels of concerning nutrients, such as sugar and sodium. Front-of-pack nutrition labelling (FOPNL) provides a mechanism for communicating the nutritional quality of food and beverage products to consumers. It is critical that the nutritional quality of these products be communicated clearly to caregivers to ensure informed decision-making for child feeding and to protect young children's diets. This study evaluated CPCFs against national FOPNL regulations.

Methods: Secondary datasets of CPCF label information for products sold online were purchased from Euromonitor International, including instant cereals, purees, and snacks/finger foods. Datasets included 41 products from Brazil, 73 from Chile, 170 from Mexico, 135 from the United Arab Emirates (UAE), and 643 from the United Kingdom (UK). Nutrient content information was evaluated against FOPNL thresholds for each country. Reconstituted nutrient content for instant cereals was calculated as per manufacturers' instructions.

Results: In the UK and UAE, 7.5% and 13.3% of CPCFs, respectively, warranted a warning sign for high levels of sugar/salt/saturated fat/fat, and 59.1% and 56.3% for moderate levels. In Chile, 45.2% of CPCFs warranted a warning sign for high levels of sugar/saturated fat/energy/sodium. In Mexico, 45.3% of CPCFs warranted a warning sign for high levels of added sugar/saturated fat/trans fat/energy/sodium. In Brazil, no CPCFs were found to contain high levels of saturated fat or sodium; however, added sugar content was not declared on any Brazilian labels and could therefore not be evaluated. Across all countries, excessive sugar content was the most prevalent reason for a warning sign, and snacks/finger foods were the most common products to warrant warning signs.

Conclusions: A substantial proportion of CPCFs evaluated in this study contained excessive levels of nutrients of public health concern that would warrant a warning label. Use of FOPNL among CPCFs would allow for clear and easy interpretation of the nutritional suitability of products for infants and young children and encourage reformulation of CPCFs to reduce concerning levels of nutrients like sugar and sodium.

PAB(T5)-85
The influence of the nutrition model on the parameters of body composition

Jaroslaw Kurek[1], Anna Borucka[1], Marek Kociuba[1]

1. Military University of Technology (Poland)

Background and objectives:

A key element of soldiers' readiness for tasks is their physical fitness, which is in correlation with their body mass, which in turn is a determinant of proper functioning of the body. In military units and other structures utilizing mass catering, proper control of caloric supply, as well as the content of macro and micro components in food is a guarantee of maintaining health, correct body weight, and desired physical fitness. Observation shows that some participants of such catering adopt their own standards and – resigning from mass catering – compose meals at their own discretion. The purpose of this study is to see if this significantly affects body composition parameters: BMI (Body Mass Index), PBF (Percentage Body Fat) BF (Body Fat).

Methods:

Two sources of observation were used:

- the measurement of body composition,
- the records from a program used for keeping track of the meals served.

The collected observations were mathematically analyzed, broken down into the group nurtured in military canteens and the group giving up such nurturing. Basic descriptive statistics were calculated, and then the conformity of the distributions within groups to the normal distribution (Lilliefors test) and homogeneity of variance (Brown-Forsythe test) were examined. Finally, using the Anova analysis of variance or the Kruskal-Wallis test, it was checked whether the diet significantly affects the body composition parameters studied.

Results:

For each type of meal, it was calculated whether the differences between the selected parameters of body composition differ significantly in the groups that participate in collective nutrition and that eat independently. An appropriate statistical test was selected for each study. It turned out that the differences in each group are statistically significant, so the nutrition model affects the value of BMI, PBF and BF. Moreover, in the group that feeds on its own, the mean values of these parameters were much higher.

Conclusions:

The study found significant effects of diet on PBF, BMI and BF levels. The results obtained show that well-balanced food served as part of mass catering favorably affects the body composition parameters and, consequently, the health of the subjects.

Factors Affecting the Application of Cultural Competence of Clinical Dietitians from Selected Urban Tertiary Hospitals in the Philippines on Diabetes Care and Education

Desiree Romano Daniega[1]

1. Far Eastern University- Nicanor Reyes Memorial Foundation (Philippines)

Background and Objective: The dynamics between culture, food and diabetes is an important process which affects and is essential in the promotion of an individual's health and well-being. In the provision of diabetes care and education, focused questions with regards food preferences, habits and choices are not enough. The concept of cultural competence inbased on the classic Campinha-Bacote model, means recognizing and forming one's attitudes, beliefs, skills, values, and levels of awareness to provide culturally appropriate,respectful, and relevant care and education. Applying it on diabetes care and education, the competencies of clinical dietitians in translating their management and recommendations to mitigate complications of diabetes reflect their cultural competence.

Methods: Using an unstructed questionnaire based on the Cultural Competent Assessment Tool, four clinical dietitians were invited for in-depth interviews from JCI-accredited urban hospitals.

Results: Results showed that clinical dietitians in the chosen four hospitals have partial practice and application of cultural competence in their approach on clinical nutrition and counseling for diabetes. Some of the identified enabling factors are: in place hospital policies, initiatives on professional training and capacity building on clinical nutrition, initiatives of lessening the effects of limited FEL and food models, the availability of translators to answer possible gaps brought about by language barrier and a good follow up package for follow up for continuity of care. Some of the limitations or obstacles in the applying cultural competence are: full understanding of what is cultural competence among clinical dietitians, the lack of National or Standardized guidelines on clinical nutrition and counseling for diabetes, the inappropriate use of FEL for non-Filipino patients, use of western-based food models, and for some lack of basic skills on counseling and patient encounters for establishing rapport

Conclusions: Standardized guidelines on clinical nutrition and counseling for diabetes need to be culturally sensitive in order to continually maintain the identified enabling factors and lessen the obstacles identified in diabetes care and education.

Efficacy of a nutrition lecture on dietary basics for athletes: protocol of a randomized controlled trial

Ryoko Mizushima[1], Yoshio Nakata[2], Keiko Motonaga[1], Akiko Kamei[1], Akira Fujiwara[1], Yuki Nakamura[1], Eri Takai[1], Jun Yasuda[1], Kanae Myoenzono[1], Kazuhiro Shimizu[1]

1. Japan Institute of Sports Sciences, Japan Sport Council (Japan), 2. University of Tsukuba (Japan)

Background and objectives: Nutrition education is essential for supporting athletes performing at a high level. However, no reports of randomized controlled trials have verified the efficacy of nutrition education for athletes. This study aimed to examine the efficacy of a nutrition lecture on the dietary basics for athletes.

Methods:This study is a 1-month parallel-group randomized controlled trial. The study protocol was registered in the University Hospital Medical Information Network Clinical Trials Registry (UMIN000048617) on August 7, 2022. We conducted this trial at the University of Tsukuba Football Club. The inclusion criteria are 1) male and female university students aged 18–30 years, 2) members of a university sports club, and 3) dedicated to sports activities. The exclusion criterion is receiving continuous nutritional support (such as nutrition lectures or consultations with a nutritionist more than once a month). A total of 62 football athletes will be randomly assigned (1:1) into an intervention or a control group with stratification by sex. The intervention group will be provided with a single nutrition lecture and educational materials. The control group will undergo no intervention. The follow-up period is 1 month. The primary outcome is the Japanese Food Guide adherence score. The secondary outcomes are energy and nutrient intake, nutritional knowledge, and stages of changes in eating behavior.

Results: We will report the results of this trial after the data collection in September 2022.

Conclusions: The results obtained from this study will contribute to the nutrition management of top athletes.

Keyword: study design, soccer, college athletes, sports nutrition, nutritional behavior

PAB(T5)-88
The effect of the nutrition education on knowledge and attitudes for dialysis nurses

Po Hung Lai[1], Hsing Hui Chen[1], Jui Fang Huang[1], Hui Chen Chen[1]

1. St. Martin De Porres Hospital (Taiwan)

Background and objective: Hemodialysis patients often suffer from protein and energy malnutrition. The aims of the study was to use literacy activities to enhance the effectiveness of nutrition care for dialysis nurses.

Methods: Forty eight participants were engaged in this study. All subjects were divided into two groups. 19 individuals were in the active group and 29 individuals in the control group. A serial of nutrition care training courses for dialysis was held from Feburary to April in 2021. The topics of the training courses were including protein, energy and electrolytes (sodium, potassium and phosphorus) requirements in dialysis patients. The knowledge questionnaires of each activity were conducted before and after course intervention. Test results were collected and scoring. Data was analyzed by using Mann-Whitney test to assess the effectiveness of the course intervention.

Results: This study has showed that intervention of dialysis nutrition care training course significantly improved the knowledge and attitude of participants. The difference is significant at $p < 0.001$ level .

Conclusions: The results show that the intervention of nutrition education can effectively improve nutrition knowledge, achieve behavior change, and strengthen the ability of nutrition care. Nursing staff become able to provide simple nutrition education to dialysis patients after intervention. The lack of long-term training courses resulted in poor outcome. Further education stragies in formulating a long-term plan is necessary.

Keyword: dialysis , nutrition education, malnutrition

PAB(T5)-89
A Questionnaire Survey of infant and toddler facility staff regarding their interest in and understanding of “Shokuiku”

Eri Nishida[1]

1. Nagasaki Junior College (Japan)

Background and objectives: Nutrition education activities for children, who will be responsible for the future generations, are important, and the Global Nutrition Target 2025 also calls for activities related to infant nutrition. Therefore, this study focused on infant and toddler facility staff, who are among the

most important people in the lives of infants and toddlers. This study aimed to understand the perception of infant and toddler facility staff toward nutrition education, with the objective of further promoting nutrition education activities for infants and toddlers. This was done by examining the influence of the staff's interest in nutrition education on their perception of nutrition education.

Methods: In February 2021, an online survey questionnaire (Google Forms) was sent to 110 infant facilities listed in the 2020 Infant Facilities Guide, published by the city where the researcher's facility is located, and 204 responses were obtained. The level of interest and perception of nutrition education were examined by creating two groups of participants: the participants that responded "interested" (111, 54.4%) as the high-interest group, and the participants that responded, "somewhat interested" (89, 43.6%) and "somewhat uninterested" (4, 2.0%) as the low-interest group.

Results: The high-interest group tended to be older than the low-interest group ($p<0.001$) and to have spent more time working at the infant facility ($p<0.001$). The percentage of respondents who answered that they knew both the definition and content of "Shokuiku" tended to be greater in the high-interest group ($p<0.001$). When the perceptions of nutrition education were compared between the two groups, there was no significant difference in response trends between them regarding daily meals and table manners. The high-interest group was significantly more likely to select "health achieved through food and distribution of food" as nutrition education ($p<0.05$). Additionally, the high-interest group selected the "effects of nutrition education on the family and the body" more often than the low-interest group ($p<0.05$).

Conclusions: The high-interest group demonstrated a broader view of nutrition education and activities than the low-interest group, and it is possible that the high-interest group expects more benefits from nutrition education than the low-interest group.

Keyword: Shokuiku, Nutrition education, Infant and toddler facility staff

PAB(T5)-90
Does the nutrient content of school meals vary by types of cuisine? Findings from a pilot study in California.

Yue Jiang[1], Emma Sanchez-Vaznaugh[2], Maria E Acosta[2], Mika Matsuzaki[1]

1. Johns Hopkins Bloomberg School of Public Health (USA), 2. San Francisco State University (USA)

Background and objectives. More than 30 million of children in the U.S. receive at least one school meal every day. School meals offer an excellent venue for providing exposure to diverse food cultures as well as healthy foods and shaping students' dietary patterns and eating habits. The current study examined the diversity of cuisine served in school meals and the nutrient content by the types of cuisine in one of the most diverse and populous states in the U.S.

Methods. We selected 27 public schools (9 each for elementary, middle, and high schools) in San Francisco School District and analyzed the school menus on March 14, 2022 through June 1, 2022. We categorized entrees by the associated racial/ethnic types of cuisines.

Results. The selected schools had high proportions of Hispanic/Latino and Asian students (mean = 40, 31, 35% and 21, 38, and 37% in elementary, middle, and high schools respectively). Over eighty percent of the entrees offered were American cuisine such as burgers, mac&cheese, and hot dogs while the remaining entrees offered were from Asian and Mexican or Latin American cuisines. While the average calories were similar across all cuisine types for each school level, fat and sodium content were much lower in Asian cuisine entrees. The average total fat was 3.1g (SD 1.9), 6.4 (4.2), 4.0 (1.7) for Asian entrees in comparison to American (12.3 (6.7). 12.9 (7.3),14.4 (7.1)) and Mexican (11.4 (3.8), 11.0 (3.2), 11.4 (2.8)) entrees for elementary, middle, and high schools respectively. Carbohydrates were higher in Asian entrees than other types of entrees.

Conclusions. The types of the cuisine served in those schools are less diverse than the racial/ethnic compositions of the student body. The most commonly served cuisine had, on average, poorer nutritional profiles of the meals than Asian entrees. Future studies are needed to examine association of diversity of school meals and diet quality, nutritional knowledge, as well as nutritional status among schoolchildren.

PAB(T5)-91
The Effect of Athletic Discipline and Nutrition Support Experience on Nutrition Knowledge Proficiency among College students in Physical Education

Tadahiro Okumura[1]

1. Nihon University Graduate School (Japan)

Background and Objectives: Knowledge of "sports nutrition" is essential for improving athletic performance. However, although lectures on nutrition are given in many settings, there is a paucity of instruction tailored to the unique characteristics of each sport's competition, and little research has been conducted on the educational effectiveness of such instruction. The purpose of this study was to examine the effects and relationships of a test of basic sports nutrition knowledge and a questionnaire on previous sports nutrition support

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

experience and specialized athletic events on the level of proficiency in nutrition knowledge among college students in physical education who are engaged in sports activities.

Methods: A total of 152 participants, eighty-eight college students specializing in team sports (e.g., ball sports events) and 64 college students specializing in individual sports (e.g., martial arts, swimming, athletics), were surveyed using two types of tests and questionnaires. The test consisted of 50 questions regarding basic knowledge of sports nutrition. The questionnaire surveyed the subject's profile, athletic life, and support experience in sports nutrition. IBM SPSS (Version 27.0 IBM) was used for statistical analysis with a significance level of 5%.

Results: An analysis of variance was performed on the test scores, with "sports category" and "experience with nutrition lectures prior to college" as the two factors. Since significant interactions were found, simple main effects of each factor were examined. The results of the simple main effect test showed that among college students who "had experience with nutrition lectures before entering college," those who specialized in individual sports showed significantly higher values than those who specialized in team sports. The results were also significantly higher for college students specializing in team sports who reported "no" experience with nutritional lectures than those who reported "yes" experience.

Conclusions: Regarding college students who had experience supporting sports nutrition, it was thought that they who specialized in individual sports were more likely to retain their knowledge than those who specialized in team sports. However, for college students who specialized in team sports, lecture experience may not necessarily lead to future knowledge retention.

A Discussion on the Effect of Using Life-Oriented Nutrition Courses to Enhance Employee Weight Loss

Xin Yu Cai[1], Miao Syue Huang[1], Li Yun Shen[1], Hui Ling Liou[1], Ya Fang Huang[1], Cho Aun Neoh[1], Wei Lun Hsieh[1]

1. Pingtung Christian Hospital (Taiwan)

Background and objectives: Healthy workplaces are able to help reduce health-related hazards for employees and enhance their overall corporate competitiveness. In order to encourage employees to maintain healthy postures, courses may be designed for weight-loss diets and exercise. The purpose of this study is to design courses for weight-loss diets and exercise in order to improve the effectiveness of employee weight-loss activities and create a healthy workplace with healthy employees.

Methods: A total of 55 participants with BMI≧24 or body fat percentage ≧30% were accepted into the 12-week course. During this period, weight-loss and nutrition classes were held on the six main categories of food, low carbohydrate diet, tips for eating out, and selection of snacks/supplement during exercise. A sports coach also led aerobic exercise activities once a week and the participants were encouraged to maintain the habit of daily independent exercise. The data collected includes measurements of pre- and post-course BMI, body fat percentage, body weight, and waist circumference as well as a curriculum satisfaction questionnaire. The survey results were compared using the Student's *t*-test analysis.

Results: During the activity, 30 participants were excluded from the results due to their inability to cooperate with the process. A total of 25 participants completed the post-course test, including 23 females and 2 males. After 12 weeks, average body weight decreased by 1.9 kg, and overall average body fat percentage levels decreased by 1.1%. The analysis showed that body weight, body fat percentage, waist circumferences and BMI were significantly decreased in the before and after comparison (P<0.0001).

Conclusions: Holding weight-loss competitions for employees together with weight-loss nutrition and exercise courses can help employees lose weight and improve their overall health.

PAB(T5)-93
Utilization and outcomes of visual aids (my nutrition calendar and food model)

Shoko Chihara[1], Miho Nozue[2], Yuko Hishida[3]

1. Jiyu Gakuen (Japan), 2. Tokoha University (Japan), 3. IC Net Limited (Japan)

Background and objectives: The Japan International Cooperation Agency (JICA) technical cooperation project "Improvement of Maternal and Child Health and Nutrition" conducted activities to improve malnutrition of pregnant women and infants in Quiche, Republic of Guatemala, from 2016 to 2021. The purpose of this course was to provide nutrition education that promotes changes in the awareness and behavior of the target residents themselves through the development and practical use of visual aids that consider the food culture of the target area.

Methods: Food models of menu examples for pregnant women and infants from early pregnancy to 2 years old were prepared, deployed in health care facilities, and used during nutrition guidance. The same nutrition and hygiene guides were made into wall-mounted calendars and distributed to pregnant women and infant households. In the end-line survey at the end

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of the project, a KAP survey was conducted on pregnant women and mothers of children under 2 years of age.

Results: Awareness and knowledge of nutrition and hygiene were improved by the individual use of visual aids with food guides and photographs showing examples of menus in line with dietary intakes during pregnancy and infant life and the amount of increase in mid-to-late childhood, and teaching materials with illustrations of nutrition and hygiene guides that consider culture and customs. In the end-line survey, 84.4% of respondents said they would "increase the amount of food they eat" when asked what they should eat appropriately during pregnancy.

Conclusions: The development and use of culturally conscious nutrition materials, visual aids incorporating illiterate drawings and photographs will contribute to the improvement of nutrition improvement activities.

Keyword: Visual aids, Maternity nutrition, Infant nutrition, Hygiene and nutrition improvement, Food guide

Editathon: a pilot event and model to support engaged, public health learning

Elizabeth Centeno Tablante[2], Anna Bennett[2], Arturo Sanchez[3,4], Hector Pardo-Hernandez[1], Amaya D Stifano[1], Juan Pablo Peña-Rosas[1], Saurabh Mehta[2]

1. World Health Organization (Switzerland), 2. Cornell University - WHO/PAHO Collaborating Center for Nutrition (USA), 3. Creative Commons Venezuela (Venezuela), 4. Laboratoire d'Annecy de Physique des Particules (France)

Background and objectives: The 2021 Wikipedia pilot event *Editathon: "Health for All"* was launched to assess the feasibility of conducting an international, fully virtual Wikipedia editathon. Conducting such work enabled an evaluation of the validity of the information being provided to the public while also assessing the health community's interest in participating in knowledge translation campaigns.

Methods: The pilot event *Editathon: "Health for All"* was a fully online hybrid event, with synchronous and asynchronous session, conducted throughout a four-day period. Volunteer editors and topic experts reviewed, updated, and created articles related to topics of human health and nutrition. Branding and dedicated communication venues were created by the event's organizers to ease communication among participants. Wikimedia was notified of the event to ensure the permanent publication of the articles edited during the event.

Results: The event was deemed to be successful. All the benchmarks of the quality assessment were met or surpassed. Furthermore, positive feedback was received from participants who expressed the desire to implement and promote similar initiatives among college students.

Conclusion: The pilot event *Editathon: Health for All*, was successful in demonstrating the feasibility of sustaining an international collaborative hybrid event with synchronous and asynchronous sessions. Positive feedback was received from participants about the experience.

Traditional and modern fast food consumption patterns and associated factors among adolescents and young adults in Hanoi, Vietnam

Atsuko Yamada[1], Ewa Szymlek-Gay[1], Ngan Hoang[2], Warren Lee[3]

1. Deakin University (Australia), 2. National Institute of Nutrition (Viet Nam), 3. FAO (Thailand)

Background and objectives: Vietnam is undergoing a nutritional transition due to the rapidly growing economy. With the influx of foreign food companies, the country's food landscape increasingly includes highly processed food such as fast food, especially among young people. Whilst having a well-entrenched culture of street food that similarly offers convenience, there is a paucity of literature on traditional fast-food consumption. Due to the increasing rate of diet-related chronic disease in the country, this study sought to understand young people's consumption and associated factors with modern and traditional fast food.

Methods: A cross-sectional online survey of 371 young people was conducted in Hanoi, Vietnam in May 2020. The samples comprised adolescents (aged 15-18) and young adults (aged 19-25) from two randomly selected high schools and two pre-selected universities respectively who provided information on fast food consumption and potential factors associated with it (e.g. proximity to fast food outlets, friends/colleagues'' influence on fast-food purchase, the influence of fast food advertising, exposure to fast food advertising, fast-food related nutrition knowledge). Generalised linear mixed models, with the school as a random effect, were used to explore factors associated with frequent (daily) fast food consumption.

Results: Almost three-quarters of total respondents reported consuming at least one fast food meal item weekly or more often. A greater proportion of the respondents reported consuming traditional style fast food meals (64%) weekly or more compared to modern fast-food meals (33.5%). Males were more likely to be daily consumers of fast food overall, which remained for traditional or modern types. A lack of knowledge on health and disease risks is strongly associated with greater consumption of fast food overall ($p < 0.05$). Additionally, females were significantly more knowledgeable of health risks associated with fast food consumption compared to males ($p < 0.05$). **Conclusions**: Intervention to reduce fast food consumption should target young males with a strong emphasis on education

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

about health and disease risks associated with frequent consumption of fast food.

Food and beverage combinations, patterns among Swedish Adolescents

Henrik Scander[1], Celia Monteagudo[2], Emma Pattersen[3]

1. Orebro University (Sweden), 2. Granada University (Spain), 3. Swedish Food Agency (Sweden)

Background: It has been shown that food and beverage combinations can be used as indicators of healthy meal patterns. Even though choices of combinations often are considered subjective properties in some part, and have been studied in several different ways, mainly within the field of sensory science on adults, this study contributes to the field of food and beverage combination studies by using self-reported habits on adolescents.

Objective: This article explores the relationships between food and beverage combinations, recorded by a Swedish adolescent population.

Method: Secondary analyses were made using data from the national dietary survey, Riksmaten Adolescent (2016-2017), performed by the Swedish Food Agency. A total of 3 477 Swedish adults aged 11, 15 and 18 years old contributed dietary intake data. Participants in the survey registered 3 days of intake where recall day one and three were non-consecutive and retrospective. All meal choices were categorized into beverage categories and food categories. Combinations between beverage and food categories were analyzed by using cross tabulation. Correlation coefficients for non-parametric variables were used to determine the association power. Predictive factors for more important beverage and food combinations were explored by logistic regression analysis.

Results: Our results show correlations in reported consumption of food and beverage, which explain the occurrences of specific patterns of combinations of food and beverages

Conclusion: More studies on choice of beverage are needed to describe the patterns of intake, in order to understand the mechanisms behind beverage choice, in different settings and cultural situations and lifestyle backgrounds. Combinations in everyday life are described here and are rather building on availability than on optimal taste combinations. Our findings can offer an understanding of some common every-day choices as habits which are of concern for future meal patterns.

PAB(T6)-2
Workplace Health Promotion by "My Plate"

Ke-Yu Chang[1], Mei-Ying Chen[1]

1. Changhua Christian Hospital (Taiwan)

Background and Objective: People in Taiwan suffers from nutritional deficiency according to the surveys conducted by the Ministry of Health and Welfare (MHW). In the previous publication of the daily dietary guidelines, the guidelines were visualized in a pie chart. MHW did not get the anticipated response and issued a new format using a plate ("My Plate") as a visualization with mnemonics to submit valuable nutrition lessons to memory and practices. To further promote healthy diet, MHW hosts workshops in various workplaces.

Methods: "My Plate" is based on the daily dietary guidelines published by the Ministry of Health and Welfare. "My Plate" visualizes the serving size for the 6 major categories of food. This allows the public to eat a variety of local food while consuming balanced nutrition proportional to "My Plate". Changhua Christian Hospital partners with the Central Health Workplace Center to promote "My Plate" in various workplaces. To assess the effectiveness of the workshops, participants were given the pre and post-tests.

Results: Based on the 146 pre and post-tests results from four different workshops, the level of understanding for the daily dietary guidelines was increased by 47.26% (from 44.06% to 91.32%) after the workshops. In addition, the level of understanding for the serving size was increased by 23.97% (from 72.95% to 96.92%). Further, the level of understanding for "My Plate" was increased by 67.12% (from 17.81% to 84.93%).

Conclusions: Per the analysis mentioned above, it is clear that the health and nutrition workshops at workplace can significantly impact people's dietary decisions, effectively promote national health policy, and most importantly, enhance overall public health in Taiwan.

Regional differences in food choice priority and related social and environmental factors in Japanese schoolchildren

Michiko Shigihara[1], Yuki Sato[2], Emiko Terauchi[3], Kae Saeki[3], Reiko Suzuki[4], Chieko Suzuki[5]

1. Tohoku Seikatsu Bunka Gakuen University (Japan), 2. National Institute of Occupational Safety and Health (Japan), 3. Graduate School of Human Science and Design, Japan Women's University (Japan), 4. Graduate School of Human Life Science, Japan Women's University (Japan), 5. Saga Medical School, Saga University (Japan)

Background and aims: After the 2011 Great East Japan Earthquake, interest in food choice might increase in Japan. In this study, we examined guardian's food choice priority for their children after the earthquake, and also revealed background factors related to food choice priority.

Methods: We administered a comprehensive questionnaire survey on schoolchildren's diet and health and on their guardians between November 2015 and March 2016. Nine elementary schools in the northern and southern districts in Japan cooperated, as well as 3,327 guardians out of 4,263 enrolees (cooperation rate: 78.0%). We used the completed response data of 3,080 guardians in the analysis. Multivariate logistic analysis was used to assess the association between food choice priority and social background.

Results: The most important factor in children's food was 'safety', which accounted for about 40% of the total. 'Nutrients' were 16%, and 'freshness' was almost 13%. Guardians living in southern area, away from the disaster area, were 1.3 times more likely to consider 'safety' as food choice priority for children. The related background factors of 'safety' were guardian age and employment, the number of family members living together, monthly food costs per person in the family, emotional capacity in life, and guardian's concerns about food education. As age increased, the tendency to place importance on children's food safety increased 2–3 times. Guardians who were uninterested in food education tended not to prioritise food safety.

Conclusion: 'Safety' was the most important concern in children's food among guardians in this study, and the tendency was higher in areas far from the affected area. The result from the related factors, guardians' understanding and knowledge about food might influence food choice for their children. There is a need for detailed research to reveal what is 'safe' in guardians' decision criteria of food choice.

PAB(T6)-4
Taste investigation of miso soup for the restriction of sodium intake

Akemi Misawa[1], Akie Abe[1]

1. Tokyo Kasei Gakuin University (Japan)

Background and objectives: It is known that Japanese foods are healthy, their nutrient balance is good and enrolled in the UNESCO Intangible Cultural Heritage. However, the salt intake of Japanese people has been exceed the target value for a long time. The lowering of salt intake is an urgent problem in Japan, but it is not easy to realize sodium restriction. One reason is that we have a custom to drink miso soup and eat pickles in Japan. Therefore, in this study, after tasting of miso soup, we aimed for exploring everyday sodium restriction method from questionnaire survey.

Methods: Subjects of the survey are 60 Female University students (Response rate 100%) in Tokyo. After tasting of two kinds of miso soup, they replied some questions in the Google form (The unsigned self-entry-style-answer). Both A and B miso soup have 150ml water, 10g miso, 1g powder bonito soup stock (Salinity 1.1%, 60℃). Only B miso soup has 1g dry seaweed. We used the same amount with their food indication. They were standard quantity in Japan.

Results: Which do you feel to be strong? It was A miso soup (A name is Ams) 87%, B miso soup (Bms) 8%. Which is delicious? It was Ams 35%, Bms 57%. Which is similar to home taste? It was Ams 30%, Bms 58%. Are you doing sodium restriction routinely? It was always 12%, sometimes 48%, not doing it at all 32%, did not remember 8%. What is an ingredient material for use in miso soup to cook at home most? It was seaweed 48%, tofu or fried bean curd 30%. What is the soup stock to use most at home? It was dried bonito (48%).

Conclusions: They replied that it was delicious like the home taste that the miso soup of the seaweed was more dilute. In Japan we have healthy custom to put seaweed in miso soup. But we will feel salt low when we put seaweed in it, it may be connected to increase of the miso (Salt intake).

Keyword: Miso soup, Sodium restriction, Salt intake, Seaweed, Taste investigation

Socio-economic factors and eating behavior of children in North Macedonia

Igor Spiroski[1,2], Elena Tortevska - Danilov[3]

1. Institute of Public Health - Skopje (Republic of North Macedonia), 2. Faculty of Medicine, Ss. Cyril and Methodius University - Skopje (Republic of North Macedonia), 3. Center of Public Health - Kochani (Republic of North Macedonia)

Background and objective: Eating foods that assure health benefits is crucial to minimize diet-related risks for developing NCDs. Diet rich in fruit and vegetables, with appropriate intake of legumes, nuts, and whole grains, and with limited intake of free sugars, salt, saturated and trans fatty acids maintains functioning of the body without increasing of the health risks. Eating habits that promote health adopted in childhood are important component for reduced health risks in adulthood. Objective of our research was to inspect the eating behaviors of second-grade children in North Macedonia and its relation to some socio-economic factors.

Methods: Total of 3246 second-grade children were selected for data collection in the frames of 5th round of the WHO's Childhood Obesity Surveillance Initiative (COSI). Frequency of consumption of fruits, vegetables, soft drinks, savory snacks, and sweet snacks was examined. "Eating habits score" for each child was calculated by converting of each dietary habit (based on consumption frequency) to a "healthy" or "less healthy" behavior. Scores ranged from 0 (indicating a very healthy diet), to 6 (indicating a less healthy diet, where all the "less healthy behaviors" were observed). Gender, BMI, urbanization level, parent's education and participation in sports activity were analyzed in relation to eating behaviors.

Results: None of the analyzed eating habits had a significant impact on BMI categories (underweight, physiological weight, overweight and obesity) in children. In general, 75% of girls and 78% of boys reported consuming breakfast every day but only 40% of children reported consuming fruit and 37% consuming vegetables every day. 63% of children whose both parents have secondary or lower education practiced "less healthy behavior" comparing to 37% of those whose at least one parent has tertiary education ($p<0.001$).

Conclusions: Daily breakfast consumption of children is around the European average but there is much room for improvement in the intake of fruits and vegetables. Most of the children practice neither "healthy" nor "less healthy" dietary behavior. Among different socio-economic factors, only lower level of parental education significantly contributes towards practicing "less healthy" dietary habits

PAB(T6)-6
Antioxidant vitamin intake and LOX-index among a Japanese working population

Mirai Sakanari[1], Masanori Ohta[1], Mayumi Nagano[1], Yoko Umeki[1], Akiko Nanri[1]

1. Fukuoka Womens University (Japan)

Background and objectives: Cardiovascular disease is a major cause of death globally. Lifestyle, including dietary factors, plays a role in the development of cardiovascular disease. Antioxidant vitamins are suggested to prevent the onset of CVD by inhibiting the oxidation of LDL cholesterol and decreasing the risk of atherosclerosis through their antioxidant effect. In a meta-analysis of 15 prospective studies, antioxidant vitamin intake was associated with decreased risk of cardiovascular disease. LOX-index, which is a new predictive index of cardiovascular disease, reflects the state of atherosclerosis. However, no study has examined the association between antioxidant vitamin intake and LOX-index. This study investigated the association between antioxidant vitamin intake (vitamin A, vitamin E, and vitamin C) and LOX-index in a Japanese working population.

Methods: Participants were 346 workers (171 men and 175 women aged 19-71 years) without a history of serious disease. Antioxidant vitamin intake was assessed using a brief-type self-administered dietary history questionnaire (BDHQ). LOX-index was calculated by multiplying the soluble form of Lectin-like oxidized LDL receptor 1 (sLOX-1) by LOX-1 ligands containing apolipoprotein B (LAB). Multiple regression analysis was used to estimate the geometric mean of the LOX-index according to tertile of intake of each antioxidant vitamin.

Results: Vitamin A intake was suggestively associated with lower LOX-index. The geometric mean (95% confidence interval) of the LOX-index for the lowest through highest tertile of vitamin A intake was 716 (617-832), 650 (560-754), and 580 (500-674) after adjustment for age; sex; BMI; job grade; overtime work; smoking; alcohol drinking; sleep duration; leisure-time physical activity; sedentary time during work; total energy intake; history of diabetes, hypertension or dyslipidemia; use of supplements; systolic blood pressure; fasting blood glucose; and LDL cholesterol (P for trend = 0.055). The geometric mean of LOX-index tended to be lower with increasing intake of vitamin C and vitamin E, although the inverse association was not statistically significant. The inverse associations between vitamin A, vitamin C, and vitamin E intake and LOX-index were more pronounced in women.

Conclusion: Our results suggest that vitamin A intake was associated with a lower LOX-index in this working population.

PAB(T6)-7
Relationship between food production experience and adherence to dietary guidelines among Japanese adults: a cross-sectional study

Daisuke Machida[1]

1. Gunma University (Japan)

Background and Objectives: The Japanese Ministry of Agriculture, Forestry and Fisheries (MAFF) has identified increasing the percentage of the population who experienced food production as one of the objectives of the Basic Program for Shokuiku (Food and Nutrition Education) Promotion. This study aimed to clarify the relationship between food production experience and adherence to dietary guidelines among Japanese adults.

Methods: This is a cross-sectional study conducted using the data of the "Survey on dietary habits and food production experiences in 2019" carried out by MAFF. The independent variable was food production experience. The dependent variables were each of the 13 goals of the dietary guideline in Japan and an aggregate score for adherence to the 13 goals (low score means good adherence). Additionally, we examined the association between which point on the life course the food production experience took place and adherence to dietary guidelines. The data of 3461 participants in their 20s–60s were used. For the analyses, multivariate logistic and linear regression analyses were used.

Results: Upon considering those who had not experienced food production as a reference, it was noted that the adherence was significantly better for 11 of the 13 goals when the participants had experienced it. In the linear regression analyses with an aggregate score for adherence as the dependent variable, when the participants were not experienced food production as the reference, B = −1.496 ($p < 0.001$) when the participants experienced it. Among the life courses, the experience in adulthood was significantly associated with the aggregate score for adherence (B = −1.556, $p < 0.001$). Experience when underage (less than elementary school, and elementary school or more) was only moderately related (B = −0.459, $p = 0.085$; B = −0.684, $p = 0.080$).

Conclusions: This study revealed that food production experience was positively associated with adherence to dietary guidelines in Japan. Particularly, there was a strong association with experiences in adulthood.

Keyword: food production experience, dietary guideline, life course, food and nutrition education, Japan

PAB(T6)-8
Hypertension and Obesity Are as Mediators from Early Menarche to Coronary Artery Disease: Mendelian Randomization Study

Kuo-Liong Chen[1,5], *Yen-Tsung Huang*[3,1], *Yun-Yu Chen*[1,4], *Justin BoKai Hsu*[2], *Hung-Yuan Li*[5], *Hsien-Yu Fan*[1,2], *Yang-Ching Chen*[2,6]

1. National Taiwan University (Taiwan), 2. Taipei Medical University Hospital (Taiwan), 3. Academia Sinica (Taiwan), 4. Taipei Veterans General Hospital (Taiwan), 5. National Taiwan University Hospital (Taiwan), 6. Taipei Medical University (Taiwan)

Rationale: Earlier age at menarche leads to the risk of coronary artery diseases; however, the risk is thought to be mediated through metabolic risk factors and may not be caused by earlier age at menarche directly. **Objective**: To investigate the role of body mass index, blood pressure, blood lipid and blood sugar in explaining the effect of earlier age at menarche on the risk of cardiovascular diseases. **Methods**: In the prospective cohort design, we included 1,598 participants from the Chin-Shan Community Cardiovascular Cohort study. Approximately 70,000 participants from Taiwan Biobank were included in the retrospective cohort and Mendelian randomization studies. We used randomly allocated genetic variants for the exposure and mediators in the Mendelian randomization study. We investigated the role of metabolic factors in mediating the causal effect of age at menarche on the risk of coronary artery diseases by using the three complementary approaches with mediation analyses: multivariable cox proportional hazard regression, multivariable logistic regression, and Mendelian randomization. **Results**: Each additional standard deviation of earlier age at menarche was associated with a 56% higher risk (hazard ratio 1.57, 95% confidence interval 1.12 to 2.19) in the prospective cohort study, a 11% higher risk of coronary artery disease (odds ratio 1.11, 95% confidence interval 1.02 to 1.21) in the retrospective cohort study, and a 2% higher risk (1.02, 1.001 to 1.03) in the Mendelian randomization study. For the effect of genetically predicted earlier age at menarche on the risk of coronary artery diseases, 40% was mediated by genetically predicted body mass index and 27% by genetically predicted systolic blood pressure. **Conclusions**: By using distinct analytical methods, including genetic approaches that can draw causal inference, our results suggest that interventions aimed at reducing BMI and SBP would lead to reductions in cases of CAD attributable to earlier age at menarche. Importantly, more than four tenth of the effect of earlier age at menarche on the risk of CAD is not mediated through the two factors and further studies are warranted to investigate this.

PAB(T6)-9
Modeling food fortification contributions to micronutrient requirements in Malawi using Household Consumption and Expenditure Surveys

Kevin Tang[1]

1. London School of Hygiene & Tropical Medicine (UK)

Background and objectives: Large-scale food fortification may be a cost-effective intervention to increase micronutrient supplies in the food system when implemented under appropriate conditions, yet it is unclear if current strategies can equitably benefit populations with the greatest micronutrient needs. This study developed a mathematical modeling framework to compare large-scale food fortification scenarios across different contexts.

Methods: The framework was applied to model the potential contributions of three fortification vehicles (oil, sugar, and wheat flour) towards meeting dietary micronutrient requirements in Malawi through secondary data analyses of a Household Consumption and Expenditure Survey. We estimated fortification vehicle coverage, micronutrient density of the diet, and apparent intake of nonpregnant-nonlactating women for nine different micronutrients, under three food fortification scenarios and stratified by subpopulations across seasons.

Results: Oil and sugar had high coverage and apparent consumption that, when combined, were predicted to improve the vitamin A adequacy of the diet. Wheat flour contributed little to estimated dietary micronutrient supplies due to low apparent consumption. Potential contributions of all fortification vehicles were low in rural populations of the lowest socioeconomic position.

Conclusions: While the model predicted large-scale food fortification would contribute to reducing vitamin A inadequacies, other interventions are necessary to meet other micronutrient requirements, especially for the rural poor.

Keyword: large-scale food fortification, HCES, micronutrient inadequacy, equity

Responsive maternal feeding behaviors used with young children in Perú

Sissy Liliana Espinoza Bernardo[1], Emma Haycraft[2], Rosario Bartolini[3], Hilary Creed Kanashiro[3]

1. Universidad Nacional Mayor de San Marcos (Peru), 2. Loughborough University, UK (UK), 3. Instituto de Investigación Nutricional (Peru)

Background and objectives Responsive feeding behaviors are related to the development of healthy eating behaviors in young children. There is evidence that positive interactions between the caregiver and child during feeding episodes can reduce malnutrition. The aim of this study was to identify dimensions of responsive feeding, and whether this varies based on the age of the child, in families living in a Peruvian city. **Methods** Eight mothers with a 6-23-month-old child, living in peri-urban areas of Huánuco - Peru, participated. Following informed consent, observations of the mother-child dyad were conducted in the family's home. The observations were carried out during January and February 2020, with an average duration of five hours, including meal preparation and mealtimes. Previously validated guides were used to code the observations, specifically examples of responsive and non-responsive feeding behavior. **Results** Mothers were differentiated according to the age of their children: 6 to 12 months of age (mean 9.6 months) and 13 to 23 months of age (mean 18.2 months). Mothers of children aged 6 to 12 months commonly demonstrated responsive behaviors that included responding to the child's feeding signals and using strategies to try to encourage their child to eat the food. Non-responsive behavior in this group was identified as not giving the child opportunities to eat on their own, because some mothers were afraid that the child would choke, get messy or were too slow. Mothers of the 13 to 23 month-olds gave their child more opportunities to eat by themself with their hands or spoon. However, talking to the child during meals was practically absent and some mothers were more controlling, exerting various forms of pressure at mealtimes. **Conclusion** Greater responsive feeding behavior was evident in mothers of younger children compared to mothers of older children. This likely reflects mothers allowing their older children greater autonomy in eating whilst engaging in fewer vocalizations at mealtimes, but also reflects greater use of pressure for older children to eat. Support is recommended to inform parents about the unintended effects that can arise from overly-controlling feeding practices and the benefits of verbalization during feeding.

Changes in food consumption and body weight during the COVID-19 pandemic

Misa Shimpo[1], Rie Akamatsu[2], Yui Kojima[3]

1. The University of Nagano (Japan), 2. Ochanomizu University (Japan), 3. University of Niigata Prefecture (Japan)

Background and Objectives: During the COVID-19 pandemic, people around the world made major changes to their lifestyle to prevent the spread of the disease. This study aimed to examine the relationship between changes in food consumption and body weight during the COVID-19 pandemic.

Methods: A cross-sectional questionnaire survey was conducted via the internet in November 2020 among 6,000 Japanese adults (aged 20–64 years) who were registered with a research company. The questionnaire included items on demographic characteristics, body weight before (November, 2019) and during (November, 2020) the pandemic, changes in food consumption (quantity of vegetable intake; frequency of intake of rice, bread, noodles, fruit, meat, fish, milk, dairy products, instant food, fried food, and confectioneries), and changes in duration (number of hours) of exercise and sleep after the COVID-19 pandemic began. Multinomial logistic regression analysis using a stepwise method was performed to analyze the relationship between changes in food consumption and body weight during the pandemic. The reference group included individuals whose weight had not changed. The demographic characteristics, pre-pandemic body weight, and changes in duration of exercise and sleep were included the analysis as adjustment variables.

Results: Of the 5,981 respondents, after excluding invalid responses, 308 respondents (5.1%) had a 5% or more decrease in body weight and 321 respondents (5.4%) had a 5% or more increase in body weight, and 5,352 respondents (89.5%) experienced no changes in weight. All food consumption changes were found to be associated with weight change. Results of the multinomial logistic regression analysis showed that people who had a weight loss of 5 % or more were more likely to have decreased the frequency of rice and fried food intake. On the other hand, people with weight gain of 5 % or more were more likely to have increased their frequency of rice, fried food, and instant food intake.

Conclusions: A decrease in frequency of rice and fried food intake is associated with weight loss, and an increase in frequency of rice, fried food, and instant food intake is associated with weight gain during the COVID-19 pandemic.

Keyword: weight change, food consumption, COVID-19

PAB(T6)-12
Indian fathers' perceptions of early childhood care and feeding: A qualitative inquiry

Sangeeta Kansal[1], Sreya Damani, Anthony Worsley[2], Neha Rathi[1]

1. Banaras Hindu University (India), 2. Deakin University (Australia)

Background and objectives: The role of fathers in child rearing and feeding has been largely overlooked in the paediatric literature, more so within the LMIC context. The emergence of nuclear families and the rise in female employment in urban India underscores the need to explore the involvement of Indian fathers in child rearing. A greater understanding of fathers' views regarding their participation in child rearing is warranted to inform the development and implementation of effective family-based interventions to promote dietary health and well-being in children while mitigating the risk of double burden of malnutrition. This present inquiry aimed to describe Indian fathers' perceptions of child rearing.

Methods: Convenience sampling was employed to recruit 22 fathers of children aged 6-59 months from Kolkata city, India. In-depth, semi-structured interviews were conducted over Zoom/telephone in Hindi, Bengali, and English. All interviews were recorded, transcribed verbatim and translated to English. Transcribed data were analysed both manually as well as through NVivo software program. Ethical approval for this qualitative study was granted by the Institutional Ethics Committee of Banaras Hindu University (Dean/2021/EC/3006).

Results: A number of themes were identified during thematic analysis which included (i) Limited engagement of fathers in feeding; (ii) Adoption of a variety of feeding practices e.g. pressuring the child to eat, incentivizing food consumption, making healthy foods available, using food to bond with the child; (iii) Active engagement of fathers in physical activity and vaccination of children; (iv) Child rearing as a responsibility of both parents; (v) Challenges to routine involvement of fathers in childcare; (vi) Lack of awareness about dietary requirements of children; (vii) Need for emphasizing adequate diet and physical activity in children.

Conclusions: The emerging findings provide novel insights about Indian fathers' experiences associated with childcare and feeding in the rapidly transforming Indian society. All fathers strongly endorsed the need for inculcating healthy eating behaviours and physical activity in formative years for the optimum growth and development of children. This growing understanding of paternal child rearing practices potentially triggers support for father involvement in diet-related interventions and efforts.

PAB(T6)-13
Elevating self-reflection on SMART eating in Sri Lankan adults using a meal tracking smartphone app

Parami Prabuddhini Weerasinghe[1], Thushanthi Perera[2]

1. Wayamba University of Sri Lanka (Sri Lanka), 2. Wayamba University of Sri Lanka (Sri Lanka)

Background and objectives: SMART eating interventions to reduce the consumption of unhealthy food and increase the consumption of a variety of healthy food is one of emerging strategies to combat non-communicable diseases worldwide. In this milieu, using photo-based food journaling to amend eating behaviours has become an up-and-coming strategy. Hence, investigating the effect of photo-based food journaling for self-reflection on SMART eating is timely. The purpose of this study was to explore the effect of photo-based food journaling on meal tracking experience, self-reflection, and self-assessment on SMART eating, and food choice intention in adults while developing a novel meal tracking application named SnaT (Snap & Track) in the Sri Lankan context.

Methods: Using sequential explanatory mixed-method, a convenient sample of 25 adults completed a photo-based food diary for three days, followed by additional three days using the SnaT meal tracking app. All the data were collected via telephone interviews in August 2021.

Results: The mean age of participants was 24±6.08 years, and 80% of participants were female. There was a significant increase in the consumption of a variety of healthy food [fruits and vegetables (p=0.00), legumes (p=0.001), fish, meat and poultry (p=0.00), eggs (p=0.00), and milk (p=0.001)] and a decrease in unhealthy food consumption [salt (p=0.025), sugar and sweet food (p=0.00)]. Busy lifestyle was identified as the primary challenge for SMART eating and 76% (19/25) accepted photo-based food journaling as a remedy to improve it. Enhancing the self-awareness on meals was the major benefit of photo-based food journaling (18/25; 72%) while forgetting to capture photos before eating was the main barrier (17/25; 68%). Nonetheless, SnaT was accepted (21/25; 84%) as a meal tracking app that is appropriate to Sri Lanka and has proven to reduce the burdens inherent to manual photo-based food journaling.

Conclusions: Photo-based food journaling showed a significant impact on SMART eating, and the acceptance of SnaT to facilitate photo-based food journaling was satisfactory. However, future studies should warrant evaluation of the SnaT on different demographic groups by redesigning the app to include features of digital nutrition education and nudging techniques to prompt and promote healthy eating.

Keyword: Meal tracking app, Photo-based food journaling, SMART eating, Self-reflection, Adults

PAB(T6)-14
Factors associated with Iron Deficiency Anaemia among Pregnant Women in Ifako Ijaiye, Lagos, Nigeria

Temitope Elizabeth Adeboye[1,2], Akinkunmi Paul Okekunle[2]

1. Radiance Holdings (Pty) , Gaborone, Botswana (Botswana), 2. University of Ibadan, Ibadan (Nigeria)

Background and Objectives: Maternal iron stores is critical to maternal health and good pregnancy outcomes. However, little is known on factors associated with iron deficiency anaemia (IDA) in pregnancy, in light of the growing burden of maternal mortality and poor pregnancy outcomes, particularly among women from low- and middle-income countries (LIMCs). This study assessed sociodemographic factors associated with IDA among pregnant women in Ifako-Ijaiye Lagos, Nigeria.

Methods: Sociodemographic information were assessed among 432 singleton pregnant women (without pre-existing medical complications) using a pre-tested questionnaire, and finger pricked blood samples were taken into capillary tubes to determine haemoglobin (Hb) concentration in g/l using the haemoglobin-cyanide technique. According to the World Health Organization criteria, IDA among pregnant women was defined as Hb < 110g/l, chi-square test or t-test was used to compare categorical and continuous variables respectively according to IDA status at a 2-sided *P*< 0.05.

Results: Mean age of respondents was 28.5±4.6years, 203 (47.3%) had at least secondary education, 4.6% were never married, and 29.2% earned less than N16,000 monthly. The average gestational age was 31 weeks, 47.7% were primigravidae, and 83.8% had IDA (Hb < 110g/l). Similarly, mean Hb concentration was lower among pregnant women with IDA (94.3±10.6g/l) than those without IDA (116.7±5.5g/l). Age, gestational age, educational status and marital status differed insignificantly by IDA status. However, the prevalence of IDA was higher among pregnant women who were primigravidae – 87.9% (compared to multigravidae pregnant women – 80.1%) and those who earned more than N16,000 monthly presented a higher prevalence of IDA (79.4%) than those who earned less than N16,000 monthly (57.1%).

Conclusion: IDA was prevalent in this population, particularly among women with first pregnancy experience and high income. Mobilizing early intervention targeted at women before pregnancy and caregiving roles might be beneficial in reducing the burden of IDA and maternal mortality and improving maternal health in LMICs.

Trends of undernourished people in South Asia: a joinpoint regression model of the sustainable development goals indicator from 2001 to 2019

Syed Mahfuz Al Hasan[1], Jennifer Saulam[2], Fumiaki Mikami[2], Kanae Kanda[1], Hideto Yokoi[2], Tomohiro Hirao[1]

1. Kagawa University (Japan), 2. Kagawa University Hospital (Japan)

Background and objectives: Even before the COVID-19 pandemic, people experiencing hunger had been rising globally since 2014. Asia-Pacific region has housed 51% of the global undernourished people. In 2019, Southern Asia had the highest number of undernourished people (257.3 million). We aimed to track the changes and assess the possible determinants of changing the number of undernourished people in South Asia from 2001 to 2019.

Methods: We used FAO's global sustainable development goals indicators database for our trend analysis. The joinpoint regression model was applied to analyze the temporal trends. We reported a relative metric, the annual percent change (APC), of the trend for each of the South Asian countries.

Results: The number of undernourished people decreased by only 1.5% from 2001 to 2019 in South Asia. Among the countries, Nepal experienced a marked decrease (7.6% per year) in the number of undernourished people followed by Sri Lanka (4.8% per year) from 2001 to 2019. Progress was not satisfactory for India (0.1% per year) and Afghanistan (0.6% per year) whereas Bangladesh (1.4% per year) and Pakistan (1.0% per year) had a slower rate of reducing the number of undernourished people. Food price volatility in 2007-2008 might have hit hard some of the South Asian countries like Afghanistan (7.8% per year) and Bangladesh (7.1% per year) and to a lesser extent in Pakistan (2.4% per year) in raising the undernourishment. This crisis had noticeably slowed down the decreasing trend of undernourishment in India. After recovery, since 2016, the number of undernourished people had been increasing at a significant rate in all the South Asian countries mostly in Nepal (APC=10.6), Afghanistan (APC=8.8), India (APC=5.1), Pakistan (APC=3.6), and Sri Lanka (APC=2.4). This increasing trend pushed 21 million more people to undernourishment in South Asia.

Conclusions: The prevalence of undernourishment has not constantly decreased in South Asia. Nepal and Sri Lanka made good progress in reducing the number of undernourished people. However, undernourishment started to increase again in South Asia in 2016. In addition, the ongoing COVID-19 pandemic will make the goal of ending hunger more difficult to achieve in South Asia.

Usefulness of plastic bag heat-retention cooking of soft dishes for the elderly in disaster situations

Toshiyuki Kohri[1], Mizuki Kondo[1], Masako Kawanishi[2], Mako Yamamoto[1], Hiroyuki Tomotake[3], Chiho Myojin[2]

1. Konan Women's University (Japan), 2. Kindai University (Japan), 3. Iida Junior College (Japan)

Background and Objectives: Plastic bag cooking (normal method) can be easily adapted to individual needs. The purpose of the current study was to find the best method of cooking soft foods for elderly people with reduced masticatory strength in times of disaster. Further, the normal method and plastic bag heat-retention cooking (heat-retention method) were compared for parameters, such as the hardness of cooked food and amount of gas used in cooking soft food.

Methods: To mimic conditions 4 to 7 days after a disaster, preserved foods, such as root vegetables and canned items, were used instead of fresh food. The dish used in the current experiment was "Mackerel and radish simmered in miso". Normal method: Water in a pot (1.5 L) was brought to a boil, and food ingredients in a polyethylene bag were put into the pot and heated continuously for 20, 30, 40, 50, and 70 minutes. Heat-retention method: After heating for 20 minutes as in the normal method, the pot was wrapped in a blanket and kept warm for 20, 40, 60, 80, and 120 minutes. Gas consumption was estimated by the difference in weight before and after the use of cassette gas. Food hardness was estimated in the radishes of "Mackerel and radish stewed in miso" by breaking load measurement using a creep meter (Yamaden: RE2-33005C).

Results: Normal method: after 20 minutes of cooking, the firmness of the radish was above the upper limit of the universal design food firmness (5×10^5 N/m^2), whereas after 50 minutes, the firmness was reduced to 2.3×10^5 N/m^2. Heat-retention method: After 60 minutes of heat-retention, the hardness was lower than that of the normal method after 50 minutes of heating. The amount of gas consumption to cook radishes to the same level of firmness was less in the heat retention method (36 g) than in the normal method (69 g).

Conclusion: The heat-retention method was found to be a better cooking method that could soften the food and save fuel in times of disaster.

Keyword: disaster, cooking, elderly, heat-retention, food

PAB(T6)-17
Trends in healthy lifestyles among Japanese adults from 2004 to 2015

Eri Imai[1], Sae Tanaka[1]

1. The University of Shiga Prefecture (Japan)

Background and objectives: Combined healthy lifestyle behaviors have been shown to be associated with lower mortality; however, how multiple lifestyle behaviors have trended in longevity country remains unknown. We examined the trends for combined health behaviors in the Shiga prefecture.

Methods: Design: Secondary data from the 2004, 2009 and 2015 Health and Nutrition Survey in the Shiga prefecture was used. Health behaviors score was calculated based on 5 lifestyle factors: higher diet quality, never smoked, non-excessive alcohol drinking, regular exercise, and enough sleep. The trends for the means of health behavior scores between 2004 and 2015 were examined using linear regression analysis by sex and age. Setting: Community living people. Participants: 20,126 people aged 20 years and over.

Results: In men, increased trends for health behavior scores were observed in the young (20–39 years) and older (≧ 65 years) age groups although not significantly in the middle-aged (40–64 years) group. In women, increased trends for health behavior scores were observed only in the older age group. In older women, the prevalence of regular exercise increased and the prevalence of higher diet quality decreased less compared with young- and middle-aged women between 2004 and 2015. Older women engaging in regular exercise had increased trends in diet quality, and never smoked.

Conclusions: This study revealed the increased trends in combined health behaviors among men and older women. The approach to establish an exercise habit may lead to combined multiple healthy behaviors, which could help extend life expectancy in the future.

PAB(T6)-18
Association between dietary patterns and visceral fat obesity in Japanese adults with normal body mass index

Yuri Yaguchi[1], Tsuneo Konta[1], Nahomi Imaeda[2], Chiho Goto[3], Yoshiyuki Ueno[1], Takamasa Kayama[1]

1. Yamagata University (Japan), 2. Shigakkan University (Japan), 3. Nagoya Bunri University (Japan)

Background and objectives: Dietary factors contributing to visceral fat accumulation have not been clarified in Japanese people with an abdominal circumference of ≧85 cm for men and ≧90 cm for women, although their body mass index (BMI) is normal. Therefore, this study clarified factors contributing to visceral fat accumulation from the dietary patterns of Japanese people with normal BMI.

Methods: In this study, 3,972 men and 2,929 women aged 39-74 years were included. They were participants in the Yamagata cohort with a normal BMI and completed a validated food frequency questionnaire (FFQ). Dietary patterns were extracted using cluster analysis from the intake of 19 food groups calculated from the FFQ. Further, the association between dietary patterns and visceral fat accumulation was evaluated by logistic regression analysis.

Results: The following three dietary patterns were identified for men: "rice" (n = 1,831), "side dishes" (n = 502), and "bread, noodles, coffee, and alcoholic beverages" (n = 1,639), and the three dietary patterns identified for women were as follows: "side dishes" (n = 145), "rice and bread" (n = 1,654), and "noodles and milk" (n = 1,130). The number of men with visceral fat accumulation for each dietary pattern was 418 (22.8%) for "rice", 127 (25.3%) for "side dishes", and 483 (29.5%) for "bread, noodles, coffee, and alcoholic beverages". The number of women with visceral fat accumulation that selected "side dishes" was 5 (3.4%), "rice and bread" was 68 (4.1%), and "noodles and milk" was 51 (4.5%). Logistic regression analysis adjusted for age, smoking habits, dietary energy intake, breakfasting habits, snacking habits, eating speed, and daily walk durations showed that the odds ratio of visceral fat accumulation in the "bread, noodles, coffee, and alcoholic beverages" pattern was significantly higher than that of the "rice" pattern for men. In contrast, there was no significant association between dietary patterns and visceral fat accumulation in women.

Conclusions: In men with normal BMI, dietary patterns with high consumption of bread, noodles, coffee, and alcoholic beverages may be associated with increased risk of visceral fat accumulation.

Keyword: dietary patterns, visceral fat obesity, normal BMI, men

PAB(T6)-19
A survey of the lifestyle habits of young Japanese women and an analysis of blood glucose using Continuous Glucose Monitoring (CGM)

Moeka Mizoguchi[1], Masaru Takenaka[1]

1. Kobe Women's University Graduate School (Japan)

Purpose: According to the Japanese Ministry of Health, Labour and Welfare, the daily energy intake requirement for women in their 20s, is 1,700–2,300 kcal/day, but the National

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Health and Nutrition Survey (NHNS–J 2019) reported that it is 1,600 ± 445 kcal/day, and 20.7% have a BMI <18.5. We conducted a fact–finding survey and measured blood glucose (BS) every 15 minutes by CGM to clarify the lifestyle and nutritional intake of female students in their 20s at Kobe Women's University.

Methods: The 25 subjects, aged 21.6 ± 0.7 years old, were enrolled in a dietitian training program.Height and weight were measured and lifestyle habits investigated via a self–administered questionnaire. Energy intake was assessed using the Self–Administered Diet History Questionnaire (DHQ), and BS using the CGM (Free Style Libre Pro, Abbott) for 14 days.The range of 70 – 80 mg/dL was defined as Normal BS, >180 mg/dL as High BS, and <70 mg/dL as Low BS.

Results: The average height and weight were 158.3 ± 5.4 cm and 51.3 ± 6.3 kg, respectively.BMI was 20.5 ± 2.2 kg/m², similar to the mean values shown in the NHNS–J 2019 survey.The percentage of subjects with a BMI <18.5 was 12.0%. The questionnaire showed that the frequency of consuming a complete meal with staple, main and side dishes at least twice a day was 3 ± 2 days/week, the frequency of snacking was 5 ± 2 days/week, and 56% of the subjects consumed an evening meal at least once a week. Assessed by the DHQ, energy intake was 1,598 ± 288 kcal/day, with no significant differences in energy intake due to differences in body size or lifestyle. During the measurement period, the Normal BS, High BS, and Low BS values were 85%, 0%, and 15%, respectively, with Low BS appearing mainly during the late night and early morning hours. All of the subjects showed BS ≦ 60 mg/dL and severe hypoglycemia lasting more than 30 minutes.

Conclusion: Nocturnal hypoglycemia was observed in one healthy Japanese female subject in her 20s. The factors contributing to the appearance of hypoglycemia are under investigation.

Factors associated with physical inactivity among community-dwelling adults in Nigeria

Patricia Ogechi Ukegbu[1], Beulah Ortutu[1], Precious Chinaza Uche[1], Andrew Ugwunna Ukegbu[2]

1. Michael Okpara University of Agriculture, Umudike (Nigeria), 2. Federal Medical Centre, Umuahia Abia State (Nigeria)

Background and objectives: Physical inactivity contributes to the magnitude of non-communicable diseases (NCDs) and is responsible for premature deaths globally. The aim of this study was to examine physical inactivity and associated factors among community-dwelling adults in Abia State, Nigeria.

Methods: A community-based cross-sectional survey was conducted among 868 adults (20 to 59 years) using multistage sampling technique. Information on sociodemographic and lifestyle characteristics was obtained using a validated questionnaire. The weight and height were measured and used to calculate the body mass index (BMI). The Global Physical Activity Questionnaire (GPAQ) was used to collect data on physical activity status. Univariate and multivariate regression were used to assess the association of physical inactivity and associated factors at a *P*-value of <0.05.

Results: The prevalence of physical inactivity was 49.8% (48.5% in males and 51.0% in females), while combined overweight and obesity was 39.4%. Older age (OR=0.49, 95% CI: 0.34- 0.71), high BMI (OR=0.67, 95% CI: 0.49- 0.91), higher income (OR=0.65, 95% CI: 0.48- 0.89), and alcohol consumption (OR=0.67, 95% CI: 0.47- 0.97) were associated with physical inactivity.

Conclusion: The high prevalence of physical inactivity among adults underscores the need for community-based physical activity interventions to reduce the burden of NCDs among adults.

Characteristics of Cooking Class Recipes following the Great East Japan Earthquake: Analysis of Dishes, Foods, and Nutrition

Yuri Kinoshita[1], Kanako Sato[2], Yuka Miura[3], Natstumi Ishii[4], Naomi Ito[5], Ai Kuroda[6], Kayako Sakisaka[6], Yoshiharu Fukuda[6]

1. Tohoku Seikatsu Bunka Junior College (Japan), 2. Chukyo Gakuin Junior College (Japan), 3. The Ajinomoto Foundation (Japan), 4. Kashinoki Internal Medicine Clinic (Japan), 5. Fukushima Medical University School of Medicine (Japan), 6. Teikyo University Graduate School of Public Health (Japan)

Background and objectives: The "Fureai Red Apron Project" aims to support the mental and physical health of victims of the 2011 Great East Japanese Earthquake. Since then, Ajinomoto Group, The Ajinomoto Foundation (TAF) and local partners have held 3,771 cooking classes in the Tohoku region (the Iwate, Miyagi, and Fukushima Prefecture) with 54,434 participants. In a 2020 survey, approximately 90% respondents acknowledged the importance of a balanced diet. This study aims to list the characteristics of the class recipes through menu analyses.

Methods: Recipe records from 2012–2020, from 3,588 cooking classes were analyzed. The analysis calculated the menu creator, single-dish meals, foods, nutrients, and ingredient costs.

Results: The number of menu creations was 625 by local partners and 2,963 by TAF. The percentage created by TAF was 24.9% in 2012, and more than 90% since 2016. Four hundred and three recipes out of the 1,435 single-dish meals had known ingredients and were devised by TAF, which collectively used 254 different foods 62,221 times. The details of single-dish meals are: 159 staple dishes, 367 main dishes, 122 combined dishes (staple and main dish, e.g. *sushi*), 426 vegetable dishes, 215

soups, and 146 desserts/snacks. The main protein sources were 42.1% for meat and 30.5% for seafood. Of the combined dishes 20.5% were categorized as "*sushi*," and 13.1% as "*donburi* (rice bowls)." The most frequently used foods in the main food groups were: grain: rice 2,920 times, legume: fried tofu 569 times, vegetables: ginger 1,500 times, algae: wakame 485 times, seafood: canned tuna 400 times, meat: chicken 675 times, and seasoning spices: "*mentsuyu*" (soy sauce and dashi) 2,400 times. The nutritional composition per meal was in line with the TAF target (approximately 500 kcal of energy, at least 20 g of protein, and less than 3 g of sodium). The average cost of ingredients was 276.4±24.1 yen.

Conclusion: Cooking classes in the disaster area used common, simple, economical, and safe ingredients, and considered nutrition, food culture and the living conditions of the victims.

Keyword: cooking class, menu, dish, food, post-disaster

Conflict of Interest Disclosure: Kayako Sakisaka is received research fund from The Ajinomoto Foundation in FY2020-2022. Yuka Miura is an employee of The Ajinomoto Foundation.

Using the Ottawa Charter for Implement Healthy Eating Programs in Taiwan's Hospital

Ya Ling Wang[1,2], Hui Min Hsieh[1]

1. Taichung Veterans General Hospital (Taiwan), 2. Hungkuang University (Taiwan)

Background and objectives: Healthy lifestyles play an important role in the prevention of premature death, chronic diseases, productivity loss, and other social and economic concerns. Diet is an important factor in preventing obesity, and chronic diseases. We want to promote workplace nutrition interventions that involved counseling, education and on-site group activities. According to the analysis of 2013-2016 Nutrition and Health Survey in Taiwan, 86% of citizens have insufficient intake of vegetables and fruits. In 2017, a survey of employees' awareness /attitudes and behaviors about healthy meals was conducted, and 98.1% agreed that healthy meals can prevent chronic diseases, but only 30.7% of people selected healthy meals at least once a day. During 2019 to 2021, the hospital planned health promotion strategy and a series of nutrition-related topics to improve the diet of hospital employees. Promote the health of workplace colleagues through continuous activities.

Methods: Use the Ottawa Charter to guide the plan. It has 4 parts: producing propaganda, holding a teaching program of healthy meals, promoting sports, providing healthy meals, "Health Expert" competition, and implementing employee health promotion projects. We set the goals:

1. Increase the proportion of healthy eating motivation by 50%

2. Willing to choose healthy meals (the number of healthy meals diners) ≧50%

3. The number of participants in the step-counting measurement has increased by >50%

Results: Nutritionists introduce the diet by using different media to publish articles, posters, and videos. We also develop teaching programs and educate colleagues of multidisciplinary team meetings and staff canteens. After the promotion in 2019, up to 99.7% are willing to follow a healthy diet. In 2020, the accuracy of Dash dietary awareness increased from the original 33.3% and 34.3% to 93.3% and 91.7%after promotion. The improvement rate reached more than 100%. The number of participants in the step-counting measurement has increased more than50%. The staff restaurant provides healthy meals and encourages employees to purchase, also holds the "Health Expert" Contest, the winner was presented by the dean every year.

Conclusions: We enhance healthy eating behaviors, promote healthy workplaces, and ensure the ability to promote clinical health through establishing a healthy eating environment.

Meat cooking methods and impaired glucose metabolism among Japanese

Sakiho Irie[1], Akiko Nanri[1,2], Takeshi Kochi[3], Masafumi Eguchi[3], Isamu Kabe[4], Tetsuya Mizoue[2]

1. Fukuoka Women's University (Japan), 2. Department of Epidemiology and Prevention, Center for Clinical Sciences, National Center for Global Health and Medicine (Japan), 3. Department of Health Administration, Furukawa Electric Corporation (Japan), 4. Kubota Corporation (Japan)

Background and Objectives: Certain hazardous chemicals produced during high-temperature cooking of meats, including heterocyclic aromatic amine, polycyclic aromatic hydrocarbon, nitrosamines and advanced glycation end products, are suggested to be associated with increased risk of diabetes. However, few studies have examined the association between cooking method for meats and diabetes and no study has been conducted in an Asian population. Here, we examined the cross-sectional association between cooking method for meat and impaired glucose metabolism. We hypothesized that the prevalence of impaired glucose metabolism would be high among participants who most frequently cook meat by deep-frying.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: Participants were 1832 men and women (aged 18-69 years) with no history of serious disease. Participants were asked to select the most frequently used cooking method for meat from 5 options (raw, stewing, broiling, deep-frying, and stir-frying). Multiple logistic regression analysis was used to estimate the odds ratios of impaired glucose metabolism (history of diabetes, current use of anti-diabetic drugs, fasting blood glucose ≧110 mg/dl, or HbA1c ≧6.0%) for each cooking method.

Results : The number of participants by the most frequently used cooking method for meat was 2 (0.1%) for raw, 68 (3.7%) for stewing, 1253 (68.5%) for broiling, 66 (3.6%) for deep-frying, and 443 (24.2%) for stir-frying. Participants who indicated raw as the most frequent cooking method were excluded from the present analysis due to their small number. Of the remaining 1830 participants, 203 participants (11.1%) were identified as having impaired glucose metabolism. Cooking method for meat was not significantly associated with impaired glucose metabolism: compared with broiling, multivariable-adjusted odds ratios (95% confidence interval) were 1.20 (0.54-2.66) for stewing, 1.19 (0.50-2.87) for deep-frying, and 0.73 (0.49-1.10) for stir-frying.

Conclusions : Contrary to our hypothesis, deep-frying as a cooking method for meat was not associated with the prevalence of impaired glucose metabolism.

Keyword: cooking method, meat, Japanese, impaired glucose metabolism, type 2 diabetes

PAB(T6)-24
The effectiveness of lifestyle interventions on the prevention of type 2 diabetes: A systematic review and meta-analysis of evidence from low- and middle-income countries

Diana Sagastume[1], Irene Siero[1], Elly Mertens[1], James Cottam[1], Chiara Colizzi[1], José L. Peñalvo[1]

1. Institute of Tropical Medicine Antwerp (Belgium)

Background and objectives: T2D is largely preventable by adhering to an optimal lifestyle as suggested by an extensive body of evidence conducted in HICs. However, its generalisability to settings with constraint resources remains uncertain. This study aims to evaluate the effectiveness of lifestyle interventions on the prevention of T2D in LMICs.

Methods: A systematic review and meta-analysis was conducted in MEDLINE, Embase, Web of Science, and Cochrane Library for studies published in English, Spanish, French, and Portuguese between 1 January 2000 and 23 June 2021. The eligibility criteria included RCTs evaluating multi-component and multi-target lifestyle interventions in high-risk populations living in LMICs. The Cochrane risk-of-bias tool for randomised trials was used to assess the risk of bias. The main outcomes were the incidence of T2D and indicators of glycaemic control. Inverse-variance random-effects meta-analyses calculated the overall effect sizes and 95% CI. Heterogeneity was measured by Cochran's Q and I^2 statistics and explored using multivariate meta-regressions. Funnel plots and Egger's test were used for publication bias assessment. If present, trim-and-fill adjusted pooled effect sizes were estimated.

Results: From 11,885 abstracts identified, 43 interventions met the eligibility criteria of which 81.4% were conducted in Asia, 16.3% in America, and 2.3% in Africa. 32.6% of the studies were considered at low risk of bias, 55.8% were ranked as moderate risk, and 11.6% as high risk. The interventions had a median of 260 (IQR: 142 to 507) participants and a median duration of 6 (IQR: 3 to 12) months. Study-specific estimates per outcome ranged between 31 - 7estimates. Overall, lifestyle interventions considerably decreased the incidence risk ratio of T2D by 28% (0.72, 95% CI: 0.58 to 0.90), and reduced the levels of HbA1c by 0.17% (-0.30 to -0.05), and 2-hr glucose tolerance by 4.98 mg/dL (-8.40 to -1.56). After adjusting for publication bias, no effect was found for FPG. Substantial, and unexplained, levels of heterogeneity were observed for all outcomes (I^2≧ 82.0%).

Conclusions: The results of this study support the use of comprehensive lifestyle interventions as an important public health strategy for the prevention of T2D, among high-risk populations in LMIC.

Effects of parental psychological factors on the anthropometric characteristics of children with intellectual disabilities

Akemi Nishide[1]

1. Ibaraki Christian University (Japan)

Background and objectives: A higher frequency of overweight in children with intellectual disabilities is well known[1,2]. Their environment, such astheir parents' attitude towards health matters, may affect this issue, however, this link has not yet been well established. The aim of study was to examine how parental psychological factors, such as self-efficacy and outcome expectancy, affect the anthropometric characteristics of children with intellectual disabilities.

Methods: We conducted a cross sectional study involving sixteen schools for special needs education in Ibaraki prefecture, Japan. A questionnaire regarding the parents' self-efficacy, outcome expectancy and a brief self-administered diet history questionnaire (BDHQ) was distributed to parents of all school children in first grade to sixth grade of elementary department aged 6 yr to 13 yr at the beginning of September. We analysed

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

children who were completely answered these questionnaires. The exposure variable was the anthropometric characteristics such as lean, normal, overweight, assessed using the height and weight measurements self-reported on the BDHQ. The parents' self-efficacy and outcome expectancy were assessed using a five-ordinal scale. We used logistic regression analysis to estimate odds ratio with 95% confidence interval for analysis of effects of these parental factors on the anthropometric characteristics of children with intellectual disabilities.

Results: We observed an association between parental psychological factors and the anthropometric characteristics of the children with intellectual disabilities.

Conclusions: Support, such as a school-based nutrition education program, may be required to develop parental attitude influencing the eating behaviour of children with intellectual disabilities. The use of these types of programmes might be required for the healthy development of mind and body, which could be one of the factors which determine their future quality of life.

Chronic non-communicable diseases in relation to healthy habits and behaviors in employees of an educational institution

Lourdes Lazo[1], Miriam Perez[1], Luciana de la Fuente[1], Jamhil Moyano[1], Jose Chaquila[1], Luis Baquerizo[1]

1. San Ignacio de Loyola University (Peru)

Background and objectives: Health is a fundamental right of all people, without distinction of religion, race, economic, social, or religious status. To achieve this, responsible and cooperative work by everyone, and from public and private entities and states, is essential. Considering that chronic non-communicable diseases are the leading cause of death worldwide, but can be controlled, and above all, preventable, and that lifestyle habits also have an impact on it, our objective was to identify healthy habits and behaviors in relation to chronic non-communicable diseases in the collaborators of an educational group. **Methods**: As part of the 2021 annual medical-occupational evaluation in San Ignacio de Loyola Corporation, clinical exams were carried out and a digital survey called “Healthy Habits and Behaviors” was applied to 610 employees between 23 and 70 years old. The descriptive analysis was expressed in proportions. **Results**: The evaluated population presents a regular sleep between 6 and 8 hours (85.08%), as recommended by the WHO, most of those who sleep between 6 to 7 hours (29.34%) and more than 8 hours (1.64%), perform physical activity for at least the recommended time. 62.62% indicate that they do not present any of the diseases consulted (heart disease, hypothyroidism, hypertension, excess weight). 48.36% perform physical activity for 30 consecutive minutes at least three times a week, while 51.64% indicate that they do not. Unlike people with heart disease, hypothyroidism or hypertension, the majority of people with obesity (3.11%) do not perform the minimum amount of physical activity recommended. Most of those with high blood pressure (3.44%) and overweight (16.39%) indicate that stress or anxiety negatively affects their diet. **Conclusions** It is extremely important to know the prevalence of knowing the prevalence of cardiometabolic risk factors to join efforts, addressing the improvement in the form and quality of life from public policies to responsible individual care. Given this, companies and workspaces become relevant with the actions they carry out to promote and raise awareness of health.

Understanding supports for and barriers to school food environment and childhood obesity prevention in Thailand: a qualitative study

Panrawee Praditsorn[1], Kitti Sranacharoenpong[1], Piyanit Churak[1]

1. Mahidol Univercity (Thailand)

Background and objective: The prevalence of childhood overweight and obesity has increased dramatically due to the school food environment. However, information on the factors linked between school food environment and childhood obesity is scarce in Thailand. This study aimed to investigate supports for and barriers to a healthy school food environment concerning obesity in school-age children.

Methods: This study was conducted at public and private primary schools in the central region of Thailand. Data were collected from sixteen in-depth interviews with school staff and 18 focus group discussions with 9 to 12 years old students. Code transcripts from the interviews were analyzed manually. Hurricane analysis was used to illustrate the relationship among variables from data analysis and gain a new perspective on those data. Concept mapping was used to depict the relationship of supports and barriers to improving the school food environment.

Results: This study found four main themes: food access, facilities, knowledge support, and school food/health policies related to childhood obesity prevention and school food

environment. Participants realized that nutrition knowledge was crucial for preventing less healthy food access to students. The current nutrition training program for school staff was needed to improve. In addition, a much more specific practice on the quality of school lunch management was required.

Conclusions: The findings point to numerous inter-and intra-relationships of support for and barriers to factors responsible for preventing childhood obesity and improving the school food environment. Understanding the risk factors in which the food environments affect childhood obesity is a crucial component to designing interventions that increase the availability of healthy and affordable foods, thus improving the health of semi-urban school communities. It is anticipated that policymakers will consider the national application of this approach for food and nutrition planning and preventing non-communicable diseases for children.

PAB(T6)-28
Understanding mothers perceptions regarding the weight of their preschool children with overweight and normal weight , Lima

Daniela Salazar Lau[1], Jannierina Flores Joaquin[1], Doris Delgado Perez[1]

1. Universidad Nacional Mayor de San Marcos (Peru)

Backgrounds and objectives: The prevalence of obesity in children under five years old has increased and it's important that mothers recognize that their child has a problem with his weight. Objectives: To understand mothers' perception of their normal or overweight children's weight from low socio-economic status in Lima, Peru.

Methods: Qualitative in-depth semi-structured interviews were conducted with 16 mothers of eight preschool children who were overweight and eight with normal weight who attended at the health facility of Lima, Peru. Interview was transcribed verbatim by hand and used thematic analysis.

Results: Two main themes were identified: 1) Interpretation of weight: most of the mothers of overweight children had a mistaken perception, indicating that their child had an adequate weight. There were also mothers with normal children's weight who expressed concern because they perceived that their child was underweight. Mothers who did not perceive excess weight in their child believed that they gave a healthy diet to their children. Those who perceived the existence of excess weight expressed two different reasons: first, the excess was due to the consumption of energy-dense foods and second, they were self-blaming for inadequate feeding practices with their child. 2) Prevention of excess weight: all the mothers considered that their children's weight should be monitored to keep them healthy and ensure adequate growth. Mothers with overweight children who see them at an adequate weight were aware that excess weight was a condition for chronic diseases.

Conclusions: The findings suggest that maternal perception of the child's weight was connected to their interpretations of their child's weight and daily dietary practices. Mothers with normal-weight children saw them as thin, while mothers with overweight children perceived them to be underweight or overweight. However, there were mothers who were aware of the fact that excess weight leads to chronic diseases and that it was important to feed them healthy for adequate growth.

Global association between Traditional Japanese diet score and hypertension prevalence: a cross-sectional and longitudinal ecological study

Chisato Abe[1,2], Tomoko Imai[2,3], Ayako Sezaki[4,5], Keiko Miyamoto[6], Takumi Kato[2,7], Norie Sugihara[8], Hiroshi Shimokata[2,4]

1. Tsu City Colleage (Japan), 2. Institute of Health and Nutrition, Nagoya University of Arts and Sciences (Japan), 3. Doshisha Women's College of Liberal Arts (Japan), 4. Graduate School of Nutritional Science, Nagoya University of Arts and Sciences (Japan), 5. Ryukoku University (Japan), 6. Nagoya University of Arts and Sciences (Japan), 7. Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital (Japan), 8. Ochanomizu University (Japan)

Background and objectives: Traditional Japanese diet is thought to contribute to the healthy longevity of Japanese people. We established the Traditional Japanese Diet Score (TJDS) using common foods and reported through ecological studies that the TJDS has associated with longer healthy life expectancy and lower incidence and mortality of several non–communicable diseases worldwide. On the other hand, the traditional Japanese diet is high in salt, which is thought to be one of the causes of elevated blood pressure and hypertension. The purpose of this cross–sectional and longitudinal ecological study is to clarify the global association between TJDS and hypertension prevalence.

Methods: Average food supply (g/day/capita) by country were obtained from the Food and Agriculture Organization of the United Nations database. TJDS by country was calculated from eight food groups and the total score ranged from –8 to 8, with higher scores indicating greater adherence to a traditional Japanese diet. Hypertension prevalence by country was obtained from NCD Risk Factor Collaboration. As covariates, we used GDP per capita, aging rate, years of education, smoking rate, physical activity, average BMI, energy supply, and sodium intake obtained from the World Bank database and other sources. We evaluated the cross-sectional and 10–year longitudinal association between TJDS and hypertension

prevalence using 2009 as the baseline in 140 countries with populations of more than one million.

Results: In cross–sectional analysis, in model 1 without controlling for covariates, model 2 controlled for GDP, and model 3 controlled for all covariates, TJDS was negatively associated with hypertension prevalence (β ± standard error; –0.010 ± 0.002, p<0.001; –0.011 ± 0.002, p<0.001; –0.007 ± 0.002, p<0.001; respectively). In 10–year longitudinal analysis, in model 1 without controlling for covariates, model 2 controlled for GDP, and model 3 controlled for all covariates, TJDS was negatively associated with hypertension prevalence (–0.010 ± 0.002, p<0.001; –0.011 ± 0.002, p<0.001; –0.007 ± 0.002, p<0.001; respectively).

Conclusions: This cross–sectional and longitudinal ecological study suggests that the traditional Japanese dietary pattern have associated with suppressed the prevalence of hypertension in the following 10 years on global scale.

An online-based, supportive group nutrition coaching program as a tool for weight loss during COVID-19: a single-arm trial

Mochammad Rizal[1,2], Desty Muzarofatus[2,3], Didit Pamungkas[2,4], Nur Mu'izza[5], Dian Agnesia[2,6]

1. Cornell University (USA), 2. Indonesia Sport Nutritionist Association (Indonesia), 3. Universitas Muhammadiyah Gresik (Indonesia), 4. DBL Academy Indonesia (Indonesia), 5. RSUD Ibnu Sina Gresik (Indonesia), 6. Politeknik Kudus (Indonesia)

Background and objectives: The global prevalence of obesity is worsened with the emergence of COVID-19, including in Indonesia. Obesity, on the other hand, is also a risk factor for severe COVID-19 outcomes. Several consequences are attributable to the implementation of physical distancing, such as limited access to healthcare and healthy food, sedentary lifestyle, and stress that may lead to weight gain. Therefore, there is a need to get past the geographical barrier in the effort of overcoming obesity. This study aimed to evaluate the effect of an online-based, supportive group Nutrition Coaching Program (NCP) on weight loss during COVID-19.

Methods: This study involved 61 participants across Indonesia (female: 91.8%) between August and September 2021. Participants were recruited from social media (Instagram) based on their interest in joining 30-day NCP. Prior to joining the program, participants self-reported their age, height, and weight to determine BMR for creating a 30-day meal plan, and they re-weighed themselves after completing the program. They were instructed to consistently measure their weight on an empty stomach in the morning. Participants were added to a WhatsApp group to receive the meal plan during the program, which they could modify using the Indonesian exchange food list table (DBMP). The meal plan consisted of a 10-day menu rotation containing food ingredients, weights, and recipe samples. They were also given exercise guidelines, weekly thematic nutrition education, daily supportive reminder, and question-and-answer sessions by registered nutritionists and a sports scientist. Paired t-test was used to analyze weight changes before and after the program.

Results: The participants' baseline characteristics were (mean±SD): age 33±5 years, height 158.3±7.2 cm, weight 71.6±12.9 kg, BMI 28.5±4.5 kg/m^2, and BMR 1311.6±161.6 kcals. Weight measurements before and after the program were 71.6±12.9 kg and 68.4±11.9 kg, respectively (p<0.001). Furthermore, the weight loss was 3.1±3.0 kg during 30 days which is considered within the healthy rate for weight loss (0.5-1 kg/week or 2-4 kg/month).

Conclusion: Online-based, supportive group NCP may potentially help weight loss during COVID-19. Further investigation is needed to obtain more robust data on the effectiveness of an online-based nutrition education program in combating obesity.

Keyword: Obesity, Overweight, Weight loss, Nutrition education, COVID-19

PAB(T6)-31
Relationship between green tea intake and human gut microbiota on glucose metabolism: a four-season nutritional survey

Aoi Ito[1], Hiroki Tachibana[1], Akiko Kawashima[1], Haruka Kawabata[1], Goto Chiho[2], Kiyonori Kuriki[1]

1. University of Shizuoka (Japan), 2. Nagoya Bunri University (Japan)

Background and objectives: Little is known about the extent to which depends on the association between green tea intake and human gut microbiota (HGM) on glucose metabolism. This study aims to examine the biological process related to glucose metabolism by modifying the human gut microbiota HGM via green tea intake, considering seasonal variations.

Methods: At each season, 89 non-diabetic participants supplied blood and faecal samples, 3-day weighed dietary records. The relative abundance of HGM was profiled using a next-generation sequencing approach. Biomarkers of glucose metabolism such as fasting blood glucose, haemoglobin A1c and insulin were measured. The respective associations among green tea and catechins intake, the HGM and the biomarkers of glucose metabolism were analysed using linear mixed-effect model with multiple imputation for missing values. We used a false discovery rate p-value to adjust for multiple comparisons with a threshold of < 0.20. Mediation analysis was performed to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

determine whether the HGM can explain the effect of green tea intake on glucose metabolism.

Results: Green tea intake was negatively associated with fasting blood glucose and insulin ($p < 0.05$), marginally lower in autumn than in winter. Green tea intake was not related to any HGM, while the relative abundance of Actinobacteria and *Bifidobacterium* were associated with lower insulin and HOMA-IR (false discovery rate $p < 0.20$). The mediation effect of HGM was not found.

Conclusions: In non-diabetic participants, we demonstrated that habitual consumption of green tea, and two types of bacteria separately modulate insulin secretion to improve glucose metabolism, which was influenced by the season.

Basic research on a proposing nutrient profile model for Japan

Yoshiko Ishimi[1], Jun Takebayashi[2], Yuri Yokoyama[3], Takahiro Yoshizaki[4], Yuki Tada[5], Emiko Okada[2], Hidemi Takimoto[2]

1. Research Institute of Agricultural and Life Sciences, Tokyo University of Agriculture (Japan), 2. National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 3. Tokyo Metropolitan Institute of Gerontology (Japan), 4. Faculty of Food and Nutritional Sciences, Toyo University (Japan), 5. Department of Nutritional Science, Tokyo University of Agriculture (Japan)

Objectives: A nutrient profile model ranks foods according to their nutritional composition, which allows individuals to make well-informed dietary choice. No nutrient profile model has yet been developed in Japan while such models are likely to be context specific. Therefore, this study aimed to propose a nutrient profile model applicable to the Japanese population.

Methods: We proposed a Japanese nutrient profile model for processed foods based on the protocol of World Health Organization (WHO) 2010 technical meeting report, WHO guiding principles and framework manual for front-of-pack labeling for promoting healthy diets in 2019, and several models used in other countries. The data from the Japanese National Health and Nutrition Survey (NHNS), Dietary Reference Intakes for Japanese (2020), Standard Tables of Food Composition in Japan 2015 (7th revised edition), and Nikkei-POS database were used as the reference data.

Results: Considering the nutrition status of Japanese population, we proposed the model to target those aged 18 years or older. A category-specific (threshold setting) model was adopted with setting thresholds to avoid overconsumption of total fat (≧30% of total energy), saturated fat (≧7% of total energy), sodium (1.25 ≧ mg/kcal) or salt equivalent (≧ 3g/650kcal meal), and energy (category specific) for processed foods and prepared foods. Processed foods were classified into 15 categories based on the Japanese NHNS. Seasonings such as soy sauce and miso, and oils were separately considered as a part of nutrient profile of dishes. We set the nutrient criteria for the proposed model and determined thresholds for each food category. When the thresholds of each food category were compared with those set in the models of other countries, no substantial difference was observed. However, more than half of food items exceeded the thresholds for salt equivalent in some categories, namely bread, dry noodles, pickles, fish, meat and egg products, and some of prepared foods.

Conclusions: The present nutrient profile model was proposed to meet the Japanese context in terms of public health nutrition status. Further consideration on the applicability is needed to improve this model in line with the practical status in Japan.

Keyword: nutrient profile models, processed foods, prepared foods, food category , threshold value

PAB(T6)-33
Relationship between maternal socioeconomic status and infant children's sleep and breakfast habits

Miyo Nakade[1], Tetsuo Harada[2], Misako Kawamata[2], Mamiko Kurotani[3], Mayuko Inari[1], Fumiaki Hanzawa[4], Hitomi Takeuchi[2]

1. Tokai Gakuen University (Japan), 2. Kochi University (Japan), 3. Aichi Gakusen University (Japan), 4. University of Hyogo (Japan)

Background and objectives: In Japan in recent years, there is concern that differences in regional and socioeconomic environments are causing significant health disparities. Parents' education level and socioeconomic status (SES) has an effect on children's sleep habits, and can lead to disparity in infants' lifestyle habits. This study investigated the relationship between maternal SES and their infant children's breakfast and sleep habits, as well as their lifestyle rhythm.

Methods: An online survey was conducted in June 2019, targeting mothers aged 20-49 with children aged 3-5. The questionnaire surveyed the mother and children's breakfast habits, sleep habits, circadian typology (CT), household income for the previous year, and the mother's level of education. 1,529 responses (average age 36.2 ± 5.0 years), were targeted for analysis. Responders were divided into two groups: the first included mothers with a high school education and below (23.8%) and those with a junior college education and above (76.2%); the second group included mothers with an annual household income of less than 4 million yen (24.3%) and those with an annual household income of 4 million yen or more (75.7%). Results were examined using the X2 test, Mann-Whitney U test, using logistic regression analysis (variable increase method).

Results: Children of higher-educated mothers were more likely to consume breakfast daily at a regular time. Children also slept earlier ($p=0.003$) and woke up earlier ($p<0.001$), but no difference was observed in sleep duration. CT was morning-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

typed (p<0.001). Children in higher-income households had consistent breakfast habits and early waking times on weekdays (p=0.048), with a morning-typed CT (p=0.020). A logistic regression analysis based on whether or not the child is evening-typed (score of 7-13) as the dependent variable determined an association with parents' CT and regularity of children's breakfast habits, but not with higher income and education.

Conclusions: Although mothers and children with higher SES (particularly higher-educated mothers) generally had better sleep and lifestyle habits, as well as higher breakfast regularity, there was no direct relationship observed between SES and children becoming evening-typed, suggesting that low SES is not necessarily associated with children becoming evening-typed.

Keyword: Socioeconomic status, Circadian typology, Breakfast habits, Sleep habits

The Evolution of Thai Dietary Assessment Software: INMUCAL-Nutrients

Punnee Ponprachanuvut[1], Nuttarat Srisangwan[1], Arisa Keeratichamroen[1], Kantanit Chammari[1], Kitti Sranacharoenpong[1]

1. Mahidol University (Thailand)

Background and objectives: Nutritionist researchers have unique computational softwares to calculate nutrients. Institute of Nutrition, Mahidol University (INMU) has been developing the INMUCAL-Nutrients (INMUCAL) software from DOS version since 1980s for Thai and Asian nutritionists and all needed. The INMUCAL is quite unique software that contained Thai and Asian food database from various sources. The objective of this study was to describe process development of the INMUCAL software for Windows version.

Methods: The INMUCAL consisted on 4 main databases; Thai food composition databases (Thai-FCDB), edible-inedible food database in gram, conversion factors from cook to raw, and household unit converting in gram. The data structure was developed and prepared based on FAO/INFOODS Guidelines by INMU-DatabasesCompiler (iDC) software. The both software are run on Windows based software, which were developed by Pascal programming language on Delphi software. MySQL sever were used to store the FCDB.

Results: The iDC was able to compile, store information and edit data. FCDB is a uniquely accurate and compliant databases containing over 3,500 food items and recipes. The number data of edible-inedible foods, household unit converting, conversion factors from cook to raw and oil absorption factors were 483, 14,899, 2,225 and 657 data, respectively. The INMUCAL was able to generate 35 nutritive vales as default comparing to the nutrient reference. It also can export food groups and food items comparing to food guidelines. The outputs were exported to Microsoft Excel format for further statistical calculation. The INMUCAL has been also provided the online training for the new users and online supported.

Conclusions: The INMUCAL for Windows version is the user friendly. It can reduce human errors. The software has the potential to increase the accuracy and efficiency in diet design and provide standardization among researchers conducting similar studies. The INMUCAL is an example of how researchers and industry can work together and develop products that not only has research benefits, but also generates follow-on research and additional commercial products and opportunities for the developer. Ultimately, the INMUCAL and associated products will result in company and employment growth while providing for government computing needs.

Estimating the future burden of type 2 diabetes in Belgium: a modelling study

Elly Mertens[1], Junior Ocira[1], Chiara Colizzi[1], Diana Sagastume[1], Maria Salve-Vasquez[2], Stefanie Vandevijvere[2], Jose L Penalvo[1]

1. Institute of Tropical Medicine (Belgium), 2. Sciensano (Belgium)

Objective: To estimate the burden [the incidence, prevalence and mortality] of type 2 diabetes [T2D] in Belgium over ten years [2018-2028] **Methods**: A microsimulation model [MSM] was developed and implemented as a discrete-event state transition model with two events T2D and death, updated annually. Information from a representative [age, sex, and province] sample of the Belgian adult population [18-80 years] provided by the latest [2018] Belgian Health Interview Survey and complemented with estimates on the prevalence of cardiometabolic risk factors from the latest [2018] Belgian Health Examination Survey was used to recreate a Belgian synthetic population using the R package SimPop after Multiple Imputation by Chained Equations. Starting annually since 2018, individuals in the MSM transition from health to death, with or without developing T2D, were estimated using the Finnish Diabetes Risk Score's concise model with prevalent risk factors [e.g. hypertension, BMI] updated via age-sex-specific transition probabilities. Mortality rates for Belgium were retrieved from the Standardized Procedures for Mortality Analysis database and used to calculate the death probabilities used through the MSM. **Results**: A total of 3275 [95%UI: 3263, 3287] incident cases T2D per 100,000 inhabitants are expected between 2018 and 2028 in Belgium, with higher rates among older individuals. A modest gender-related gap in T2D incidence, unfavorable to females, is foreseen to increase over the course of 10 years. A total of 393 [387, 400]/100,000 new cases among females compared to 378 [371, 384]/100,000 in males are estimated for 2028. Prevalent T2D is expected to increase by 2028 for both females [+16.4%] and males [+12.6%] from 2018 levels (5419 [5387, 5442]/100,000, and 5627 [5605, 5650]/100,000 respectively). Mortality rates attributed to T2D are expected to remain relatively low (119 [117, 122]/100,0000) and stable up to 2028. A slight decrease in mortality rates among the 65+ years

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

old is expected. **Conclusion**: The burden of T2D in Belgium is expected to remain high over the next years. Preventive strategies should be strengthened to delay the onset of new T2D cases and decrease the burden.

Keyword: Type 2 diabetes, Burden, Microsimulation model

PAB(T6)-36
Assessing food environments in low- and middle-income countries—unlocking the potential to improve diets, nutrition, and health outcomes

Jennifer Crum[1], Selena Ahmed[2], Gina Kennedy[3], Chris Vogliano[1]

1. USAID Advancing Nutrition (USA), 2. Montana State University (USA), 3. Global Alliance for Improved Nutrition (GAIN) (USA)

Background and objectives: Poor diets are a major contributor to the global burden of disease. Various food system factors shape diets, especially through food environments where food and consumers meet. Globally, foods are increasingly procured from markets. Understanding market food environments is critical to influence food choices toward safe, nutritious diets. However, few assessments are suitable for use in diverse LMIC contexts. USAID Advancing Nutrition is helping identify suitable assessments to support practitioners to implement market food environment assessments and to use resulting data to influence food environments toward safe, nutritious diets.

Methods: Through literature review and expert survey, USAID Advancing Nutrition identified a set of seven existing food environment assessments for adaptation and testing in diverse LMICs. Through market vendor interviews and focus group discussions, we are gathering primary data on key dimensions of market-based food environments, such as accessibility, availability, affordability, and desirability of foods, and qualitative data on implementers' experiences conducting assessments. USAID Advancing Nutrition is analyzing the data to understand if the assessments are suitable for capturing food environment data that supports programmatic actions, and if modifications can facilitate implementing the assessments in LMICs.

Results: This ongoing pilot study will test market-based assessments in multiple LMICs. In Liberia, we found that modifying existing assessments enhanced their suitability for use in markets to collect data on vendor characteristics, diverse food availability, and costs of nutritious foods. We found that a more complex assessment may not be suitable across contexts, and can be replaced with a simpler validated assessment to gather data on nutritious food availability. Through qualitative assessment of implementation experiences, we identified additional modifications that will further support assessment suitability in LMICs.

Conclusions: Results from this study will enhance market food environment data collection across LMICs by providing evidence-based tools suitable for use in diverse contexts. Results will enable a more comprehensive understanding of market food environments in LMICs to support food systems approaches that improve the affordability, availability, and desirability of safe, nutritious food. Equipped with suitable assessments, practitioners will be empowered to unlock the potential for food environments to improve diets, nutrition, and health.

PAB(T6)-37
Different types of fats but not total fat intake are associated with cardiometabolic risk factors in adults of a population-based study in Brazil

Lais Duarte Batista[1], Mariane de Mello Fontanelli[1], Regina Mara Fisberg[1]

1. University of Sao Paulo (Brazil)

Background and objectives: Emerging evidence has suggested that fats would have complex health effects, and their role in the etiology of cardiometabolic diseases is not fully elucidated. Thus, this study aimed to evaluate dietary fat adequacy and explore the relation between cardiometabolic risk factors and dietary intake of different types of fats among São Paulo residents.

Methods: Data came from the Health Survey of São Paulo, a cross-sectional population-based study including 603 individuals aged 20+ years representative of the population of São Paulo, Brazil. Dietary intake of total fat, saturated fat, MUFA, and PUFA was assessed by 24-hour recalls, and adequacy was evaluated according to the Brazilian Society of Cardiology, which is based on the markers of dyslipidemia. Cardiometabolic risk factors included: total cholesterol, HDL-c, LDL-c, triglycerides, waist circumference, fasting plasma glucose, and body mass index (BMI). Associations between risk factors and dietary fats adequacy (the proportion of individuals meeting the recommendations) were evaluated by logistic regression models. The association between the percentage of energy intake from each type of fat and cardiometabolic risk factors was assessed by generalized linear models. All models were adjusted by age, sex, and energy intake.

Results: Adequacy of total fat intake was 72%. On the other hand, 96.8% of the population had a consumption of saturated fat above the recommendations, while most of the population did not ingest enough MUFA and PUFA (91.5% and 97.4%, respectively). Individuals with a saturated fat intake above recommended levels had higher *odds* of having a waist circumference indicative of very high cardiometabolic risk (OR=2.96; p=0.044). The intake of saturated fats was positively associated with waist circumference (p=0.007) and BMI (p=0.01). No significant results were found for total fat intake.
Conclusions: There was excessive consumption of saturated fat and an insufficient intake of MUFA and PUFA among São Paulo adults. This inadequate intake was associated with cardiometabolic risk factors, especially related to saturated fat. Rather than recommending the reduction of total fat intake, policies should emphasize the consumption of MUFA and PUFA to the detriment of saturated fat as a strategy to prevent cardiometabolic issues.

Food handling practices, nutrition knowledge and attitude of staff at Early Childhood Development centers in the Western Cape Metropole, South Africa.

Yolande Smit[1], Lisanne Du Plessis[1], Rafael Perez-Escamilla[2]

1. Stellenbosch University (South Africa), 2. Yale School of Public Health (USA)

Background: Early childhood development centres (ECDCs) provide a potential environment where children can develop healthy eating behaviors. A well-planned menu, prepared in a safe and nutritious way can meet up to a third of a young child's daily dietary needs whilst in a day-care facility. Guidelines for the provision of food in ECDCs in South Africa (SA) exist but data on the implementation is required. Objectives were to evaluate the food preparation environment, staff food handling practices and nutrition knowledge and attitudes of staff in promoting healthy eating.**Methods**: A cross-sectional, descriptive study was conducted. An observational audit was completed at 46 randomly selected ECDCs. For inclusion, ECDCs had to be in operation for at least 6 months, cater for children 0-5 years and serving at least a meal and a snack per day (for children >6 months). Census sampling of ECD staff was done. Staff (N=162) completed a self-administered questionnaire. **Results**: Mean overall score for the observational audit was 50% (SD 11.78). Highest scores were obtained for personal hygiene (86.5%; SD 11.17), although regular handwashing was not observed (34.7%). Dry store storage scored 72.6%. Food handling practices had a mean score of 48.8%. Cleaning of work surfaces were insufficient (54.7%). Only 23.9% had a separate meal area. Staff sat with children during mealtimes (84.7%) and enough cutlery and crockery was available at 44 ECDCs (95.6%). Mean nutrition knowledge of ECD staff were 69.9% (SD 10.15). Lowest scores related to calcium-rich foods (17.3%) incorrect practice of replacement of fruit with fruit juice (38.2%), safe meat defrosting (30.8%) and safe storage of meat products (27.7%). The majority of staff (68%) disagreed with the statement: “It is only the parents' responsibility to ensure children eat healthy”. A statistically significant association was found between higher staff education level and disagreeing with this statement (p=0.042).**Conclusion**: There is substantial opportunity for improvement in the food environment at ECDCs in the Western Cape Province, SA. Regular monitoring should be a priority to ensure implementation and adherence to food provision guidelines with the aim of protecting and promoting the health of children attending ECDCs.

Correlation between Consumers' Inclination towards Healthy, Sustainable Food and Willingness to Pay: Analysis from the Standpoint of Socioeconomic Background, State of Food Intake, and Food Environments

Yukiko Ueda[1], Yukiko Kobayashi[1], Rikako Horie[2], Fumio Ohtake[2], Ayako Sezaki[1], Takahiro Mieda[3], Michitoshi Yamaguchi[1], Hajime Daimon[4], Akiko Kiyohara[5]

1. Ryukoku University (Japan), 2. Osaka Univesity (Japan), 3. Waseda University (Japan), 4. Kokugakuin Univarsity (Japan), 5. Fukuyama City University (Japan)

Background and objectives: As the media has great influence on daily food sales, consumers' food choice behavior is not necessarily rational. This is because individuals tend to prioritize immediate gains over long-term ones. In order to explore strategies to encourage rational behavior, this study examines the correlation between the inclination to buy healthy, sustainable food and willingness to pay (WTP) and the factors related to WTP.

Methods: An online survey among females aged 20 to 49 was outsourced to a private research firm. Survey items were: basic attributes, socioeconomic status (SES), eating habits, stores they frequently use, social capital (SC) index, and food insecurity (FI) index. A total of 1,110 responses were obtained, and the participants who do not shop and those with insufficient responses were excluded, which left 850 subjects to be analyzed. The Chi-square test was used to examine the correlation between consumers' inclination and WTP, and the logistic regression analysis was used for the factors related to WTP.

Results: The subjects inclined to buy food that leads to healthy meals (22.4%, “healthy group”) and those inclined to buy sustainable food (14.2%, “sustainable group”) showed their willingness to purchase despite the price. However, 30% of the subjects who responded “I would buy” did not show willingness after the price was shown. In the healthy group, the factors related to their willingness to buy were age, income, and educational background. As for the factors related to adjusted SES index and willingness, the subjects in the healthy group eat soy products at least once a day and the subjects in the sustainable group eat soy products and green and yellow

vegetables at least once a day. Furthermore, the healthy group was more actively involved in their local community.

Conclusion: Although there was a correlation between inclination and WTP, the gap between the two was also confirmed. In order to achieve consumers' rational behavior, it is necessary to create food environments that prompt people to choose healthy and sustainable food and to encourage them to change their behavior.

Increase in ultra-processed food consumption and micronutrient inadequacy in Indian population

Srishti Mediratta[1], Pulkit Mathur[2], Santu Ghosh[3]

1. University of Delhi (India), 2. Lady Irwin College, University of Delhi (India), 3. St John's Medical College (India)

Background and Objectives: Increased consumption of ultra-processed foods which are high in energy, fat, sugar and salt and low in micronutrients raises many public health challenges. This study assessed the consumption of ultra-processed foods and explored its impact on macronutrient intake and risk of micronutrient inadequacy.

Methods: A cross-sectional study design with non-probability purposive sampling followed by snowball sampling was used to collect dietary data from 589 adults (20-40 years) in Delhi, India. Nutrient intake was assessed using 24-hour dietary recall method on two non-consecutive days. Statistical software R (version 4.1.1) was used to analyse data. Mann- Whitney U test was used to assess difference in probability of nutrient inadequacy between males and females. The association between energy contributed by ultra-processed food and risk of micronutrient inadequacy was calculated by spearman's rank correlation. The p-value <0.05 was considered as statistically significant.

Results: The contribution to energy intake by fat, protein and carbohydrate was 33%, 9.5% and 56% respectively. Ultra-processed foods contributed to 17% of total energy intake, 12 % of protein, 17% of carbohydrate, 29% of added sugar, 20% of total fat and 33% of sodium intake. The nutrient contribution from ultra-processed food intake was significantly higher among males than females for energy (17.7% vs 16.7%), total fat (22% vs 19.2%) and free sugar (32.7% vs 24.1%). The average risk of nutrient inadequacy was above 90% for calcium, zinc, riboflavin, vitamin B6, vitamin B12, vitamin D and males had a higher risk of inadequacy ($p<0.001$). The average risk of niacin inadequacy among males was 83% and 44% among females ($p<0.001$). The average risk of iron inadequacy among males was 6.5% and 58% among females ($p<0.001$). The average risk of vitamin A inadequacy among males was 44% and 68% among females ($p<0.001$). There was positive correlation between energy contributed by ultra-processed food and the risk of niacin ($\rho=0.136$, $p=0.001$) and folate ($\rho=0.089$, $p=0.049$) inadequacy.

Conclusions: Reformulation of ultra-processed food to reduce fat, sugar and salt, behaviour change communication strategies to encourage healthier food choices and promotion of dietary diversity will help improve micronutrient adequacy and quality of diets.

Association between dietary behavior and psychological impact on university students during the state of emergency in Kochi, Japan

Masayuki Nakano[1], Yuko Araki[1], Keiko Watanabe[1]

1. Kochi Gakuen University (Japan)

Background and objectives: The negative psychological impacts induced by stressful events alter dietary habits and eating patterns. To prevent the spread of SARS-CoV-2, many countries employed various measures such as restrictions on movement of people. Such restrictions might induce psychological distress. The restrictions were also implemented in Japan, but these were much less restrictive than the lockdown introduced in other countries. In addition, the number of infection cases varies between small regional towns and the major cities in Japan. The purpose of this study was to access the psychological distress and changes in dietary habits under the restrictive measures implemented in a small regional city in Japan with low number of infections.

Methods: A questionnaire-based cross-sectional survey was conducted on university students (N = 356) in the Kochi prefecture of Japan. We asked participants about their lifestyle and dietary habits during the restrictive measures. We also assessed their psychological distress levels using a distress index. To evaluate the association between psychological distress and dietary habits, we performed statistical analyses using a multiple logistic regression analysis.

Results: The prevalence of moderate and severe psychological distress was in 17% of the population. Furthermore, 38% of participants exhibited irregular eating habits. Participants who had irregular eating habits increased consumption of snacks and the ready-to-eat meals. We found that psychological distress levels were higher in participants who

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

had irregular eating habits compared to those with normal eating habits. A multiple logistic regression analysis for checking the prevalence of irregular eating habits revealed the extent of participants' psychological distress score (odds ratio [OR]: 1.07, 95% confidential interval [CI]: 1.04-1.10, for every one point increase) and human-to-human contact (OR for normal opportunity, OR: 5.02, 95% CI: 1.51-16.70, vs less opportunity).

Conclusions: Our results indicate that residents who lived in a small regional city in Japan with low infection cases experienced psychological distress and irregular dietary habits during the restrictive measures. The association of psychological distress and the prevalence of irregular dietary habits among the population, as shown by this study, could be due to the additive effects of restrictive measures and lifestyle of residents.

Evaluation of the usefulness of the number of vegetable items as a simple indicator of vegetable intake

Mari Kitamura[1], Hiroko Nakanishi[1]

1. Mukogawa Women's University (Japan)

Background and objectives: This study aimed to clarify the relationship between the number of vegetables and vegetable intake in daily diet and examine the efficacy of the number of vegetables as a simple indicator of vegetable intake.

Methods: In May 2020, 88 female university students participated in a two-day dietary record survey. We examined their intake of vegetables and the number of vegetable items at home. Correlation coefficients between the amount of vegetable intake and number of vegetable items were obtained. The second survey was conducted using ready-made lunch boxes. Twenty-seven types of lunch boxes containing vegetables sold in convenience stores, supermarkets, department stores, and school cafeterias were used, and the number of vegetable items and vegetable weights in each box were measured. The vegetables were classified using the Standard Tables of Food Composition in Japan 2021 (Eighth Edition). A correlation coefficient between the number of vegetable items and vegetable weight was used in the analysis.

Results: In the dietary record survey, the average number of vegetable items was 5.61 ± 2.466 (2, 12)/day, and the vegetable intake was 202.4 ± 107.99 (0, 524.0) g/day. A positive correlation was found between the number of vegetable items and vegetable intake (ρ = 0.655). The second term of the National Health Promotion Movement in the 21st century (Health Japan 21 [second term]) proposed 350 g as the target of the mean daily intake of vegetables. From the regression equation, a 350-g vegetable intake represents approximately 11 vegetable items. In the ready-made lunch box survey, the average number of vegetable items was 6.7 ± 2.46 (2, 9)/day, and the vegetable weight was 72.8 ± 43.73 (9.0, 175.6) g/day. A positive correlation was found between the number of vegetable items and vegetable weight (ρ = 0.874).

Conclusions: This study found a positive correlation between the number of vegetable items and vegetable weight (intake) in daily diet and ready-made lunch boxes. The number of vegetable items can be used as a simple indicator of vegetable intake (weight).

Keyword: vegetable intake, indicator, daily diet

PAB(T6)-43
Associations of soy food intake with menopausal symptoms, including hot flushes, in Japanese women

Michiko Tsuji[1,2], Keiko Wada[2], Chisato Nagata[2]

1. Nagoya Women's University (Japan), 2. Gifu University Graduate School of Medicine (Japan)

Background and objectives: Soy foods contain isoflavones that are structurally similar to endogenous estrogens and thus have been suggested to alleviate menopausal symptoms. We aimed to assess the associations of soy food intake with menopausal symptoms, including hot flushes, in Japanese women.

Methods: This cross-sectional study included 382 Japanese women aged 40–59 years who participated in a medical health check-up program provided by a general hospital in Gifu, Japan, between 2003 and 2006. Diet, including soy food, was estimated by a validated food-frequency questionnaire. Soy food intake was log-transformed and adjusted for total energy using the method proposed by Willet. Menopausal symptoms were assessed using the Kupperman test of menopausal distress. The associations of soy food intake with menopausal symptoms were determined using the Spearman rank correlation coefficient.

Results: The average (standard deviation, SD) age of study participants was 46.4 (5.3) years. The participants comprised 299 (78.3%) premenopausal and 83 (21.7%) postmenopausal women. The averages (SD) of hot flush severity and menopausal index score were 0.6 (0.8) and 14.4 (8.3), respectively. Soy isoflavone intake was significantly negatively correlated with the hot flush severity (r = -0.12, p = 0.02) and menopausal index score (r= -0.11, p = 0.04) after controlling for age and menopausal status. Soy fermented food intake was significantly negatively correlated with hot flush severity (r = -0.13, p = 0.01) and menopausal index score (r = -0.10, p = 0.046). Soy food intake was not significantly correlated with hot flush severity or menopausal index score.

Conclusions: Our study showed that the intake of soy isoflavones and soy fermented foods were negatively correlated with hot flushes and menopausal index scores in Japanese women. These data suggest that soy isoflavones and soy

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

fermented foods might have beneficial effects on menopausal symptoms, including hot flushes, among Japanese women.

Feasibility study of a nutrient profile model to support healthy eating behaviors in Japan: A cross-sectional study focusing on the motivation of behavioral change

Yuki Tada[1], Takahiro Yoshizaki[2], Yuri Yokoyama[3], Jun Takebayashi[4], Emiko Okada[4], Hidemi Takimoto[4], Yoshiko Ishimi[1]

1. Tokyo University of Agriculture (Japan), 2. Toyo University (Japan), 3. Tokyo Metropolitan Institute of Gerontology (Japan), 4. National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Objective: To assess the feasibility of a nutrient profile model (NP model) in Japan, we used informational materials about the utilization of the NP model, we previously developed, and conducted internet research. **Methods**: In January 2022, an online cross-sectional survey was conducted among 3,000 Japanese consumers, aged 18 years or older. Participants initially responded to questions regarding their characteristics, daily processed food purchases, and use of nutrition facts labels. Thereafter, they read the informational materials about utilization of the NP model and predicted how it would affect their food purchasing behavior. Based on the results of the participants' current motivation for behavioral change, they were divided into seven groups: not interested (n=468), interested but do not intend to improve (n=719), intend to improve (generally, within six months) (n=542), intend to improve in the near future (generally, within one month) (n=248), already making improvements (for less than six months) (n=242), already making improvements (for more than six months) (n=433), and not required to improve because there is no problem with eating habits (n=348). The association between each variable and the motivation to improve eating habits was assessed using the Mantel-Haenszel test for trends. **Results**: Taste (67.7%) and price (57.3%) were the most important factors when purchasing foods; those less motivated to improve their eating habits were more likely to place importance on the appearance, price, and less effort required for processed foods. The higher the motivation to improve dietary habits, higher the frequency of referring to the nutrition facts label, and higher the number of respondents who answered that the markings that warn against overconsumption based on the NP model would influence their food purchasing behavior. Regardless of the strength of motivation, more than 90% of respondents found the informational materials regarding the NP model, easy to understand. **Conclusions**: Our results indicated that the effect of food labeling based on the NP model was higher for individuals with higher motivation to improve their eating habits. It is necessary to further examine how packaging labels can encourage healthy eating behaviors among those who are not interested in improving their eating habits.

Do caregivers understand Demographic and Health Survey infant and young child feeding questions? Cognitive interviewing to improve dietary measurement in Nepal

Nisha Sharma[1], Seema Khadka[1], Katelyn Yuen[2], Babita Adhikari[1], Alissa M Pries[2]

1. Helen Keller International (Nepal), 2. Helen Keller International (USA)

Background and objective: Demographic and Health Survey (DHS) findings are key to inform nutrition policy and programs. Without careful testing and adaptation to local contexts, these findings are at risk of inaccurately representing participants' experiences and behaviors. Cognitive interviewing is a research methodology used to assess and improve the cognitive match between a quantitative survey's intent and the respondent's interpretation and response. We used this method to assess comprehension, retrieval, judgement, and response of DHS dietary recall questions for infant and young children feeding.

Methods: We conducted a cross-sectional qualitative study among 60 caregivers of children 6-23 months of age, utilizing semi-structured questions, in three purposively selected districts of Nepal. Caregivers were purposively sampled in all three districts and recruited through local community liaisons. Individual interviews began with the Infant and Young Child (IYC) dietary assessment module and were followed by cognitive interviewing to assess discrepancies in the intent and interpretation of the question. For analysis, we organized data into four cognitive themes and further identified common and distinct themes for each question tested.

Results: We identified five themes of discrepancies in intent of the questions and participants' response. These included (1) Recall: caregivers not understanding that the recall period includes night; (2) Retrieval: could not recall instruction to omit foods consumed in small quantity/used for flavor; (3) Interpretation: tinned and powdered milk were understood as infant formula products or condensed milk; fresh milk was interpreted as milk directly from an animal and consumed within a day; the terms ‘flavored' and ‘sweetened' interpreted same as

sweetening with the addition of sugar (4) Judgement: food items considered unhealthy (sweet food group, sugar sweetened beverages) were associated with negative social desirability potentially leading to bias in response; (5) No specific names in Nepali: participants had difficulty in understanding breast-milk substitutes as inclusive of infant formula, follow-up formula and toddler milk.

Conclusion: These findings will be valuable to improve Nepal-specific infant and young children dietary recall DHS questionnaire. Further, the study findings illustrate that understanding local interpretation of adapted global DHS questionnaires is important to ensure accurate measurement in varying contexts.

Global changes in Mediterranean Diet Score: A Comparative study of 52 years using international database

Ayako Sezaki[1,2], Tomoko Imai[3,8], Keiko Miyamoto[4,8], Chisato Abe[5,8], Takumi Kato[6,8], Norie Sugihara[7], Hiroshi Shimokata[4,8]

1. Graduate School of Nutritional Science, Nagoya University of Arts and Sciences (Japan), 2. Ryukoku University (Japan), 3. Doshisha Women's College of Liberal Arts (Japan), 4. Nagoya University of Arts and Sciences (Japan), 5. Tsu City College (Japan), 6. Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital (Japan), 7. Ochanomizu University (Japan), 8. Institute of Health and Nutrition, Nagoya University of Arts and Sciences (Japan)

Background and Objectives: While the relationship between diet and non-communicable diseases (NCDs) has been recognized, it is still unclear how diets eaten around the world are changing. In this study, we focused on the Mediterranean diet and examined the changes in the Mediterranean Diet Score (MDS) worldwide from 1961 to 2013, using databases from international organizations on dietary changes.

Methods: Individual countries were scored from 0-9 to indicate adherence to the Mediterranean diet according to the MDS-scoring method by Trichopoulou et al. The supply of vegetables, legumes, fruits and nuts, cereals, fish, and olive oil per 1,000 kcal per country was calculated from the Food and Agriculture Organization of the United Nations Statistics Division database (FAOSTAT), with a score of 1 for above the median and 0 for below. For ethanol, a score of 1 was given for 50 g or more of consumption. Depending on the score, countries were classified into two to six groups using latent class mixed model with random effects of fiscal year. The changes in score from 1961 to 2013 on 170 countries for which all data were available were shown as spline curve.

Results: The results of the optimal model, which consists of 4 groups as determined by the AIC, showed a decline of MDS in countries with the highest scores in 1961, which include the Mediterranean regions. Countries with the lowest scores in 1961, represented by landlocked countries and the Nordics, showed a significant increase in score. The scores did not change drastically in Japan and in many developed countries. Globally, the difference in MDS showed a narrowing trend. Analyses by food group revealed that in Mediterranean countries, the increase in meat and milk supply led to a decrease in score. Meanwhile, in Nordic and landlocked countries, meat and milk supply was still high, but the increase in vegetable and fish supply led to an increase in score. **Conclusion**: These results suggest that there has been a change in access to food worldwide due to the globalization of diet, and the relationship between this change and NCDs needs to be further analyzed.

PAB(T6)-47
Eater profiles of young adults in Canada based on factors determining eating behaviours

Sadaf Mollaei[1], Goretty M Dias[1], Jennifer K Lynes[1], Leia M Minaker[1], Derek T Robinson[1]

1. University of Waterloo (Canada)

Background and objectives: A shift in eating behaviours is needed for positive human and planetary health outcomes. However, changing eating behaviours is challenging as food decisions are complex and impacted by both personal and environmental factors. Young adults are a critical target population for shifting diets due to their poor eating habits and because they are in a transition phase where their diets can be influenced. The purpose of this research is to: 1) understand the factors affecting food choices of young adults in Canada based on environmental perceptions, personal, and behavioural factors as determinants of eating behaviours; 2) segment Canadian young adults based on the strength of these factors. The outcomes are important for designing effective interventions for shaping eating behaviours. **Methods**: An online survey was administered to Canadians aged between 18 and 24 to collect data on socio-demographic factors and eating behaviours. An Exploratory Factor Analysis was used to identify the main factors affecting eating behaviours in young adults, followed by K-means clustering to categorize the respondents into consumer segments based on their propensity to agree with the factors. **Results**: There were 297 respondents, with socio-demographic characteristics representative of Canadian population within the same age group. Six factors were extracted: Beliefs (ethical, environmental, personal), Familiarity and Convenience, Joy and Experience, Food influencers and

Sociability, Cultural identity, and Body image. Using these factors, six consumer segments were identified whereby members of each segment has more similar scores on each factor than members of other segments. The six consumer segments were: “conventional”; “concerned”; “indifferent”; “non-trend follower”; “tradition-follower”; and “eat what you love”. The last three categories represent new segments relative to what has been found in the literature. The largest segment was the “conventional” consumer, who is extremely sensitive to the ‘familiarity and convenience' factor (e.g. fast and easy preparation, brand recognition). **Conclusions**: Identifying major factors influencing eating behaviours and consumer segmentation provides insights on how eating behaviours might be shaped. For example, interventions that include changes in the food environment to facilitate access to environmentally sustainable foods could be used for “conventional” consumers.

A simulation model of the effect of changes in salt intake on long-term trends in cardiovascular mortality during the period 1950-2017 in Japan

Takehiro Sugiyama[1,2,3], Kazuko Minowa[3], Nayu Ikeda[3], Nobuo Nishi[3]

1. National Center for Global Health and Medicine (Japan), 2. University of Tsukuba (Japan), 3. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Background and objectives: In Japan, a decrease in cardiovascular mortality coincided with that in mean salt intake since the 1950s. The purpose of this study was to quantitatively examine the effect of reduced population salt intake on long-term trends of cardiovascular mortality.

Methods: Using government statistics and epidemiological study results, we developed a system dynamics model of age-specific cardiovascular mortality and salt intake for 20-69-year-olds during the period 1950-2017. Based on the age-period-cohort model, we estimated the period effect of salt intake at that time and the cohort effect of past salt intake and modeled these effects on cardiovascular mortality. We calibrated the historical decrease in salt intake. We then simulated a counterfactual scenario of no decrease in salt intake since the 1950s to estimate the reduction in cardiovascular deaths associated with decreased mean salt intake.

Results: Compared with the counterfactual scenario, observed cardiovascular mortality in the 1950 and 1990 cohort was lower by 2.8% and 4.1%, respectively, for men, and 2.4% and 3.6%, respectively, for women. It was estimated that approximately 208,000 and 115,000 deaths in men and women, respectively, had been prevented through reduced salt intake over the entire period.

Conclusions: The simulation results from the system dynamics age-period-cohort model suggested that decreased salt intake saved about 300,000 adults from cardiovascular death in Japan during the past 67 years. The systems thinking approach will also help examine the effects of future decreases in salt intake.

Development and validation of a diet quality score for Japanese adults

Fumi Oono[1], Kentaro Murakami[1], Aya Fujiwara[2,1], Keiko Asakura[3], Shizuko Masayasu[4], Satoshi Sasaki[1]

1. University of Tokyo (Japan), 2. National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 3. Toho University (Japan), 4. Ikurien-naka (Japan)

Background and objectives: Evidence mainly accumulated from Western countries suggests that four diet quality scores (Healthy Eating Index, Alternative Healthy Eating Index, Mediterranean Diet Score, and Dietary Approaches to Stop Hypertension) have protective associations with health outcomes, including mortality, cardiovascular disease, type 2 diabetes, and total cancer. The purpose of this study was to develop a diet quality score for Japanese adults on the basis of these four well-established diet quality scores and to evaluate its validity.

Methods: The present study was based on 4-day dietary record data obtained from 396 Japanese adults aged 20–69 years. For each dietary component included at least in two well-established diet quality scores, we examined the distribution of intake levels in Japanese, in addition to the potential health effect in Japan (using the Global Burden Disease Study). Consequently, the diet quality score consisting of 10 components was developed: fruits, vegetables, whole grain, dairy, legumes, nuts, fish, red and processed meat, sugar-sweetened beverages, and sodium. The total score was the sum of 10 components having a possible range of 0–20, with a higher score indicating a better diet quality. The validity of the diet quality score was evaluated by examining associations with sociodemographic factors and intakes of foods and nutrients.

Results: The mean diet quality score was 9.2 (sd 3.0). A higher diet quality score was observed in women (than men), older (45–69 years) participants (than younger participants), and non-smokers (than smokers). The diet quality score was associated positively with intakes of fruits, vegetables, whole grain, dairy, legumes, nuts, fish, protein, n-3 fatty acids, carbohydrate, total fiber, and most vitamins and minerals, and inversely with intakes of red meat, sugar-sweetened beverages, refined grain, poultry, total fat, and saturated fatty acids, but was not associated with sodium intake. No association was

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

observed between the diet quality score and energy intake, suggesting its independence of the quantity of diet.

Conclusions: The diet quality score developed for Japanese adults was associated with sociodemographic factors and intakes of most foods and nutrients in expected directions. Further evaluation against biomarkers and health outcomes is warranted.

Keyword: Diet quality, Japan, DASH, Mediterranean diet, Healthy Eating Index

PAB(T6)-50
Eating behaviors and depressive symptoms among Japanese workers

Akiko Nanri[1,2], Norika Yoshimaru[1], Masafumi Eguchi[3], Takeshi Kochi[3], Isamu Kabe[4], Tetsuya Mizoue[2]

1. Fukuoka Women's University (Japan), 2. National Center for Global Health and Medicine (Japan), 3. Furukawa Electric Corporation (Japan), 4. Kubota Corporation (Japan)

Background and objective: Recent accumulating evidence indicates that when and how we eat is as important to health as what and how much we eat. For example, skipping breakfast and eating alone have been reported to be associated with increased risk of depressive symptoms. However, few studies have examined the association between eating behaviors and depressive symptoms in Japan. We prospectively investigated the association between eating behaviors and depressive symptoms in a Japanese working population.

Methods: Participants were 914 workers (816 men and 98 women aged 19-68 years) without depressive symptoms at baseline who completed a 3-year follow-up survey. Unhealthy eating behaviors such as skipping breakfast ≧3 times/week, eating dinner within 2 hours before bedtime ≧3 times/week, and snacking after dinner ≧3 times/week were assessed via a health checkup questionnaire. Depressive symptoms were assessed using the Center for Epidemiologic Studies Depression (CES-D) scale. Multiple logistic regression was used to estimate the odds ratio of depressive symptoms according to tertile of the number of unhealthy eating behaviors (0, 1, and 2-3) with adjustment for covariates.

Results: At the time of the 3-year follow-up survey, 155 workers (17%) were newly identified as having depressive symptoms (CES-D score ≧16). The odds ratio of depressive symptoms among participants with 2-3 unhealthy eating behaviors was significantly higher than in those without these behaviors, after adjustment for age, sex, and worksite (odds ratio, 1.88; 95% CI, 1.14-3.11). This association was substantially attenuated after adjustment for lifestyle factors, including BMI, marital status, living status, job grade, night or rotating shift work, overtime work, sleep duration, smoking status, alcohol consumption, physical activity, and job stress (corresponding odds ratio, 1.38; 95% CI, 0.78-2.46). After additional adjustment for dietary factors such as folate, vitamin B6, vitamin B12, n-3 polyunsaturated fatty acids, magnesium, and zinc, the odds ratio was 1.36 (95% CI, 0.76-2.44) (*P*for trend = 0.27).

Conclusions: Our results suggest that the increased risk of depressive symptoms associated with unhealthy eating behaviors may be explained by lifestyle factors such as night shift, overtime work, smoking, job stress, and living alone.

Keyword: breakfast, depressive symptoms, eating behavior, Japan

A Longitudinal Study on the Relationship of Oranges and Mandarins Supply with Life Expectancy and Healthy Life Expectancy: An Ecological Study Using International Data

Norie Sugihara[1], Tomoko Imai[2,3], Ayako Sezaki[4,5], Keiko Miyamoto[3,6], Chisato Abe[3,7], Takumi Kato[3,8], Hiroshi Shimokata[3,4]

1. Ochanomizu University (Japan), 2. Doshisha Women's College of Liberal Arts (Japan), 3. Institute of Health and Nutrition, Nagoya University of Arts and Sciences (Japan), 4. Graduate School of Nutritional Science, Nagoya University of Arts and Sciences (Japan), 5. Ryukoku University (Japan), 6. Nagoya University of Arts and Sciences (Japan), 7. Tsu City College (Japan), 8. Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital (Japan)

Background and objectives: The average life expectancy and healthy life expectancy in many Mediterranean countries are known to be long. The Mediterranean diet is a typical healthy diet. Oranges have been eaten in the Mediterranean region thousands of years. In Japan, where life expectancy is one of the highest in the world, mandarins have been cultivated and eaten. In this study, we aimed to clarify the relationship of oranges and mandarins supply with average life expectancy and healthy life expectancy through longitudinal analysis using data from an international database.

Methods: Average life expectancy (LE) by country was obtained from the World Bank database, and healthy life expectancy (HALE) was obtained from Global Burden of Disease (GBD) database. Oranges and mandarins supply (kg/day/capita) by country, excluding loss between production and household, were obtained from the Food and Agriculture Organization of the United Nations Statistics Division database (FAOSTAT). A cross-sectional association of oranges and mandarins supply with LE and HALE in 2009 was examined controlling for covariates. Longitudinal association of oranges and mandarins supply and interaction between supply and year in 2009 with LE and HALE from 2009 to 2019 were also examined using linear mixed model controlling for covariates. Number of the countries used in the analysis was 140 countries with populations of 1 million or more for which all data were available.

Results: In the cross-sectional model, oranges and mandarins supply was significantly associated with LE (β ± SE; 48.1 ± 15.1, p = 0.002) and HALE (33.2 ± 12.2, p = 0.007). In the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

longitudinal model with the interaction term, the main effects of the supplies on LE and HALE were 66.3 ± 12.0 ($p < 0.001$), and 44.3 ± 10.1 ($p < 0.001$), respectively. The interaction terms were also significant both in LE and HALE ($p < 0.001$).

Conclusions: Oranges and mandarins supply was associated with increase in LE and HALE by cross-sectional and longitudinal analysis. In the longitudinal analysis, the interactions between supply and year were significant, which indicated that the rates of increase in LE and HALE by year were different depending on the supply.

Using a SWOT Analysis to determine the problems arising from the operation of the school lunch program in Thailand

Nuttarat Srisangwan[1], Piyanit Churak[1], Panrawee Praditsorn[1], Punnee Ponprachanuvut[1], Arisa Keeratichamroen[1], Kantanit Chammari[1], Kitti Sranacharoenpong[1]

1. Mahidol University (Thailand)

Background and objective: Thai school lunch program (Thai-SLP) has been a national program solving Thai children's nutritional program since 1980. The purpose was to understand barriers and supports of Thai-SLP arising from management, prioritize problems, and possible strategies resolving for the program.

Method: School principal (SP) is the key person formulating clear policies, action plans, and assign various tasks to teachers. Educational local staff from Ministry of Education were responsible for supervision, monitoring, and evaluating program implementation. They exchanged experiences and discussed problems and supports to implementation. Sixty participants were invited from selected 30 medium-sized schools from rural, semi-urban, and urban areas across Thailand and divided into 6 groups for focus groups and in-depth interviews. SWOT Analysis was used to analyze the implementation of Thai-SLP through brainstorming activities.

Results: Key issues of Thai-SLP is that schools should implement proactive strategies. The strengths-opportunities took advantage of the strengths and external opportunities of schools. This strategy was a priority that should be maintained and supported. Adequate budget management, whether it was managed within schools or supported by external agencies, also good collaborating community networks for sustainability. However, barriers was opportunity of weakness-threat, which proposed having nutria-teachers by training for schools related health program supporting reduced teachers' workload. The current situation at schools teachers who are responsible for the program having a teaching workload, also menu planning, purchasing ingredients and serving food. In addition, they were not trained nutritional knowledge or having health background. Budget was another issues, but required multi-stakeholders and community participatory approach.

Conclusion: Thai-SLP is important program for children. The program can alleviated malnutrition problems. However, some obstacles should be concerned and solved by all stakeholders. Top-down or bottom up strategies were required to solve operating problems under the lunch program to improve the quality of school lunches. Priority solution should start with strategies that the school can implement itself. Forming network, building capacity among schools, communities and local government for sustainable management could also improve quality of school lunch program and children's health.

PAB(T6)-53
Risk of hip fracture in meat-eaters, pescatarians, and vegetarians: results from the UK Women's Cohort Study

James Webster[1], Darren C Greenwood[1], Janet E Cade[1]

1. University of Leeds (UK)

Background and objectives: Hip fracture affects 18% of women globally, increases morbidity and mortality, and reduces quality of life. There are growing concerns regarding the adequacy of plant-based diets for bone health, but their association with hip fracture risk is unclear. We aimed to investigate the risk of hip fracture in occasional meat-eaters, pescatarians, and vegetarians compared to regular meat-eaters in the UK Women's Cohort Study, and to determine if potential associations between each diet group and hip fracture risk are modified by body mass index (BMI).

Methods: UK women, ages 35–69 years, were classified as regular meat-eaters, occasional meat-eaters, pescatarians, or vegetarians based on a survey that collected dietary and lifestyle information at recruitment (1995–1998), including a validated 217-item food frequency questionnaire. Incident hip fractures were identified by record linkage to Hospital Episode Statistics up to March 2019. Cox regression models were used to estimate associations between each diet group and hip fracture risk, with regular meat-eaters as the reference, over a mean follow-up time of 21.1 years.

Results: Among 30,244 women, 993 hip fracture cases were observed (637,427 person-years). After adjustment for confounders, vegetarians (HR (95% CI): 1.36 (1.06, 1.75)) but not occasional meat-eaters (1.01 (0.86, 1.19)) or pescatarians (0.99 (0.76, 1.28)) had a greater risk of hip fracture than regular meat-eaters. Hip fracture risk appeared higher in vegetarians with a BMI < 23.5 (1.52 (1.12, 2.07)) than in vegetarians with a BMI > 23.5 (1.04 (0.68, 1.60)), but there was no evidence of effect modification by BMI in any diet group.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: Vegetarian women had a higher risk of hip fracture than regular meat-eaters. Further research is needed to confirm this in other populations, and to identify factors responsible for the observed risk difference. In particular, further research exploring the role of BMI and nutrients abundant in animal-sourced foods is recommended.

Trends in dietary salt sources in Japanese adults: data from the National Health and Nutrition Survey 2007–2019

Mai Matsumoto[1], Ryoko Tajima[1], Aya Fujiwara[1,2], Xiaoyi Yuan[1,2], Emiko Okada[1], Hidemi Takimoto[1]

1. National Institutes of Biomedical Innovation, Health, and Nutrition (Japan), 2. University of Tokyo (Japan)

Background and objectives: High salt intake was the leading dietary risk for deaths and disability-adjusted life-years in Japan. Identifying the trends in dietary salt sources is important in order to effectively reduce salt/sodium intake. This study aimed to examine the trends in dietary salt sources in Japanese adults.

Methods: Participants were 95,581 adults (43,129 men and 52,452 women) aged 20 years and over, who participated in the 2007–2019 National Health and Nutrition Survey. Dietary intake data were collected using a one-day semi-weighed household dietary record. Based on previous studies in Japan and other countries, we classified food sources of sodium/salt into 21 groups as follows: grains, bread, noodles, instant noodles, vegetables, pickled vegetables, unprocessed fish and shellfish, dried fish and shellfish, processed fish and shellfish, unprocessed meats, processed meats, seasonings, kitchen or table salt, soy sauce, soybean paste, sauce, soup stock, dressing, mayonnaise, roux, and other seasonings. Salt intake for each food group was adjusted using the density method based on the energy intake. Trends in dietary salt intake based on food sources by sex and age groups (20–39 years, 40–59 years, and 60 years and older) were analysed using the Joinpoint Regression Program.

Results: Salt intake decreased over time between 2007 and 2019. The major dietary source of salt continued to be seasonings such as soy sauce and soy bean paste in all age categories for both sexes (approximately 70%), followed by different food groups according to sex and age. Salt intake from seasonings decreased over time in both men and women aged 40 years and over, but did not change in those aged 20-39 years. In addition, a decreasing salt intake from unprocessed fish and shellfish and an increasing salt intake from unprocessed meat were observed in all age categories among both men and women.

Conclusions: This study demonstrated that a strategy targeting different age groups may be needed to reduce salt consumption from seasonings among the Japanese population. Further studies on the continued monitoring of trends in dietary salt sources including various types of seasonings, occasional consumption and timing are required.

Prevalence and modifiable risk factors of non-communicable diseases among traders in major markets in Nigeria

Peace Nwanneka Ani[1], Chika Nwanma Onwasigwe[2], Vivienne Nkiru Ibeanu[1], Amarachi Benedicta Eze[1], Justina Nkechi Okoli[3]

1. University of Nigeria, Nsukka (Nigeria), 2. University of Nigeria, Enugu Campus (Nigeria), 3. Michael Okpara University of Agriculture, Umudike (Nigeria)

Background and objectives: Non-communicable diseases (NCDs) are the leading cause of death globally. Available evidence has shown that they significantly affect the economic growth and development of any nation through increased health care cost, and loss of individual/countries productive capacity. Considering the consequences of NCDs, it becomes crucial to monitor the trend of these diseases among populations who play active roles in driving the national economy. This study therefore seeks to determine the prevalence and risk factors of NCDs among traders in major markets in Enugu metropolis, Nigeria.

Methods: Cross-sectional descriptive survey design was adopted and multistage random sampling technique was used to select 514 respondents from major markets in Enugu metropolis, Nigeria. Data on background information, food consumption pattern, and lifestyle behaviours were obtained using questionnaire. Blood pressure and anthropometric measurements of weight, height, waist and hip circumference were also collected. Blood samples were analysed for blood glucose and lipid profile. Data obtained were subjected to statistical analysis using SPSS, version 22. Descriptive and inferential statistics were used to compare and determine the relationship between variables. Significance was accepted at $p < 0.05$.

Results: Obesity (25.5%), overweight (40.7%), hypertension (35.2%), diabetes (15.6%) and dyslipidemia (70.3%) were prevalent among the study population. Factors associated with obesity/overweight were frequency of fruit consumption (OR= 6.00, 95% CI = 1.05 – 16.77), physical activity pattern (OR= 2.27, 95% CI = 1.42 – 3.62) and waist circumference (OR= 0.12, 95% CI = 0.08– 0.19), while dietary diversity (OR= 0.25, 95% CI = 0.07 – 0.95) and knowledge of health status (OR= 4.15, 95% CI = 1.04 – 16.57) were associated with dyslipidemia.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: NCDs are highly prevalent among traders in the Enugu metropolis, Nigeria hence the need for nutrition education and health sensitization programmes.

PAB(T6)-56
Countries with Mandatory Large Scale Food Fortification Lack Fundamental Elements Important in Legislation, Standards, and Monitoring Documentation

Florencia Vasta[1], Floyd Stern IV[2], Michelle Duong[3], Karen Codling[4], Becky Tsang[3,4], Helena Pachón[2,5]

1. Global Alliance For Improved Nutrition (Switzerland), 2. Emory University (USA), 3. Food Fortification Initiative (USA), 4. Iodine Global Network (Canada), 5. Food Fortification Initiative (USA)

Background/objectives: One hundred and thirty-seven countries mandate fortification of maize flour, oil, rice, salt, or wheat flour, however, not all programs are well-supported by a legislative and regulatory framework. Mandating fortification is necessary, but not sufficient to a successful program; countries must clearly define parameters of the program's implementation and monitoring. The Global Fortification Data Exchange (GFDx) collates data on Large Scale Food Fortification (LSFF) globally, including documentation on legislation, standards, and monitoring protocols. Through a review of the GFDx repository, we aimed to review how many countries with mandatory fortification had documentation containing key foundational program elements.

Methods: We developed a 19-point check list of items deemed essential to include in a set of LSFF documents, based on a previously published 44-point checklist review process developed for cereal grains (Marks et al.). We reviewed each country's LSFF legislation, standards, and monitoring protocols against the checklist and computed the scores and percentage of elements present for each country. Examples of checklist elements include defined roles/responsibilities of government agencies in fortification, checklists for monitoring protocols, among others.

Results: According to documents available in the GFDx repository, 137 countries mandated fortification of at least one food and were included in this review. Of the 253 country-food combinations, 17(7%) maize flour, 26(10%) oil, 7(3%) rice, 121(48%) salt, and 85(34%) wheat flour countries were included. On average, the score (checklist items fulfilled/checklist items applicable) was 56% across all vehicles. The highest score was achieved by rice with 66%, followed by maize flour(55%), salt(54%), wheat flour(53%), and oil(52%). One major gap observed across all vehicles was in affirmative checklist items related to monitoring protocols, e.g., for both external and import monitoring, roles were clarified between government agencies only 7% and 8% of the time respectively; import auditing checklists were present in only 10% of fortification documentation.

Conclusions: As LSFF programs are planned, implemented, and scaled, it is critical that the foundational structure, as defined in key elements of legislation, standards, and monitoring protocols can support ongoing success and sustainability. Identifying and understanding gaps in key fortification documents could help improve existing mandatory fortification programs/provide countries with a planning framework when developing new LSFF programs.

PAB(T6)-57
Thailand's demographic trend and future greenhouse gas emissions from protein food choices

Piyanit Churak[1], Nobuo Nishi[2]

1. Mahidol University (Thailand), 2. National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Background and objectives: The Sustainable Development Goals have been a global agenda to achieve a better and more sustainable future for all. Food security, nutrition, and well-being were recognized at least 2 goals. Considered the importance of Thailand's population structure and its alteration towards aged society, System Dynamics approach were used to simulate how environmental outcome was influenced by population dynamics and their sources of protein consumption. The link between food systems, public health, and the environmental impact were explored in terms of greenhouse gas emissions (GHGe).

Methods: Lifecycle was made by age group of infants, children, adults and elderly. GHGe were calculated from their protein choices. Population for each age group and their consumption were optimized to actual numbers. GHGe contributed by proportion of protein food sources according to Food-based Dietary Guidelines (FBDGs) considering as inevitable emissions to maintain balance between healthy diets and sustainable consumptions. Protein choices data from the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

national food consumption surveys were added into 5 groups: meats, fish, pulses, milks, and eggs. Simulations were set during the year of 2006-2030.

Results: Meats were increasingly consumed in all age groups, while pulses consumption were decline. Milks were less consumed comparing to FBDGs, especially in elderly. The highest contribution of overall GHGe was from adults specifically by meats consumption since these groups are majority. Scenarios were made by replacing actual food consumption quantity to illustrate how change of GHGe over time. Meats consumption reduction by adults and substituted their energy intake by consuming more pulses, which seem to be the low carbon choices, resulted in decreasing GHGe in early years and projected to slightly rise after 2022. Partially covered meat eating by fish (maintained energy intake) did not decrease GHGe trend. Additional 50% milk intake of actual consumption in elderly to catch up FBDGs did not alter GHGe by the whole population.

Conclusion: These findings suggested that food choices played a critical role not only for health but also environmental impacts. Simulation analysis may be useful when defining leverage points to tackle nutrition problems and exploring effective strategies to promote environmental-friendly healthy eating.

Global Longitudinal Study of the Association of Dietary Na/K Ratio with Ischemic Heart Disease Mortality and Incidence

Takumi Kato[1,2], Tomoko Imai[1,3], Keiko Miyamoto[1,4], Ayako Sezaki[5,6], Chisato Abe[1,7], Norie Sugihara[8], Hiroshi Shimokata[1,5]

1. Institute of Health and Nutrition, Nagoya University of Arts and Sciences (Japan), 2. Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital (Japan), 3. Doshisha Women's College of Liberal Arts (Japan), 4. Nagoya University of Arts and Sciences (Japan), 5. Graduate School of Nutritional Science, Nagoya University of Arts and Sciences (Japan), 6. Ryukoku University (Japan), 7. Tsu City College (Japan), 8. Ochanomizu University (Japan)

Objective: The dietary Na/K ratio is one of the indicators used to assess the risk of cardiovascular disease and death. Ischemic heart disease (IHD) is one of the leading causes of death worldwide, and excessive sodium intake and increased potassium intake are considered risk factors and protective factors, respectively. In this study, we aimed to investigate the association of the dietary Na/K ratio with IHD incidence and mortality through a longitudinal study using the latest international data.

Materials & Methods: Per capita sodium and potassium intakes for each country were obtained from the Global Dietary Database 2018, and the dietary Na/K ratio was calculated by dividing sodium intake by potassium intake. Age–standardized IHD mortality and incidence rates per 100,000 population were obtained from the Global Burden of Disease 2019 database. Energy intake, obesity ratio, smoking prevalence, years of education, physical activity, aging rate, and gross domestic product (GDP) per capita were used as controlling factors. The analysis included 149 countries with populations of 1 million or more for which all data were available. We examined longitudinal associations of IHD incidence or mortality with dietary Na/K ratio and interaction with year using linear mixed models over a 28-year period from 1990 to 2018.

Results: The main effect of dietary Na/K ratio on IHD mortality was 13.8±6.9, $p<0.05$, which was a significantly positive association. Also, the main effect of dietary Na/K ratio on IHD incidence was significantly positively associated with 16.2±6.3, $p<0.05$. Furthermore, the interaction between dietary Na/K ratio and year and the incidence of IHD was 1.32±0.39, $p<0.001$, and dietary Na/K ratio of 1.1 or less was associated with a significantly lower incidence of IHD over 28 years.

Conclusion: This study suggests that higher dietary Na/K ratios may increase the IHD incidence and mortality. Avoiding excessive sodium intake or increasing potassium intake to lower the dietary Na/K ratio may be protective against IHD.

PAB(T6)-59
Health survey of Japanese and Chinese university students under effects of COVID-19

Zhu Lingxiao[1], Reiko Ohmori[1]

1. Utsunomiya University (Japan)

[Background and objectives] The epidemic of the COVID-19 has significantly changed people's lifestyles. There is a high possibility that lifestyles have changed in all generations, such as loss of opportunities to go out and changes in eating habits. The purpose of this study is to clarify the lifestyle and health conditions of university students in Japan and China under effects of COVID-19.

[Method] Surveys related to lifestyle / health and eating habits were conducted with 47 questions of "(DIHAL.2)" and 9 questions originally created for 319 Chinese and 98 Japanese.

[Results] In China and Japan, the mean score of taking exercise was 32.3±5.0, 25.7±5.9, the mean score of diet was 51.3±8.3, 44.1±8.8 , the mean score of having a rest was 53.6±10.0, 45.9±9.2 ($p<0.001$), respectively. In the each classification of lifestyle and health, full-fledged was 62%, 42%, being aware of the type was 14%, 36%, which indicated that the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

health level of Chinese students was better than Japanese.17% of the students in China and 18% in Japan answered that their physical condition was "worse" than before the COVID-19, and 36% of the students in China and 25% in Japan said that they had gained weight. 35% Chinese students were being aware of type, responded about their physical condition was "worse" than before, however, there were 61% in Japan. 25% Chinese students were being precautionary type who responded that their weight had "gained" compared to 42% in Japan. With nutritional knowledge, the percentage of those who were well-informed was higher than those who were not well-informed, and there was an association with lifestyle and health, especially in China

[Conclusions] Although the lifestyle and health of Chinese students were good compared with Japanese, it was shown that the degree of knowledge about changes in physical condition and nutrition due to COVID-19 is related to the health of students. Many of the university students in China live in dormitories, suggesting that the environment may lead to desirable lifestyles and high health even in COVID-19.

Applying the concept of the Thai nutrient-profiling to develop the Thai school lunch planning program for lay-teachers

Arisa Keeratichamroen[1], Kantanit Chammari[1], Punnee Ponprachanuvut[1], Nuttarat Srisangwan[1], Nattvara Nirdnoy[1], Kitti Sranacharoenpong[1]

1. Mahidol University (Thailand)

Background and objective: Although teachers who were responsible for the school lunch program were trained by the staff of Ministry of Education (MOE), they were not equipped with the basic knowledge of nutrition for children. This study aimed to develop the Thai school lunch planning program based on nutrient-profiling for lay-teachers.

Methods: We collected 52 Thai popular school lunch menus from outsource company where managed lunch for students in Bangkok. All menus were determined in 2 portion sizes for kindergarten and for students. The menus also were calculated nutrients contents by the Thai food composition software (INMUCAL-v 4.0). The menus were classified by characteristic of foods and cooking methods, such as clear soup, stir flied vegetable, hot and spicy soup/curry with or without coconut milk. The menus were calculated scores based on Thai nutrient-profiling criteria, which were 'grade A' (score >16), 'grade B' (12-16), and 'grade C' (score <12). Thai school lunch guideline was used to manage the patterns.

Results: The Menus were classified in 9 groups; single dish, curry/soup with or without coconut milk, stir-fried foods, deep-fried foods, spicy salad, steamed food, fruits and Thai desserts. None was passed the 'grade A'. Forty-five menus were accepted to 'grade B' while 7 menus were accepted to 'grade C'. When we developed an algorithm for lunch patterns, we found 153 patterns in total. However, 120 possible lunch patterns were passed the Thai school lunch guideline. Thirty-three percent (n=40) lunch patterns were passed the macronutrient for 30% while the less needed to improve some nutrients.

Conclusion: This study was applied the concept of nutrient profiling on the domain of Thai school lunch planning program to help lay-teachers gained a better understanding of the nutrition in school lunch menus and maximize the nutritional value of their choices. We expect that this tool will be usable, and that all of its interfaces are easy to understand for lay-teachers.

Keyword: Thai school lunch program, Nutrient profiling, Lay-teachers, Menus

PAB(T6)-61
Global ecological study on Traditional Japanese diet score and SDGs

Tomoko Imai[1,2], Keiko Miyamoto[2,3], Ayako Sezaki[4,5], Chisato Abe[2,6], Takumi Kato[2,7], Norie Sugihara[8], Hiroshi Shimokata[2,4]

1. Doshisha Women's College of Liberal Arts (Japan), 2. Institute of Health and Nutrition, Nagoya University of Arts and Sciences (Japan), 3. Nagoya University of Arts and Sciences (Japan), 4. Graduate School of Nutritional Science, Nagoya University of Arts and Sciences (Japan), 5. Ryukoku University (Japan), 6. Tsu City College (Japan), 7. Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital (Japan), 8. Ochanomizu University (Japan)

Background and objectives: Reducing the environmental impact of the food supply is important for the SDGs in the world. We developed the Traditional Japanese Diet Score (TJDS) and reported in a global ecological study that Japanese food is associate with reducing obesity and extending healthy life expectancy (Imai et al. J Nutr Health Aging. 2019). We conducted an ecological study to examine whether Japanese food contributes to sustainability, using the TJDS and environmental indicators.

Methods: Average food (g/day/capita) and energy supply (kcal/day/capita) by country were obtained from the Food and Agriculture Organization of the United Nations Statistics Division database (FAOSTAT) from 1990 to 2013. TJDS was calculated from eight food groups (beneficial food components in Japanese diet; rice, fish, soybeans, vegetables, and eggs, food components that are relatively unused in traditional Japanese diet; wheat, milk, and red meat) by country and calculated the total score from -8 to 8, with higher scores means greater adherence to the TJDS. As for environmental indicators, we used Greenhouse gas (GHG) emissions 2013 (kg CO_2eq), Land-Use (m^2), Acidifying Emissions (Acid; g SO_2eq) per food weight by Poore et al. (Science 360, 2018), and multiplied these indicators by the average food supply of FAOSTAT in each country to obtain the environmental impact of food supply. Latitude was derived from

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

the Global Burden of Disease 2019 database. We evaluated the cross-sectional association between TJDS and 3 environmental indicators in 2013, and the longitudinal association between TJDS and 3 environmental indicators from 1990 to 2013 using linear mixed-effect model. This study covered 138 countries with populations of 1 million or greater.

Results: GHG (β ± standard error; -0.232 ± 0.070, p=0.001), Land-Use (-0.882 ± 0.175, p<0.001), and Acid (-1.215 ± 0.380, p=0.002) were negative associated with TJDS after controlling for energy supply and latitude in 2013 data. In longitudinal analysis, GHG (-0.083 ± 0.010, p<0.001), Land-Use (-0.243 ± 0.026, p<0.001), and Acid (-0.463 ± 0.055, p<0.001) were negative associated with TJDS after controlling for confounders.

Conclusions: This ecological study suggests that the traditional Japanese dietary pattern might have associated with SDGs.

Keyword: Traditional Japanese diet score, SDGs, Greenhouse gas emissions, cross-sectional analysis, longitudinal analysis

PAB(T6)-62
Association between dietary pattern and prevalence of depressive symptoms among community dwelling Japanese pregnant women: a cross-sectional study

Tohru Kobayashi[1], Reiji Kojima[2], Emiko Okada[3]

1. Rakuno Gakuen University (Japan), 2. University of Yamanashi (Japan), 3. National Institute of Biomedical Innovation, Health and Nutrition (Japan)

Background and objectives: Dietary pattern may affect to mental health condition during pregnancy. We aimed to clarify the association between dietary pattern and the prevalence of depressive symptoms among community-dwelling Japanese pregnant women.

Methods: The study included community-dwelling pregnant women recruited from July 2019 to December 2021 in Ebetsu, Hokkaido, Japan. Data on food intake, sociodemographic and socioeconomic factors, lifestyle factors, and health status during the gestation period were obtained using self-administered questionnaires that were handed over to participants on notification of their pregnancy. Depressive symptoms were assessed using the validated Japanese version of the Kessler 6 scale. Participants with a history of depression or other mental illnesses were excluded, and finally, 638 participants were eligible for this study. A validated brief-type self-administered diet history questionnaire and factor analysis were used to identify dietary patterns. The association between dietary pattern and prevalence of depressive symptoms was examined using multiple logistic regression analysis.

Results: The mean ± standard deviation of the gestation period was 15.4 ± 9.0 weeks. Three different dietary patterns were identified. The first pattern included fish, potatoes, beans, and vegetables and was named the healthy Japanese food pattern. The second pattern included confectioneries, spaghetti, and fruit and vegetable juice and was named the snack pattern. The third pattern included citrus fruits, persimmons, strawberries, kiwis, and other fruits and was named the fruit pattern. The first to third dietary patterns accounted for 25.2% of the total variance. Each dietary pattern was categorized into low, middle and high scoring groups based on tertiles of the factor scores. A multiple logistic regression analysis showed that after adjusting for potential confounding factors, the odds ratio and 95% confidence interval (CI) of the high score group in the healthy Japanese food pattern was 0.56 (95% CI, 0.34–0.90) compared with those of the low score group. Other dietary patterns were not significantly related to the prevalence of depressive symptoms.

Conclusions: We found that the healthy Japanese food pattern may useful to the prevention of depressive symptoms among Japanese pregnant women. This study was supported by the JSPS KAKENHI Grant, number: JP19K19465.

Parents' communication with teachers about food and nutrition issues of primary school students

Gozde Aydin Aydin[1], Claire Margerison[1], Anthony Worsley[1], Alison Booth[1]

1. Deakin University (Australia)

Background and objectives: Globally, many primary school-aged children have nutritionally deficient diets, with low vegetable intakes and excessive consumption of energy-dense and nutrient-poor foods and beverages. Dietary habits are usually established in early childhood and track over time into later life. Parents and teachers have a major influence on the formation of these habits. Although the cooperation of parents and teachers has frequently been emphasised in the promotion of healthy eating habits among primary school children (5-12 years old), little is known about the communications between these two groups regarding food and nutrition related issues. This study explored parents' communication with and expectations of teachers in the Australian context. Methods: An online nationwide cross-sectional survey of 787 parents (M_{age} = 40 years, 95 % female, 72 % university degree) was conducted in Australia between March and April 2021. Descriptive statistics were calculated for the survey responses using SPSS software. Results: Parent-teacher communications involved various topics, including allergies, children's lunchbox content and parents' supervision requests for their children while eating their lunch. Parents mainly expected teachers to ensure their children were given enough time to eat their lunch (89%), teach healthy eating (89%), and model healthy eating (79%). Only a few parents preferred to receive feedback from teachers about the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

content of the lunch box (17%). Conclusions: These findings highlight the need to enhance communication between parents and teachers in order to promote healthy eating among primary school children. Teachers should be supported through pre-service and in-service training to develop their social and communicative skills to cooperate effectively with all types of parents regarding food and nutrition related issues.

Improving Nutri-Score (Front-of-Pack nutritional label) classifications of foods through food reformulation.

Elly Steenbergen[1], Elisabeth H.M. Temme[1]

1. National Institute of Public Health and the Environment (Netherlands)

Background and objectives: Unhealthy dietary patterns are a major risk factor for non-communicable diseases. To improve consumers' health, several strategies can be used to aid consumers to make healthy food choices. One strategy is the implementation of a Front-of-Pack nutritional label, such as Nutri-Score. Based on a scientific algorithm, Nutri-Score classifies foods by means of letter codes A (dark green) to E (red) according to the nutritional quality. A secondary objective of Nutri-Score is to stimulate food reformulation by producers. This study examines the impact on Nutri-Score classifications of foods after food reformulation and investigates whether Nutri-Score would be an incentive to producers to improve foods.

Methods: Nutri-Score classifications were calculated for foods included in the Dutch Reformulation Monitor 2020. This monitor assessed changes in food composition between 2018 and 2020, after agreements were made with the industry to improve foods. Food composition data of these foods were available from the Dutch Branded Food database from 2018 and 2020. The final sum of points calculated with the Nutri-Score algorithm and the corresponding classifications allocated to foods were compared between 2018 and 2020. The percentage of foods with improved, unchanged or deteriorated Nutri-Score classifications were calculated.

Results: The percentage of foods with improved, unchanged or deteriorated Nutri-Score classifications in 2020 compared to 2018 varied between food groups. For three quarters of the foods, Nutri-Score classifications did not change. Improvements in Nutri-Score classifications were observed for bases (pizza bases, wraps), spring rolls (savory snack), formed crisps and gingerbread after reformulation of salt or saturated fat contents. Except for gingerbread, agreements on lowering nutrient contents exist for these food groups. Nutri-Score classifications for these food groups ranged over multiple classes (A to D/E). Up to 21% of the foods shifted towards a better Nutri-Score classification. Deteriorated classifications were observed in a variety of food groups at low percentages.

Conclusions: Improved Nutri-Score classifications were particularly observed in food groups for which reformulation agreements exist and for which classifications range over multiple classes. Depending on food group, reformulation could result in improved Nutri-Score classifications. Therefore, Nutri-Score may be an incentive for food reformulation to producers.

Keyword: Front-of-Pack nutritional label, Nutri-Score, food reformulation, dietary pattern, food choice

Conflict of Interest Disclosure: From 2021, Elly Steenbergen is member of the international technical committee of Nutri-Score.

From 2021, Elisabeth H.M. Temme is member of the international scientific committee of Nutri-Score.

Introducing iron-folic acid supplements through community-based intervention improves pregnancy outcome

Morseda Chowdhury[1]

1. BRAC (Bangladesh)

Background and objective: BRAC is implementing community-based reproductive healthcare interventions across Bangladesh covering around 80 million population. In 2021, 457,895 pregnant women were enrolled and received antenatal care from community health workers (CHW). Majority of them are located in rural areas and urban slums belonging to poor to low socio-economic group. This paper presents findings on the impact of this program on birth outcomes.

Methods: Data from the year 2021, collected digitally by CHWs, was analysed in R programming for descriptive and bivariate analysis. Dependent variable was iron-folic acid (IFA) consumption. A p value of less than 0.05 was considered as significant. Wilcoxon rank sum test and Pearson's Chi-squared test Chi-square test was done calculation of rates.

Results: A total of 14,930 mothers had abortion or miscarriage, the rate was significantly high (4.8% vs 3.3%, p value <0.05) among mothers who did not take IFA regularly compared to those who did. Stillbirth rate was apparently low in the intervention area, however, for those who had taken IFA the rate was lower (2.1% vs 1.5%, p value <0.05). This was also evident that c-section rate was also lower among mothers consumed IFA (34% vs 30%, p value <0.05).

Conclusions: Results showed that IFA consumption at pregnancy improves pregnancy outcomes by reducing miscarriage/abortions, still births and reduces the chances of c-section rate which itself can give rise to many complications. CHWs were able to successfully encourage pregnant women to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

consume IFA with repeated interaction and making IFA accessible to them. Women's connectedness with local community clinics and primary public healthcare system might also enabled them to access to IFA free of cost. Community-based interventions are effective to positively change the behaviour of IFA consumption even among less privileged women.

PAB(T6)-66
Association between selection behavior for food purchase channels and food intake frequency in women aged 20–49

Akiko Kiyohara[1], Hajime Daimon[2], Yukiko Ueda[3], Michitoshi Yamaguchi[3]

1. Fukuyama City University (Japan), 2. Kokugakuin University (Japan), 3. Ryukoku University (Japan)

Background and objectives: Previous studies suggest that individual access to grocery stores influences people's eating habits. However, few reports in Japan consider the qualitative characteristics of accessible grocery stores and target young people. This study focused on the quality of grocery stores that are actually used by women aged 20–49 in the Chugoku region of Japan and examined their relationship with eating habits.

Methods: In July 2020, we conducted a questionnaire survey on women aged 20–49 residing in Hiroshima and Okayama prefectures. Of the 1110 responses obtained, 1077 were valid and thus analyzed. Questions included respondents' age, family structure, annual household income, and names of frequently used food retail stores(up to three stores). From the obtained data, an index of food intake frequency was created, and the respondents were divided into a low group (≦3) and a non–low group (>3) according to the score. The retail stores in the responses were classified into four types according to their management characteristics. Thereafter, the quality of the stores most frequently used for food purchases and the relationship between the number of stores used and the above index were examined using the Chi–square test.

Results: The average food intake frequency was 3.77. The greater the number of food purchasing channels, the higher the food intake frequency score. The group that used a major supermarket as the first-use store had significantly more people with low scores, and the group that used small-scale / local supermarkets tended to have fewer people with low scores. Also, there was no significant difference in the types of stores selected by income group.

Conclusions: The results suggest that the behavior of consumers who buy at multiple stores enables a variety of food intakes. And the fact that many major supermarket users score lower than small-scale / local supermarkets suggests that quality factors may be more relevant than the quantity of food sold. A more detailed analysis should be considered, including the distance traveled to the store and the quality of food sold.

PAB(T6)-67
Food security and health behaviour of elderly people in India

Alok Kumar[1], Sangeeta Kansal[1]

1. Banaras Hindu University (India)

Background and objectives: In India many people have uncertain access to adequate quantity and quality of food due to constrained resources, either temporary or on a chronic basis. Also, food availability, variety, and quality are often not enough to meet household needs. The specific objectives of this study are to see the association between some domains of food & nutrition security of the elderly i.e., skipping meals or reducing size of meals, getting enough food of their choice, hungry but didn't get food due to shortage in the household, didn't get food for a whole day, etc. and elderly health behaviour i.e., tobacco habits, depression status etc.

Methods: The data used in this study comes from the recently completed Longitudinal Ageing Survey of India (LASI, 2017-18). The LASI is a large-scale, nationwide survey of the health, economic, and social drivers of elderly people and their consequences. The LASI gathered the data of 31168 elderly aged 60 and above from all Indian states.

Results: The elderly who didn't eat enough food of their choice was significantly associated with their gender, marital status and inter-generational living arrangement. Food and nutrition insecurity of the elderly were found to be significantly associated with elderly worsening the feeling of being sad, blue and depression. The elderly who couldn't eat for a whole day in last 12 months due to shortage of food in household or hungry but didn't eat were significantly more using the tobacco products mainly in raw form.

Conclusions: From the results it is found that elderly people need a sympathetic, sharing attitude and behaviour from their family members and govt attention regarding their food and nutrition security. Also, the female elderly who are living lonely, not currently married and in low wealth quintile require special attention by the government. It is also seen that food and nutritional insecurity leads to depression among them and as a result might using cheap and highly injurious tobacco products to reduce the appetite.

Impact of second-wave of COVID-19 pandemic on the food systems of *Ho* indigenous community, Jharkhand, India

Suparna Ghosh-Jerath[1], Ridhima Kapoor[1], Ayushi Dhasmana[1], Archna Singh[2], Shauna Downs[3], Selena Ahmed[4]

1. Public Health Foundation of India (India), 2. All India Institute of Medical Sciences (India), 3. Rutgers School of Public Health (USA), 4. Montana State University (USA)

Background and Objectives: India experienced second wave of COVID-19 pandemic from April to June 2021, which led to spiralling cases, increased deaths and consequently, state-imposed lockdowns. This impacted the lives of Indian indigenous communities, particularly the smallholder farm communities, disrupting their sustenance and livelihood. A study was undertaken to explore the impact of second-wave of COVID-19 pandemic on food environment, diets and food security of *Ho* indigenous community of Jharkhand, India.

Methods: A cross-sectional household survey was conducted in September 2021 in randomly selected villages of West Singhbhum district, Jharkhand. The survey elicited information regarding the perceptions on impact of COVID-19 second wave on household food security, income, and farming systems. The survey tool was incorporated in CS-Pro software, version 7.6 and administered by local *Ho* field investigators. The data was analysed in R software.

Results: A total of 214 *Ho* households were surveyed, amongst which 50% households experienced hardships in accessing cultivated and wild food environment, while 89% households faced difficulties in accessing local markets during second-wave of COVID-19 pandemic. About 73% households claimed improved distribution of dry ration while 70% households reported receiving additional free rations through Government's food supplementation programs during COVID-19 second-wave. About 79% households experienced a reduction in income due to reduced sales of farm and wild produce, lack of opportunities for daily wage labouring, and restrictions on migration. A few households (8-12%) reported selling of farm and wild produce in local weekly markets for additional income. About 67% households reported reduced food consumption, attributed to increased food prices, reduced income and closure of weekly markets. Although majority of households (74%) did not experience an impact on farming practices, few households (18%) reported engaging family members for labour, 17% households started using organic manure, 15% households shifted to indigenous seeds for cultivation and 8% households resorted to early/delayed sowing of the crops.

Workplace cafeteria and other multicomponent interventions to promote healthy eating among adults: A systematic review

Ashika Naicker[1], Archana Shrestra[2], Chandni Joshi[3], Walter Willett[4], Donna Spiegelman[2]

1. Durban University of Technology (South Africa), 2. Yale University (USA), 3. Tufts University (USA), 4. Harvard University (USA)

Background and objectives: The objective of this review is to evaluate evidence for the effectiveness of workplace cafeteria and other supporting multicomponent interventions to promote healthy eating and reductions in health risks among adults.

Methods: We conducted an electronic search in EMBASE, CINAHL, EconLit, Ovid, Cochrane, Web of Science and PubMed for English-language articles published from 1985 to July 2019. Studies were original articles reporting the results of workplace cafeteria interventions to promote healthy eating and reduction in health risks. Outcomes were classified as changes in fruit and vegetable intake, health risk indicators, dietary intake, and food sales. Interventions were categorized as interventions targeting food quality or quantity, targeting price, targeting food choice at point of purchase, targeting improved supply, targeting client's information, education or motivation and targeting organization policies. Behavioral change conditions used in interventions were identified using the COM-B system of behavioral change.

Results: Results were presented in a narrative summary. A total of 55 studies out of 6285 articles were identified for this review. Several studies used multicomponent interventions and the most featured interventions included interventions targeting food quality or quantity, targeting client's information, education or motivation and targeting food choice at point of purchase. There is evidence that workplace cafeteria and other supporting multicomponent interventions resulted in higher intake of fruit and vegetables, improved dietary intake, improved health outcomes and healthy food sales.

Conclusion: The findings of this review have the potential to inform future cafeteria-based and other supporting multicomponent workplace health interventions.

PAB(T6)-70
Relationship between green tea beverages and cedar pollen reactivity: a population-based large cohort study

Nozomi Aoki[1], Mai Suzuki[1], Yuki Sato[2], Hirohide Yokokawa[1], Toshio Naito[1]

1. Juntendo University (Japan), 2. National Institute of Occupational Safety and Health, Japan (Japan)

Background and Objectives: Green tea is a beverage that Japanese people are familiar with, and it has reported benefits on a wide range of diseases such as lifestyle-related diseases, infectious diseases, and allergies. Although, beverages containing catechins are reported to have a favorable effect against allergic factors, there is a lack of epidemiological evidence. Therefore, the present study examined the association between the intakes of several kinds of teas and allergic diathesis due to cedar pollen.

Methods: The cross-sectional data of 16,623 subjects (6,306 men; 10,317 women) who were included in the Tohoku Medical Megabank Cohort from January 2012 to December 2015 were used in the present study. We analyzed the association between intake frequency (G1: less than once a week; G2: once to six times per week, G3: more than once a day) of several types of teas (green tea, coarse tea, oolong tea and black tea) and the serum level of cedar pollen-specific immunoglobulin E (IgE; Lumicount <2.78 or ≧2.78) using a logistic regression model.

Results: A high intake frequency of green tea and coarse tea was significantly inverse associated with a high serum level of cedar pollen-specific IgE. In comparison to G1, a significant difference was seen with G2 (p<0.001, odds ratio [OR]=0.89, 95% confidence interval [CI]=0.817-0.976), and G3 (p<0.001, OR=0.69, 95%CI=0.64-0.75) for green tea, and with G2 (p<0.01, OR=1.27, 95%CI=1.17-1.37), and G3 (p<0.01, OR=1.26, 95%CI=1.16-1.38] for coarse tea. In contrast, no statistically significant association was seen with oolong tea or black tea.

Conclusion: Our results showed a significant inversely association between a high cedar pollen-specific IgE level and intakes of green tea and coarse tea. Thus, these teas may have a potential effect against allergic diathesis. Further analyses are required to determine the causal relationship between the teas and the cedar pollen-specific IgE level.

PAB(T6)-71
Association between low carbohydrate diet score and incidence of type 2 diabetes among Japanese adults The JACC study

Akinori Yaegashi[1,2], Takashi Kimura[1], Takumi Hirata[3], Hiroyasu Iso[4], Akiko Tamakoshi[1]

1. Hokkaido University (Japan), 2. Hokkaido Bunkyo University (Japan), 3. Nara Medical University (Japan), 4. Osaka University (Japan)

Background and objectives: Most of the studies included in the meta-analysis examining the association between low–carbohydrate diet (LCD) and the development of type 2 diabetes (T2D) were conducted in non–Asians. Thus, the results of previous meta-analysis study may not be applied to Asians including Japanese who consume more carbohydrates than non–Asians. Therefore, we prospectively examined the association between LCD score and T2D risk in Japanese adults in Asia using Japan Collaborative Cohort Study for Evaluation of Cancer Risk (JACC Study) data.

Methods: A total of 19,099 (7,051 in men and 12,048 in women) Japanese non–diabetic participants aged 40 to 79 years, who enrolled in the JACC study between 1988 and 1990, were included. Dietary intake was evaluated by using a validated food–frequency questionnaire. The overall, animal, and vegetable LCD scores were calculated by dividing the study participants into eleven categories based on the percentages of energy from carbohydrates, protein, and fat. A higher score indicated a higher proportion of energy intake from protein and fat and a lower proportion of energy intake from carbohydrates. T2D was assessed using self–questionnaire. We used the multivariable logistic regression to estimate the odds ratios (ORs) and 95% confidence intervals (CIs) of incident T2D across the quintiles of each LCD scores with adjustment for potential confounders. All analyses were conducted separately by sex.

Results: During the five–year period, 491 adults (247 in men and 244 in women) developed T2D (2.6%). The multivariable–adjusted OR of incident T2D for the highest versus lowest quintiles of overall and animal LCD scores were 0.65 (95% CI 0.42–0.99) and 0.83 (95% CI 0.55–1.27) for men, respectively, and 0.78 (95% CI 0.51–1.19) and 0.84 (95% CI 0.57–1.24) for women. Vegetable LCD score was associated with a decreased risk of T2D only in men [OR: 0.51; 95% CI: 0.33, 0.77].

Conclusions: Overall, animal LCD scores did not increase with the incidence of T2D in both sexes, while vegetable LCD score was associated with the lower incidence only in men. Our results suggest that LCD unlikely increases the T2D risk among Japanese.

Evaluation of dietary aflatoxin exposure of lactating mother-child pairs and nutritional status of breastfeeding children 0-6 months in Makueni County, Kenya

Isaac Otieno Ogallo[1,2], Dasel Mulwa Kaindi[2], George Ooko Abong[2]

1. Tokyo University of Agriculture (Japan), 2. University of Nairobi (Kenya)

Background and objectives: Aflatoxins once ingested, they are transferred into breast milk, urine and tissues. Their accumulation can lead to malnutrition, aflatoxicosis, or cancer which are predominant in sub-Saharan Africa. South-eastern region of Kenya is prone to aflatoxin outbreaks yet exposure levels of vulnerable population such as breastfeeding children and lactating mothers remain unclear. Objective of this study was to determine the exposure of lactating mothers and breastfeeding children to aflatoxin and its influence on their nutritional status.

Methods: A descriptive cross-sectional study with an analytical component was conducted. Information on socio-demographic characteristics, dietary habits, breastfeeding practices, maize handling and storage practices, and weight of 170 lactating mother-breastfeeding child pairs were collected using structured questionnaire. A total of 48 breast milk and urine samples were collected from a sub-group of respective lactating mothers whose food samples were picked for analysis. Aflatoxin was quantified using enzyme linked immunosorbent assay (ELISA). Statistical analysis was done using the Statistical Package for Social Sciences (SPSS) with significance level set at $p< 0.05$.

Results: Forty five percent (45.3%) of lactating mothers were from low socioeconomic status. Mean women dietary diversity was low (3.4, *SD* = 1.5). Exclusive breastfeeding rate was 44.1%. About 50% never treated their maize, and at least 20% stored maize in containers that promote aflatoxin contamination. Aflatoxin was detected in 85.4% (41/48) food samples. Mean concentration of total aflatoxin was 97.8 mg/kg (*SD,* 57.7), and aflatoxin B1 was 9.0 mg/kg (*SD*, 7.7). Aflatoxin M1 was detected in 77.1% (37/48) in breast milk with a mean concentration of 35 ng/l (*SD*, 0.0). All urine (100%) had aflatoxin M1 with a mean of 0.39 ng/ml (*SD*, 0.16). No significant correlation was reported between weight-for-age z-scores of children with aflatoxin exposure ($p_{all} > 0.05$).

Conclusions: This study concludes that mothers' diet exposed exclusively, and non-exclusively breastfeeding children aged 0-6 months to high aflatoxin intake in the study area. As a result, knowledge, attitude and practices that mitigate aflatoxin contamination in diets and breast milk of lactating mothers as well as clear county government policy on sale and distribution of aflatoxin contaminated maize should be introduced in the study area.

Environmental enteric dysfunction and small intestinal histomorphology of stunted children in Bangladesh

Md Shabab Hossain[1], S M Khodeza Nahar Begum[2], M Masudur Rahman[3], Subhasish Das[1], Mustafa Mahfuz[1], Ramendra Nath Mazumder[1], Shafiqul Alam Sarker[1], Tahmeed Ahmed[1,4,5]

1. International Centre for Diarrheal Disease Research, Bangladesh (icddr,b) (Bangladesh), 2. Bangladesh Specialized Hospital (Bangladesh), 3. Sheikh Russel National Gastroliver Institute and Hospital (Bangladesh), 4. University of Washington (USA), 5. James P Grant School of Public Health, BRAC University (Bangladesh)

Background and objectives: There is lack of information on the histological characteristics of intestinal mucosa in Bangladeshi children, which is considered to be the traditional gold standard for diagnosis of environmental enteric dysfunction (EED). The purpose of the study was to evaluate the intestinal histological characteristics of stunted children aged between 12-18 months with possible EED.

Methods: 110 children with chronic malnutrition (52 stunted with length-for-age Z score, LAZ<-2 and 58 at risk of stunting with LAZ <-1 to -2) from the Bangladesh Environmental Enteric Dysfunction (BEED) study protocol who underwent upper gastrointestinal (GI) endoscopy were selected for this study. To explore the association of EED with childhood stunting, upper GI endoscopy was done and the biopsy specimens were studied for histopathology. Villous height and crypt depth were measured and the presence and intensity of inflammatory infiltrates in the lamina propria was investigated. Bivariate analysis was performed to examine the relationship between stunting and histologic morphology.

Results: More than 90% children irrespective of nutritional status were diagnosed to have chronic non-specific duodenitis on histopathology. Half of the children from both groups had villous atrophy as well as crypt hyperplasia and lymphocytic infiltration was present in more than 90% children, irrespective of groups. However, no statistically significant difference was observed when compared between the groups.

Conclusions: The prevalence of chronic non-specific duodenitis in Bangladeshi children, irrespective of nutritional status, was high. A significant number of these children had abnormal findings in intestinal histomorphology.

Natural food environments of Santhal indigenous communities of Jharkhand, India, and their potential for improving micronutrient status

Archna Singh[1], Ayushi Dhasmana[2], Ashish Bandhu[3], Ridhima Kapoor[2], Sivasankar Baalasubramanian[4], Suparna Ghosh Jerath[2]

1. Department of Biochemistry, All India Institute of Medical Sciences, New Delhi (India), 2. Indian Institute of Public Health-Delhi, Public Health Foundation of India, Haryana (India), 3. School of Institute of Health Management Research, IIHMR University, Jaipur (India), 4. Indoor Biotechnologies Private India Limited, Bangalore (India)

Background and objectives: The Santhal indigenous communities of Jharkhand have a high prevalence of micronutrient malnutrition among women of reproductive age (WRA). This is despite possessing extensive knowledge about their natural food environment, which are potentially rich and diverse sources of nutrition. The objective of this study was to understand the potential of natural food environments to contribute to improved micronutrient status.

Methods: A cross-sectional study was conducted among WRA of Santhal communities (n=212) from 17 randomly selected villages in the Godda district. Research activities included HH survey for information on the socio-demographic profile and food environment; dietary surveys-using 24-hour dietary recalls, and collection of capillary blood samples. Blood samples were analyzed by Luminex based method for selected micronutrients. Bivariate analysis was done for exploring the associations of biomarkers with the food environment characteristics. The associations, statistically significant at p-value < 0.05 were transferred to the LMER model for multivariate analysis.

Results: The food environment of Santhal community consisted of diverse food sources-agricultural land (92.5%), kitchen garden (*baari*) (71.3%), water bodies (55.7%), and forests (54.3%). However, the diversity in access to food from these sources expressed as FADI, an agroforestry diversity index, was low. The dietary diversity of women expressed as MDD-W was also low. The mean nutrient intake was less than the EAR for each nutrient, thus reflecting inadequate nutrient intake. Approximately 70% women were anemic based on hemoglobin levels and 73.2% had ferritin levels less than 30 ng/ml. Half of the women were Vitamin A insufficient, while 28.4% were deficient based on levels of Retinol Binding Protein (RBP). The LMER model showed that HH access to *baari* was positively associated with RBP levels, and access to ponds with the ferritin levels. The women accessing *baari* had 18.53% higher level of RBP (p<0.05, 95% CI: 2.33, 36.21). Women accessing ponds had 27.12% higher ferritin levels (p=<0.05, 95% CI: 1.82,58.57).

Conclusions: Our findings support the potential of indigenous foods from natural food environments like *baari* and water bodies in contributing to improved micronutrient status. Strategies are required to promote their cultivation and increase awareness on their nutritional benefits.

PAB(T6)-75
Poverty and food insecurity in Amazonian children associated with SARS-CoV-2 infection and COVID-19

Marly Augusto Cardoso[1], Isabel Giacomini[1], Priscila Morais Sato[1], Barbara Hatzlhoffer Lourenco[1], Vanessa Nicolete[1], Lewis Buss[1], Alicia Matijasevich[1], Marcia Caldas Castro[2], Marcelo Urbano Ferreira[1]

1. University of Sao Paulo, Brazil (Brazil), 2. Harvard T.H. Chan School of Public Health (USA)

Background and objective: The nutritional associated factors with childhood SARS-CoV-2 infection and COVID-19-related illness remains little studied in high-transmission tropical settings, partly due to the less severe clinical manifestations typically developed by children and the limited availability of diagnostic tests. We investigate the prevalence and risk factors for infection (either symptomatic or not) and disease in 5 years-old Amazonian children.

Methods: We estimated SARS-CoV-2 attack rates and the proportion of infections leading to COVID-19-related illness among 660 participants in a population-based birth cohort study in the Juruá Valley, Amazonian Brazil. Children were physically examined, tested for SARS-CoV-2 IgG and IgM antibodies, and had a health questionnaire administered during a follow-up visit at the age of 5 years in January or June-July 2021. Evidence of household food insecurity defined when household members have "no access to sufficient safe and nutritious food to meet their dietary needs and food preferences for an active and healthy life" were assessed using a validated, 5-question version of the Brazilian Food Insecurity Scale.

Results: We found serological evidence of past SARS-CoV-2 infection in 297 (45.0%; 95% confidence interval [CI], 41.2-48.9%) participants, but only 15 (5.1%; 95% CI, 2.9-8.2%) of the seropositive children had a prior medical diagnosis of COVID-19 reported by their mothers or guardians. The period prevalence of clinically apparent COVID-19, defined as the presence of specific antibodies plus one or more clinical signs and symptoms suggestive of COVID-19 (cough, shortness of breath, and loss of taste or smell) reported by their mothers or guardians since the pandemic onset, was estimated at 7.3% (95% CI, 5.4-9.5%). Children from the poorest households and those with less educated mothers were significantly more likely to be seropositive, after controlling for potential confounders by mixed-effects multiple Poisson regression analysis. Likewise, the period prevalence of COVID-19 was 1.8-fold (95%, CI 1.2-2.6-fold) higher among participants exposed to food insecurity and 3.0-fold (95% CI, 2.8-3.5-fold) higher among those born to non-White mothers.

Conclusions: Childhood SARS-CoV-2 infection and COVID-19-associated illness are substantially underdiagnosed and underreported in the Amazon. Children in the most

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

socioeconomically vulnerable households are disproportionately affected by SARS-CoV-2 infection and disease.

Trans fatty acids and potential factors influencing their occurrence in plantain chips sold within the Accra Metropolis, Ghana

Phyllis Addo[1,2], Jinyao Chen[1,3], Bo Zheng[1,3], Kwaku Tano-Debrah[4,5], Xiaomeng Li[1,3], Lishi Zhang[1,3]

1. Sichuan University (China), 2. University of Health and Allied Sciences (Ghana), 3. Food Safety Monitoring and Risk Assessment Key Laboratory of Sichuan Province (China), 4. University of Ghana (Ghana), 5. International Life Science Institute (ILSI) Food Safety Training Center, Ghana (Ghana)

Background and objectives: Despite conclusive evidence of the harmful effects of trans fatty acids (TFAs) on health, legislation regulating TFAs in foods remains voluntary in Ghana. There is scarce documented data on the concentration of TFAs in the national food supply and population consumption levels that could aid policymakers. Our pilot study assessed the TFAs content of a popular deep-fried snack as part of the effort to provide data on TFAs in Ghanaian foods. **Methods**: We used gas chromatography with a flame-ionizing detector (GC-FID) to determine the levels of 18-carbon TFAs (C18:1, C18:2 and C18:3) in plantain chips. One hundred and twenty plantain chips were collected from various processors and vendors in Accra. A questionnaire survey was also conducted to assess oil usage among commercial plantain chips processors. **Results**: Seven trans isomers of oleic acid (t9-C18:1), linoleic acid (LA), and alpha-linolenic acid (ALA) were detected in all samples: one of OA (t9-C18:1), two of LA (c9, t12-C18:2; t9, c12-C18:2), and four of ALA (c9, c12, t15-C18:3; c9, t12, t15-C18:3; c9, t12, c15-C18:3; t9, c12, c15-C18:3). TFA concentrations varied between samples, with the mean ranging from 1.4/100g fat to 2.9/100g fat and 0.4/100g food to 0.8/100g food. Trans isomers of LA (1.25g/100g fat and 0.34g/100g food) were the most significant contributors to total TFAs. The fat content ranged from 26.0g-30.9g. TFA levels were not always highest in samples with the highest fat content. Commercial processors' oil usage practices were generally poor. The vast majority (97%) admitted to reusing oils multiple times, with more than half of these processors reusing oils four or more times before discarding them. **Conclusion**: Plantain chips from various parts of Accra contain TFAs and a high amount of fat. Data on the use of oils by commercial processors suggest that the types of oils used for frying and the repeated use of oils are potential entry points for TFAs into this snack food. We recommend that plantain chips be consumed in moderation, and future efforts to eliminate TFAs from the national food supply should include public education campaigns on the proper selection and use of oils.

PAB(T6)-77
"Some are healthy some are not…" Accra-based food retailers' characterization of the healthiness of the food they sell.

Silver Nanema[1], Akosua Adjei[1], Gideon Amevinya[1], Amos Laar[1]

1. Department of Population, Family & Reproductive Health, School of Public Health, University of Ghana (Ghana)

Background and objectives: Increasing the availability of healthy foods within food retail outlets can improve consumers' food environment. Such actions or inactions by food retailers may affect people's food purchasing behavior and consumption. This study explored Accra-based food retailers' perceptions and understanding of healthy food as well as the measures they adopt to encourage healthy food choices.

Methods: In-person semi-structured interviews were conducted with owners and managers of Accra-based supermarkets (n=7) and corner stores (n=13) in March 2021. The interviews were recorded, transcribed and coded in excel. We employed thematic analysis to analyze the transcripts.

Results: The retailers' understanding of healthy food is exemplified by such expressions as "health, absence of disease, longevity, balanced diet, diversity, sanitation, and certification" - describing what they sell as "therapeutic, healthy, balanced diet, certified, and or approved". A handful of retailers were neutral, or uncertain about the healthiness of what they sell. They evoked terms like "fitting consumer needs, innocent or generally good". Very few openly described what they sell as "junk" (high in sugar), high in salt, or risky (posing some health threats). Some of the retailers indicated that they advise against the overconsumption of such foods. Overall, retailers were not knowledgeable about the health impacts on health, of very salty, very sugary, and very fatty foods.

Conclusions: Retailers in Accra require interventions that improve their health, nutrition, and food literacy. Any efforts to introduce healthy food retail policies should be coupled with nutrition literacy interventions for key stakeholders such as food retailers.

Interpreting compliance to the EAT-Lancet diet using dietary intakes of lactating mothers in rural Western Kenya

Wilhemina Quarpong[1], Samson Wakoli[2], Shadrack Oiye[3], Anne M Williams[1,4]

1. Emory University (USA), 2. Taraund Consulting Group (Kenya), 3. Independent Public Health, Nutrition and Research Consultant (Kenya), 4. University of Otago (New Zealand)

Background and objectives: The EAT-Lancet reference diet aspires to be a "planetary healthy diet". We compared lactating mothers' diets to this diet, investigated associations between compliance and body mass index (BMI), and estimated costs of the mothers' diets.

Methods: We used single 24-hour dietary recall data from a cross-sectional survey nested within a cluster-randomized trial in Western Kenya (n=242). Mothers' intakes were compared to recommended intake ranges of 11 EAT-Lancet food groups, defining compliance (maximum score of 11) two ways: daily intake within the recommended ranges (including 0g as an acceptable intake for some food groups), or intake with a lower bound > 0g. Ordinal logistic regression models assessed associations between compliance and BMI. Cost of mothers' diets and hypothetical diets with intakes within recommended ranges were estimated using dietary data and food price survey data of two markets within the mothers' locality.

Results: Mean energy intake was 1,827 (95%CI: 1,731, 1,924) kcal/day. Relative to the reference diet, mothers' diets were on average higher for grains (63.5% of total energy vs. <60%); within recommended ranges for tubers (49.6g vs 0-100g) fish (61.7g vs. 0-100g), beef (16.8g vs. 0-28g), and dairy (165.2g vs. 0-500g); closer to the lower bounds for chicken (1.4g vs. 0-58g), eggs (5.0g vs. 0-25g), legumes (10.1g vs. 0-100g), and nuts (5.0g vs. 0-75g); and lower for fruits (25.0g vs. 100-300g) and vegetables (180.0g vs. 200-600g). Mean (95%CI) compliance scores were 8.2 (8.0, 8.3) when recommended ranges included 0g as acceptable and 1.7 (1.6, 1.9) otherwise. BMI ranged from 16.8-34.8 kg/m^2 and there were no significant associations between compliance and BMI. Mothers' diets and hypothetical diets within recommended ranges (with lower bounds >0g) averaged 184.6 KES (1.6 USD) and 357.5 KES (3.1 USD) per person daily, respectively.

Conclusions: Diets of lactating mothers in rural Western Kenya were not diverse and diverged from the EAT-Lancet reference diet when an intake of 0g was considered unacceptable for protein-rich food groups. Lower bound intakes of 0g are inappropriate when describing compliance to recommended diets in food-insecure populations. It would likely cost more than mothers currently spend to tailor their diets to the EAT-Lancet reference diet.

PAB(T6)-79
Nutrition practices and work environment affect the health of Canadian long-haul truck drivers

Gordon Alexander Zello[1], Alexander Michael Crizzle[1]

1. University of Saskatchewan (Canada)

Background and objectives: In Canada, the long-haul truck driver (LHTD) industry is the 2nd largest employer of males. However, the health of drivers is an immense concern with increased risks for non-communicable diseases (NCDs) which include obesity, type 2 diabetes, and cardiovascular associated diseases. These health risks may, in part, be responsible for a shortage of LHTD. Research in the relationship of demographics of the drivers, the working environment, and nutrition practices is lacking. We hypothesize that nutrition practices and work settings of LHTD associate with poorer health. The objective of this presentation is to examine the relationship between nutrition behavior and work conditions that can affect the perceived health of LTHD. **Methods**: Objective nutrition measures and surveys (i.e. nutrition behavior, working environment, truck driver demographics) were completed by 206 LHTD across 7 truck stops in the Provinces of Alberta and Saskatchewan, Canada. Objective nutrition/health measures included anthropometry, body composition by bioimpedance, and blood pressure (BP). body mass index (BMI), fat mass, and BP were used as proxies for health. These were then associated with nutrition practices and the work environment of LHTD. **Results**: Participants were 51.6±12.4 years of age and the majority male (96.5%). Most LHTD (>50%) were classified as overweight (BMI range 25-29.9) or obese (BMI >30) and their BPs were elevated above normal. Higher BMI was associated with poorer self-reported health ($p<0.05$) and higher BP ($p<0.05$). Increased body fat ($p<0 .001$) and lower muscle mass ($p<0.001$) were also related to health. Lower vegetable and fruit consumption ($p=0.05$) and increasing meal frequency ($p=0.07$) trended towards significance with higher BMI. More than half of the sample reported being sedentary or only taking part in light physical activity (54.5%). Sedentary/low activity approached significance ($p=0.06$) with poorer reported health being related to less activity. **Conclusions**: Less desirable nutrition behavior, activity patterns, and the work setting of LHTD are indicative of poorer perceived health that relate to higher rates of overweight and obesity and increased BP. Lifestyle and the food environment are contributing factors to drivers' health.

Predicting Overweight and Obesity Status among Malaysian Adults Using Supervised Machine Learning

Jyh Eiin Wong[1], Miwa Yamaguchi[2], Nobuo Nishi[2], Michihiro Araki[2], Lei Hum Wee[1]

1. Universiti Kebangsaan Malaysia (Malaysia), 2. National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Background and objectives: One in two adults in Malaysia suffers from overweight or obesity (OW/OB), which is a primary health concern that significantly impact non-communicable disease burdens and threatens the national productivity and economic growth. Given the large complexity of obesity etiology, machine learning algorithms offer a novel approach in disentangling interdependent factors for OW/OB prediction. This study proposes a machine learning model that predicts OW/OB among working adults in Malaysia based on multi-domain data collected in the Malaysia's Healthiest Workplace by AIA Vitality 2019 survey.

Methods: Using data of 16,860 participants (mean age 34.2 ± 9.0 years, 41% males), predictor variables comprising sociodemographic, job characteristics, health and weight perception and lifestyle-related factors were selected, one-hot encoded and normalised. After a 70:30 train-test data split, the training set was trained using the Extreme Grading Boosting (XGBoost) algorithm with 10-fold cross validation repeated three times to predict OW/OB based on body mass index cut-off of 25. The predictive performance of the trained model in predicting OW/OB in the test set was evaluated using Area under the Receiver Operating Characteristic curve (AUC). Comparison was also done for predictive models built on data stratified by sex.

Results: The prevalence of OW/OB was 41.8% in this sample. Weight satisfaction, ethnicity, age and sex were the top OW/OB predictor variables for the overall model. The AUC were 0.81 (95%CI: 0.80, 0.82) for the overall OW/OB model. The predictive performance of the male model (AUC 0.78, 95%CI: 0.76, 0.80) was similar to that of the female model (AUC: 0.81, 95%CI: 0.80, 0.82).

Conclusions: This study produced predictive models with machine learning that are able to identify OW/OB with moderate-to-high accuracy. Our findings suggested that weight satisfaction, along with ethnicity, age and sex, are important predictors of obesity among working adults in Malaysia.

Evaluation of body dissatisfaction using our developed Japanese version of Body Image Scale among healthy Japanese adults

Yukina Yumen[1,2], Yumi Takayama[1], Akio Iida[1], Miyoko Okuzono[1], Ayano Morimoto[1], Fumiaki Hanzawa[3], Naoki Sakane[4], Narumi Nagai[1,3]

1. Graduate School of University of Hyogo (Japan), 2. Kyoto College of Nutritional & Medical Sciences (Japan), 3. University of Hyogo (Japan), 4. National Hospital Organization, Kyoto Medical Center (Japan)

Background and objectives: Body dissatisfaction can lead people to engage in unhealthy behaviors, such as unnecessary weight control or under eating. It has been reported more frequently among women though, body dissatisfaction among men and gender differences have not been well understood. We therefore aimed to examine Japanese men and women of wide range of ages using our newly developed Japanese version of Body Image Scale (J-BIS) (Yumen et al. 2021).

Methods: The subjects were 438 Japanese men and 698 Japanese women aged 20-75 who responded to a web-based questionnaire form (age, gender, height, weight, and body image) in 2020. Body image was examined using the J-BIS, which contains 10-point pictures from thin (score 1) to obese (score 10) for men and women, respectively. Subjects responded to both the picture closest to their current body image (CBI) and the picture closest to their ideal body image (IBI); the difference between CBI and IBI was quantified as body dissatisfaction, and compared between men and women.

Results: The BMI score for men was 23.9 ± 3.8 kg/m^2 (mean ± SD), and the prevalence of underweight (BMI < 18.5 kg/m^2) and overweight (25 kg/m^2 ≦) was 3.2% and 29.5%, respectively. On the other hand, the BMI score for women was 21.1 ± 2.9 kg/m^2, and the prevalence of underweight and overweight was 15.6% and 9.2%, respectively. The body dissatisfaction score was -1.4 ± 1.9 for men and -1.5 ± 1.7 for women with no significant by gender (p = 0.780). Of overweight men, 95.3% wished to become thinner. Of underweight women, 29.4% wished to become thinner and 21.1% wished to remain the same.

Conclusions: The results suggest that Japanese men and women have the same level of dissatisfaction with their body shape (desire to be a little thinner), although the percentages of underweight and overweight remarkable differ between the two groups. However, women, even if they were underweight, desired to be even thinner. To prevent unhealthy eating behavior and weight control, nutrition education is required for both men and women with normal weight or thinness to avoid unnecessary body dissatisfaction.

Impact of the COVID-19 pandemic on mother's experiences during pregnancy, breastfeeding practices, and supporting environment for infants: A comparison between mothers delivered before and after the State of Emergency

Masaharu Kagawa[1,2,3,4,5], Mari Shinde[1,6], Eri Matsuzaki[1,7]

1. Kagawa Nutrition University (Japan), 2. Curtin University (Australia), 3. Queensland University of Technology (Australia), 4. Mahidol University (Thailand), 5. Universitas Airlangga (Indonesia), 6. Health Support Lab CANNAN (Japan), 7. Japan Nutrition Testing Association (Japan)

Background and objectives: The COVID-19 pandemic is making a considerable impact to the society and medical sites. Risk of infection might have increased anxiety among pregnant mothers and also reduced social support during early stage of raising infants. In the present study, differences in experiences during pregnancy, breastfeeding practices, and perceived support from surroundings were investigated among mothers who had childbirth in Japan using the State of Emergency (SoE) as a turning point of the COVID-19 pandemic in Japan.

Method: An online questionnaire survey was conducted on mothers met inclusion criteria of 1) 18 years and above at the time of delivery, 2) gave birth in Japan, and 3) have a child under 24 months. The questionnaire included items on socio-demographics as well as experiences during pregnancy, breastfeeding practices, and support on breastfeeding and infants. Participants were informed about the background of the study and provided a consent prior to their participation to the study. All analysis was conducted using the SPSS package (version 27, Tokyo, Japan) and a significance level of 5% was used.

Results: Of 1,022 responses, 994 responses were considered eligible for analysis and divided into Pre-SoE (n = 426) and Post-SoE (n = 568) based on the timing of childbirth. The Post-SoE experienced a greater concern to visit hospital during pregnancy (86.0% vs 29.1%, p<0.01) and had no attendees except medical staff at delivery compared with their Pre-SoE counterparts (69.4% vs 34.9%, p<0.01). No group differences in breastfeeding practices were observed and more than 85% of mothers who selected exclusive breastfeeding at three months continued at six months. The Post-SoE mothers perceived that they did not receive sufficient education on breastfeeding practices at hospitals (12.2% vs 8.0%, p<0.05) and insufficient support on breastfeeding from family and friends (72.9% vs 60.6%, p<0.01). Overall, the Post-SoE mothers felt that they had insufficient support from surroundings to their infants (47.1% vs 37.8%, p<0.01).

Conclusion: The COVID-19 pandemic did not influence a method of breastfeeding. However, mothers who had childbirth after the SoE experienced a greater concern during pregnancy and also perceived less support from surroundings on breastfeeding and infants.

Breakfast for students at primary schools in Bangkok, Thailand: Opportunities and potential impacts on meal quality based on Thai nutrient-profiling

Kantanit Chammari[1], Punnee Ponprachanuvut[1], Arisa Keeratichamroen[1], Nuttarat Srisangwan[1], Nattvara Nirdnoy[1], Kitti Sranacharoenpong[1]

1. Mahidol University (Thailand)

Background and objective: The benefits of breakfast, the first meal of the day, as part of a healthy and balanced lifestyle, are widely known from a nutritional, psychological, and societal point of view. The breakfast meal is related to several critical health factors that include healthy body weight, especially among children. The objective was to assess the adequacy of Thai breakfast for children available at schools in Bangkok, applying nutrient-profiling criteria and Thai Dietary Reference Intakes (Thai DRIs).

Methods: Twenty popular menus for breakfast at primary schools in Bangkok were collected. Most menus normally were single dishes and easy to eat. We determined serving sizes for two levels; small and medium sizes for kindergarten and students (grade 1-6), respectively. The nutritive values of all menus were calculated by the Thai food composition software (INMUCAL-Nutrients V.4.0). The nutrient-profiling criteria were used to grade quality of breakfast as follows; grade A (score >16), 'grade B' (12-16), and 'grade C' (score <12). The grading of menus was developed scenarios for breakfast patterns per week. The goal of breakfast is 20% of the total day, based on Thai DRIs.

Results: One menu was passed the 'grade A', while 6 and 13 menus were accepted as 'B' and 'C', respectively. The exceeding sodium was concerning for some menus based on nutrient-profiling criteria. The total scenarios of breakfast for 5-day a week were 5,292 patterns, which all reached 20% of the DRIs, including a variety of menus per week, and passing nutrient-profiling criteria. Among 5,292 patterns, 8 patterns (0.15%), 4,335 patterns (81.92%), and 949 patterns (17.93%) passed grade A, B, and C, respectively. When we added at least one serving size of fruit, the dietary fiber and some vitamins were improved.

Conclusion: The nutrient-profiling is a helpful tool to use in conjunction with interventions aimed at improving diets. It can also be used in implementing the recommendations on the breakfast to children. This study also provided a general picture of children's breakfast in Bangkok, mainly focusing on reducing sodium, salt and increasing dietary fiber, fruits and vegetables offering healthier meals.

Association between barley intake and blood pressure and HbA1c in a real-life setting: A longitudinal observational study among male workers in Japan

Masae Sakuma[1], Yoshiro Shirai[2], Mieko Nakamura[3]

1. Fukuoka Women's University (Japan), 2. Kinjo Gakuin University (Japan), 3. Hamamatsu University School of Medicine (Japan)

Background and objectives: β-glucan, the primary dietary fiber in barley, has been reported to have various health benefits. In a previous study, we reported an inverse association between the cumulative number of intake times of rice with barley in the 12 weeks before the follow-up and systolic blood pressure and HbA1c in a workplace cafeteria. The purpose of this longitudinal observational study was to examine if the frequency of rice with barley consumption by workers is inversely associated with changes in their systolic blood pressure and hemoglobin A1c (HbA1c) in their workplace cafeteria where information on the functional properties of barley was displayed on the tabletop pops and workers were allowed to freely choose rice with barley.

Methods: The study subjects were male workers (n = 890). The number of bowls of rice with barley consumed was assessed through an electronic purchase system using an integrated circuit (IC) - chip with menu information - equipped tableware and personal identification cards in the cafeteria. Outcomes were based on data from annual health examinations. Multiple linear regression analysis was performed using the change in systolic blood pressure and HbA1c measurements as the objective variable and the average weekly intake of rice with barley consumed during the 12 weeks before the follow-up health checkup as the explanatory variable.

Results: After adjusting for age, body mass index, alcohol use, smoking, exercise, total energy intake, medication for hyperlipidemia, and intakes of soy products and green tea as confounders, there was a significant inverse association between systolic blood pressure and intake of rice with barley, 2.0-3.9 times a week (β= -9.14, $p < 0.05$). On the other hand, a marginal inverse association was found between HbA1c and when rice with barley was consumed 1.0-1.9 a week (β= -0.13, $p = 0.06$).

Conclusions: Serving rice with barley, providing information on barley's functional properties, and allowing employees to consume of their own free will in a workplace cafeteria may promote the benefits of barley on systolic blood pressure and HbA1c.

Keyword: Barley, HbA1c, Systolic blood pressure, Food environment, Employee cafeteria

Health and economic impacts of dietary salt reduction policies in Japan, 2019–2028: a Markov model simulation analysis

Nayu Ikeda[1], Hitomi Yamashita[1], Jun Hattori[1], Kazuko Minowa[1], Megumi Yamada[1], Hiroki Kato[2], Katsushi Yoshita[3], Nobuo Nishi[1]

1. National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 2. The University of Tokyo Hospital (Japan), 3. Osaka City University (Japan)

Background and objectives: Reducing dietary salt intake is an important population strategy for prevention of cardiovascular diseases (CVD). Evidence from health economic evaluation is useful for policymakers to determine how to allocate limited resources among nutrition programs. We aimed to evaluate economic impacts of salt-reduction policies in Japan over 10 years. **Methods**: We assessed costs and benefits of four salt-reduction policies examined in a previous study in England: a national media campaign (Policy A), voluntary reformulation of processed food by the food industry (Policy B), mandatory reformulation (Policy C), and front-of-pack traffic light labelling (Policy D). We constructed a Markov cohort simulation model of the Japanese population over the period 2019 to 2028. The model consisted of four health states: well, acute CVD, chronic CVD, and dead. We adopted the health sector's perspective and a 2% discount rate. We used epidemiological data in Japan obtained from national surveys and a global database, and estimates from previous meta-analyses on the changes in CVD incidence and mortality associated with salt reduction. We applied a costing method and estimates on effectiveness of policies on salt intake from the previous study in England. We defined benefits as a decrease in national medical costs associated with CVD and costs as the sum of monitoring costs and policy costs. We calculated net benefits by subtracting costs from benefits to compare among policies. We conducted one-way sensitivity analyses to examine potential impacts of uncertainties. **Results**: The net benefit accumulated over 10 years was largest for Policy C at US$95.1 billion (cost: US$11.8 billion, benefit: US$106.9 billion), followed by Policy B at US$83.9 billion (cost: US$48.3 million, benefit: US$84.4 billion), Policy D at US$11.4 billion (cost: US$90.7 million, benefit: US$12.3 billion), and Policy A at US$11.2 billion (cost: US$109.5 million, benefit: US$12.3 billion). These estimates were sensitive to the effects of policies on salt reduction. **Conclusions**: According to the net benefits, all the salt reduction policies were likely to be worthwhile the investment in Japan. The mandatory reformulation was preferred to other three alternatives, but budget constraints should be carefully considered in decision-making.

Keyword: salt intake, nutrition policy, cardiovascular disease, simulation, economic evaluation

The association between dietary habits and the estimated 24-hour urinary salt excretion and sodium-to-potassium ratio in 3-yr old children

Akane Higashi[1,2], Natsuki Maruyama[1], Kiyoko Odani[1], Sayumi Takahata[1], Chikako Seko[1], Kengo Yoshii[3]

1. Former affiliation; Kyoto Prefectural University (Japan), 2. Kyoto Sangyo University (Japan), 3. Kyoto Prefectural University of Medicine (Japan)

Background and objectives: In this study we examined the association between dietary habits and the estimated 24-hour urinary salt excretion as well as the urinary sodium-to-potassium (Na/K) ratio in 3-yr old children.

Methods: The participants were 639 3-yr old children who underwent a health checkup in two cities and two towns in Kyoto Prefecture from January to November 2019. The urinary salt and Na/K ratios were obtained from the participants' first-voided urine in the morning. In addition, a questionnaire was employed to assess the dietary habits, etc., of the participants. Administered by the guardians of the children, the questionnaire included 5 items related to physical characteristics, 10 items on food intake frequencies and the awareness of the necessity to restrict salt intake for the children. The medians of the urinary salt and Na/K ratios among the higher intake and lower intake groups were examined using Mann–Whitney U test.

Results: Dietary habits and urinalysis were confirmed for 294 children. The median urinary salt (g/day) observed was 2.6 (25%tile, 75%tile, 1.7, 3.4), and median urinary Na/K ratio (mEq/mEq) was 2.6 (25%tile, 75%tile, 1.6, 4.1). The urinary Na/K ratios were significantly higher for the group that consumed a higher percentage of processed meat intake, showing a median of 2.9 (1.9, 4.7), compared with the lower group, median of 2.5 (1.5, 3.8), and the lower vegetable intake group, median of 3.1 (1.9, 4.9), compared to the higher intake group, median of 2.5 (1.6, 3.8) . There were no significant associations between the urinary salt values and the food intake or the mother's awareness of the necessity to restrict salt intake.

Conclusions: Significant associations were found between the processed meat intake and the vegetable intake and the urinary Na/K ratio in the 3-yr old children. Along with an appropriate education program, in the future these findings may aid in preventing cardiovascular diseases in the local community.

Understanding the environmental impacts of ultra-processed foods: insights from group model building with food system experts

Kim Anastasiou[1], Phillip Baker[1], Michalis Hadjikakou[1], Gilly Hendrie[2], Mark Lawrence[1]

1. Deakin University (Australia), 2. CSIRO (Australia)

Background and objectives: The global food system is a leading driver of global environmental change due to significant use of resources (e.g. land and water), and production of pollutants (e.g. greenhouse gases). Finite environmental resources are being used to produce ultra-processed foods (UPFs). While a growing evidence base demonstrates UPFs are harmful to human health, much less is known about the environmental impacts. This study aims to develop and validate a model of the environmental impacts of UPFs. In doing so, this study a) better conceptualises the relationships between environmental sustainability and UPF production throughout each stage of production; b) identifies relationships between environmental issues to create a dynamic conceptual systems model; and c) differentiates the impacts of UPFs from less-processed foods.

Methods: Group-model building (GMB) is a system dynamics approach that allows a group of people to develop a shared understanding of how complex systems operate and can be used to test systems diagrams. A conceptual diagram displaying the known environmental impacts of UPFs, developed in a recent review, was converted into a causal loop diagram (CLD) by conducting an unstructured scoping review of scientific papers and reports to identify the relationships between variables. The CLD was subsequently expanded and tested for validity with food system experts using GMB.

Results: The final conceptual model illustrating the environmental impacts will be presented. The model is divided into 7 subsystems: 3 exploring the drivers of UPF production (social, biological and political economy drivers) and 4 exploring the environmental impacts of UPFs (impacts on climate, land, water and aquatic ecosystems, and waste). The model highlights the complex bi-directional relationships between UPF production and the natural environment. The model can be used to a) identify key parameters in quantitative analyses of the environmental impact of diets; b) provide a food-systems context for interpreting findings of quantitative analyses, particularly in relation to UPFs.

Conclusions: The relationship between UPF production and environmental degradation is complex and dynamic. This research can be used to guide future studies quantifying and understanding the environmental impact of diets and system-based policies for a healthier and more sustainable food system.

Monitoring and compliance of salt reduction targets in processed foods in South Africa

Beulah Pretorius[1], Pamela Naidoo[2], Terry Harris[3], Karen Charlton[4]

1. University of Pretoria (South Africa), 2. University of the Western Cape (South Africa), 3. Discovery Vitality (South Africa), 4. University of Wollongong (Australia)

Background and objectives: Great strides in reducing salt intake have been made globally. In 2016, the South African Government implemented regulations to enforce mandatory reduction in the sodium content of a wide range of processed foods. A stepwise approach was adopted (target dates June 2016 and April 2020) to allow the food industry to achieve the final recommended sodium levels. Some reports of food labelling indicate compliance with targets, but in the absence of routinely collected laboratory analytical data, these cannot be validated.

Methods: The sodium content of key foods in 8 of 13 of the food categories included in the mandatory sodium reduction legislation were sampled and analysed using dry-ashing and Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES). Calibration was done using an acidified calibration range. The analytical values were compared with sodium content information provided on food packaging labels.

Results: More than 80% of the foods analysed have sodium levels below the Phase 2 salt targets. For the categories of dry soup powders, fat and butter spreads, processed meat (cured), stock cubes/powders/ granules/emulsions/pastes or jellies, food labels had higher sodium content compared to the analytical values. The only food category that had a labelling value that was less than the analytical value for sodium was processed meats (uncured).

Conclusions: There is evidence that salt reduction regulations are effective in reducing population-level salt intake. However, this requires strong governmental leadership with multi-stakeholder buy-in. A key component to demonstrating the success of the sodium reduction legislation is systematic monitoring and surveillance of the sodium content of packaged foods, however there is no system in place for this to occur.

Keyword: sodium, salt reduction regulations, processed food

Developing preconception Multiple Micronutrients Supplementation (MMS) program for stunting reduction acceleration: Lesson learn from 5 districts in Indonesia

Sri Sumarmi[1], Maya Sari Dewi[1], Maulana Hasan[2], Quinn Harvey[2], Otte Santika[2], Kristen Hurley[3,2]

1. Universitas Airlangga (Indonesia), 2. The Vitamin Angels Alliance, Inc (USA), 3. Johns Hopkins Bloomberg School of Public Health (USA)

Background and objectives: Indonesian Government targeting the reduction of stunting prevalence about 14% in 2024. Intervention of multi micronutrients supplementation (MMS) beginning at preconception period might become an effective strategy on reducing stunting prevalence. This study aims to pilot an MMS intervention during pre-conception periods to accelerate the reduction of stunting prevalence. **Methods**: An implementation research was conducted gradually in 5 districts. Initially, in 2010 we developed the integrated pre-marriage services in one district in East Java, as pilot project, in which the MMS for pre-conception and pregnant women was included. MMS from UNIMMAP formulation was used in this service. The new model was implemented in 9 subdistricts, until 2014. Year 2017, the model was adopted by other Districts Government, piloting in two subdistrict areas until 2018. In last 2019, we strengthen two Districts Government to implement the pre-marriage services system with the main intervention of MMS for total coverage of the brides to be and continued during pregnancy. Year 2020, we scale up the implementation in three districts areas (South Kalimantan, North Maluku, Madura Island).

Results: The implementation of pre-conception MMS program in 5 districts had wide variation depend on the local government commitment and supply of MMS. MMS supply for this intervention was attained form The Vitamin Angels Alliance. The mechanism of services involved multi sectoral begin at village level, subdistrict public health center (PHC), and subdistrict Religious Affair Office (RAO). The MMS was distributed in Public Health Center. The bride to be attended Village office to receive marriage registration form, then attended PHC to receive health services and MMS, finally registered in RAO. During 3 years (2018-2021), there is significant reduction of stunting prevalence in 5 districts: in Probolinggo from 49% to 23.3%, In Sidoarjo reduce form 27%-14.8%, in Sampang Madura form 47% to 17%, in Barito Kuala from 34,12% to 32.4%, in West Halmahera from 30,8% to 30%.

Conclusions: The MMS program begin at pre-conception with the target of brides to be may have significant contribution on stunting reduction strategy in 5 districts, but it need more information about the contribution of other programs

Association between soy products intake and low-density lipoprotein cholesterol in a real-life setting: A longitudinal observational study among male workers in Japan

Yoshiro Shirai[1], Masae Sakuma[2], Mieko Nakamura[3]

1. KInjo Gakuin University (Japan), 2. Fukuoka Women's University (Japan), 3. Hamamatsu University School of Medicine (Japan)

Background and objectives: Soy protein has beneficial effects on serum lipids. In a previous study, we reported that the cumulative number of intake times of soy products in the 12 weeks before the follow-up was inversely associated with low-density lipoprotein (LDL) cholesterol levels among workers in a workplace cafeteria. The workers had a free choice of soy products, and tabletop pops displayed the functional properties of soy protein. To further add to this research, the present study investigated the association between the frequency of soy products intake and LDL cholesterol levels among these workers.

Methods: The number of soy products consumed by 890 male workers was assessed through an electronic purchase system using an integrated circuit (IC) - chip with menu information - equipped tableware and personal identification cards in their workplace cafeteria. The workers had a free choice of soy products, and tabletop pops displayed the functional properties of soy protein. Outcomes were based on data from annual health examinations. Multiple linear regression analysis was performed; the response variable was the change in LDL cholesterol levels while the explanatory variable was the average weekly intake of soy products within the 12 weeks before the follow-up health checkup.

Results: In a model adjusted for age, body mass index, alcohol use, smoking, exercise, total energy intake, medication for hyperlipidemia, and intake of rice with barley and green tea as confounding factors, significant inverse associations were found between LDL cholesterol levels and soy products intake, 1.0-1.9 times a week (β= -7.16, $p < 0.05$), 2.0-2.9 times a week (β= -9.50, $p < 0.05$), and 3.0-3.9 times a week (β= -12.23, $p < 0.05$). The association was slightly attenuated by further adjustment with the baseline value of LDL cholesterol.

Conclusions: In a workplace cafeteria with soy products and available information on their functional properties, the consumption of soy products of the employees' own free will may benefit LDL cholesterol levels.

Keyword: Soybeans, LDL cholesterol, Food environment, Employee cafeteria, Objective assessment

Geographical variation in the consumption of dairy products in adults in China: preliminary results from a systematic review

Shuhua Yang[1,2], Nupur Bhargava[1,2], Aileen O'Connor[1,2], Simone Dunne[1,2], Emma L Feeney[1,2], Eileen R Gibney[1,2]

1. Food for Health Ireland, University College Dublin (Ireland), 2. Institute of Food and Health, University College Dublin (Ireland)

Background and Objective: Dairy intakes are known to vary according to geographical regions, age and sex amongst others. Research on the variation in the consumption of dairy foods in China is lacking, specifically the influence of geographical location. To fully understand factors influencing the differences in dairy consumption among people living in China, a systematic review was conducted. Studies reporting dairy intakes according to classifications of geographic location were summarized in the present review.

Methods: Web of Science, Embase, and PubMed databases were searched for studies published between January 2000 to October 2021. The following search terms were used: Dairy OR Milk OR Cheese OR Yogurt OR Yoghurt OR Yoghourt OR Butter OR Cream OR Milk powder OR Food AND Intake OR Consumption OR Market OR Diet OR Dietary AND China OR Chinese OR Asian. The search was limited to studies carried out in human adults (≧18 years), written in English or Chinese languages. Papers reporting dietary intakes of dairy consumption across geographical location sub-groups were considered for inclusion in this review.

Results: 11 studies reported dairy consumption across different location-specific cohorts in China. Different regions reported in studies were classified as urban v rural; North v South, coastal v inland; East, West and Central, as well as by the size of city or country region. Papers examining dairy consumption between urban and rural areas, reported higher intakes of dairy products in urban populations compared to those living in rural areas. Coastal, Northern and Eastern residents consumed more dairy products than those living in other regions in China, and people in larger cities had higher reported intakes than smaller cities.

Conclusions: Population sub-groups in varied geographic locations across China displayed significant differences in the amount of dairy consumed. Information on dairy intake across different regions in China may help to understand variations in dairy consumption and could aid targeted strategies to enhance intakes in areas of nutrient inadequacy.

The work described herein was supported by the China Scholarship Council (CSC) and Food for Health Ireland (FHI), from Enterprise Ireland under Grant No. TC20180025.

Humanitarian impact of climate change on nutrition security in low-income countries and conflict zones

Ayuko Hirai[1], Saskia van der Kam[2]

1. Medecins Sans Frontieres (Japan), 2. Medecins Sans Frontieres (Netherlands)

Background and Objectives: Over the last several decades, natural disasters such as droughts and floods triggered by the climate change are fast becoming a threat for the already vulnerable population living in places which lack access to health care. The climate crisis not only negatively impacts the quantity and quality of the food, but may cause high inflation which aggravates local conflict and results in severe food insecurity in many countries. Médecins Sans Frontières (MSF) is a non-governmental humanitarian medical organization founded in 1971, operating in over 80 countries and providing free health care to the people affected by conflict, epidemics, or disasters. In 2020, MSF globally treated 161,400 severely malnourished children including 64,300 hospitalizations for severe acute malnutrition (SAM). We assessed the impact of these climate-induced disasters on undernutrition among the children under 5 years-old in neglected, fragile, conflict-affected settings.

Method: The data was collected from MSF nutrition surveillance and clinical databases in MSF intervention areas where significant climate change has been reported. Nutritional screening was done by mid-upper arm circumference (MUAC).

Results: In Somalia, long term insecurity and conflict, exacerbated by frequent floods and droughts combined with desert locust swarms aggravated the food insecurity. In February 2022, among 81,706 children screened by MSF team in Baidoa area (South West of Somalia), 16.6% of the children were acutely malnourished of which 3.4% severe. In response to the consequences of the drought, MSF scaled up emergency nutrition support to five regions in Somalia. In 2021, Madagascar faced worst drought in 30 years, causing 740,000 children fall into acute malnutrition of which 120,000 were SAM cases this number was 80% higher than that of 2020. In Amboasary district in Anosy region (a fragile region in Southern Madagascar), 28% of the children were malnourished, one-third of them were SAM. MSF set up more than 15 mobile clinic sites in this region for malnutrition screening and treatment.

Conclusions: Climate change, exacerbated by conflict caused a serious nutrition crisis among children, demanding an urgent humanitarian response.

Keyword: climate change, nutrition security, conflict zone

A survey of the most memorable tasks or turning points performed by dietitians working in Japanese local governments

Tatsuya Koyama[1], Yusuke Arai[2], Ayaka Iida[3], Sumie Isobe[4], Rie Okamoto[5], Osamu Kushida[6], Idumi Shibuya[7], Kazumi Tanaka[8], Ayumi Morooka[9], Katsushi Yoshita[10]

1. Aomori University of Health and Welfare (Japan), 2. Chiba Prefectural University of Health Science (Japan), 3. Kanagawa University of Human Services (Japan), 4. Niigata Prefecture (Japan), 5. Kanazawa University (Japan), 6. University of Shizuoka (Japan), 7. Aichi Prefecture (Japan), 8. Kanagawa University of Human Services (Japan), 9. Hyogo Prefecture (Japan), 10. Osaka City University (Japan)

Background and objectives: The number of dietitians implementing dietary projects per local government is limited. Therefore, dietitians should strive to increase their self-efficacy. Self-efficacy is based on four major sources of information: performance accomplishment, vicarious experience, verbal persuasion, and emotional arousal. In this study, we aimed to identify tasks that improved the self-efficacy of municipal dietitians by assessing their routine dietary projects.

Methods: We conducted a web survey of dietitians working in Japanese local governments from January to March 2021. We asked them to describe their most memorable tasks or turning points. The tasks were defined as a successful experience and were categorized based on the basic guidelines for health promotion and improvement of nutrition and dietary habits by the administrative dietitians in the community.

Results: We received responses from 452, 323, and 1031 dietitians working in prefectures, cities with public health centers or special wards, and municipalities, respectively. The top five tasks that impressed dietitians in prefectures were establishing systems with related departments and securing human resources; establishing joint systems with municipalities; collecting and organizing municipal health checkups; collecting, organizing, and analyzing various surveys; and planning, goal setting, and evaluating. Most of the top five tasks were similar for dietitians in municipalities and cities with public health centers and special wards, including establishing nutrition education promotion network; implementing, evaluating, and improving nutritional education leading to behavior change; analyzing and clarifying challenges, planning, goal setting, and implementing nutritional education based on specific health checkups and guidance; and health promotion activity for children. However, dietitians from municipalities worked on the health promotion activity for older adults, and dietitians from the cities worked on guiding, supporting, and evaluating specific foodservice facilities. Approximately 17%-20% of the dietitians had no memorable tasks.

Conclusion: The most impressive tasks for dietitians working in Japanese local governments, regardless of their working site, were multidisciplinary cooperation and implementation of projects planned by themselves. being involved in these tasks could improve the self-efficacy of dietitians working in Japanese local governments.

Dietary habits associated with dental caries in Japanese elementary school children: a cross-sectional study

Airi Sekine[1], Kae Saeki[2], Emiko Terauchi[2], Yuri Ogata[2], Aya Sato[3], Yuki Sato[4], Chieko Suzuki[5], Reiko Suzuki[1,2]

1. Japan Women's University (Japan), 2. Japan Women's University (Japan), 3. Tokyo Healthcare University (Japan), 4. National Institute of Occupational Safety and Health (Japan), 5. Saga University (Japan)

Background and objectives: Dental caries is multifactorial-induced infectious disease and a major oral health problem in children. We examined the association between dietary habits and dental caries in Japanese elementary school children.

Methods: A cross-sectional study was conducted with 2457 first to sixth grade students from seven public elementary schools and their guardians residing in Saga, Japan. Dietary habits were measured using anonymous self-reporting questionnaires. The questionnaire contained basic items about the participants' living environment, lifestyle habits, and typical dietary menu (breakfast, dinner, snacks). Final data analysis was performed on a total of 2412 children. All statistical analyses were performed using JMP® 14 (SAS Institute Inc., Cary, NC, USA). All reported *P* values were two-tailed, and $P < 0.05$ was regarded as statistically significant.

Results: Compared with school children without cavities (n = 721), those with cavities (n = 1691) tended not to eat a variety of food items for breakfast and dinner ($p < 0.05$), tended not to eat green and yellow vegetables and other vegetables for breakfast and dinner ($p< 0.05$), tended to eat a snack before breakfast ($p = 0.01$) and after dinner ($p < 0.0001$), tended not to have breakfast every day ($p = 0.0006$), and tended to have a higher frequency of eating instant foods ($p < 0.0001$).

Conclusions: These results suggest that school children with dental caries tend to have unhealthy dietary habits such as a lower intake of vegetables and a higher intake of snacks and instant foods compared with those without dental caries.

Keyword: dietary habits, dental caries, Japanese children, a cross-sectional study

PAB(T6)-95
Are Front-of-Pack nutritional labels effective in improving food choices of consumers and nutritional quality of food products? A narrative review

Véronique Braesco[1], Kevin Burke Miller[2], Clélia Bianchi[1], Anne-Lise Guion[1]

1. VAB-nutrition (France), 2. General Mills, Inc. (USA)

Context: Front-of-Pack nutrition labels (FOPNL) are increasingly being used globally with the goal of driving healthier consumer food choices and incentivizing food manufacturers to improve their products. This critical review of the relevant scientific literature was conducted to determine the effectiveness of FOPNLs against the desired outcomes/goals.

Methods: Four FOPNL (Multiple Traffic Lights, Warning Signs, Nutri-Score, Health Star Rating) were evaluated for their impact on consumers' food purchase or selection (FPS), consumption habits (CH) and on product reformulation (PF) .) Studies were searched with appropriate keywords, included when original and examining the relevant FOPNL and outcomes, and analyzed in detail.

Results: Research studies were identified addressing FPS (31 studies), CH (6) and PF (7). FOPNL, overall, appear to have a beneficial effect on the healthiness of FPS, but this effect is of very small magnitude in empirical studies and only slightly higher in experimental studies, highlighting the importance of study design. Very few data exist on FPS in populations of public health interest, especially in low-income consumers. Regarding CH, scarcity of data did not allow conclusions. A few favorable changes were observed in the nutrient composition of foods after implementation of FOPNL, however concerning only nutrients included in the nutrient profiling system underlying the FOPNL (sugars primarily). Product reformulation to reduce nutrients to limit may have unintended consequences such as more complex processing and/or ingredient use. **Conclusion**: The four FOPNL seem to have small but measurable effects on guiding consumers towards healthier dietary choices. However, their implementation may have unintended and potentially unfavorable consequences such as decrease in intakes of nutrients not targeted by the FOPNL systems. Some favorable trends were observed on the nutritional quality of the food supply, although the voluntary and recent implementation of FOPNLs prevents reliable conclusions. The heterogeneity of designs associated to the inconsistencies of findings hinder any ranking between the four FOPNLs of interest and no single FOPNL ideally addressed all outcomes. Further and higher quality research is needed to confirm the real effects of these four FOPNLs, their magnitude and their maintenance over the time on both food demand and supply.

Latent Class Analysis to identify and describe dietary patterns of women in Ibadan, Nigeria.

Giulia Pastori[1], Raymond H Ssenyonga[1], Elise F Talsma[1], Oluyemisi O Shittu[2], Folake O Samuel[2], Inge D Brouwer[1], Hans Verhoef[1]

1. Wageningen University and Research (Netherlands), 2. Univeristy of Ibadan (Nigeria)

Background and objectives: Latent class analysis is a method to identify and characterize unmeasured classes of women based on their dietary patterns (DP). Women within the same latent class are relatively homogeneous regarding their food group (FG) intake patterns. We used latent class analysis to characterize distinctive DP among urban Nigerian women; and to assess the relationship between these DP and nutritional status.

Methods: We used 24h-recalls to assess dietary intakes in 225 women aged 18-49 years from Ibadan, Nigeria, complemented with anthropometric measurements. Foods consumed were classified into the 10 FG as defined for the Minimum Diversity Score for Women. For each FG, intake was categorized as 'negligible' (<15g), 'low' and 'high' (>=15g) by median split, and used as input variables for latent class analysis (Latent Gold vs 6.0). The number of DP was determined using Bayesian and Akaike Information Criteria, and likelihood ratio tests. DP were described by the conditional probabilities of intake category for each FG. To investigate the relationship between DP and body mass index, we used logistic regression.

Results: Three patterns (DP1-3) were identified, with DP1 (prevalence: 57%) characterized by high consumption of meat and fish and other vegetables, low/negligible consumption of leafy vegetables, and nuts and seeds; DP2 (31%) with low or negligible quantities of all FG, mainly fruits and vegetables; and DP3(12%), with high consumption of starchy foods, pulses, meat and fish, leafy and other vegetables. All DP presented negligible intake of dairy, eggs, vitamin-A rich fruits and vegetables and other fruits. The difference between DP was explained by leafy vegetables, other vegetables and meat and fish FG. Compared to DP1, the odds of being underweight increased by 51% in DP2, and decreased by 38% in DP3; the odds of being obese increased by 17% in DP2, and 35% in DP3.

Conclusions: Three DP were identified in the studied Nigerian women and they mainly differ in consumption of vegetables and animal protein rich foods. The application of latent class analysis can contribute to the identification of groups with specific consumption patterns and needs in order to inform appropriate and tailored interventions to combat all forms of malnutrition.

Transforming food waste into functional ingredients: Lessons from a Dutch case study

Madhura Rao[1], Lea Bilić[2], Anouk van Weert[3], Alie de Boer[4]

1. Maastricht University (Netherlands), 2. Maastricht University (Netherlands), 3. Maastricht University (Netherlands), 4. Maastricht University (Netherlands)

Background and objectives:
Several million tonnes of nutritionally dense by-products such as peels and trimmings of fruits and vegetables end up in landfills every year. Through technological innovation, it is possible to upcycle at least a part of this waste into ingredients that can be used to improve or fortify existing food products. However, for this kind of valorisation to be commercially feasible, entrepreneurs must overcome several legislative and logistical barriers. Through this case study, we present the example of a Netherlands-based start-up that has been able to successfully transform fruit peels into valuable products such as additives, oils, and functional fibre. By critically examining the barriers and drivers of such a business, the study contributes to a deeper understanding of the intersection of the circular bioeconomy and functional ingredients derived from food waste.

Methods:The study uses a qualitative case study approach wherein a real-life bounded system is investigated by drawing from multiple sources of information. We investigate data generated through in-depth unstructured interviews, field observations, and analyses of documents and digital material.

Results: Our results indicate that factors such as funding opportunities, legislative flexibility, ability to exercise intellectual property rights, and community support play a critical role in valorising food waste as functional food ingredients.

Conclusions:A circular bioeconomy where food waste can be transformed into nutritionally valuable food ingredients is feasible only through multi-stakeholder cooperation. Next to financial and technological resources, setting up such operations requires support from policy makers, legislators, and various supply chain actors.

Keyword: circular economy, functional foods, bioactive compounds, food waste, case study

Conflict of Interest Disclosure: The authors hereby declare that there are no conflicts of interest.

Comparing health insurance data and survey data in estimating prevalence of chronic diseases

Maria Salve Vasquez[1], Elly Mertens[2], José Luis Peñalvo[2], Stefanie Vandevijvere[1]

1. Sciensano (Belgium), 2. Institute of Tropical Medicine (Belgium)

Background and objectives: As part of the development of a life course microsimulation model that aims to understand the relationship of diet to non-communicable diseases (NCDs) and to estimate the burden of diet-related chronic conditions, it is of interest to compare population prevalence estimates of NCDs using national health surveys and administrative insurance records. This study specifically compares the agreement between the Belgian Health Interview Survey (BHIS) and the Belgian compulsory health insurance data (BCHI) in ascertaining chronic hypertension, hypercholesterolemia and diabetes in Belgium.

Methods: The most recent cycle of BHIS (2018) and BCHI records were linked through unique identifiers by Sciensano. BHIS provided the self-reported information on diabetes, hypertension, and hypercholesterolemia among a representative sample of Belgian adults. For BCHI, the chronic condition was attributed for every individual reviewing the medication prescription records identified using the ATC/DDD system. Chronic patients were defined as those individuals consuming a total of at least 90 DDD of chronic-indicated medication in a year. Disease prevalence, Cohen's kappa coefficient, sensitivity, specificity, negative predictive value (NPV), and positive predictive value (PPV) with BHIS as the reference standard were estimated and used to assess the agreement between both data sources.

Results: BHIS and BCHI identified 5.4% and 5.1% diabetes cases in 2018, respectively. For hypertension, BHIS has an estimated 15% cases while BCHI has 20%. Diabetes has kappa coefficient of 0.8, sensitivity of 78%, specificity of 99%, PPV of 83%, and NPV of 99%. Hypertension, on the other hand, has kappa coefficient of 0.6, sensitivity of 77%, specificity of 90%, PPV of 59%, and NPV of 96%. The results for hypercholesterolemia are currently being calculated.

Conclusion: BCHI underestimated and overestimated diabetes and hypertension prevalence, respectively. Moreover, the two data sources have a stronger agreement for diabetes prevalence than for the prevalence of the other NCDs.

Keyword: chronic disease, administrative data, health interview survey

Relationship between vegetable and fruit intake, their biomarkers and health indicators: Epidemiological literature review in Asians.

Yuko Tousen[1], Reina Ikaga[2], Ai Yasudomi[1], Hidemi Takimoto[1]

1. National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 2. Department of Domestic Science, Otsuma Women's University (Japan)

Background and objectives: Accurate estimation of food intake is necessary to clarify the relationship between dietary intakes and particular health conditions, but self-reported assessments often results in estimation errors. Biomarkers of vegetable and fruit intake can be important tools to objectively estimate dietary intake in nutritional epidemiological studies. To establish the relationship between vegetable and fruit intake, their blood biomarkers, and health indicators, we conducted a systematic review of literature.

Methods: We searched peer-reviewed articles published on PubMed and CiNii Articles to create a search formula for vegetable and fruit intake, serum vitamin C and 5 carotenoid types (α-carotene, β-carotene, β-cryptoxanthin, lutein and lycopene) as biomarkers in Asians, and considered the relationship between vegetable and fruit intakes, their biomarkers and health indicators.

Results: Five articles, including 3 cross-sectional studies, 1 longitudinal study and 1 randomized controlled trial, were selected. The participants of the studies were local residents (3 articles), textile workers (1 article), and type 2 diabetics (1 article), and the number of participants varied from 27 to 7012. The methods applied in estimating vegetable and fruit intakes were Food Frequency Questionnaire (FFQ) – (5 cases), FFQ combined with 24-hour dietary recalls (1 case), FFQ combined with a dietary record (1 case). Four articles showed a significant positive correlation between the fruit and/or vegetable intake and the serum concentrations of α-carotene, β-carotene, β-cryptoxanthin, α-tocopherol, γ-tochopherol, and/or vitamin C. Threonic acid or proline betaine were reported as new biomarkers for vegetable or fruit intakes, respectively in 1 article. However, there was no article which examined the relationship between vegetable and fruit intakes, their biomarkers and health indicators.

Conclusion: Serum α-carotene, β-carotene, β-cryptoxanthin, α-tocopherol, γ-tochopherol, and/or vitamin C were proposed to be useful biomarkers for estimating vegetable and/or fruit intake in nutritional epidemiological studies. In the future, it will be necessary to accumulate evidence, including the quantitative relationship between vegetable and fruit intake and their biomarkers and the relationship between them and health indicators.

Keyword: biomarker, vegetable, fruit, carotenoids, literature review

A qualitative exploration of the socio-psychological factors associated with young Australian adults' consumption of Energy Dense and Nutrient Poor (EDNP) foods

Krupa Thammaiah Kombanda[1], Anthony Worsley[1], Alison Booth[1], Claire Margerison[1]

1. Deakin University (Australia)

Background and objectives: Young Australian adults exhibit the highest consumption of Energy Dense and Nutrient Poor (EDNP) foods (commonly referred to as discretionary foods), when compared to all age cohorts in Australia. This research aimed to explore the socio-psychological factors associated with young Australian adults' consumption of EDNP foods. The uniqueness of this study resides in its focus on EDNP foods, as most studies until now have focussed on identifying factors associated with healthy eating. While factors influencing the consumption of EDNP foods are yet to be fully explored and defined, this study addresses this important research gap. **Methods**: Using qualitative descriptive research methodology and based on the interpretivist approach, thirty-eight young adults were interviewed Australia-wide. Participants needed to be aged between 18 and 30 years, English speaking and residing in Australia. Interviews were conducted either online or over the phone. Data obtained from the semi-structured interviews were analysed using a thematic data analysis technique.

Results: Five themes were noted: (1) psychological factors, (2) social factors, (3) intrinsic qualities of EDNP foods, (4) accessibility and affordability and (5) health related beliefs. Firstly, motivation, perceived behaviour control (habits and self-restraint), impulsivity, craving and coping strategies were identified as the five psychological factors influencing participants' intake of EDNP foods. Secondly, social norms, peer pressure and social media were noted as key social factors. Third, taste, appeal and convenience were observed as intrinsic qualities driving participant's EDNP food intake. Fourth, accessibility and affordability determined participants' intake of EDNP foods. Lastly, perceptions concerning health and perceived consequences of consumption determined the young adults' intake of EDNP foods.

Conclusions: The key socio-psychological factors identified in this study impacted participants' consumption of EDNP foods in both positive and negative ways. This research is significant as it is one of the first studies that has qualitatively explored the socio-psychological factors associated with young Australian adults' consumption of EDNP foods. The findings may help guide future behaviour change interventions and public health programs aimed at ameliorating young adults' EDNP food behaviours

Comparison of nutrient intake on weekdays and holidays and evaluation using the Dietary Reference Intake of infants attending nursery schools in Japan

Atsuki Sakai[1], Katsushi Yoshita[1], Takako Takahashi[1], Tetsuko Okabe[2], Ruriko Sasaki[3], Hiromi Ishida[4], Yukiko Yoshioka[5], Miho Nozue[6], Tatsuaki Sakamoto[7], Nobuko Murayama[8]

1. Osaka City University (Japan), 2. Tenshi College (Japan), 3. Miyagi Gakuin Women's University (Japan), 4. Kagawa Nutrition University (Japan), 5. Sagami Women's University (Japan), 6. Tokoha University (Japan), 7. Prefectural University of Kumamoto (Japan), 8. University of Niigata Prefecture (Japan)

Background and objectives: The objective of this study was to clarify the current state of nutrient intake in Japanese infants attending nursery schools.

Methods: 798 infants attending nursery schools in Japan were targeted. In 2019 or 2020 a dietary survey was conducted on two nonconsecutive weekdays and two holidays from October to November. The nutrition calculation software Shokujisirabe was used to calculate the nutrient intake. SPSS 27 (IBM Corp., Armonk, NY, USA) was used for statistical analysis. This study was approved by the research ethics committee of the relevant university and was conducted with the consent of the parents and the target facility.

Results: The average daily intake (standard deviation) of energy and major nutrients are presented in the order of energy, protein, lipid, carbohydrate, vitamin A, vitamin B_1, vitamin B_2, vitamin C, calcium, and iron. The intake on weekdays was 1,430 (229) kcal, 51.9 (9.9) g, 47.5 (11.5) g, 194.2 (32.7) g, 466 (240) µg retinol activity equivalents (RAE), 0.76 (0.22) mg, 0.94 (0.27) mg, 61.0 (28) mg, 522 (167) mg, and 5.3 (1.4) mg. The intake on holidays was 1,372 (295) kcal, 45.7 (12.1) g, 46.9 (14.7) g, 187.5 (42.5) g, 338 (227) µg RAE, 0.66 (0.25) mg, 0.81 (0.33) mg, 60.8 (44) mg, 396 (199) mg, and 4.4 (1.7) mg. The nutrients that had significantly higher values on weekdays than on holidays were energy, protein, carbohydrates, vitamin A, vitamin B_1, vitamin B_2, vitamin C, calcium, and iron. When each nutrient was evaluated in comparison with the Dietary Reference Intake, the proportion of infants who exceeded the estimated average requirement (EAR), the recommended dietary allowance, and the tentative dietary goal for preventing life-style related diseases for all nutrients was significantly higher on weekdays than on holidays. However, even on weekdays, 44% of infants did not meet the EAR for calcium.

Conclusions: The findings suggest that nursery school meals may be the basis of the infants' intake of nutrients on weekdays. In addition, weekday meals are desirable meals for infants. However, calcium intake tends to be deficient, even on weekdays. In the future, countermeasures will be necessary to consider.

An example of a convergent mixed-methods analysis in examining food security: the case of Popokabaka

Branly Kilola Mbunga[1], Landry Egbende[1], Ingunn Engebretsen[2], Tor Strand[2], Anne Hatloy[2], Paulin Mutombo[1], Mala Ali Mapatano[1]

1. Kinshasa School of Public Health, Faculty of Medicine, University of Kinshasa, Kinshasa (Democratic Republic of the Congo), 2. Centre for International Health, Department of Global Public Health and Primary Care, University of Bergen, Bergen (Norway)

Background: Food security as a unique multi-dimensional concept may underly multiples nutrition problems within a community. Popokabaka is an entirely rural setting with multiple nutrition problems such as Selenium deficiency, Zinc deficiency, iron deficiency, Stunting, etc. To develop effective and long-term interventions to address these nutrition problems, a comprehensive analysis of the burden of food security is needed. We attempted to measure food security at four levels of the food chain and adapt a theory change for a transformative impact on hunger and malnutrition in Popokabaka.

Methods: We designed a convergent parallel mixed-method study with four-level data sources collected from rural Popokabaka, DR Congo: a household food survey (using the Household Food Insecurity Access Scale, Food Consumption Score), a market food census (assessing food availability and cost per 100g), an exit food market survey (assessing food choice and customer's satisfaction) and on-farm qualitative research with food producers (exploring challenges and opportunities). Descriptive statistics from quantitative data were triangulated with emergent themes from qualitative data, and the food and nutrition security's theory of change was used as the framework for interpretation.

Results: The population of Popokabaka experienced severe food access insecurity (89% of Households) and poor food consumption (40,7% of Households), with cassava farming as the primary food stock and subsistence source. Animal sources like meat, fish, and insects were under-consumed and estimated as the most expensive and rare foods on the market. Customers raised poverty and lack of food variety as primary drivers for food choice. Soils scarcity and lack of drugs for epidemics inbreeding emerged as main challenges to food production.

Conclusion: Ending hunger and eliminating malnutrition should be possible through multiple actions along the food chain cycle.

Association between night-oriented lifestyle and visceral obesity: a cross-sectional study in Japan

Yukihiro Tanikawa[1,2], Koki Beppu[1], Minoru Ishikawa[2], Tomoichiro Hisada[2]

1. Beppu Clinic (Japan), 2. Health Examination Center Urasoe General Hospital (Japan)

Background and Objectives: Obesity, especially visceral obesity, is a serious risk factor for mortality and cardiovascular diseases. In addition, it is known that night-oriented lifestyle, such as late dinner and late bedtime, is related to obesity. However, little is known about the association between night-oriented lifestyle and visceral obesity. To investigate that association, we performed the cross-sectional study.

Methods: Between April 2012 and March 2019, we recruited 2010 participants who underwent healthcare examination in a single healthcare examination center in Japan and met the inclusion criteria, namely, age 20-65 years, measured visceral fat area (VFA) by dual bioelectrical impedance analysis. Lifestyle behaviors, such as dinner-time and bed-tine, were inquired by a questionnaire. To explore the relationship between night-oriented lifestyle and visceral obesity, defined as VFA ≧100 cm^2, a multivariable logistic regression model was used.

Results: Overall, 1,846 participants were eligible for analysis, 1,124 (60.9%) were men, 618 (33.5%) met the criteria of visceral obesity. There was a significant relationship between late dinner-time and visceral obesity. Compared with dinner-time before 19:00 as the reference category, adjusted odds ratios (AOR) were 1.49 (95 percent confidence interval [CI], 1.00 to 2.22) for dinner-time of 19:00 to 20:00; 1.89 (95% CI, 1.24 to 2.88) for dinner-time of 20:00 to 21:00; 1.83 (95% CI, 1.12 to 2.99) for dinner-time after 21:00. By contrast, obvious relationship was not recognized between late bed-time and visceral obesity. Compared with bed-time before 22:00, AOR were 1.25 (95% CI, 0.71 to 2.17) for bed-time of 22:00 to 23:00; 1.41 (95% CI, 0.84 to 2.36) for bed-time of 23:00 to 0:00; 1.34 (95% CI, 0.79 to 2.25) for bed-time after 0:00. Additionally, compared to participants with early dinner-time (before 20:00) and early bed-time (before 0:00), participants with late dinner-time (after 20:00) and early bed-time (before 0:00) were associated with the risk of visceral obesity. (AOR 1.70; 95% CI 1.24 to 2.33)

Conclusions: In Japanese adults, late dinner was associated with increased risk of visceral obesity. Further research is needed to understand the association between night-oriented lifestyle and visceral obesity.

Nutrient profiling of Indian processed packaged foods using Warning Label, Health Star Rating, and Nutri-score

Bhavya Pande[1], Suneeta Chandorkar[1]

1. The Maharaja Sayajirao University of Baroda, Vadodara, Gujarat (India)

Background and Objectives: Processed foods are high in one or more of the nutrients of concern, namely, sodium, sugar, and saturated fat. Front of Pack Labeling (FoPL) assists consumers in making healthy food choices. India has not yet ratified the FoPL. Thus, the aim was to compare three FoPL models in evaluating the Indian processed packaged foods.

Methods: The present study re-evaluated the processed packaged foods (N=1020) studied in 2014-15 for food labels. After scrutiny, 502 products were found eligible for evaluation using Warning Label (WL), Health Star Rating (HSR), and Nutri-score models and were categorized according to the three systems.

Results: Forty percent of the food products (fried snacks, chocolates, soups) qualified for three WLs; 3% had four WLs (non-dairy beverages, fried snacks); 3% were found to be healthy with no WLs (few RTE foods). Majority of these products (73%) were high in calories (chocolates, RTE sweets), 60% were high in sodium (ketchup, RTE foods, noodles), 37% were high in sugar (beverages, RTE sweets) and 55% were high in saturated fat (chips, fried snacks). Thirty-six percent of RTE foods, soups, chocolates received HSR score of 0.5 while jellies, juices, RTE sweets (23%) received 1 star and 1 product earned a score of 5 (breakfast cereal). Twelve percent of products (RTE foods, breakfast cereal) were identified as healthy by Nutri-score (A), 31% (soup, chocolates, fried foods, ketchup) as less healthy (Nutri-score D), and 24% as least healthy Nutri-score of E (non-dairy beverages). Breakfast-cereals (n=35), high in calories and sugar (WLs less than or equal to 2) had good HSR (3 to 5) and Nutri-score (A and B). HSR and Nutri-score award points for positive components (fiber, FVNL, and protein), which offset the negative nutrient points. Ten percent of Non-dairy beverages (fruit juices, and aerated soft drinks; n=81) were identified as unhealthy by WLs (4), Nutri-score (E), and HSR (1) due to high sugar content.

Conclusion: There was fair degree of alignment observed across three FoPL models used for the evaluation of selected Indian processed packaged foods.

Development and evaluation of a multidisciplinary education intervention to support the management of malnutrition and oral nutritional prescribing by Irish general practitioners

Clare Anne Corish[1], Aisling Geraghty[1], Sarah Browne[1], Sharon Kennelly[2]

1. University College Dublin (Ireland), 2. Health Service Executive (Ireland)

Background and objectives: Approximately 10% of adults requiring general practitioner (GP) care are at risk of protein-energy malnutrition (PEM). Prevention of PEM includes identification of risk, nutrition counselling and oral nutritional supplementation (ONS). The Irish Health Research Board-funded *Oral Nutritional Supplement Prescribing (ONSPres)* project aimed to investigate clinical, social and other factors that influence malnutrition identification, management and ONS prescribing by Irish GPs and other healthcare professionals (HCPs) working in the community/primary care setting. These data were used to inform the development and evaluation of an evidence-based e-module for GPs to support malnutrition management and prescribing of ONS.

Methods: Qualitative interviews and focus groups were undertaken with key community/primary care HCPs: GPs, nurses, dietitians, pharmacists, physiotherapists, occupational therapists and speech and language therapists, and with patients with PEM. Interviews and focus group discussions were audio-recorded and transcribed verbatim. The data were coded, analysed and key themes identified. Quantitative analysis of an anonymous dispensed pharmacy claims database that represents 30% of the national claims for ONS in the Republic of Ireland was undertaken to complement the qualitative data and further inform the development of the malnutrition management e-module. The e-module was evaluated by 31 GPs and GP trainees.

Results: The lack of nutrition training amongst GPs and other HCPs was apparent. Due to insufficient awareness, lack of prioritisation and knowledge and inadequate multidisciplinary communication, malnutrition screening did not happen in practice. Poor understanding and negative associations with the term 'malnutrition' were clear amongst patients and non-dietetic HCPs. The quantitative analysis highlighted disparities in ONS use across patient groups, with higher ONS use amongst younger males, patients living in residential care and those on central nervous system polypharmacy. Long-term (12 consecutive months) usage of ONS was characterised by older age and polypharmacy. The malnutrition e-module was well-received and effective in improving knowledge and practice relating to the identification and management of malnutrition, with knowledge retained after 6 weeks.

Conclusions: Availability of an e-module, along with resources to support clinical practice, is an effective method to improve adult malnutrition screening and management among GPs and community/primary care-based HCPs.

Optimizing local diet using linear programming to improve micronutrient intakes of lactating women in rural area of Senegal

Mbeugue Thiam[1], Adama Diouf[1], Babacar Mbaye Ndiaye[1], Ousseynou Baba Coly[1], Saliou Diombo Kébé[1], Abdou Badiane[1], Ousmane Diongue[1], Nicole Idohou-Dossou[1], Jean Michel Medoc[2]

1. Cheikh Anta Diop University (Senegal), 2. CIRAD, the French Agricultural Research and International Cooperation Center (Senegal)

Background and objectives: Micronutrient deficiencies remains a great public health challenge particularly in rural settings. In Senegal, the double burden of malnutrition currently highlighted among women of reproductive age of the groundnut basin become worrisome. To tackle these malnutrition issues, it would be useful to determine the best foods combination to balanced diets. We aimed to use a linear programing method to examine whether optimized diet using a locally-made porridge containing millet, cowpea and orange fleshed sweet potato could meet nutrient requirements of lactating women.

Methods: A dietary survey was carried out among 59 rural lactating women and their children using the weight food record method. All foods and beverages consumed during a whole day were quantify. Nutrient intakes were calculated using the west African food composition tables. Prices (per kg) of foods were obtained from the local shops/markets and the harmonized index of the national agency of statistics. The 22 foods items daily consumed by women with an average of consumption of 15 g were selected for the model. A linear programming method of the excel solver was used to optimize diet with the overmentioned locally-made porridge. The objective function was to minimize the cost of the diet taking into account the constraints related to the recommended intakes of the selected nutrients.

Results: According to the results, the median intakes of the staple diet cover around 70% of the energy and proteins requirements of the women. While, iron, zinc and vitamin A intakes were lower than the recommended dietary allowances. The optimum diet obtained with the add of the porridge (1.46 mg iron, 2.13 mg zinc and 4025 µgRE vitamin A) covers the total (100%) energy (2620.7 kcal), proteins (76.6 g) and iron (15 mg) requirements and more than 200% of the adequacy of fibers, zinc, vitamin C, folate and vitamin A.

Conclusions: These findings support the potential impact of nutrient dense complementary porridge to improve the iron, zinc and vitamin A status of rural lactating women. This model could be adapted for children to reduce micronutrients deficiencies in rural area in Senegal.

Keyword: Linear programming, Micronutrients deficiencies, Lactating women, Rural area, Senegal

PAB(T6)-107
Association of changes in dietary variety with all-cause mortality among older Japanese adults with/without frailty

Toshiki Hata[1,2], Satoshi Seino[1], Yui Tomine[1], Yuri Yokoyama[1], Miki Narita[1], Mariko Nishi[1], Shoji Shinkai[3], Akihiko Kitamura[4], Yoshinori Fujiwara[1]

1. Tokyo Metropolitan Institute of Gerontology (Japan), 2. Graduation school of Tokyo University of Agruculture (Japan), 3. Kagawa Nutrition University (Japan), 4. Health Town Development Science Center, Yao City Health Center (Japan)

Background and objectives: Eating a variety of foods maintains nutritional status and prevents frailty or mortality. We conducted a 2-year community-wide intervention for promoting dietary variety and preventing frailty. However, it remained unclear whether the effect of changes in dietary variety on health outcomes differs with/without frailty. This study examines the influence of changes in dietary variety during 2-year on all-cause mortality among older Japanese adults living in a metropolitan area.

Methods: We performed secondary analysis of data from a community-wide intervention focused on promoting dietary variety in Ota City, Tokyo, Japan. Participants were 7,505 non-disabled residents (3,867 men and 4,137 women) aged 65–84 years who responded to self-administered questionnaire surveys in 2016 and 2018. Frailty was defined as a score of ≧4 on the Kaigo-Yobo Checklist (range: 0-15). Dietary variety was assessed using the dietary variety score (DVS: 0–10 points) and defined as low (0–3) or high (4–10). Participants were classified according to changes in the DVS category between 2016 and 2018; high–high, high–low, low–high, low–low groups. Multilevel survival analyses were conducted to calculate the adjusted hazard ratio (HR) and 95% confidence interval (CI) for all-cause mortality by with/without frailty.

Results: The numbers and rate of high–high, high–low, low–high, and low–low groups were 2110 (35.3%), 549 (9.2%), 852 (14.2%), and 2469 (41.3%) in the non-frailty group, respectively. Corresponding numbers and rate were 325 (21.3%), 125 (8.2%), 211 (13.8%), and 864 (56.7%) in the frailty group. During a follow-up of 3-year, 352 (4.7%) individuals died. Compared with high–high group, HR (95% CI) for all-cause mortality for high–low, low–high, and low–low groups were 1.64 (0.96-2.80), 1.03 (0.66-1.60), and 1.31 (0.74-2.31) in non-frailty group, respectively. Corresponding HR (95% CI) were 2.49 (1.15-5.34), 1.56 (0.61-4.01), and 2.74 (1.14-6.58) in frailty group.

Conclusions: Although changes in DVS categories were not associated with all-cause mortality among non-frail respondents, even those with frailty may be able to reduce their risk of all-cause mortality by maintaining or increasing dietary variety.

PAB(T6)-108
The influence of content, context, and perceptions on defining meat alternatives – A scoping review

Linsay Ketelings[1], Alie de Boer[1], Stef Kremers[1], Remco Havermans[1]

1. Maastricht University (Netherlands)

Background and objectives: During the global nutritional transition over the last decade, consumption of meat increased causing irreversible damage to the environment. Since awareness of eating behaviour repercussions is increasing, a shift is observed towards consuming more (plant-based) alternatives to meat. Consequently, this resulted in a novel research area with increasing scientific publications addressing meat alternatives in nutritional, environmental, and consumer sciences. In different fields, researchers use diverging definitions, and no universal definition of what meat alternatives should entail is thus endorsed. Different interpretations could result in discrepancies in research and between researchers, where there is no equal understanding of what is considered a meat alternative. Therefore, we aim to create a definition of what meat alternatives should entail.

Methods: Guided by the PRISMA extension for scoping reviews, literature over the past ten years was systematically searched using keywords like 'meat alternative', 'meat substitute' and 'meat analogue'. This initial search resulted in over 10.000 hits, which were reduced to 2000 during the first exclusion round. Titles and abstracts of these academic published sources were screened, which resulted in 195 articles included in the present review.

Results: Three major influencing facets on the definition of a meat alternative can be derived from the included literature. The first facet describes the production, where the ingredients (like soy, wheat, and textured vegetable protein) and the production process influence the final meat alternative product. Based on this first dimension, a second facet becomes apparent through which several factors are determined, namely sensory characteristics, nutritional value, and sustainability. The third facet observed is the target consumer and the intended consumption context. This last facet, related to the first two, especially determines whether a product is considered an alternative to meat or not.

Conclusions: By considering the different facets presented, we recommend that continuous efforts are made by researchers, policy makers and companies to make meat alternatives more accessible to the different types of consumers. Future research and product development could focus on improving the dietary composition and the addition of functional ingredients of meat alternatives by, for example, the addition of fibre.

PAB(T6)-109
Comparison of observed non-compliance with the WHO Code across seven international studies (Indonesia, Vietnam, India, Thailand, Nigeria, Philippines and Mexico)

Nadine Bahjat Nasser[2], Alexander Evans[1], Raydel Valdes Salgado[1], Brenda K. Brewer[1]

1. Westat (USA), 2. Access to Nutrition Foundation (Netherlands)

Background and Objective: Over 30 years' studies estimate that increased breastfeeding could prevent 832,000 child and 20,000 breast cancer deaths in low and middle-income countries. Children breastfed for longer periods have fewer infections resulting in morbidity and mortality and have higher intelligence. Inappropriate marketing of breast-milk substitutes (BMS) has i shown to undermine optimal breastfeeding practices. The WHO Code was developed to regulate marketing of BMS, and many countries have adopted its provisions into local legislation but to a varying extent. Assessments of the largest global baby food companies' compliance with the WHO Code reveal varying levels of compliance across seven country studies. Westat conducted studies funded by the Access to Nutrition Foundation.

Materials and Methods: All seven studies assessed baby food companies' compliance with WHO Code, including all subsequent World Health Assembly resolutions, and relevant national regulations that go beyond the WHO Code. Westat followed The Interagency Group on Breastfeeding Monitoring protocol in Vietnam, Indonesia, and India. The remaining assessments utilized the WHO/UNICEF Network for Global Monitoring and Support for Implementation of the Code (NetCode) protocol. Researchers systematically collected data of marketing of breast-milk substitutes/complementary foods (BMS/CF) across different channels to assess compliance to WHO Code. Data included: exposure of women to BMS marketing; promotional/educational materials observed in health facilities; marketing/promotions observed in selected retail and online stores; review of baby food product labels/inserts; and media monitoring (traditional and online).

Results: Each country had laws/regulations related to BMS/CF marketing and labeling in varying alignment with WHO Code. Number of non-compliances found varied widely by country and company. In interviews with mothers of infants and young children, television and radio were most frequently cited sources of BMS/CF advertisements across seven countries. Mothers also reported some activity in receiving product samples and contact with company representatives. Key findings

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

reveal that all countries except Thailand, online media promotions far exceeded traditional media promotions. In all countries except Vietnam, online retail promotions were significantly greater than promotions observed in physical retail outlets.

Conclusion: Studies found fewer non-compliances in countries with more Code-aligned regulations. Online promotions contributed to most non-compliances.

Over 80% Vitamin A supplementation coverage reached during the Cameroon's national Health and Nutrition Week Campaign amidst COVID-19 pandemic.

Fatou Berete NDIAYE[5], Ismael Teta[1], Cecile Ngo-Sack[2], Martin Nankap[3], Jules Guintang[4], Adjidja Amani[2], Estelle Mahop[2], Steve Ahanda[1], Marc Nene[3]

1. Helen Keller International (Cameroon), 2. Ministry of Public Health (Cameroon), 3. Unicef (Cameroon), 4. Nutrition International (Cameroon), 5. Helen Keller International (Senegal)

Background and objectives: Vitamin A deficiency affects 35% of children under the age of five years in Cameroon. The Ministry of Public Health Cameroon, and international actors support the delivery of a twice-yearly integrated package of health interventions including vitamin A supplementation (VAS) through the Maternal and Child Health Nutrition Actions Week (SASNIM). One goal of the SASNIM is to achieve at least 80% VAS coverage among children aged 6-59 months.

Methods/Intervention: The second round of SASNIM was held in Cameroon from November 26-29, 2021. In total, 5,383,077 children aged 6-59 months were targeted during this nation-wide, four-day campaign. Each VAS distribution team consisted of two people (one distributor and one recorder). Social mobilization activities were held two days prior to, and during the first two days of the campaign. The SASNIM followed GAVA's guidance for delivering VAS during the COVID-19 pandemic, a door-to-door campaign strategy for implementation was adopted to administer VAS outside the household or in well-ventilated areas, and personal protective equipment were provided to all front-line workers administering VAS. Training of the importance of COVID-19 prevention measures, and Supervision checklists were enforced among distributors, supervisors and front-line workers.

Results: A total of 4,495,680 (84%) children received VAS during the second campaign in 2021. Coverage results displays three clear patterns, across 10 regions: 1) regions with the majority of the population living in semi-urban or rural sittings obtained a coverage >90% (Adamaoua, North, South, East and Far-North regions), 2) regions with the majority of its population living in urban areas reached a coverage between 70%-90% (Littoral, Center and West regions), and 3) regions in acute civil crisis achieved < 50% (North West and South West).

Conclusion: The second national VAS campaign of 2021 achieved an average administrative coverage of approximately 84%. This coverage is impressive in the context of COVID-19, although further efforts are needed to improve coverage in the country's highly insecure areas.

Keyword: VAS, Vitamin A, Cameroon, SASNIM

A Peer-led Integrated Nutrition Intervention Using the Care Group Model Improved Infant Growth in South-Sudanese Refugees in Post-Emergency Settlements in the West Nile Region in Uganda

Joel Joshua Komakech[1], Hasina Rakotomanana[2], Christine Nicole Walters[1], Deana Hildebrand[1], Sam R. Emerson[1], Ki L. Cole[1], Margaret Kabahenda[3], Barbara J Stoecker[1]

1. Oklahoma State University (USA), 2. World Food Programme (Italy), 3. Makerere University, Kampala (Uganda)

Background and objectives: Several nutrition-sensitive interventions have been implemented to address malnutrition. However, the efficacy of these programs to reduce undernutrition among refugees remains largely unknown. This study examined the effects on infant growth of a peer-led integrated nutrition education intervention with maternal social support using Care Groups among South Sudanese refugees in Uganda.

Methods: A longitudinal RCT (2 treatment arms and 1 control arm) was conducted among 390 women in their third trimester from different settlements in Adjumani district, Uganda. The moms-only (n=130), moms&dads (n=143) treatment arms and control (n=117) had 10–20 members per group. The treatment arms received the integrated nutrition education intervention using the Care Group model while the control received only standard of care. The WHO standards were used for defining infant LAZ, WAZ, and WLZ. The Medical Outcomes Study (MOS) social support index was used to measure maternal social support. Interaction effects of intervention, social support, and time on infant growth were tested with split-plot ANOVA. Post-hoc analyses determined mean differences in infant growth among the study arms after adjusting for covariates.

Results: The Dinka were the most prevalent (63.3%) ethnic group. More than half (55.6%) of moms were stay-home spouses. The least average stay in a refugee setting was 4.1±1.3 yrs. The mean infant birth weight was 3.1±0.5 kg. Infant stunting was most prevalent in the control arm (> 14%). There were

significant interaction effects of the intervention and social support by time on infant mean LAZ ($F_{(6,560)}$ = 28.91, *p*=0.000), WAZ ($F_{(5.8,539.4)}$ = 12.70, *p*=0.000) and WLZ ($F_{(5.3,492.5)}$ = 3.38, *p*=0.004) with effect sizes *f*=2.4, *f*=1.6, and *f*=0.72, respectively. By the end of the study, simple main effects showed that the intervention improved infant mean LAZ (moms-only vs control (mean difference, *MD*) = 2.05, *p*=0.000; moms&dads vs control, *MD* = 2.00, *p*=0.000) and WAZ (moms-only vs control, *MD* = 1.27, *p*=0.000; moms&dads vs control, *MD* = 1.28, *p*=0.000).

Conclusion: The Care Groups intervention with maternal social support improved infant stunting and underweight. Nutrition-sensitive approaches integrating social behavioral change may provide sustainable cost effective strategies to reduce child undernutrition among refugees.

Well Connected Communities - Culture of health initiative on the Lower Eastern Shore of Maryland: Youth conducting community health assessment using social determinants of health metrics

Virginie Zoumenou[1], Marietherese Oyalowo[1], Naveen Kumar Dixit[1]

1. University of Maryland Eastern Shore (USA)

Background and Objectives: Health behaviors and the social and physical environment in which individuals live and work have a stronger influence on well-being than clinical services alone. The proliferation of stakeholders' efforts to promote wellness and prevent diseases has led to a vision for a culture of health where every person has equal opportunity to live the healthiest life regardless of their neighborhood, income, or their color. The objectives of the Well Connected Communities - Culture of Health Initiative are to: 1-emphasize community engagement through coalition building; 2-engage Youth in assessing community health needs, developing, and implementing action plans.

Methods: The Culture of Health Action Framework includes four action areas and one outcome area. This project focused on two action areas: "Making health, a shared value" area, and "Fostering cross-sector collaboration for well-being" area. A coalition-building and a multi-sector health council were used to foster cross-sector collaborations – Under youth leadership, a community health assessment survey was developed and conducted. Youth and the research team ensured that each question was associated with the social determinants of health (SDH) metrics. Data were collected in the target community and analyzed using descriptive statistics. The top three issues in the community were identified. Action plans were developed.

Results: Approximately 24 questions were developed. The following SDH metrics were associated with the survey: SDH Health Care metrics(5 questions); SDH Food Metrics (4 questions); SDH environment Metrics (10 questions); SDH Education metrics (3 questions): SDH Economics Metrics (2 questions). No question was associated with SDH Social Metrics. Approximately 120 participants completed the survey. Three top trends were identified: 1-Affordable afterschool programs 2-Food access, and 3- Affordable housing. Two action plans were developed: "Healthy Street Healthy Me" and "Make Fruits and Vegetables Available to All".

Conclusions: Through this project, Youth had a better understanding of their own community health (physical, mental, environmental, and socio-economic health). Their interactions with the adults also emphasized the importance of making health, a shared value in the community. Community Engagement is essential for sustainable changes and equity especially historically marginalized populations and those facing the greatest barriers to good health.

PAB(T6)-113
Nutrient profiles of dishes eaten by high salt consumers and adequate salt consumers in the 2014-2018 National Health and Nutrition Survey, Japan

Emiko Okada[1], Hidemi Takimoto[1], Jun Takebayashi[1], Yuki Tada[2], Takahiro Yoshizaki[3], Yuri Yokoyama[4], Yoshiko Ishimi[2]

1. National Institute of Biomedical Innovation, Health and Nutrition (Japan), 2. Tokyo University of Agriculture (Japan), 3. Toyo University (Japan), 4. Tokyo Metropolitan Institute of Gerontology (Japan)

Background and objectives: Dish based nutrient profile analyses are essential in setting goals to achieve a balanced diet. The Japanese enjoy longevity, but their current diet is still high in salt, which was 10.1g/day among adults in the 2019 National Health and Nutrition Survey. In 2020, the Dietary Reference Intakes for Japanese proposed that adult salt intake to be limited

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

to 7.5g/day for men, and 6.5g/day for women. In order to compare the amount of salt in dishes consumed among the nationally representative sample, we conducted the secondary analyses of the 2014-2018 National Health and Nutrition Survey data.

Methods: Dietary data from 35,915 participants in the 2014-2018 National Health and Nutrition Survey aged 18-74 years who ate three meals on the survey day, were applied for analyses. We extracted 554,257 dishes from each meal, and categorized them according to the definition of "staple dish" (grain dish), "main dish" (meat, fish, eggs, or beans), and "side dish" (vegetables, seaweeds, potatoes, or mushrooms) shown in the 2005 "Japanese Food Guide Spinning Top". Participants were grouped as "high salt" consumers if their intake were equal to or higher than the Dietary Reference Intakes for Japanese (2020), and "adequate" consumers if they consumed less. The nutrient profile of each dish category was compared between the two groups.

Results: 29,403 participants were identified as "high salt" and 6,512 as "adequate". The mean age of the "high salt" group (52.7 years) was higher than the "adequate" group (50.2 years). The mean salt intake in the "high salt" group was 11.3 g/day and the "adequate" group was 5.5 g/day. Among the dishes, 56,701 were categorized as "staple dish", 44,510 as "main dish", 43,868 as "side dish", 28,132 as "combined dish", and 381,046 as "miscellaneous". Regardless of type of dishes, dishes consumed by the "high salt" group were significantly 1.4 to 2.3 times high in salt intake, compared to the "adequate", but not in energy, protein, fat, and carbohydrate.

Conclusions: Our results showed that the "adequate" group was able to consume reduced-salt dishes with most nutrient intake unchanged, compared to the "high salt".

Establishing targets, self-monitoring and decentralized decision making at the health post improves routine VAS coverage in Senegal

Maguette Fall Beye[1], Fatou Berete Ndiaye[2], Aissatou Diop[3], Sokhna Sene[4], Moussa Sarr[5], Djeinam Toure[6]

1. Helen Keller International (Senegal), 2. Helen Keller International (Senegal), 3. Child Survival Ministry of Health (Senegal), 4. Helen Keller International (Senegal), 5. Helen Keller International (Senegal), 6. Helen Keller International (Senegal)

Background and objectives: Coverage rates for vitamin A supplementation (VAS) delivered through routine health services remains low across sub-Saharan Africa. In Senegal, targets for VAS are set and monitored by semester at the district level, but activities are planned for and implemented monthly by health posts. Capacitating health posts to self-monitor monthly VAS coverage and identify solutions to improve coverage regularly is a promising approach to improve routine coverage.

The objective of this research is to document the implementation of the self-monitoring approach and assess its impact on routine coverage rates and in Pete, Podor, Kanel and St Louis health districts of Senegal.

Methods: A cross-sectional representative survey of 1365 households was conducted to assess baseline VAS coverage for the first semester of 2020. Administrative coverage data was recovered from the national DHIS2 monitoring system to report on monthly evolution of coverage from July 2020 to December 2021. Project monitoring reports were exploited to report on the degree of implementation.

Results: Over 18 months, the average VAS coverage increased from 44% to 93%, with all four districts achieving coverage of at least 80%. Baseline coverage was 64% in Podor, 54% in Saint-Louis, 45% in Pete and 12% in Kanel. After one semester of the intervention, average VAS coverage increased to 86%. These improvements were sustained in the first and second semesters of 2021, where average coverage was 92% and 93%, respectively. In the first year, the directorate of maternal and child health (DSME), health districts, and partners outlined an operational plan detailing training, tools, coaching, and coordination needs. All training took place in the first year and included 646 health workers serving 149 health posts. In the second year, the health districts with project staff conducted 81% (n=8) of planned supervisions, 100% of DSME, regional and partner joint supervision. A total of 96% of health center monthly coordination meetings (n=1178) and 66% of monthly district coordination meetings (n=32) integrated the new self-monitoring of VAS targets.

Conclusions: Embedding simple self-monitoring of VAS coverage into health posts monthly coordination is a feasible and an effective strategy to improve routine coverage.

Validity of Calculation Value of Nutrient Intake by Photographic Dietary Assessment

Tomomi Nagahata[1], Maki Igarashi[2], Yuko Mekata[3], Yuki Kokubo[4], Naoki Takayanagi[5], Noriko Suzuki-Kemuriyama[6], Sosuke Amano[7], Kiyoharu Aizawa[2], Hisanori Kato[2]

1. Kyoto Prefectural University (Japan), 2. The University of Tokyo (Japan), 3. Bunkyo University (Japan), 4. Aichi Shukutoku University (Japan), 5. Tokaigakuen University (Japan), 6. Tokyo University of Agriculture (Japan), 7. foo.log Inc. (Japan)

Background and Objectives: Nutritional intake estimation from photographs is a simple meal investigation method. We investigated the validity of a method for assessing daily diet.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: Overall, 17 University students (1 man and 16 women, age: 20 or 21 years) enrolled in a dietetic course photographed meals, and kept traditional weighted dietary records for 4 days. Participants were instructed to take pictures with a smartphone camera of all foods and beverages they consumed during 4 consecutive days (2 week days and weekends) and registered all photos, meal times, and food name in dishes using FoodLog Athl, a smartphone application developed for diet recording by Aizawa et al. In addition, participants were asked to keep traditional weighted dietary records on the same days. The individual nutrient intakes were independently calculated two methods. Pearson correlation coefficients for the nutrient intakes were calculated using crude and energy-adjusted values based on the residual method after logarithmic transformation.

Results: The correlation coefficients between two crude and energy-adjusted nutrient intakes by respective methods were high validity (energy (only crude): r = 0.898, protein (crude, energy-adjusted): r = 0.815, 0.752, total fat: r = 0.880, 0.902, carbohydrate: r = 0.884, 0.762, total fiber: r = 0.905, 0.869, calcium: r = 0.834, 0.824, iron: r = 0.821, 0.877, vitamin C: r = 0.929, 0.944 (p < 0.001, respectively). However, the validity of salt was moderate (r = 0.512, 0.705, p = 0.036, 0.002).

Conclusions: Although some adjustments are required for salt, the photo method appears to be useful as a tool for dietary recording tool.

The macro- and micronutrient compositions of vegan diet compared to non-vegan alternatives, and their nutritional and health implications in the UK

Liangzi Zhang[1], Ellie Langlois[1], Anastasia Nikolaeva[1], Maja Omieljaniuk[1], Paul Finglas[1], Maria Traka[1]

1. Quadram Institute (UK)

Background and objectives: Plant-based diets have become increasingly popular in recent years. Many choose to live vegan by following a 100% plant-based diet. With an increasing range of vegan products on the market, questions arise as to whether these products are nutritionally equivalent to meat-based products. In addition, whether self-prepared vegan meals differ in their nutrient contents compared to meat alternatives. This study aimed to assess the nutritional quality of vegan diets by comparing the nutrient content of vegan products, recipes and meal plans to their non-vegan counterparts.

Methods: The nutrient content of ten popular vegan products from each of the food groups (Fish, Chicken, Beef, Sausages, Cheese, Milk and Ready meals) sold in leading UK supermarkets were analysed against non-vegan alternatives. In addition, ten popular recipes and a 7-day meal plan published on BBC Good Food website in 2021 were selected and their nutritional compositions were calculated and compared between vegan and non-vegan versions.

Results: All categories of vegan products had significantly higher fibre content compared to non-vegan counterparts (P=0.000-0.033). All food categories showed no significant difference in energy, except non-vegan sausages has higher energy (P=0.023) than vegan sausages. Vegan dishes (14.0mg±3.8mg) have higher iron content than meat dishes (12.3mg±1.2mg), however, the bioavailable iron from meat dishes was higher than vegan dishes, estimated using a novel tool developed in-house. The protein content was significantly higher in non-vegan diet than vegan (P<0.001), while the content in both diets fell within the Recommended Nutrient Intakes (RNIs). The vegan diet had significantly lower amount of vitamin B12 (P=0.007), selenium (P=0.002) and iodine (P<=0.001) than non-vegan. Moreover, most vegan products do not commonly or adequately fortify their products with the limiting nutrients in vegan diet.

Conclusions: This study gives an overview of the nutrient profile of vegan products, dishes, and meal plans. A well-planned vegan diet contains enough protein, higher amount of fibre and less saturated fat compared to a non-vegan diet. However, results showed the risk of deficiency in iron, vitamin B12, selenium and iodine in vegan diets and a limited supplementation of these nutrients through vegan products on the UK market.

PAB(T6)-117
Fasting duration and metabolic health among men and women: results from a nationally representative nutrition and health survey

Ling-Wei Chen[1,2], Hsin-Jen Chen[3], Wen-Harn Pan[1,4]

1. Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University (Taiwan), 2. Master of Public Health Program, College of Public Health, National Taiwan University (Taiwan), 3. International Health Program, Institute of Public Health, School of Medicine, National Yang Ming Chiao Tung University (Taiwan), 4. Institute of Biomedical Sciences, Academia Sinica (Taiwan)

Background and objectives: Recent evidence from animal studies and human clinical trials suggests that intentional longer daily fasting duration (time-restricted eating) improves weight management and metabolic health. However, there is a dearth of research investigating the relationship of daily fasting

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

duration and metabolic outcomes in real-world, free-living population. We aimed to assess this relationship using data from a representative survey in Taiwan. **Methods**: We used data from the Nutrition and Health Survey in Taiwan (NAHSIT) in 2005-2008, a nationally representative survey with a multistage, clustered and stratified complex sampling scheme. Diet was assessed using a one-day 24-h recall. Fasting duration was computed by subtracting the elapsed time between the first and last eating episode (amounting to >=5 kcal) from 24 hours. Outcomes were components of metabolic syndrome [body mass index (BMI), waist circumference, systolic and diastolic blood pressures (SBP, DBP), and fasting plasma triglycerides, high density lipoprotein cholesterol, glucose level], measured during physical examination 1-3 weeks after the dietary interview. Associations between daily fasting duration and outcomes were assessed using multivariable linear regressions adjusting for participant age, sex, educational attainment, employment status, and total energy intake. Survey sampling weight and design were accounted for. **Results**: We included adults (age>=19 years) with plausible energy intake (within 600-4000 kcal/d) and covariates information (*n*=1549–1588 depending on the outcome measures). In total study population, a longer fasting duration was associated with a lower SBP (ß=-0.20 mmHg per 1-h increment in fasting duration, 95% CI: -0.40, -0.01, *P*=0.044) but not with other metabolic components. When stratified by sex, longer fasting duration was significantly associated with a lower BMI (ß=-0.14 kg/m^2, 95% CI: -0.27, -0.01; *P*=0.032) and a lower waist circumference (ß=-0.34 cm, 95% CI: -0.67, -0.01; *P*=0.042) only in women (with further adjustment for menopausal status) and a lower SBP (ß=-0.40 mmHg, 95% CI= -0.75, -0.05; *P*=0.028) only in men. These patterns of observations were similar when fasting duration was modeled as >11.5-h compared to <=11.5-h (population median). **Conclusions**: A longer fasting duration in a real world setting potentially confers sex-specific metabolic health benefits. These observations warrant further replication given the scarcity of evidence.

Keyword: fasting duration, fasting interval, metabolism, metabolic health, chrono-nutrition

PAB(T6)-118
Vitamin D deficiency is associated with less favourable body fat content and distribution in healthy adults-findings from the cross-sectional BODYCON study

Ezgi Ozen[1], Rada Mihaylova[1], Julie A. Lovegrove[1], Kim G. Jackson[1]

1. University of Reading (UK)

Background and objectives: Although lower 25-hydroxyvitamin D (25(OH)D) concentrations are associated with a greater body mass index (BMI) and increased risk of cardiometabolic diseases (CMD), the relationship with body fat distribution is unclear. Therefore, our objective was to analyse the associations between 25(OH)D concentrations with body composition and CMD risk markers in healthy adults.

Methods: The BODYCON cross-sectional study was conducted in 401 healthy adults (mean age 42 (SE 1) y and BMI of 24.1 (SE 0.2) kg/m^2). Dual energy x-ray absorptiometry assessed body composition and dietary intakes evaluated using a 4-day weighed diet diary. A fasting blood sample was collected to measure CMD risk markers and 25(OH)D concentrations (UPLC-MS/MS). Subjects were stratified according to serum 25(OH)D levels: I (<10ng/mL, severe deficiency), II (10-19.9 ng/mL, moderate deficiency), III (20-29.9 ng/mL, insufficient) and IV (≧30 ng/mL sufficient) and data analysis adjusted for covariates (age, sex, total dietary energy intake and season of study visit).

Results: In this cohort, only 35% of the subjects had sufficient serum 25(OH)D levels, with 3.3% consuming adequate dietary vitamin D. After dividing the group according to serum 25(OH)D levels, the waist:height ratio was significantly higher and android lean mass lower in group I versus group IV (p≦0.02). Percentage android fat and total fat mass were lower in group IV compared to I and II and these findings were associated with a higher total and high-density lipoprotein cholesterol (HDL-C) concentrations (p≦0.01). Percentages of body fat and gynoid fat were also lower in group IV versus all other groups whereas visceral adipose tissue fat mass was lower in group IV compared with group II (p≦0.01). Moreover, there was a tendency for a higher vitamin D intake (p=0.07) and lower BMI (p=0.08) and waist circumference (p=0.09) in group IV. Interestingly, total bone mineral density was not different between groups (p=0.72), with dietary and serum 25(OH)D concentrations only weakly correlated (r=0.15, p=0.01).

Conclusion: These findings suggest that vitamin D deficiency is prevalent in our cohort of healthy UK adults and that sufficient serum 25(OH)D concentrations are associated with more favourable effects on body fat distribution and HDL-C concentrations.

Keyword: Vitamin D, body fat distribution, cardiometabolic diseases

Trans fatty acid intake and risk of type 2 diabetes: findings from the NutriNet-Santé prospective cohort

Gaelle Wendeu-Foyet[1,2], Alice Bellicha[1,2], Véronique Chajes[2,3], Inge Huybrechts[2,3], Charlotte Debras[1,2], Bernard Srour[1,2], Laury R. Sellem[1], Léopold Fezeu[1], Mélanie Deschasaux-Tanguy[1,2], Mathilde Touvier[1,2]

1. Sorbonne Paris University (France), 2. French network for Nutrition And Cancer Research (NACRe network) (France), 3. International Agency for Research on Cancer (IARC) (France)

Background and objectives: Type 2 diabetes is one of the most common noncommunicable diseases worldwide, with an

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

increasing prevalence at the global level and a considerable global health burden. Substantial evidence has linked consumption of trans fatty acids (TFAs) to an increased risk of cardiovascular disease. However, the effects of TFAs on type 2 diabetes (T2D) remain unclear. We aimed to investigate the associations between different types of TFAs (total, ruminant, industrial and corresponding specific isomers) and risk of T2D in the NutriNet-Santé prospective cohort.

Methods: Participants aged 18 years or older from the French NutriNet-Santé cohort (2009-2021) were included. Dietary intake data, including usual TFA intake, were collected using repeated 24-hour dietary records. Associations between sex-specific quartiles of dietary intake of TFAs and T2D risk were assessed using multi-adjusted Cox proportional hazard models adjusted for known risk factors (sociodemographic, anthropometric, lifestyle, medical history, and nutritional factors). A total of 969 incident T2D cases occurred during follow-up.

Results: A total of 105,551participants (21,992 men [20.8%] and 83,559 women [79.2%]) were included. Mean age (SD) at baseline was 42.7 (14.6) years. Total TFAs was associated with higher T2D risk ($HR_{for\ quartile\ 4\ versus\ 1}$=1.38; 95% CI=1.11-1.73; P_{trend}<0.001). This association, specifically observed for industrial TFAs (HR=1.45; 95% CI=1.15-1.83; P_{trend} <0.001), was mainly driven by elaidic acid (HR=1.37; 95% CI=1.09-1.72; P_{trend}<0.001), octadecadienoic acid (HR=1.29; 95% CI=1.04-1.58; P_{trend}=0.07) and the *18:t* isomer (HR=1.31; 95% CI=1.06-1.62; P_{trend}=0.006).

Conclusions: Results from this large prospective cohort suggest that dietary intakes of total and several industrial types of TFAs are associated with increased T2D risk. These epidemiological observations are supported by consistent mechanistic plausibility from experimental data. Although these findings need to be replicated in independent cohorts with detailed dietary data, they support WHO's recommendation to eliminate industrially-produced TFAs from the food supply worldwide. In the meanwhile, consumers and patients should be advised to avoid the consumption of food products containing partially hydrogenated oils. This may contribute to lower the substantial global burden of T2D.

Reformulation of Spanish food products with effects on people's health

Montserrat Rivero[1,2], Eulàlia Vidal[1,3], Cristina Moraza[4], Miguel Julio Ocejo[4], Ricard Celorio[1]

1. Food Sciences Catalan Association (ACCA) (Spain), 2. Royal Academy of Pharmacy of Catalonia (RAFC) (Spain), 3. Ramon Llull University (URL) (Spain), 4. University of Barcelona (UB) (Spain)

Background and Objectives: FAO promotes a health approach as an integrated way to prevent and mitigate health threats at the Animal-Human-Plant-Environment interface. WHO, 2013, present their Global action plan for the prevention and control of non-communicable diseases and assert that the excessive consumption of salt, saturated fat and added sugar has been associated with negative health effects, including obesity, diabetes, cardiovascular disease (CHD), and stroke. European Member States agreed on a Road Map for Action on Food Products Improvement in 2016. Spain agreed to collaborate with it for the improvement of the composition of food and drink and other measures 2017-2020. In order to improve the quality of foods in this way, the industries started to reformulate their products in accordance with the NAOS Strategy in Spain, aligned with European health policy. The objective of this study is to ascertain the level of reduction of salt, saturated fat and added sugar in different groups of foods.

Methods: We selected 8 food groups (250 products) that are those that contribute more than 45% of the total daily energy intake and determined theaverage reduction of salt, sugar and saturated fat, for each group. All values were taken of the nutritional label information.

Results: Dairy products: 47% sugar free; Cookies: reducing 47% saturated fat, 7% of add sugar and 30% of salt; Industrial pastries: reducing 21% saturated fat, 13% of add sugar; Breakfast cereals: reducing 10% of sugar; Vegetables creams: reducing 6.7% of salt; Pre-prepared dishes: reducing 10% of salt; Processed meat: reducing between 5 and 15%; Snacks: reducing 5-13%% of salt and 10% of saturated fat

Conclusions: Our study of such food products demonstrates the effort made by companies to improve their compositions with reformulations in the reduction of sugar and/or saturated fat and/or salt content.

Keyword: Reformulation, Food, Healthy , Industry

Who is consuming ultra-processed food in Canada? A cross-sectional analysis of the 2018/2019 International Food Policy Study

Virginie Hamel[1], Milena Nardocci[1], Jane Polsky[2], Sharon Kirkpatrick[3], Lana Vanderlee[4], Maria Laura da Costa[5], Carmen Byker Shanks[6], Éric Robitaille[7], David Hammond[3], Jean-Claude Moubarac[1]

1. Montreal University (Canada), 2. Statistics Canada (Canada), 3. University of Waterloo (Canada), 4. Laval University (Canada), 5. Sao Paulo University (Canada), 6. Montana State University (USA), 7. Institut National de Sante Publique (Canada)

Background and objective: High consumption of ultra-processed food (UPF) is associated with low-quality diet and risk of non-communicable diseases, including obesity, cancer, and metabolic diseases. In 2015, nearly half of calories in the Canadian diet were estimated to come from UPF. This study aimed to update estimates of UPF consumption for 2018-2019 and to characterize any variation across sociodemographic subgroups including age, sex, education, income, ethnicity, household food security status, and province.

Methods: This cross-sectional study used data on adults (≧18 years, *n*=5,907) from the International Food Policy Study (2018-2019). All foods and drinks reported in a single 24-hour dietary recall were classified according to the NOVA classification as 1) unprocessed and minimally processed foods; 2) processed culinary ingredients; 3) processed foods; and 4) UPF. Mean relative intakes (% kcal of total energy) of total UPF and subcategories of UPF (e.g., commercial bread, fast-food and frozen dishes, cheese products) among sociodemographic subgroups were estimated using population ratios. Multivariable linear regression analyses evaluated the association between sociodemographic characteristics and UPF consumption.

Results: Adults consumed, on average, 45.3% of their energy from UPF, 40.9% from unprocessed and minimally processed foods, 7.0% from processed foods, and 6.2% from processed culinary ingredients. Overall, UPF consumption was higher among respondents with inadequate versus adequate income (49.3% vs. 45.0% of total energy, p<0.04). Adults aged 51-64 years consumed less UPF (46.8% of total energy) than younger adults aged 18-30 years (49.6%, p<0.04). There was also variation by province of residence, but not by other sociodemographic characteristics such as sex and education. For all subcategories of UPF, except for cheese products, several differences were observed across sociodemographic subgroups. For example, males and younger individuals (18-30 years) consumed more calories from fast-food and frozen dishes than females and older individuals (65+ years), respectively.

Conclusions: UPF consumption was relatively high among Canadian adults in all sociodemographic subgroups, but there was variation by income adequacy, age group and province. Additional research is needed to better understand these differences and to design effective interventions aimed at decreasing UPF consumption in the overall population and in specific subgroups.

Characterizing the retail food environment in three regions of Niger uncovers opportunities to invest in nutrition

Djeinam Toure[1], Adele Meley Bienvenue[2], Haoua Aouami[2], Jennifer Nielsen[3], Tom Van Mourik[1], Sidikou Sambo[2], Mohammed Yattara[1,2]

1. Helen Keller International (Senegal), 2. Helen Keller International (Niger), 3. Helen Keller International (USA)

Background and objectives. Consumers in low-income countries are increasingly purchasing their food. However, little is known of these retail food environments and how they influence food access and choice. The study aimed to characterize the retail food environment in the Tillabéry, Maradi and Zinder regions of Niger to inform an intervention that supports food supply chain actors in order to increase consumer access to nutritious foods.

Methods. We conducted (i) a market census in 10 large weekly sentinel markets divided into segments and (ii) point of sale surveys of vendors in 16 villages in September 2021. The nutrition environment monitoring survey for stores (NEMS-S) was adapted for use in informal markets. The census covered all market food vendors (n=4080) to assess food availability, and a detailed survey was conducted with a sub-sample (n=177). In villages, we identified five common vendor typologies (boutiques, semi-permanent stands, prepared food stands, butchers, and street vendors) and sampled two of each per village (n=197). Point-of-sale surveys assessed price, quality, marketing practices, and vendor characteristics.

Results. Snacks were the most carried food item in both villages and markets (22% of market vendors - 71% of boutiques). Marketing was limited to these items (84% of messages), though the use of marketing overall was low. Vegetables (16%), pulses (19%), and dairy products (13%) were the most commonly available micronutrient-rich foods. Animal source foods were carried by few vendors (7%), with poultry and eggs being especially scarce. The 10 cheapest food items included five fruits and vegetables, two snacks, fresh milk, and chicken pieces. Easily storable foods had the most stable reported prices across seasons. Nearly all market segments had visible waste (94%) and few had any waste management (20%).

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Villages had similar results, with better hygiene and were open longer hours and more days per week.

Conclusions. Consumers are confronted with high availability and advertising of snack foods, in environments with varied availability of fruits and vegetables, low availability of animal source foods, and limited hygiene. These results suggest transitioning food environments. Efforts to improve these should increase transformation of perishable nutritious foods and reduce marketing of snack foods.

Keyword: Nutrition transition, Food Environment , Informal markets , Food systems, Supply chain interventions

PAB(T6)-124
An audit of plant-based meat alternatives available in the UK and Ireland

Leona Maria Lindberg[1], Jayne V. Woodside[1], Janette Walton[2], Anne P. Nugent[1]

1. Queen's University (UK), 2. Munster Technological University (Ireland)

Background and objectives: A growing concern around animal welfare and the environmental impact of food production and consumption has resulted in an increased demand for plant-based meat alternatives (PBMAs) in the UK and Ireland.[1] While the popularity of these products is increasing, little is known about their nutritional and ingredient composition.[2] Therefore, this study aims to provide an insight into the profile of PBMAs available in the U.K and Ireland.

Methods: An online audit was conducted from February – April 2021. On-pack information was extracted for PBMAs available in the two largest supermarkets in the U.K and Ireland (Tesco and Sainsbury's). PBMAs were defined as products which aimed to imitate meat. Extracted data was organised into four interrelated databases and analysed using descriptive statistics.

Results: 351 products were identified across 20 categories. Meat-free chicken (n=71), sausages (n=56) and burgers (n=49) were the largest product categories accounting for ~50% of all products. The number of ingredients ranged from 3 to 86 with the largest number of products containing between 21-30 ingredients (30%, n=117). Soy and pea protein were the most used protein sources, found in 80% of products collectively (45%, n=157 and 35%, n=122 respectively). 88% of products (n=308) contained ≧ 1 identified allergen. The mean nutrient ranges across the 20 categories per 100g of product were, energy: 86.0-207.5kcal, protein: 2.8-23.3g, fat: 2.0-12.1g, saturated fat: 0.4-2.5g, carbohydrates: 7.3-24.5g, sugars: 1.3-6.7g, fibre: 1.7-8.5g and salt: 0.5-1.9g.

Conclusions: Half of the 351 products identified in this audit fell into the chicken, sausages or burger category. The large range in the number of ingredients and mean nutrient content across the different categories indicates variability in composition. The presence of allergens in majority of these products limits their consumption for a sub-set of the population, unlike most meat products (except fish and shellfish). Therefore, careful consideration should be made when selecting PBMAs from a nutritional and allergen perspective.

[1] Mintel. Plant-based push: UK sales of meat-free foods shoot up 40% between 2014-19. Mintel Reports. 2020.

PAB(T6)-125
Nutrient Adequacy and Environmental Impact of Derived Dietary Patterns in Vietnam

Son Duy Nguyen[1,2], Elise F Talsma[2], Sander Biesbroek[2], Tuyen D Le[1], Edith J.M Feskens[2], Inge D Brouwer[2]

1. National Institute of Nutrition (Viet Nam), 2. Wageningen University (Netherlands)

Background and objectives: Accomplishing the target of balancing both environmentally sustainable and healthy diets is a challenge for many countries. Few studies so far have investigated diet quality in Vietnam and its potential impact on the environment. However, there is no study in Vietnam on dietary patterns and the relationship between nutrient adequacy and environmental impact. Therefore, this study aims to analyze the most common dietary patterns of Vietnamese women and explore the association between nutrient adequacy and the environmental impact of these patterns.

Methods: The nationally representative General Nutrition Survey of 2009-2010 was used to analyze the dietary patterns. Dietary patterns were derived using principal component analysis (PCA). Nutrient adequacy and dietary diversity scores were applied to measure diet quality, and greenhouse gas emissions (GHGE) were selected as an environmental impact indicator. The generalized linear model was used to determine the association between diet quality (nutrient adequacy) and the environmental impact (GHGE) of those dietary patterns.

Results: With PCA, three dietary patterns were identified: An Omnivorous, Traditional, and Pescatarian pattern. All three patterns were associated with better diet quality compared to the average diet. Within three dietary patterns, the Omnivorous dietary patterns performed best with the highest mean probability of nutrient adequacy and dietary diversity scores. When adjusted for the region and socioeconomic status, we found positive associations between nutrient adequacy and GHGE in the average diet, a Traditional, and Pescatarian patterns, i.e. every 1kg CO2 eq. increase in the GHGE increased the odds of nutrient adequacy by 1.04 (average diet), 1.09 (Traditional pattern), and 1.07 (Pescatarian pattern). However, no association was found between nutrient adequacy and GHGE in the Omnivorous pattern.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: The findings indicated that there would be trade-offs between improving diet quality (nutrient adequacy) and reducing the environmental impact. Switching to a diet with lower GHGE may not achieve nutrient adequacy among Vietnamese women. To accomplish both a reduction of GHGE and sufficient nutrient adequacy, a substantial change of diet would be required.

Keyword: Nutrient adequacy, Greenhouse gas emissions, Dietary patterns, Dietary diversity, Food system

PAB(T6)-126
The carbon footprint of moderate-cost food basket in Serbia

Vanja Todorovic[1], Nevena Dabetic[1], Sladjana Sobajic[1]

1. University of Belgrade - Faculty of Pharmacy (Serbia)

Background and objectives: Climate change and food production are closely related. The food chain emits greenhouse gases (GHGs) at each stage; e.g. throughout farming process, production, distribution, refrigeration, retailing, food preparation, and waste disposal. One-third of global greenhouse gas emissions comes from food production and consumption. Food chain sustainability, including reducing food emissions is one of the best and easiest approaches to reduce human impact on the planet. National shopping basket is a tool that reflects the product's share of households' spending in the certain country. This study was designed to examine the sustainability of Serbian affordable foods by calculating their carbon footprint using food items of moderate-cost shopping basket in Serbia.

Methods: The structure of the moderate-cost shopping basket for a family of three in Serbia is published on a monthly basis by the Ministry of Trade, Tourism and Telecommunications. Food list includes 73 food items categorized into 9 groups such as cereals, vegetables, fruits, meats, fish, fats and oils, dairy products, non-alcoholic beverages, and miscellaneous other foods. Food carbon footprint calculator *My Emissions* was used for estimation of emission of all food items in the basket.

Results: The monthly quantities, intended for family of three, of each food item were multiplied by its carbon footprint and summed up the values to derive an estimate of greenhouse gases emission (335504 gCO2e). Comparing obtained estimates with globally fair daily food emissions value of 3.05 kgCO2e, it was pointed out that emissions of moderate-cost food basket in Serbia per person on daily basis is around 20% higher.

Conclusions: Based on that, it can be concluded that Serbian government should introduce educational and official programs towards promoting the idea of sustainable food choices in order to contribute worldwide strategy for lower global emission.

Are communities ready to address the issue of poor food safety and nutritional quality in urban Senegal?

Julia Liguori[1], Agnès Le Port[1], Moustapha Seye[2], Rebecca Pradeilles[3], Nicolas Bricas[4], Abdou Salam Fall[2], Michelle Holdsworth[1]

1. French National Research Institute for the Development (IRD) (France), 2. Laboratoire de Recherche sur les Transformations Economiques et Sociales (LARTES) (Senegal), 3. Loughborough University (UK), 4. French Agricultural Research Centre for International Development (CIRAD) (France)

Background and objectives: In Senegal, increased prevalence of overweight/obesity and diet-related non-communicable diseases is of paramount concern, urging the transformation of food systems to deliver more nutritious and safe foods. Community involvement is recognised as an important factor in the success and sustainability of efforts to promote healthy eating and prevent overweight/obesity. Therefore, this study aimed to assess communities' readiness to address the issue of poor food safety and nutritional quality of foods available in their food environments (i.e., places where consumers acquire or consume foods) in urban Senegal.

Methods: The Community Readiness Model (CRM), consisting of 36 open questions that revolves around five dimensions of readiness (community knowledge of efforts, leadership, community climate, knowledge of the issue and resources) was used. Community leaders and actors who play a key role within the food environment were individually interviewed in two neighbourhoods of Guediawaye (n=9) and Dakar (n=10). Interviews were scored with a maximum of 9 points per dimension (1= no awareness, 9= high level of community ownership) and thematic analysis was conducted on key informants' recommendations to ensure nutritious and safe food systems.

Results: Both communities reached the stage of 'vague awareness' of the issue, with a mean score of 3.00 ± 1.94 in Guediawaye and 3.11 ± 1.58 in Dakar. Both communities scored highest for 'knowledge of the issue' (6.00 ± 2.44 in Guediawaye; 5.69 ± 2.08 in Dakar), while the lowest scores were found for 'community knowledge of efforts' (1.46 ± 0.81 in Guediawaye; 1.86 ± 2.30 in Dakar). Leaders' concern and prioritisation of this issue was perceived as inexistent in both neighbourhoods, contrasting with high levels of community concern. Proposed solutions included: raising community awareness, improving sanitation infrastructure locally and nationally, and increasing government involvement.

Conclusions: While several key informants recognised the lack of nutritious and safe food is a concern, they also

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

highlighted other priority issues, such as lack of financial security, infrastructure and/or food insecurity/hunger within their communities. Encouraging community readiness through public awareness campaigns and increasing government engagement is needed before interventions to promote safe and nutritious food in urban Senegal can be introduced.

Short stature in relation to severity of anemia using 2 hemoglobin correction factors to altitude in Peruvian 6 to 59 months old children

Luis Baquerizo Sedano[1,2], Jose A Chaquila[1,2], Dayana Barriga[1], Juan Aparco[1], Pamela Santillán[2], Pabel Lazo[2], Pedro González-Muniesa[1,2,3,4,5,6]

1. San Ignacio de Loyola University (Peru), 2. Centro de Investigación en Hipoxia y Obesidad (Peru), 3. University of Navarra; Department of Nutrition, Food Science and Physiology (Spain), 4. University of Navarra, Center for Nutrition Research, School of Pharmacy and Nutrition (Spain), 5. IdISNA- Navarra Institute for Health Research (Spain), 6. CIBER Fisiopatología de la Obesidad y Nutrición (CIBERobn), Instituto de Salud Carlos III (Spain)

Background and objectives: Child malnutrition is a serious public health problem in the world, as it compromises physical and cognitive development and negatively impacts health throughout life. Anemia and short stature are two consequences of malnutrition, which tend to occur together, especially in developing countries. In addition, in populations living at high altitudes, it is proposed to use a hemoglobin correction factor. Our objective was to assess the risk of short stature in relation to the presence and severity of anemia using 2 hemoglobin correction factors.

Methods: The open database of the Peruvian government for 2019, 2020 and 2021 was used, with 760763 children between 6 and 59 months, living from 2 to 4801 meters above sea level. The raw value for WHO was used, the conventional correction factor proposed by the CDC: [adjusted Hg] (g/dL) = -0.032 x (Altitude in meters x 0.0033) + 0.022 x (altitude in meters x 0.0033)^2 and the most recent by Sharma et al. [Adjusted Hg] (g/dL) = 0.0048108*altitude+0.0000004*altitude^2. The cut-off points were mild (10-11 g/dL), moderate (7-9.99 g/dL) and severe anemia less than 7 g/dL. A prevalence ratio was performed with the statistical program SPSS 16.

Results: The percentage of children with total anemia were according to WHO (15.97%), CDC (28.07%), Sharma (34.31%). The following risk values for short stature are presented with a 95% confidence interval, according to the WHO, for mild anemia 1.06 (1.04-1.08), moderate 1.24 (1.20-1.27), severe 3.02 (2.27-4.04); according to the CDC, mild anemia 1.24 (1.22-1.26), moderate 1.52 (1.49-1.55), severe 2.34 (2.11-2.60); and according to Sharma, mild anemia 1.15 (1.14-1.17), moderate 1.49 (1.46-1.52), severe 2.56 (2.26-2.89). These results indicate a significant increased risk of short stature even with mild anemia and it increases as the severity of anemia increases, with the highest risk of short stature with severe anemia.

Conclusions: At the public health level, it is a great challenge to reduce malnutrition in children, however, it is necessary longitudinal studies to establish the optimal growth pattern and hemoglobin levels at high altitude and thus choose the best correction factor, and in this way direct resources more precisely.

PAB(T6)-129

Food security implications of COVID-19 pandemic among Indigenous peoples living in urban areas of Saskatchewan, Canada

Mojtaba Shafiee[1], Hassan Vatanparast[2], Ginny Lane[3]

1. University of Saskatchewan (Canada), 2. University of Saskatchewan (Canada), 3. University of Idaho (USA)

Background and objectives: The COVID-19 pandemic and associated economic and social responses (e.g., quarantines, business closures) may adversely affect food access and increase food insecurity among at-risk populations such as Indigenous peoples. Therefore, we aimed to assess the food security implications of COVID-19 pandemic and lockdown among off-reserve Indigenous people in Canada. **Methods**: In collaboration with Indigenous co-researchers, we developed an online survey questionnaire containing four subscales: background information, Household Food Security Survey Module (HFSSM), food access, and traditional food consumption. The survey was distributed via SurveyMonkey® to Indigenous adults living in urban areas of Saskatchewan, Canada between August 2021 and March 2022. **Results:** Out of 99 off-reserve Indigenous peoples who participated in our survey, 78.6% were females, 18.4% were males and 3.0% were other genders with mean age of 35.8 ± 12.5 years (18-75 years). A large proportion of the respondents were single (47.4%), had full-time jobs (50.5%), had at least a bachelor's degree (33.3%), and lived in households with four or more members (46.3%). During the first four months of COVID-19 pandemic, 65.9% of off-reserve Indigenous peoples in Saskatchewan experienced some level of food insecurity (27.3% severe, 28.4% moderate, 10.2% marginal). During the same time period, food price increases (47.0%) and limited food availability at markets (38.6%) were reported as the main challenges in accessing food. About 39.2% of respondents also reported challenges in accessing traditional foods during COVID-19 pandemic. Eating less than usual and less preferred foods (25.9%) along with seeking help from food banks, welfare and

community agencies (25.9%) were the most frequently reported coping strategies used by individuals living with food insecurity. About 50% of respondents reported receiving no government financial support during the COVID-19 crisis. **Conclusions:** The short-term effects of the COVID-19 pandemic are exacerbating existing disparities and disproportionately affecting off-reserve Indigenous households that already struggle to meet their basic needs. The issues with supply chain and consequent increase in food cost are creating additional concerns. A rapid, comprehensive policy response is required to mitigate the adverse effects of COVID-19 pandemic on food security status of off-reserve Indigenous peoples in Canada.

PAB(T6)-130
Using formative research to design an environmental and participatory intervention program for promoting healthy eating and physical activity in elementary schools in Acatlán de Juárez, México: methods and results.

Laura Patricia Arellano Gomez[1], Roberto Paulo Orozco Hernandez[1], Clio Chavez Palencia[2], Cesar Octavio Ramos Garcia[2], Salvador Ivan Rodriguez Preciado[1], Hector Ochoa Gonzalez[1], Oscar Loreto Garibay[2]

1. ITESO, Universidad Jesuita de Guadalajara (Mexico), 2. Universidad de Guadalajara (Mexico)

Background and objectives: In Mexico, one in three children between 5 and 11 years old is overweight or obese; likewise, since 2006, Jalisco has maintained one of the highest prevalences of overweight and obesity. One of the main reasons is the consumption of ultra-processed foods and sugary drinks and low physical activity levels. Mexican children spend about a third of their time awake in school; unfortunately, most offer a food environment that promotes these unhealthy behaviors. This work describes the methods and key findings of formative research conducted in 3 elementary public schools in a semi-urban municipality in Jalisco, Mexico, intended to help design an environmental and participative program to promote healthy eating and physical activity.

Methods: Formative research was based on a similar project in Mexico City, based on the ecological model with a mixed-method approach. Qualitative (direct observation, in-depth interviews, and focus group discussions) and quantitative (closed-ended surveys, checklists) methods were employed to identify context, dynamics, resources, barriers, and facilitators to healthy eating inside the school and surroundings. BMI for age was measured in a parallel evaluation in the nearby schools.

Results: Formative research key findings were used for designing environmental, inter, and intrapersonal strategies to discourage the consumption of energy-dense foods and sugary beverages. The three schools have a food environment that promotes sedentarism and unhealthy eating several times of the day, from before the classes begin until the children go home. Also, a high prevalence of overweight and obesity was found (35%). Furthermore, parents, principals, and teachers' beliefs, motivations, and daily dynamics influence these unhealthy food environments, like time to prepare food, financial issues, and misunderstanding about healthy and unhealthy foods and beverages. Moreover, there was a lack of staff and infrastructure maintenance. Besides, some aspects that could facilitate healthy eating and physical activity were observed, like large areas inside the school and some interested parents.

Conclusions: Formative research was essential to understand the school's food environment and key actors' dynamics to design a context-specific healthy eating and physical activity promotion program.

Keyword: childhood obesity, school environment, healthy eating, physical activity, Mexico

Conflict of Interest Disclosure: All authors declare that they have no conflicts of interest.

PAB(T6)-131
Landscape analysis of nutrition services at preschools and primary schools in Vietnam

Masayo Nakamori Rossignoli[1], Nhung Bui Thi[2], Hien Vu Thi Thu[2], Tuyen Le Danh[2], Thu Nghiem Nguyet[2]

1. Kyoto Kacho University (Japan), 2. National Institute of Nutrition (Viet Nam)

In Vietnam, double burden of malnutrition, which is the coexistence of under- and over- nutrition in the same population, is a prominent public health concern. While prevalence of stunting is still high, account for 19.6%, overweight and obesity has been increasing to 11.1% in under 5 children. The latest annual national nutrition survey shows that the prevalence of overweight and obesity increases as children get older from 7% in under 5 to 19% in 5-19 years old. The reason of having more overweight among older children is implied due to unhealthy diets and physical exercise. Since schools are an attractive entry point to improve children's dietary habits and their life style, the National Strategy on Nutrition for 2021-2030 and the School Health Scheme for 2021-2025, signed by the Prime Minister in 2021, both set goals on school meals and nutrition education for students at all levels. To implement school-based programs and projects, Vietnam is gradually developing policies and relevant resources for school nutrition. A training system on dietitian has been established over 8 years with intensive supports from Japan Dietetic Association. Bachelor training programs for dietitian started from Hanoi Medical University and recently is expanded

to other 8 universities nationwide. About 200 dietitians graduated from these universities are trained for meal management and nutrition education at multiple facilities. There is a rise of public expectation for the bachelors in playing a role to facilitate school nutrition in the future and to improve nutritional status among school children. This study will introduce a landscape analysis used mixed method of a quantitative study followed by qualitative exploration regarding the current school meal provision and nutrition education in selected preschools and primary schools, and to discusspotential entry points for dietitians to play key roles at schools in Vietnam.

PAB(T6)-132
Association between personality traits and food stockpiling for disaster

Moeka Harada[1,2], Nobuyo Tsuboyama-Kasaoka[1], Jun Oka[2], Rie Kobayashi[2]

1. Section of Global Disaster Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 2. Tokyo Kasei University (Japan)

Background and objectives: 46.2% of the households had no food stockpiled for potential disasters in Japan in 2019. although Japan has experienced many large disasters in the last 10 years, the improvement rate from 2011 (the year of the Great East Japan Earthquake) is only 6.4%. In order to improve the food stockpile rate of households, it needs a new approach that is different from the past. By clarifying the personality traits associated with not having food stockpiling, it may be possible to find an approach suitable for that personality traits. However, it is unknown whether personality traits are associated with food stockpiling for disaster. The purpose of this study is to clarify the association between personality traits and food stockpiling for disaster. **Methods:** A survey was conducted between December 18 and 20, 2019, using a web-based questionnaire. The participants were 1200 adults registered with an online survey company who live in the top five prefectures with a high risk of food shortage due to the Nankai Trough earthquake. It was analyzed the association between the Big Five personality traits and food stockpiling status. The Big Five personality traits assess five basic dimensions of personality. To measure these personality traits, we used the Japanese version of the Ten-Item Personality Inventory (TIPI-J). **Results:** In total, 1192 responses were analyzed, excluding those whose responses to sex and educational background are “others” (n = 3 and n = 8, respectively). The Mann-Whitney test revealed that no significant difference between any Big Five personality scores and food stockpiling status. Additionally, logistic regression analysis reported that none of the Big Five personality traits were significantly associated with food stockpiling. **Conclusions:** The Big Five personality traits may not be associated with food stockpiling for disaster. In order to clarify a new approach to promoting food stockpiling for disaster, it may be necessary to consider from another perspective in the next study.

Keyword: Food stockpiling, Food for disaster, Disaster preparedness, Big Five personality traits

Arsenic exposure increases the risk of mild cognitive impair and dementia

Liping Liu[2], Shaozhan Chen[2], Tianhui Zhou[2], Huijun Wang[3], Bing Zhang[3], Annie Green Howard[1], Shufa Du[1]

1. University of North Carolina at Chapel Hill (USA), 2. Beijing Municipal Center for Disease Prevention and Control (China), 3. National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention (China)

Background and objectives: A few studies have explored the relationship between arsenic exposure and dementia, but the results are inconsistent. The purpose of this study is to test the hypothesis that arsenic exposure increases the risks of mild cognitive impair (MCI) and dementia.

Methods: We used data from 1899 adults aged 55 years and older who participated in the China Health and Nutrition Survey, an ongoing cohort study, and provided toenail samples in 2009 and were followed up in 2015. We measured arsenic concentrations (As) using inductively coupled plasma mass spectrometry (ICP-MS) and assessed cognitive impairment and dementia by the Montreal Cognitive Assessment (MoCA) and Mini-Mental State Exam (MMSE) test. We used generalized logit model to explore the relationship between arsenic concentrations on toenail samples and MCI and dementia.

Results: About 18.2% of participants in the study had MCI and 11.7% had dementia. Compared to participants with low levels of As, participants with intermediate levels of As had a 40% higher risk of MCI (RR = 1.40, 95% CI: 1.01–1.82, $p < 0.05$) and a 42% higher risk of dementia (RR = 1.42, 95% CI: 0.99–2.04, $p = 0.055$); participants with high levels of As had a 30% higher risk of MCI (RR = 1.30, 95% CI: 0.97–1.75, $p = 0.082$) and a 57% higher risk of dementia (RR = 1.57, 95% CI: 1.11–2.24, $p < 0.05$). After adjusting for age, sex, education, occupation, and resident areas, their RRs were 1.30 (95% CI: 0.96–1.76, p =0.096), 1.34 (95% CI: 0.91–1.97, p =0.13), 1.21 (95% CI: 0.88–1.65, p =0.24), and 1.52 (95% CI: 1.04–2.23, p =0.030), respectively.

Conclusions: Relatively high levels of arsenic exposure significantly increase the risk of MCI and dementia among older Chinese. These findings could have significant impacts on policies and interventions to control and prevent dementia older adults.

Estimates and trends of zero vegetable or fruit consumption among children aged 6-23 months in 64 countries

Rukundo K Benedict[1], Courtney Allen[2,1], Shireen Assaf[1], Sorrel Namaste[1]

1. The DHS Program, ICF (USA), 2. University of Washington (USA)

Background and objectives: Children require a diverse diet, that includes vegetables and fruits, to support growth and development and prevent non-communicable diseases. The WHO-UNICEF established a new infant and young child feeding (IYCF) indicator: zero vegetable or fruit (ZVF) consumption among children aged 6-23 months. We estimated the prevalence, trends, and factors associated with ZVF consumption in low-and-middle-income countries.

Methods: We examined 129 Demographic and Health Surveys in 64 countries with data on whether a child ate vegetables or fruits the previous day. Prevalence of ZVF consumption was calculated by country, region, and globally. Country trends were estimated and tested for statistical significance (p<0·05). A multivariate analysis was used to examine the relationship between ZVF and child, mother, household, and survey cluster characteristics by world region and globally.

Results: Globally ZVF consumption was 46·3%, with the highest prevalence in West and Central Africa (56·1%) and the lowest in Latin American and the Caribbean (34·5%). Recent trends in ZVF consumption varied by country (17 decreasing, nine increasing, 14 no change). Children from wealthier households and children of mothers who are employed, more educated, and have access to media were less likely to consume ZVF.

Conclusions: The prevalence of children aged 6-23 months who do not consume any vegetables or fruits is high and is associated with wealth and characteristics of the mother. Programs should focus on improving the food environment and providing IYCF counseling.

PAB(T6)-135

Relationship between the decrease of energy intake in summer and fat energy ratio

Naomi Hirano[1], Noriko Tanaka[2], Aya Kaizaki[3], Nao Nishi[1]

1. Kobe Women's Junior College (Japan), 2. Kobe Women's University (Japan), 3. Japan Sport Council (Japan)

Background and objectives: Dietary intake changes seasonally and decreases in the hot summer environment, resulting in weight loss (Nutrients 2022, 14, 506). Decrease in dietary intake is considered to promote histamine synthesis in a high-temperature environment, and the intake is suppressed by stimulation of the satiety center via histamine neurons. Preliminary experiments have shown that dietary intake suppression tends to be accelerated when the F % (fat energy ratio) in the diet is low, such as in high-carbohydrate diets during summer. In this study, we conducted experiments on young athletes to test the hypothesis that a low-fat diet induces a decrease in dietary intake as compared to a high-fat diet during summer.

Methods: 1. Twenty-eight young women participated in the study during winter and summer. A dietary survey was conducted using the weight-recording method, and body composition was measured using bioelectrical impedance method. 2. Forty-two male high-school baseball players participated in the study during winter and summer. A dietary survey was conducted using the same method as in experiment 1. The body weight, midarm circumference (MAC), and calf circumference (CC) were measured as physical parameters.

Results: Changes in the energy intake during summer and winter were negatively correlated (p = 0.082) with the energy composition ratio (F %) of fat in baseball players. Thus, energy intake may easily decrease during summers in players consuming a low-fat diet. The subjects were divided into two groups: one with a decrease of energy (L) and the other with no decrease of energy (H) during summer. F % of the L group (26.8%) tended to be lower than that of the H group (30.5%, p=0.056). The MAC of the H group tended to slightly increase and be subsequently maintained, while that of the L group tended to decrease (p=0.074).

Conclusions: The decrease in energy intake during summer indicated a large negative effect on physique, including body weight and MAC. For school baseball players, high-carbohydrate diets may not be optimal during summers.

PAB(T6)-136

Nutrient adequacy of Japanese schoolchildren on days without a school lunch as an alternative to household income

Chika Horikawa[1], Nobuko Murayama[1], Hiromi Ishida[2], Taeko Yamamoto[3], Sayaka Hazano[4]

1. University of Niigata Prefecture (Japan), 2. Kagawa Nutrition University (Japan), 3. Kanagawa University of Human Services (Japan), 4. Matsumoto University (Japan)

Background and objectives: School lunches are important for adequate nutrient intakes in children. Nutrient intake is inadequate among children from low-income households on days without a school lunch. However, questions about household income are often not responded to due to privacy reasons. We conducted a cross-sectional study to develop a questionnaire to assess nutrient adequacy of children on days without a school lunch as an alternative to household income.

Methods: Participants were 691 children aged 10-11 years from 19 public primary schools in four prefectures of East Japan. The participants completed 24-h dietary records with meal photographs for 2 days without a school lunch. Children's guardians completed a questionnaire about reducing their intakes of the following foods due to economic reasons: “fruits and vegetables”, “meat and fish”, “food you wanted”, and “food you needed”. Using reference dietary intakes, intakes of energy and 25 nutrients were evaluated to assess nutrition adequacy. Logistic regression analyses were used to estimate the odds ratio for poor nutrient intake in participants, after adjustment for confounders.

Results: Participants who often or occasionally reduced their intakes of fruits and vegetables due to economic reasons had significantly higher rates of inadequate intakes of energy and 7 nutrients (vitamins A, E, and B_2, K, Ca, Mg, and P) compared to those who did not or rarely reduced their intakes. Participants who often or occasionally reduced their intakes of the foods they wanted due to economic reasons had significantly higher rates of inadequate intakes of energy and 7 nutrients (proteins, fibers, vitamins E, B_2, and C, Ca, and P) compared to those who did not or rarely reduced their intakes. Only a few nutrients showed significant differences between the respondents to questions about reducing their intakes of meat and fish, and foods they needed. Importantly, those nutrients also showed significant differences among respondents to the first two questions.

Conclusions: The questions about reducing children's intakes of fruits and vegetables, and food they wanted due to economic reasons are useful to assess nutrient adequacy on days without a school lunch as an alternative to household income.

PAB(T6)-137

The effectiveness of workplace-based nutrition-specific or -sensitive interventions in improving nutritional outcomes among women and their offspring in low-and middle-income countries: a mixed-methods systematic review

Ana Irache[1], Sophie Goudet[1], Jacob Clere[2], Su Mon Thair[2], Aye Sandar Aung[2], Rebecca Pradeilles[1]

1. Dikoda (UK), 2. sequa gGmbH Myanmar Office (Myanmar)

Background and objectives: Women working in the factory sector are highly vulnerable to poor diets, malnutrition and associated health issues. This review aimed to synthesise the most recent evidence from LMIC settings on i. the impact of workplace-based (i.e., factories/industries) nutrition-specific or -sensitive interventions on nutritional outcomes amongst women and their offspring, and ii. barriers and facilitators influencing these outcomes in the workplace.

Methods: We conducted a mixed-method systematic review (PROSPERO CRD42021246799) of peer-reviewed literature including searches in the following databases: PubMed (Medline), Cochrane CENTRAL, CINAHL, EMBASE and Google Scholar. Risk of bias was assessed using the RoB2 tool for trials and CASP for qualitative studies. Narrative synthesis will be performed alongside meta-analysis where possible. Certainty of evidence will be assessed using GRADE.

Results: Nine articles from five countries located in Africa and Asia, published over the last decade, were included: two quantitative, four qualitative and three mixed-methods. Most studies were conducted in factories within the readymade garment industry. All interventions were nutrition-specific, including dietary supplementation with or without behaviour change communication programmes, and counselling on infant and young child feeding practices. The quantitative evidence yielded mixed results. Barriers to the successful implementation of a nutrition-specific intervention were reported in one study. These included the intervention delivered during working hours; lack of support from managers; and lack of information on benefits regarding dietary supplementation. Other factors that act as barriers within the workplace to women and their offspring achieving good nutrition included absence of maternity leave; excessive workload; safety issues (chemicals); inadequate health services; lack of facilities to express/ store breastmilk and lack of childcare options. Facilitators of good nutrition practices included women-friendly workplace policies; provision of canteen food; and support from family members, caregivers and peers with childcare.

Conclusions: This review highlighted a paucity of literature investigating the effect of workplace-based nutrition interventions on nutrition outcomes, particularly for nutrition-sensitive interventions. The limited evidence suggests that the workplace could be considered as a suitable avenue to tackle multiple forms of malnutrition among women and their offspring providing key barriers to good nutrition in the workplace are addressed.

Fresh large fish are commonly consumed among women in Nigeria, but dried small fish are the richest in iron, zinc, calcium, and vitamin B-12

Kendra Byrd[1,2], Hina Li[3], Kafayat Fakoya[4], Kathryn Fiorella[3]
1. University of Greenwich (UK), 2. WorldFish (Malaysia), 3. Cornell University (USA), 4. Lagos State University (Nigeria)

Background and objectives: Fish is the most consumed of the animal-source foods among vulnerable populations in Nigeria, though little is known about the categories of fish consumption. Fish is generally presented as a homogenous category in dietary surveys; however, the category of 'fish' varies widely in nutrient composition, based on the form consumed, and the physical characteristics of the fish. Our aim was to compare the nutrient composition and the consumption of different categories of fish among Nigerian women.

Methods: Fish intakes were obtained from a survey of 693 women of reproductive age in August – October of 2019 across nine states in Nigeria, where women were asked qualitatively about their fish consumption in the previous 24 hours. The reported fish were sorted into the following categories: fresh large fish, fresh small fish (less than 25 cm at maturity), fresh shellfish, brackish/marine fish, freshwater fish, dried shellfish, dried large fish, and dried small fish. The average iron, zinc, calcium, and vitamins A and B-12 composition of a 25-gram serving was calculated for each category. The nutrient composition of the fish categories was an average based on nutrient composition data from FishBase and FAO INFOODS.

Results: The most consumed category of fish was large fresh fish, with 70% of women reporting consumption in the previous day. Few women (1%) reported consuming dried small fish, which was also the most nutrient-dense of all the fish categories. 25 grams of dried small fish fulfilled 41% of the daily recommended nutrient intake (RNI) of iron for women, 51% of the zinc RNI, 70% of the RNI for calcium, and 204% of the RNI for vitamin B-12. Dried large fish were the second most nutrient-dense and were reported by 19% of women the day prior, while dried crayfish were the third most nutrient-dense; they were consumed by 8% of women the day prior.

Conclusions: Large fish make up an important component of the Nigerian food supply. However, increased domestic production, processing, and consumption of small fish and crayfish can improve micronutrient intakes for vulnerable populations, thus reducing the burdens of undernutrition of generations to come.

Baseline assessment of knowledge and attitudes towards maternal and infant and young child feeding and nutrition in Cambodian workplaces

Kroeun Hou[2], Ngik Rem[2], Senveasna Chum[2], Kyly Whitfield[1], Emily Meier[1], Gwyneth Cotes[2]

1. Mount Saint Vincent University (Canada), 2. Helen Keller Intl (Cambodia)

Background: In Cambodia, women are increasingly engaging in the paid labor market, while rates of exclusive breastfeeding and dietary diversity for women are declining. Workplace lactation support programs may enable employees to continue breastfeeding, while providing a platform for nutrition and health information. Elsewhere, such programs have increased employee productivity and workplace satisfaction while decreasing absenteeism and health insurance costs. Helen Keller Intl is developing workplace nutrition guidelines and supporting 26 workplaces (factories, banks, and government offices) to establish lactation support programs. Here, we present baseline results collected prior to project implementation.

Methodology: Interviewers administered questionnaires to 648 participants in eight workplaces: 308 women employees with children <12 months ('mothers'), 321 other employees (107 men, 214 women), and 26 managers (10 men, 16 women). The survey assessed infant and young child feeding (IYCF) and women's nutrition practices (mothers only), and knowledge and attitudes related to breastfeeding and current labor laws (all participants).

Results: The mean (SD) age of mothers' infants was 7.5 (2.8) months. Three quarters (75%) of women reported feeling comfortable taking lactation breaks during work hours, and 81% believed a workplace lactation room would be useful. Managers and other employees reported being supportive of breastfeeding staff or co-workers: (93% other employees, 88% managers). While 69% of managers believed human milk was the ideal food for infants, 19% reported that infant formula and human milk were equally good (compared with 84% and 4%, respectively, among women; and 86% and 7% among other employees, respectively). Two thirds (63%) of mothers met the minimum dietary diversity for women. Although 89% of children <12 months reached the minimum meal frequency, only 41% met the minimum dietary diversity score (MDD), and 36% had a minimum acceptable diet (MAD).

Conclusion: Both workers and managers self-report strong support for breastfeeding employees, but managers show less understanding and support of breastfeeding at work. Children of mother employees are not meeting standard MDD and MAD indicators, indicating higher risk of malnutrition. A follow-up assessment will be conducted after 12 months to assess changes related to the intervention.

PAB(T6)-140
Nutrient profiling and food prices: the cost of choosing healthier packaged foods

Guanlan Hu[1], Mavra Ahmed[1], Allan Batalla[1], Emily Ziraldo[1], Jennifer Lee[1], Mary L'Abbe[1]

1. University of Toronto (Canada)

Background and objectives: Unhealthy diets, as characterized by high intakes of nutrients of public health concern, are one of the leading modifiable risk factors for the prevention of non-communicable diseases. Nutrient profiling (NP) is a tool to help classify foods according to their healthfulness score, based on comprehensive nutritional composition criteria. Price is an important determinant of food choice, however, previous research on the relationship between food healthfulness and price has focused on single nutrients of public health concern. Therefore, the objective of this study was to assess the relationship between the healthfulness score of a food product in relation to price.

Method: Using the University of Toronto Food Label Information Program (FLIP) database 2020 (n=17,453), the nutritional scores for packaged foods and beverages were derived using the Food Standards of Australia and New Zealand (FSANZ) NP system, ranging from -15 (most healthy) to 40 (less healthy) and categorized by Health Canada's Table of Reference Amounts. FSANZ is a validated NP system, that calculates a summary score based on the amount of nutrients to limit and components to encourage in a food. Generalized linear models were used to assess the association between FSANZ score and food price, adjusted for container size, brand and store.

Results: The FSANZ healthfulness score was not consistently related to price. One score increase in FSANZ (less healthy) was associated with higher price ($p<0.05$) for dairy products ($0.11), beverages ($0.08), soups ($0.05), bakery products ($0.04) and vegetables ($0.04). However, negative associations were observed for snacks ($0.04), meat and poultry ($0.04), fruits and fruits juices ($0.07) and legumes ($0.12), where healthier products were higher in price ($p<0.05$).

Conclusions: Our findings show that healthier products were not consistently more expensive than less healthy products, however, for some food categories they may be. This study provides a comprehensive estimate of the relationship between nutritional composition and the price of foods in the Canadian food supply. It can also serve as the baseline from which to evaluate the impact of the key national food policies aimed at improving the nutritional quality of food on price in the future.

Changes over 11 years in vitamin D and sun exposure knowledge, attitudes and behaviours of parents of young children in New Zealand

Pamela Ruth von Hurst[1], Esme Reynolds[1], Cathryn Conlon[1]

1. Massey University (New Zealand)

Background and Objectives Vitamin D deficiency can have serious health implications for infants and young children. Therefore, parents' knowledge about vitamin D and sun exposure is important to ensure optimal vitamin D status during childhood. In 2013 the New Zealand (NZ) Ministry of Health (MoH) released a consensus statement on vitamin D supplementation and sun exposure during pregnancy, infancy and childhood. The aim was to investigate change over time in the knowledge, attitudes and behaviours of New Zealand parents on vitamin D and sun exposure, and identify sources of information. **Methods** This ecological study recruited parents of infants and young children throughout NZ at two time points - 2009 and 2021 to compare knowledge, attitudes and behaviours, and assess the impact of the NZ MoH statements. An online questionnaire was administered to parents. Inclusion criteria included: youngest child ≦5 years, living in NZ, and understanding written English. **Results** The analysis included parents (2009 N=8,032, 2021 N=1,802) of children ≦5 years. Two thirds (63.1%, 61.3%) identified the role of vitamin D in bone health, awareness of its role in immunity increased in 2021 (29.1% vs. 48.2%). Most parents lacked knowledge of high-risk factors for deficiency, including exclusive breastfeeding (98.1, 95.1%) and darker skin colour (92.9%, 77.5%). Health professionals were not the main source of information on supplementation and sun exposure (15.8%, 24.8%) and low rates of advice were reported. Health professionals or the MoH (60.2%) were the preferred source of information on vitamin D, followed by the media, including social media (24.5%). Safe sun exposure practices were followed during the summer, with concerns about skin cancer high (86.5%, 83.3%). Additionally, 72.4% and 78.4% found vitamin D and sun exposure recommendations confusing because of skin cancer prevention messages. **Conclusion** Overall, the impact of the MoH statements and subsequent public health messaging on parents' knowledge has been minimal. To ensure public health information is communicated effectively to parents, the MoH and health professionals could utilise emerging tools, including social media, to improve parents' knowledge.

Recurrent flooding and household diet quantity in Central Java, Indonesia 1988-2015

Breanne K Langlois[1], Leah Beaulac[1], Katherine Berry[1], Timothy Griffin[1], Erin Coughlan de Perez[1], Magaly Koch[2], Elena N. Naumova[1]

1. Tufts University (USA), 2. Boston University (USA)

Background and objectives: Increasing flooding events in Central Java are impacting food availability through direct losses to agricultural crops, but it is not well-understood how recurrent floods are affecting diet-related aspects of food security at the household level. We evaluate how recurrent flooding has impacted household diet quantity over a 20-year span in Central Java.

Methods: The Indonesian Family Life Survey (IFLS) is a longitudinal household economic and health survey of the Indonesian population with 5 waves: 1993, 1997, 2000, 2007, 2014. We use IFLS to measure diet quantity through household food expenditure share (HFES) based on the Data4Diets framework using monthly aggregates from the consumption and expenditure module. Information pertaining to floods was collected for IFLS waves 4 and 5, covering a 10-year time span only. We use an objective measure of flood exposure at the sub-district level using flood monitoring data. We examine the relationship between floods and HFES using generalized linear mixed-effects models.

Results: Across Central Java, IFLS includes a total of 828 households appearing in all 5 waves and 1,121 households, containing a target member from a previous wave. From waves 1 to 5 HFES was 60%, 59%, 61%, 57%, and 53%, respectively. In waves 4 and 5, 37% and 44% of households, respectively, reported being affected by flood in the past 5 years. Data analysis is ongoing.

Conclusions: Objective measures (along with their risk misclassification) are needed to quantify household exposure to floods. A deeper understanding of how flood impacts household physical and economic food access should guide mitigation, planning, and adaptation in areas vulnerable to recurring flooding events.

The different pathway to stunting among Under Five Children in Indonesia based on Basic Health Survey 2013 and 2018

Soenarnatalina Melaniani[1], Sri Sumarmi[1], Kuntoro Kuntoro[1], Nunik Puspitasari[1], Qonita Rachmah[1], Zida Husnina[1], Agus Triwinarto[2], Doddy Izwardy[2], Patrisia Helena Saraswati[3], Takashi Yamano[3]

1. Faculty of Public Health Universitas Airlangga (Indonesia), 2. National Institute of Health Research and Development, Ministry of Health (Indonesia), 3. Asian Development Bank (Philippines)

Background and objectives: Stunting is a growth failure among children with multi causal. It is important to identify what are the factors influence it and how did stunting occur with some factors inter-correlated. The study objective was analysed the pathway of possible factors affecting stunting among children under five years old based on national data from Indonesian Basic Health Survey (BHS) 2013 and 2018.

Methods: A study using secondary data from the Indonesia Basic Health Survey year 2013 and 2018. The samples size are 10,209 maternal-child paired data from BHS 2013 and 9,315 paired data form BHS 2018. Pathway of some factors affecting stunting occurrence was modelling using the theoretical framework from The Lancet 2013. Path analysis using partial least squares structural equation modelling (SmartPLS) was used to explain the pathway of stunting. Significant value is showed by T value > 1.96.

Results: Based on path analysis, it shows that the pathway of some factors affecting child stunting are different between data 2013 and 2018. In year 2013 stunting was significantly affected by birth size (T value=9.78) (low birthweight, neonatal stunting), as well as the diseases factors (T=2.48). In 2018, despite of birth size influence stunting (T=8,75), but diseases factors do not influence stunting (T=1.57). The consistent pathway between two datasets, that maternal factor affects access of health services (T=8.78 and T=4.86), then affect the hygiene & sanitation practices (T=2.11 and T=2.07). Maternal factor did not affect birth size (T=0.28 and T=1.77). In 2013, Socio-economic factor affects stunting indirectly through maternal factor (13.86) and hygiene sanitation (T=23.76), it consistent in 2018 with T value of 18.82 and 17.96, respectively.

Conclusion: There are different pathway of factors affecting stunting between two dataset of basic health survey 2013 and 2018, particularly diseases factor and practice of breast feeding, but the consistent factors are birth size, maternal factors, and socio-economic factors.

User characteristics of healthcare applications among middle-aged and older Japanese adults: a special focus on nutrition applications

Maki Nishinakagawa[1,2], Ryota Sakurai[2], Hiroyuki Sasai[2], Toru Takebayashi[1]

1. Keio University (Japan), 2. Tokyo Metropolitan Institute of Gerontology (Japan)

Background and objectives: Healthcare applications (apps) are increasingly expected to maintain and improve health status among middle-aged and older adults. However, the prevalence and characteristics of the usage of the apps remain unclear among the middle-aged and older populations. These knowledge gaps are evident in apps for recording nutritional intake and supporting healthy eating (nutrition apps), providing nutritional knowledge and expert advice on dietary habits. Therefore, this study aimed to clarify the characteristics of users of health apps, focusing on nutrition apps.

Methods: We conducted an internet questionnaire survey on registrants of a research company. The target population was divided evenly by sex and age, in their 40s, 50s, 60s, and 70s, for 6,000 respondents in the metropolitan area. From 243,529 registrants who matched the sex and age groups in the registered information, 16,136 were randomly selected and asked to participate in the survey by e-mail, and responses to the survey questionnaire were obtained. Questionnaire items included sociodemographic, psychological, and physical characteristics, healthcare apps usage, and health-related behaviors. Respondents were categorized based on the healthcare app usage: nutrition apps users, non-nutrition healthcare apps users, and never users.

Results: Of the 6,000 respondents, 5,933 (aged 40-79 years, mean age 59.3 years, SD=10.8) provided valid responses, comprising 252 (4.3%) nutrition apps users, 1,555 (26.2%) non-nutrition healthcare apps users, and 4,126 (69.5%) never users. Multinomial logistic regression models showed that younger age, higher health literacy, currently working, more comorbidities, better subjective financial status, regular exercise habits, non-smoking, and non-underweight were significantly associated with being the non-nutrition healthcare apps compared to the never users. In addition to these factors, having frequent balanced meals and frequent home-meal replacements were associated factors with being the nutrition apps users.

Conclusions: We found that healthcare apps users tended to have high health consciousness and practice behaviors. Furthermore, those who used nutrition apps tended to have good dietary habits. Although careful attention should be paid to causality, nutrition apps may contribute to maintaining good nutritional status among middle-aged and older adults.

Keyword: healthcare applications, nutrition applications, user characteristics, middle-aged and older adults, health consciousness

Determining the cut off values for hypovitaminosis D among pregnant mothers in Colombo District-Sri Lanka

Anusha Kaneshapillai[1], Usha Hettiaratchi[2], Shamini Prathapan[2], Guwani Liyanage[2]

1. The Open University of Sri Lanka (Sri Lanka), 2. University of Sri Jayewardenepura (Sri Lanka)

Background and objectives: Vitamin D testing have exponentially increased in recent years. The relevance of vitamin D deficiency on non-skeletal health is still under debate. Recent observational data have suggested that 62.9% of Sri Lanka pregnant women are vitamin D deficient (25-hydroxyvitamin D (25-OHD) <20ng/ml). The relevance of this widespread deficiency and necessity for supplementation has been questioned. There is no consensus on the cut-off values for 25-OHD) levels. Thus, we aimed to determine (25-OHD) cut-off values for pregnant mothers in Western Sri Lanka.

Methods: We recruited 393 healthy pregnant mothers in 3rd trimester from primary healthcare units in the Colombo District. Multistage, stratified random sampling was used for recruitment. Venous blood sample was collected for analysis of serum 25(OH)D and parathyroid hormone (PTH). Chemiluminescent immunoassay (CLIA) was used to measure the 25OHD levels. Deficiency cut-off value with highest sensitivity and specificity was obtained using receiver operating characteristic (ROC) curve analysis based on PTH level.

Results: 25(OH)D concentrations were inversely correlated with PTH levels (Spearman's r= -0.220, p=0.000). Serum 25(OH)D cutoff point was 8.1 ng/mL based on PTH level (66.5 pg/mL). By using this cutoff value, the prevalence of vitamin D deficiency was 4.1% in this study population of healthy pregnant women with an accuracy rate of 95.6% and corresponding sensitivity, specificity, and AUC of 0.961, 0.667 and 0.933 respectively.

Conclusions: Our study found that the 25(OH)D cutoff value based on PTH is 8.1ng/mL for healthy pregnant women on chemiluminescence technology.

Field experience in developing an action plan to integrate early detection and treatment of wasting services in Ethiopia

Wossen Assefa Negash[1], Mary D'Alimonte[1], Frezer Abebe[2]

1. Results for Development (R4D) (Ethiopia), 2. Ministry of Health (Ethiopia)

Background and objectives: According to the Ethiopian Mini-EDHS 2019, 37% of children under age five are stunted while 7% are wasted. In 2021, the Ethiopian Federal Ministry of Health began a journey to develop a national plan to further integrate wasting treatment into routine primary healthcare services across all health system building blocks. Goals are to increase coverage of wasting services, increase efficiency of service delivery and ensure financial sustainability.

Methods: A six-step process was utilized to develop the wasting integration action plan: 1) **establish the process** to develop a work plan and decide who to involve in the process; 2) **articulate intended aims** of the integration and end goals; 3) **take stock of the current situation** to identify wasting program constraints and opportunities within the broader health system for integration; 4) **identify possible integration actions** based on the findings; 5) **assess integration actions** for feasibility, benefits and risks to develop recommendations; and 6) **decide on a way forward** to present options and recommendations to senior officials for decision.

Results: Major constraints and enablers to achieving wasting integration program goals were identified across all health system components, including limitations in accountability, uncertain sustainability of wasting services due to continued reliance on external partners, insufficient screening and early detection of child wasting, low treatment coverage for moderate wasting services, substandard quality of wasting treatment services, limited capacity of health staff, limited availability of high-quality wasting data for routine monitoring, gaps in use of wasting data in health sector decision-making, insufficient funding, under-prioritization of RUTF as an essential commodity, and inefficient RUTF Supply chain. Based on the findings, a wasting integration action plan was developed.

Conclusions:

-Stakeholders have a wealth of knowledge and experiences related to child wasting and their effective engagement helped for effective action plan development.

-Assessment is critical to identify the specific barriers to wasting integration in each context and develop effective integration action plan.

-Positioning wasting integration across all the six health system components helps to address integration issues in a more comprehensive way.

Food and nutrition security amongst garment female workers in Myanmar: Evidence from a remote longitudinal survey conducted during the COVID-19 pandemic and political crisis

Rebecca Pradeilles[1,4], Ana Irache[4], Sabrina Eymard-Duvernay[4], Jacob Clere[3], Aye Sandar Aung[3], Su Mon Thair[3], Rebecca Chekaraou[4], Sophie Goudet[1,2,4]

1. Loughborough University (UK), 2. Dikoda (Fiji), 3. sequa Gmbh Myanmar Office (Myanmar), 4. Dikoda (UK)

Background and objectives: In Myanmar, the ready-made garment (RMG) sector has heavily been hit by the COVID-19 pandemic and the current political crisis. Women in the RMG factories are highly vulnerable to poor diets and malnutrition in Asia. The aim of this study was to evaluate, during the health and political crisis, the impact of a nutrition-sensitive intervention (i.e., unconditional cash transfer combined with a targeted social and behaviour change component) on food and nutrition security amongst a sample of garment female workers in urban Myanmar. **Methods:** We conducted a remote longitudinal study of women of reproductive age in May/June 2021 (baseline; *n=800*) and December 2021/January 2022 (endline; *n=678*). The Minimum Dietary Diversity (MDD-W) was generated using reported qualitative intakes of foods and beverages during the past 24-h. Food insecurity (FI) at the household level was measured using the Food Insecurity Experience Scale (FIES). Changes in key indicators were assessed by comparing endline and baseline data. Multivariable regression analyses were performed to assess the relationship between the amount of cash transfer and key outcomes at endline. **Results:** Moderate or severe household FI decreased (38.3% vs. 36.5%; p<0.001) whilst severe FI remained stable (10.1% vs. 8.9%; p=0.13) over time. The proportion of women eating a quality diet remained low over time and was not significantly different between the two time points (27.1% vs. 31.8%; p=0.10). The consumption of sugar-sweetened beverages (SSB) decreased (25.6% vs. 17.7%; p=0.008). Consumption of eggs and/or flesh foods was high with no noticeable differences between the two time points (84.5% vs. 87.2%; p=0.66). The proportion of women consuming zero fruit or vegetable decreased significantly (15.7% to 9.9%; p=0.007). The amount of cash received was positively associated with fruit (OR=1.14 [0.97; 1.33]; p=0.10) and SSB (OR=1.14 [0.97; 1.33]; p=0.12) consumption, although the results are not statistically significant. **Conclusions:** The social safety net might have prevented further deterioration of indicators which was anticipated given the health and political crisis in Myanmar. Given the positive association between cash transfer and SSB consumption, the use of conditional cash transfers should be considered to prevent malnutrition.

Measuring adherence to sustainable healthy diets: A scoping review of diet quality metrics

Priscila Machado Machado[1], Mark Lawrence[1]

1. Deakin University (Australia)

Background and objectives: Addressing unhealthy and unsustainable diets is a key priority on the agendas of governments, academia, and civil society worldwide. Despite the significance of the topic, it is unclear how dietary metrics used to monitor the quality of diets account for all components of sustainable healthy diets. This scoping review aims to explore how principles of sustainable healthy diets are considered in global diet quality metrics used worldwide.

Methods: A scoping electronic search comprised a hand-search of metrics included in relevant reviews of the field; and due to the novelty of the topic, additional sustainability-focused metrics were identified through an electronic systematic search. Food-based 'a priori' dietary metrics developed to assess diet quality among free-living, healthy children and/or adults at individual or household level were included. The 16 guiding principles to achieve sustainable healthy diets developed by the Food and Agriculture Organization of the United Nations and the World Health Organisation in 2019 were used as a framework to assess the metrics.

Results: A total of 48 diet quality metrics were assessed. The analysis revealed a strong alignment of the metrics with health-related guiding principles (particularly Principles 2 to 4), but a critically weak alignment with principles related to environmental impact and sociocultural aspects (except Principle 14).

Conclusions: No existing dietary metric captures all components of sustainable healthy diets. Notably, the significance of ultra-processing, environmental and cultural aspects of diets is generally understated. These results highlight the importance of revising current dietary recommendations, especially to include emerging topics.

A critical analysis of the relevance of evidence used to inform nutrition policy recommendations in Australia

Patricia Ribeiro de Melo[1], Phillip Baker[1], Priscila Pereira Machado[1], Elly Howse[2], Mark Lawrence[1]

1. Deakin University (Australia), 2. The Australian Prevention Partnership Centre (Australia)

Background and objectives: Nutrition policy-making is a scientific and political process that needs to navigate contested views towards the causes of and the solutions to public health nutrition problems and consequently, to determine what constitutes quality evidence to inform policies. Often, evidence relevance is not considered in assessing evidence quality, which raises questions about whether the design of evidence-informed nutrition policies is always fit-for-purpose for developing the safest and most effective of the policy options that might be available. This study aimed to identify the most recent nutrition policy recommendations in Australia and critically analyse the relevance of the evidence synthesis and translation processes that informed their developments.

Methods: A framework underpinned by the principles of ecological and evolutionary theories, and which was designed for guiding the selection of fit-for-purpose evidence synthesis and translation processes for promoting healthy and sustainable diets, was used in this study. Data on policy recommendations were collected from a content analysis of the 2021 Australian National Health Preventive Strategy (ANHPS) and 2022 Australian National Obesity Prevention Strategy (ANOPS). The relevance of the evidence synthesis and translation processes used in the policy decision-making process was analysed by comparing their alignment with the principles outlined in the fit-for-purpose guiding framework.

Results: The content analysis of the ANHPS and ANOPS revealed that recommendations used for the development of nutrition policy actions were mostly around front-of-pack labelling, food taxation, and food marketing restrictions to children. Evidence relevance was not found to be an explicit criterion considered in the evidence synthesis and translation processes that were used to inform the making of the assessed policy recommendations. Thus, the resulting design of the recommended policy actions did not align closely with the guidance provided in the fit-for-purpose framework.

Conclusions: These preliminary findings show that evidence relevance is being significantly overlooked in decision-making processes when developing nutrition policy recommendations in Australia. These findings raise questions about whether the current nutrition policy recommendations in Australia are necessarily the best fit among available options to achieve preventive health and obesity prevention purposes.

Reducing Food waste: Changing Awareness and Behavior in Elementary School Students, Parents, and Teachers

Chie Tokuhiro[1], Ikuko Shimada[2]

1. Mimasaka University (Japan), 2. University of Kochi (Japan)

Background and purpose: The United Nations has set Sustainable Development Goals (SDGs), and efforts to implement them have begun in various countries and regions regarding food waste, poverty, and deterioration of the global environment. In Japan, foods that can still be eaten but are often thrown away. In response to this situation, we conducted a survey for elementary school students, parents, and teachers regarding their awareness and behavior regarding food waste reduction and created teaching materials to modify behavior and attitudes.

Method: Target: Elementary school students, parents and teachers Subjects: 57 children, 38 parents, 15 teachers in 2020 56 children, 34 parents, 11 teachers in 2021 Timing: June 2020 – July 2021 The survey was anonymous and consisted of a self-administered questionnaire. Excel statistics (BellCurve for Excel) Ver.2.21 (Social Information Service Co. Ltd.) was used to analyze the results.

Results: The percentage of children who answered that they "know the word food waste" increased from 36.8% to 78.6%. Responses for "it is not good to leave food uneaten" increased from 59.6% to 76.8%. We created a booklet to encourage students to think about sustainable development goals on a global scale using a familiar food-related issue, "Let's get rid of *mottainai*. M*ottainai* means wastefulness.

Conclusion: Through hands-on activities such as planting rice, harvesting rice, and planting sweet potato seedlings, the children learned that making food takes more time and effort than they had imagined. They developed their understanding and attitudes through sharing experiences with friends and local people and seeing how vegetables and rice grow on a daily basis. As a result, they developed a feeling of gratitude and appreciation for the people that produce and process food. This will continue to increase. We also expect that the amount of leftover food and wasted food will be reduced. Survey results confirmed that the knowledge about reducing food waste increased and awareness and behavior changed in the desired direction due to aa continuous process of instruction and activities. The booklet we created, will be used for future instruction in primary schools on reducing food waste.

Keyword: SDGs, Food Waste Reduction, Food education, Attitude of appreciation and gratefulness

Knowledge and skills to counsel on infant and young child feeding during and after illness among community health volunteers in Turkana County, Kenya

Beatrice N. Kiage-Mokua[1], Tabither Gitau[2], Akriti Singh[3], Qian Yi Pang[4], Kristen Cashin[5], Habtamu Lashtew[6], Eric Swedberg[6], Lynn Kanyuuru[7], Rashed Shah[6]

1. Jomo Kenyatta University of Agriculture & Technology (Kenya), 2. Independent Consultant (Kenya), 3. USAID Advancing Nutrition/Helen Keller International (USA), 4. USAID Advancing Nutrition/JSI Research and Training Institute, Inc. (USA), 5. USAID Advancing Nutrition/Save the Children (USA), 6. Save the Children (USA), 7. Save the Children (Kenya)

Background and objectives: Appropriate infant and young child feeding (IYCF) for a sick child includes continuing to feed during illness and feeding extra after illness. These recommendations are critical to ensure children effectively fight the illness, experience minimum weight loss, and recover quickly. Thus, programs such as integrated community case management (iCCM) include IYCF for sick children. In Kenya, community health volunteers (CHVs) implement iCCM, which has a significant focus on disease treatment. However, it is unclear what level of counseling CHVs provide to support IYCF of sick children. The objective of this study was to examine the knowledge and skills CHVs have to counsel caregivers on IYCF during and after illness.

Methods: In Kenya, we purposively selected two sub-counties within Turkana County, Loima, and Turkana Central. We conducted 36 in depth interviews with national, county, and sub-county health managers; community health extension workers; community health committee members; CHVs, and mothers of children under 5. We also conducted four focus group discussions with CHVs and mothers. We reviewed the CHV iCCM training manual, job aid, and supervision checklist to assess whether these materials provide/assess the knowledge and skills for counseling on feeding during and after illness. **Results:** Mothers reported that messages on feeding a sick child from CHVs were on continuing to feed during illness with much of the focus on giving fruits (e.g., banana, oranges, and mangoes). CHVs confirmed this finding. Only one mother shared that her CHV told her to continue feeding solids while also breastfeeding. Neither mothers nor CHVs described how to feed during the recuperative period after illness. The iCCM training manual, job aid, and supervision checklist for CHVs provides/assesses knowledge on how to feed solids during illness, but does not cover age-appropriate information on feeding during and after illness. Further, the manual does not give CHVs an opportunity to practice counseling on sick child feeding.

Conclusions: The limited content of sick child feeding in iCCM contributed to poor CHV counseling of mothers on age-appropriate IYCF during and after illness. The Government of Kenya should consider revising the sick child feeding component of iCCM.

Night Eating Syndrome and its association with lifestyle characteristics among a selected group of working adults in Kuala Lumpur, Malaysia

Snigdha Misra Misra[1], Anthri Nimala Anthonisamy[1], Ankur Barua[1]

1. International Medical University (Malaysia)

Background and Objectives: Night eating syndrome (NES) is a disordered eating behaviour characterised by hyperphagia at night, often accompanied by a sleep disturbance. It impacts the healthy lifestyle of the individuals. NES is gradually gaining attention as it is a growing global concern due to its clinical implications. This study aims to determine the impact of NES on the lifestyle characteristics of working adults.

Methods: This is a cross-sectional study with 217 participants, who were recruited from a selected inbound call centre at Kuala Lumpur, Malaysia. A simple random sampling was carried out and the employees who met the selection criteria were selected for this study. A self-administered night eating questionnaire (NEQ) was used to determine the night eating syndrome among the employees. Simple Lifestyle indicator questionnaire (SLIQ) was used to assess their lifestyle characteristics.

Results: The mean age of the participants was 24.1± 6.0 years. About 12% of the inbound call centre employees who had scored >25 in NEQ, indicates the presence of NES. Majority (57.1%) of the employees reported an unsatisfactory level of dietary intake. About 27.6% of them were smokers and nearly three quarters (72.4%) of the employees did not consume alcohol. Life stress was reported by 79.3% of the employees. Univariate analysis showed that the employees with satisfactory level of exercise were more prone to have NES as compared to their counterparts with unsatisfactory level of exercise (OR = 4.410, 95% CI = 1.464-13.288, p = 0.005]. The employees with satisfactory level of diet intake were less likely to have NES when compared to those with unsatisfactory level of diet intake (OR = 1.026, 95% CI = 0.448-2.351, p = 0.952]. Alcohol intakes (p = 0.705), smoking habits (p = 0.705) and presence of life stresses (p = 0.840) were not associated with NES.

Conclusion: The prevalence of NES among this group of working adults is very high. Unhealthy food choices and late-night eating leads to unhealthy weight gain, resulting in increased prevalence of overweight and obesity. Early screening and nutrition education could reverse the eating behaviour of employees to manage their NES, resulting in improved health outcomes.

Exploring the factors affecting indigenous food consumption in *Ho* community of Jharkhand, India

Ridhima Kapoor[1], Manisha Sabharwal[1], Ayushi Dhasmana[2], Suparna Ghosh-Jerath[2]

1. Lady Irwin College, University of Delhi (India), 2. Public Health Foundation of India (India)

Background and Objectives: *Ho* indigenous community of Jharkhand, has access to diverse indigenous food (IF) systems, characterized by agroforestry and traditional ecological knowledge. However, a paradox exists between access to diverse food sources and poor utilization, resulting in high levels of malnutrition in the community. A study was conducted to explore the factors affecting IF consumption in *Ho* community of Jharkhand, India.

Methods: A qualitative study with 7 focus group discussions (FGDs) and 2 in-depth interviews were conducted in September 2021 across 9 randomly selected villages of West Singhbhum district, Jharkhand. FGD participants included adult men, women and elders, who were identified using snowball sampling, while interviews were conducted with village leaders and/or health and nutrition workers. All qualitative inquiries were recorded, transcribed and translated. The data were coded using deductive approach; similar codes were identified and merged to produce main themes and sub-themes related to the research question. Data analysis was done in Atlas.ti version 7.5.7.

Results: Qualitative enquiries revealed that *Ho* community accesses IFs from diverse natural food environments like agricultural lands, forests, water bodies and local markets. The facilitators associated with IF access and consumption included their i) desirable taste, ii) perceived satiety, iii) ethnomedicinal properties, iv) socio-cultural value leading to use in special occasions and v) preservation of certain varieties (indigenous leafy vegetables, mushrooms and small fishes) for consumption during lean periods. Additionally, factors promoting indigenous crop production included low resource requirements, climate change resilience and suitability of indigenous seeds for prolonged storage. Barriers of IF production, access and consumption included i) high opportunity cost of accessing foods from wild habitats ii) lack of awareness and intergenerational knowledge gap about IFs from wild habitats, iii) higher crop yields of hybrid seeds and iv) climate variability impacts resulting in reduced IF availability and production.

Conclusion: Culture and context-sensitive policies and interventions promoting IFs valued by the communities should be given due attention. Barriers need to be addressed through strategies promoting access to indigenous seeds, climate-specific agronomic support, and incorporation of IFs in government supplementary feeding programs

Are popular books on diet and health written based on scientific evidence?: A comparison of references cited in books between the US and Japan

Riho Adachi[1], Fumi Oono[1], Akinori Yaegashi[2,3], Madoka Kishino[4], Risa Ogata[5], Mizuki Suga[6], Ayari Tsumura[7], Anna Kinugawa[8], Moe Matsumoto[5], Satoshi Sasaki[1]

1. The University of Tokyo (Japan), 2. Hokkaido Bunkyo University (Japan), 3. Hokkaido University (Japan), 4. Tokyo University of Agriculture (Japan), 5. Ochanomizu University (Japan), 6. Nakamura Gakuen University (Japan), 7. Tokushima University (Japan), 8. Tohoku University (Japan)

Background and objectives: There is a tendency among the general population to obtain information on diet and health from popular books. However, the scientific accuracy of the information presented in them is not necessarily guaranteed, making them often unreliable. References, the sources supporting the presented information, allow for the judgment of information reliability. Although the presence of references does not fully guarantee that the information is trustworthy, it is considered a minimum requirement of reliable information. Therefore, we examined the references in popular books on diet and health sold in the US and Japan.

Methods: We selected 100 books in each country based on the ranking order among diet and health categories in online bookstores. We excluded books not related to diet or health as well as books for professionals, textbooks, magazines, and calorie guides. The main themes of books were categorized using the summaries available at the bookstores. We analyzed the entirety of each book for the references to examine where the references were cited (text or figures and tables) and the number of references.

Results: The most frequent main themes were general health (US, 31%, Japan, 38%), recipes (US, 44%, Japan, 31%), and weight loss (US, 13%, Japan, 11%). In both countries, 66 books had references. Among these, all books had references on the text (not only on figures and tables) in the US, while this was true for 73% of books in Japan. Furthermore, the books from the US cited many more references than those from Japan. Thirty-seven books cited more than 100 references in the US, but only five books cited more than 100 references in Japan.

Conclusions: The proportion of the books with references was similar in the US and Japan, but whether the references were cited in the text and the number of references differed between the two countries. These may reflect the different perceptions of referencing to make presented information trustworthy. The quality of the referencing is under investigation.

Availability of healthy and unhealthy foods in modern retail outlets located in selected districts of Greater Accra region, Ghana.

Akosua Pokua Adjei[1], Gideon Amevinya[1], Wilhemina Quarpong[1], Akua Tandoh[1], Richmond Aryeetey[1], Michelle Holdsworth[2], Charles Agyemang[3], Gershim Asiki[4], Stefanie Vandevijvere[5], Amos Laar[1]

1. University of Ghana (Ghana), 2. UMR, MoISA (Montpellier Interdisciplinary centre on Sustainable Agri-food systems), (Univ Montpellier, CIRAD, CIHEAM-IAMM, INRAE, Institut Agro, IRD) (France), 3. University of Amsterdam (Netherlands), 4. African Population and Health Research Center (Kenya), 5. Sciensano (Belgium)

Background and objective: Availability of unhealthy (nutritionally poor) foods can influence preference, purchasing and consumption of such foods. This study determined the healthiness of foods sold at modern retail outlets- supermarkets and mini-marts in the Greater Accra Region of Ghana.

Methods: All modern retail outlets located in six districts of Greater Accra were eligible. Permanent structured outlets with floor area <200m^2 were categorised as mini-marts; and those ≧200m^2 as supermarkets. Shelf length of all available foods were measured. Healthiness of food was determined using two criteria - the NOVA classification and energy density of foods. Thus, ultra-processed foods or food items with >225kcal/100 g were classified as unhealthy. The ratio of the area occupied by unhealthy to healthy foods was used to determine the healthiness of modern retail outlets.

Results: Of 67 retail outlets assessed, 86.6% were mini-marts. 85.0% of the total shelf area was occupied by foods categorized as unhealthy. Refined grains/grain products were the most available, occupying 30.0% of the total food shelf space, followed by sugar-sweetened beverages (20.1% of total shelf space). The least available food group–unprocessed staples, and occupied 0.1% of the total food shelf space. About two-thirds of food products available (n =3952) were ultra-processed. Across retail outlets, the ratio of ultra-processed-to-unprocessed foods ranged from 3 to 7 with an average (SD) of 5(2). Thus, for every healthy food, there were five ultra-processed ones in the studied retail outlets.

Conclusion: This study reveals widespread availability of ultra-processed foods in modern retail outlets within the selected districts. Towards a healthier food retail environment, public health and food regulators, in partnership with other stakeholders need to institute measures that improve availability of healthy foods within supermarkets and mini-marts.

PAB(T6)-158
Food groups consumption in Japanese schoolchildren with a low diet cost and good nutrient intake

Yui Kojima[1], Nobuko Murayama[1], Hiromi Ishida[2], Taeko Yamamoto[3], Sayaka Hazano[4]

1. University of Niigata Prefecture (Japan), 2. Kagawa Nutrition University (Japan), 3. Kanagawa University of Human Services (Japan), 4. Matsumoto University (Japan)

Background and Objectives: High diet quality is associated with high monetary cost. To achieve both a high-quality diet and low dietary cost, this study aimed to investigate the characteristics of food groups consumed by schoolchildren who have a low diet cost and good nutrient intake.

Methods: We analyzed dietary records with photographs of 402 fifth grade students (195 boys, 48.5%) aged 10-11 years from nine public elementary schools in two prefectures in eastern Japan. Records were from 4 days (2 with school lunch and 2 without). Diet cost per day was calculated using the prices in the 2013 National Retail Price Survey. School lunch costs were set at 241.5 Japanese yen (the national average school lunch fee per meal). Adequacy of nutrient intake was assessed by the number of nutrients meeting the dietary reference intake values among 12 nutrients (DRI score). Children with a low diet cost (≦850 yen/day) were divided into three groups according to the DRI score, and the intake of food groups was compared by using the Jonckheere-Terpstra test.

Results: Median (interquartile range; IQR) of diet cost was 868.9 (751.2-1031.0) yen. There were 185 children (46.0%; 84 boys [45.4%]) with low diet cost who were divided into low (0-3 points, n=40), middle (4-6 points, n=77), and high (7-12 points, n=68) DRI score groups. Comparison of food group intakes among the three groups showed that the high DRI score group consumed higher amounts of green and yellow vegetables, other vegetables, fruits, mushrooms, and eggs ($p < 0.001$, < 0.001, < 0.001, $= 0.021$, and 0.004, respectively), while consuming less meat ($p = 0.010$). In the high DRI score group, intakes of carrots, spinach, cabbage, and onions were high among vegetables and intakes of citrus fruits and apples were high among fruits.

Conclusions: In school children with a low diet cost and good nutrient intake, intakes of vegetables, fruits, mushrooms, and eggs were high. For vegetables, intakes of carrot, spinach, and cabbage may be associated with good nutrient intake in spite of their lower cost.

Keyword: Schoolchildren, Monetary diet cost, Food group intake, Dietary reference intakes

Content analysis of TV food advertisements targeted to children in the Philippines

Elaine Quintana Borazon[1], Michelle Joanne De Leon De Los Santos[2], William Ng[3], Tilakavati Karupaiah[3], Sally Dorothy Mackay[5], Bridget Kelly Gillot[4], Boyd Anthony Swinburn[5]

1. National Sun Yat-sen University (Taiwan), 2. University of the Philippines-Diliman (Philippines), 3. Taylor's University (Malaysia), 4. University of Wollongong (Australia), 5. University of Auckland (New Zealand)

Background and objectives: Exposure to TV food advertisements is considered as a potential factor influencing dietary and food consumption behavior among children. However, there are no policies regulating child-targeted TV food advertisements in the Philippines. Furthermore, there is limited literature that explores the influence of TV food advertisements on the dietary health of Filipino children in which overweight and obesity are prevalent. This study aims to (1) assess the frequency and level of exposure of children to food promotions and their content through televisions, (2) evaluate marketing practices, such as the use of licensed characters or celebrities from movies or popular children's television programs, use of humor, use of premiums or competitions, use of healthy food claim, and depiction of physical activity, which are known to affect children's perceptions of advertised product. **Methods:** Therefore, this study conducted an exploratory content analysis of TV food advertisements aired on the most popular channels for Filipino children aged 2 to 12 (GMA, GNTV, and TV5). Data were collected from January to April 2021 through manual recording of aired advertisements which were then monitored using a categorical sampling design. A thematic analysis of food ads was also conducted to identify persuasive techniques and elements used in food ads. **Results:** Findings reveal that the frequency of non-permitted food ads aired per hour is significantly higher than permitted food ads. Additionally, there are more non-permitted food ads aired during peak viewing times that exhibit strong persuasive content. Qualitative themes prevalent in food ads include audio-visual cues, representation of family, depiction of exercising, and emotional appeal. **Conclusions:** This study recommends that TV food ads and child-targeted marketing should be regulated to minimize the advertisement of non-core foods and its effects on children's diets and food choices.

PAB(T6)-160
Comparative Validity and Reliability of the Temporal Pattern of Dietary Intake (TPOD) Questionnaire

Hsin-Jen Chen[1]

1. National Yang-Ming Chiao Tung University (Taiwan)

Background and objectives: Temporal patterns of dietary intake are emerging risk factors for metabolic disorders, as shown in randomized controlled trials and epidemiologic studies. However, there is no convenient tool to assess the usual temporal patterns of dietary intake of people. We developed a questionnaire for epidemiologic assessment of this dietary risk factor.

Methods: The 17-item TPOD questionnaire was developed to capture eating frequency and meal regularity over the last three months. Adult volunteers (n=125) were recruited on a university campus in Taipei, Taiwan. Three (3) non-consecutive 24-hour dietary recalls were collected within about 2 months (45-110 days, median 59 days), where details of time and amount of food intakes in the previous day of interview were collected. In the first- and last-day dietary recall interviews, the pre- and post-test of the TPOD questionnaire were administered, respectively. The interview process was standardized and conducted by trained interviewers. To assess meal regularity, the Chaotic Eating Index and the Meal Regularity Score were constructed using the TOPD questionnaire and the 3-day dietary recall separately. TPOD questionnaire's pre-post reliability was assessed by correlation coefficient between the first- and last-day interview. The comparative validity of TOPD questionnaire was assessed by the correlation between TOPD and 3-day dietary recall.

Results: The average age of the subjects was 22.5 years (SD=2.9), and 58% of them were women. Most of the subjects were students (91.2%). The proportion of subjects reporting always, usually, and rare/never having regular meals were 31%, 43%, and 26%, respectively. The reliability of the eating frequency assessment ranged from 0.63-0.67. The reliability of Chaotic Eating Index based on the TOPD assessment was 0.44-0.48. Comparative validity of the eating frequency showed correlation coefficients ranging between 0.33-0.40. The single meal irregularity question showed a moderate validity (r ranging between 0.31-0.41) compared to the Chaotic Eating Index and Meal Regularity Score assessed by 3-day dietary recalls.

Conclusions: The questionnaire shows values of assessing adults' usual temporal patterns of dietary intakes, and measures the patterns of a longer term (i.e. 3 months) than what food records or dietary recalls could have done.

Keyword: assessment instrument, dietary patterns, meal regularity, meal timing

Conflict of Interest Disclosure: No conflict of interest.

PAB(T6)-161
Association between food subsistence level and dietary intake among farmers in peri-urban Kenya

Madoka Kishino[1], Azumi Hida[1], Kenta Hara[1], David Nguatha Mungai[2], Rose Okoyo Opiyo[2], Hirotaka Matsuda[1], Yuki Tada[1], Kazuko Takata-Ishikawa[1], Kenji Irie[1], Yasuyuki Morimoto[3]

1. Tokyo University of Agriculture (Japan), 2. University of Nairobi (Kenya), 3. Alliance Bioversity International and CIAT (Kenya)

Background and objectives: Kenya has experienced the double burden of malnutrition, such as overweight and micronutrient deficiencies among women. In vegetable growing areas, promoting subsistence may increase dietary quality through vegetable consumption, but increased subsistence may affect household incomes, worsening overall diet quality. This study examined the impact of food subsistence levels (FSL) on dietary intake.

Methods: Women farmers aged 20-56 years (n=64) in Kabete sub-county Kiambu County in Central Kenya, a peri-urban vegetable-growing area, participated in this cross-sectional study. Face-to-face interviews were conducted on participants' dietary intake (two days-24-hour recalls), characteristics and agricultural production. We defined the proportion of own-produced food in all consumed food excluding condiments and beverages as FSL. Dietary intake was assessed by participants' adherence to Kenyan food pyramid (FP) score (maximum 50), dietary diversity scores (maximum 10), and food group intake. The association of the tertiles of FSL and agricultural production and dietary intake were investigated. Multiple regression analysis was performed with FP score or dietary diversity as dependent variable and FSL and confounders as independent variables.

Results: Average FSL was 39.6±16.3%. The FSL was not associated with household income or agricultural production. Nearly 90% of households cultivated green leafy vegetables (GLVs) in all three groups during the survey. Of the 23 frequently consumed foods, 8 items (variety of GLVs, eggs, pulses, and plantains) were from own-produced (more than 70%) in the high-FSL group, while only 2 items were in the low-FSL group. The FSL tended to be positively associated with intake of GLVs but negatively associated with intake of animal-source foods (ASFs) and other vegetables. The FSL had a significant positive impact on dietary diversity (β=0.300, p=0.013) but not on the FP score.

Conclusions: The FSL was positively associated with dietary diversity but negatively associated with ASFs intake. The lack of a significant association with the FP score may reflect differences in food grouping and inadequate intake. To improve dietary quality, promoting the consumption of own-produced crops and enhancing the availability of healthy foods such as ASFs may be needed. Further large-scale studies are required, including the effects on health status.

Not the usual subjects: Engaging the non-health sector to enforce the International Code of Marketing of Breast-milk Substitutes in Cambodia

Senveasna Chum[1], Kroeun Hou[1], Theng Dim[2], Samnang Tum[2], Mackenzie Green[1]

1. Helen Keller Intl (Cambodia), 2. Ministry of Commerce (Cambodia)

Background and objectives: In 1981, the World Health Organization established the International Code of Marketing of Breast-milk Substitutes (Code) to restrict promotion and safeguard infant and young child health. In the subsequent four decades, the health sector has primarily been held responsible for enforcement of national Code regulations. The Royal Government of Cambodia enacted the Sub-Decree on Marketing of Products for Infant and Young Child Feeding (SD133) in 2005, adopting many provisions of the Code. SD133 designates four ministries to uphold the law, with the Ministry of Health leading enforcement. However, in recent years the Ministry of Commerce (MOC) has actively embraced Code monitoring in their retail inspection activities, providing a unique example of a non-health body controlling marketing of breastmilk substitutes and protecting breastfeeding.

Methods: MOC officials revised their existing checklists, training materials, procedures, and reporting formats to integrate SD133 monitoring into their routine inspections of retail locations selling breastmilk substitutes. MOC inspectors from all 25 provinces of Cambodia were trained in SD133 monitoring from 2019 to 2022. They conduct monthly inspections at retail locations to identify marketing violations, submitting reports by mobile messaging app. The MOC also ensures the nutrient composition of breastmilk substitutes marketed in Cambodia adhere to global standards through laboratory nutrient content testing and takes actions to hold companies accountable.

Results: In total, 123 provincial-level MOC inspectors were trained and all 25 provincial inspector teams developed work-plans for integrated SD133 monitoring. Inspectors conducted 1,176 monitoring visits to 165 locations between January 2021 and February 2022, with 3,528 reports generated. Inspectors have educated 330 shop owners and issued 1,176 verbal warnings, 36 written warnings, 36 financial penalties, and suspended the sale of 21 products violating SD133. MOC sent 194 unique products for nutrient content testing, finding 12 products non-compliant with global nutrient content standards, leading to a criminal court case.

Conclusions: The MOC has taken full ownership of enforcement of SD133, building a system to monitor breastmilk substitute promotions and ensure product quality through integration with their routine responsibilities. The non-health sector can successfully be engaged to uphold national Code legislation and protect breastfeeding.

PAB(T6)-163

A Study on the Reduction of Simple Urinary Sodium/Potassium Ratio Caused by Potassium Fortification with Foods for the Prevention of Cardiovascular Disease

Keiko Mori[1]

1. Aichi Gakuin University (Japan)

Background and Objective: Cardiovascular disease is one of the leading causes of death in Japan. Lowering the urinary sodium(Na)/potassium(K) ratio is effective in preventing hypertension and cardiovascular disease. The sodium/potassium ratio measured by spot urine has been validated in relation to the Na/K ratio from 24-hour urine storage. This study examined the effect of changes in potassium intake from vegetables and fruits, but not salt, on the urinary Na/K ratio.

Methods: The subjects were 8 healthy young people (6 females and 2 males), and the trial lasted 3 weeks during the winter season. Height, weight, and blood pressure were measured. The diets were adjusted based on the data of the same age group in the National Health and Nutrition Examination Survey. This basic diet was used for the first week, a banana equivalent to 400 mg of potassium was added for the second week, and vegetable juice for the third week. The urinary Na/K ratio was measured using a urinary Na/K ratio-measuring device called HEU-001F (OMRON Healthcare Co., Ltd., Kyoto, Japan)

Results: Mean body weight and blood pressure did not differ significantly during the period. The mean urinary Na/K ratio at week 1 was 3.92±0.19, 3.19±0.19 for the addition of banana and 3.14±0.13 for the addition of vegetable juice, showing a significant difference among the three groups ($p<0.01$). Significant urinary Na/K ratio reductions were observed with the addition of banana and vegetable juice compared to the basal diet ($p<0.05$).

Conclusions: In Japan, salt intake has remained high in recent years, while vegetable and fruit intake has declined. The addition of fruits and vegetables and juices with the equivalent to only 400 mg of potassium may help prevent cardiovascular disease.

Correlation Between Behavior In Choosing Instant Noodles, Reading Labels, Family Income, And Nutritional Knowledge On Instant Noodle Consumption Patterns During Distance Learning For Nutrition Student

Ikha Deviyanti Puspita[1], Ibnu Malkan Bakhrul Ilmi[1], Firlia Ayu Arini[1]

1. Universitas Pembangunan Nasional Veteran Jakarta (Indonesia)

Background and Objectives: West Java Province occupies the first position (65.1%) the most frequent consumption of instant noodles (1-6 times/week) and the highest consumption of instant noodles is in the age group 15-19 years (72.74%). The habit of eating frequent instant noodles can increase the risk of poor health (Huh et al, 2017). This study aims to determine the determinants of instant noodle consumption during the Covid-19 pandemic among Nutrition Students at UPN Veterans Jakarta while they were doing distance learning program.

Methods: This study used a cross-sectional design with a sample size of 111 people. The data was taken by filling out an online questionnaire through the google form platform. Data analysis was conducted with Chi Square test (bivariate analysis).

Results: Based on the results of statistical tests there was no relationship between the behavior of reading food labels (p = 0.438), the availability of instant noodles (p = 0.438), nutritional knowledge (p = 0.528) and family income (p = 0.867) on students' eating behavior of instant noodles and there was the relationship between the behavior of choosing instant noodles (p=0.000).

Conclusion: The behavior of eating instant noodles is influenced by various factors. Students who have a positive attitude towards food choices are related to good eating behavior and are beneficial to their health. Parents and environment support are needed to optimize better eating behavior of students.

Keyword: Instant Noodle Consumption, students, the covid 19 pandemics

Assessment of Nutritional Status of Underweight and Severely Underweight children aged 3 to 5 years old using Nutripacks with Vita Meena Micronutrient Powder (MNP)

Gayle Bautista Urrera[1], Paul John De Leon[1], Joyelli Anne Recon[1], Lauren Lalaine Lao[1], Ma. Christella Inumerable[1]

1. Philippine Nutri-Foods Corporation (Philippines)

Background and objective: Malnutrition is a problem of public health significance. One form of malnutrition is being underweight where children have low weight-for-age. National survey of Food and Nutrition Research Institute (FNRI) recorded 21.8% of underweight children ages 3 to 5 years old. To help alleviate the prevalence of malnutrition, the Department of Social Welfare and Development (DSWD) conducts Supplementary Feeding Programs (SFP). The COVID-19 pandemic created a situation that posed challenges to nutrition programs like this, and utilizing ready-to-cook food packs with vitamins and minerals was convenient to make sure that the program will continue even in the comforts of the participant's home. Nutri-Foods Ready-to-Cook Food Packs (NutriPacks) with VitaMeena Micronutrient Powder (MNP) is developed by Philippine Nutri-Foods Corporation. This comes in a 50 g pack. Each pack gives 215 kcal of energy and 7.34 g of protein. It also contains 22 vitamins and minerals that provides more than 40% of Recommend Energy and Nutrient Intake (RENI) of children ages 3-5 years old. The main objective of the study is to determine the effectiveness of the NutriPacks+VitaMeena in improving the nutritional status of the children.

Methods: The study involved 334,715 underweight and severely underweight children aged 3-5 years old from Region V and Region IV-A. The children were fed for 120 days with supplementary food, wherein Nutripacks with VitaMeena is served twice to thrice, weekly. The improvement in the nutritional status of children was assessed by comparing their weight for age, based on the Child Growth Standards provided by World Health Organization, before and after the feeding activity.

Results: 64.62% in Region IV-A and 83.32% in Region V were reported to have improvement in nutritional status, provided that NutriPacks were served to them twice to thrice a week. The percent distribution of the fortified Nutripacks+VitaMeena for the whole feeding program of region IV-A and V is 25% and 40%, respectively.

Conclusion: Nutripacks with Vita Meena effectively contributed to the improvement of the nutritional status of children by providing a balanced macronutrient and micronutrient to assure the complete nourishment of the children daily.

Partial replacement of red meat with legumes among healthy males for six weeks does not affect bone turnover but results in differences in amino acid intakes

Suvi T. Itkonen[1], Piia Karhu[1], Tiina Pellinen[1], Mikko T. Lehtovirta[1], Satu Männistö[2], Niina Kaartinen[2], Essi Päivärinta[1], Anne-Maria Pajari[1]

1. University of Helsinki (Finland), 2. Finnish Institute for Health and Welfare (THL) (Finland)

Background and objectives: A shift towards more sustainable diets is needed to mitigate climate change. More plant-based diets, however, may be harmful for bone health due to lower calcium and vitamin D content. Studies have also shown a role of specific amino acids such as arginine and lysine on bone. We studied the effects of replacing part of the red and processed meat with legume foods in a habitual Finnish diet on bone turnover and amino acid intakes.

Methods: Healthy adult men (n=102) were stratified by age and randomized into two dietary intervention groups for 6 weeks in parallel design. Group 1 received 760 g of red and processed meat per week (cooked, boneless), corresponding to 25% of protein intake, and representing the current average intake of red and processed meat in Finnish men. Group 2 received 200 g of red and processed meat per week (5% of protein intake), and pea and faba bean products (20% of protein intake). Otherwise, the volunteers followed their habitual diets. Bone turnover and mineral metabolism biomarkers were assessed (ANCOVA, baseline-adjusted). Amino acid intakes based on 4-day food records were calculated at the endpoint of the study (t-test). Results: No differences in bone formation (bone-specific alkaline phosphatase) or resorption (tartrate-resistant acid phosphatase 5b) between the groups at the endpoint were observed (p>0.05). 25-hydroxyvitamin D decreased (p≦0.043) and parathyroid hormone increased (p≦0.006) in both groups without differences between the groups (p>0.05), neither in dietary vitamin D intakes (p>0.05). Mean dietary vitamin D intakes and serum concentrations were according to recommendations (>10 µg/d, >50 nmol/l). Intake of methionine was higher in the meat group, whereas intakes of arginine, asparagine acid, glutamic acid, leucine, phenylalanine, proline, serine, and tryphophan were higher in the legume group (p<0.05). Intakes of all amino acids in both groups were adequate according to WHO recommendations.

Conclusions: Our results indicate that decreasing red and processed meat consumption in Finnish diet to the upper level suggested by the Eat Lancet Commission and replacing the meat products with legume foods does not cause a risk for bone health and provides adequate amount of amino acids.

Keyword: bone turnover, legumes, red meat, plant protein, vitamin D

PAB(T6)-167

Food environment and food systems influence on food choices and nutrition transition in Limpopo province, South Africa

Vhushavhelo Nedzingahe[1], Ayuk Betrand Tambe[2], Mthokozisi Kwazi Zuma[3], Xikombiso Gertrude Mbhenyane[4]

1. Stellenbosch University (South Africa), 2. Stellenbosch University (South Africa), 3. Stellenbosch University (South Africa), 4. Stellenbosch University (South Africa)

Background and objectives: The food environment interacts with the food system, as it influences a person's food procurement and consumption. The objectives were: 1. To determine the socio-demographic profile and bio-physical environment of households; 2. To assess the communities, schools and households food environments and households' food systems; 3. To determine food choices using Dietary Diversity Score (DDS); 4. To assess the food security status and food availability in households using Household Insecurity Access Scale (HFIAS) and Coping Strategies Index (CSI); 5. To assess the health risk of the participants using anthropometric indicators , biochemical indicators and clinical indicators; and 6. To determine the association among socio-demographic information, bio-physical environment, food environments, food systems, food choices and nutrition transition.

Methodology: The study design was an analytical, cross-sectional study, using quantitative techniques. A total of 429 households were randomly selected. Food environment, food system, food choices and nutritional measurements of the households were measured and assessed, using a researcher-administered questionnaire.

Results: A majority of household informants responsible for food procurement were females (80.4%). There was a significant association ($p < 0.001$) between proximity to food stores and dietary diversity of the households. Staple foods were available in almost all surveyed households (95.6%). Food prices were reported to influence household food choices. More than half of the households (59.8%) had home gardens in their yards. Almost half of the households (48.4%,) had a low DDS score (score of 4 to 7). The study revealed that 46.0% of households were food secure. Over a third (36.2%) of households' informants were obese and 32.5% were diabetic. The mean total blood cholesterol was 3.69 ± 0.74 mmol/L. A high rate of both females (89.6%) and males (91.5%) had normal haemoglobin levels. Most of the informants had normal systolic blood pressure levels (63%), with just over half who had high diastolic levels (57%).

Conclusion: The presence of food stores in the areas provided access to obesogenic and protective foods. There is a shift from consuming more of traditional foods, fruits and vegetables to more of refined carbohydrates, animal source foods and sugar sweetened beverages.

Food system interventions and intake of fruits and vegetables in urban Vietnam and Nigeria.

Elise F. Talsma[1], Giulia Pastori[1], Meike Siemonsma[1], Hans Verhoef[1], Le Thi Huong[2], Le Thi Thanh Xuan[2], Oluyemisi O Shittu[3], Folake O Samuel[3], Inge D Brouwer[1]

1. Division of Human Nutrition and Health, Wageningen University (Netherlands), 2. Institute of Preventive Medicine and Public Health, Hanoi Medical University (Viet Nam), 3. Department of Human Nutrition and Dietetics, University of Ibadan (Nigeria)

Background and objectives: Increasing the intake of fruits and vegetables (FV) may be critical to reduce the burden of non-communicable diseases and micronutrient deficiencies in many low- and middle-income countries. We implemented a non-randomised study of food system interventions to increase affordability, acceptability and accessibility of FV. This study evaluates the effect of a combination of these three interventions in urban and peri-urban Vietnam and Nigeria.

Method: We used Dietary Quality Questionnaire to assess FV food groups consumed by 600 Vietnamese and 610 Nigerian women from the intervention neighbourhoods. Data on the number of FV groups consumed was collected before, during and after the interventions, for a total of 6 times, per country. A FV score was calculated (0-6) and information about the exposure to interventions were collected to classify respondents in the number of exposure classes (0-3). FV score was analysed over time and compared between exposure groups using (mixed) count regression models. The trend of individual FV groups was analysed with mixed logistic regression. Analysis was performed separately for each country.

Results: Both Vietnam and Nigeria, the FV score was relatively stable over time, with no increase observed from before to after the intervention period. In Vietnam, differences were found between peri-urban and urban areas with a decrease in the total score in peri-urban and an increase in urban area. Differences in the probability of consumption of individual FV groups over time were observed, especially within the fruit groups. These differences in intake over time might be linked to the seasonal availability of the products. No large difference in mean FV score was observed between the exposure groups. The degree of exposure could not explain differences in FV intake.

Conclusion: The failure of finding an effect of the interventions can be due to the low sensitivity of FV score to detected possible changes in portion sizes, the temporal changes due to Covid-19 pandemic, or the interventions not being effective on FV intake. A combination of quantitative and qualitative assessments of intakes and changes in knowledge and attitudes could provide deeper insight on the effect of the interventions.

Conformity of packaged food and non-alcoholic beverages labelling in supermarkets in Dakar

Mane Helene FAYE[1], Adama Diouf[1], Yassarath Onifade[1], Fatou Fall[1], Stefanie Vandevijvere[2], Olouwafemi Mistourath Mama[1], Nicole Idohou-Dossou[1], Gary Sacks[3]

1. Laboratoire de Recherche en Nutrition et Alimentation Humaine, Département de Biologie Animale, Faculté des Sciences et Techniques, Université Cheikh Anta Diop (UCAD), Dakar (Senegal), 2. Public Health Nutrition Epidemiology and Public Health, Sciensano, Brussels (Belgium), 3. Global Obesity Centre (GLOBE), Institute for Health Transformation, Deakin University, Burwood, Victoria (Australia)

Background and objectives: The World Health Organization (WHO) recommends that manufacturers improve packaged food and non-alcoholic beverage labelling to better guide consumers in their purchasing choices. Those products are required to be labelled with mandatory (food name, manufacturer, list of ingredients, nutritional value, expiry date, country of origin) and optional information (claims). In Senegal, little is known on packaged food labelling compliance with WHO guidelines, hence the aim of this study is to investigate this issue.

Methods: A market survey was conducted in the largest stores of two of the most popular retailers in Dakar between August-September 2021. Labeling data (presence and position of list of ingredients, nutritional declarations, claims and promotional strategies) were collected from food packaging.

Results: Overall, labelling data were collected of 7398 food products. All foods presented an ingredient list but only 44% had it quantified and 6% had it presented on the FOP. The nutritional value was present on 82% of products, 91% of which indicated it in the panel. Only 26% of products mentioned an GDA. Over 50% of products displayed a claim (53%) of which nearly 58% were on the FOP. Claims were more frequent in the following food categories: bakery products (82%), cereals products (81%), confectionery (78%), snacks (68%). Health-related claims were the most represented (47%), followed by environment-related ones (42%). Nutritional claims were the least mentioned (26%). Health-related claims were mostly found in spreads (84%), ready-to-eat foods (83%), condiments (80%), beverages (81%), canned fruits and vegetables (49%) while nutritional claims were more common in canned fish and sea food (68%), beverages (45%), dairy products (29%), cereals products (23%). On-pack promotions were found in 10% of products. Major promotional practices were the presence of cartoon characters (46%), characters for children (24%), and offer premium (13%). Promotions were mainly observed in confectionery (53%), bakery products (16%), cereals products (15%).

Conclusions: Food companies are getting better at providing mandatory information on packaged food, but greater efforts should be considered with regard to quantified nutritional information and use of easy labelling to recognize food products nutritional quality as already established and mandatory in many developed countries.

South East Asia Obesogenic Food Environment (SEAOFE) Study to address the Double Burden of Malnutrition through Healthier Food Retail: Preliminary Findings

Bee Koon Poh[1], Cut Novianti Rachmi[2], Sameeha Mohd Jamil[1], Elaine Q Borazon[3], Sirinya Phulkerd[4], Helen Trevena[5], Anne-Marie Thow[5]

1. Universiti Kebangsaan Malaysia (Malaysia), 2. Reconstra Utama Integra (Indonesia), 3. National Sun Yat-sen University (Taiwan), 4. Mahidol University (Thailand), 5. University of Sydney (Australia)

Background and objectives: The double burden of malnutrition in Southeast Asian countries is of concern. Although undernutrition rates are decreasing, overweight and obesity is rising, and micronutrient deficiencies are also prevalent. Tackling dietary intakes through multi-pronged approach focussing on retail food environment is expected to improve access to healthier foods in the community. As such, the SEAOFE Study was designed to examine the retail food environment, perspectives of consumers and retailers regarding factors influencing food retail-related decisions, and existing policies influencing food retail in four Southeast Asian countries. **Methods:** The SEAOFE study is conducted in four phases in Indonesia, Malaysia, Thailand and Philippines. Phase I involved document and database review to provide in-depth analysis of retail food landscape and health status in each country. Phase II will be conducted in two parts, namely consumer intercept survey on perception of their retail food environment, and audit of selected food retailer outlets. Phase III is a qualitative study involving in-depth interviews with food retailers to understand decision-making related to stocking of food and beverages. Phase IV involves document review and in-depth interviews with stakeholders related to retail food policy to identify opportunities for change towards healthier food retail. Throughout the study, researchers will engage closely with relevant stakeholders through regular meetings. **Results:** Phase I has been completed and findings indicate that adult malnutrition and non-communicable diseases are prevalent in all four countries, with Malaysia having the highest prevalence of overweight/obesity and diabetes, and Indonesia having the highest prevalence of hypertension. The major player in food retail industry in Indonesia, Malaysia and Philippines are local companies, whereas in Thailand it is a multi-national company. In Indonesia, traditional food retail format is more commonplace, while in the other three countries modern and traditional formats are equally frequented. With the COVID-19 pandemic, however, there is increasing evidence that online food retail and e-commerce are becoming more common. **Conclusions:** The SEAOFE study will generate evidence on consumer and retailer perspectives of the food environment. We hope to also identify opportunities and barriers towards food policy changes in order to develop evidence-informed policy recommendations in this region.

Associations of plant-based foods, red meat, and dairy with gut microbiota in a population-based sample of Finnish adults

Mirkka Maukonen[1], Kari K Koponen[1], Aki S Havulinna[1,2], Niina E Kaartinen[1], Teemu Niiranen[1], Michael Inoye[3,4], Rob Knight[5], Veikko Salomaa[1], Satu Männistö[1]

1. Finnish Institute for Health and Welfare (Finland), 2. Institute for Molecular Medicine Finland (Finland), 3. Baker Heart and Diabetes Institute (Australia), 4. University of Cambridge (UK), 5. University of California San Diego (USA)

Background and objectives: Current global food systems threaten both human health and environmental sustainability. There is an urgent need for a shift to more sustainable diets with more plant-based foods and less red meat and dairy. However, little is known on the associations of these dietary factors with gut microbiota in population-based samples. Therefore, we examined whether the consumption of plant-based foods (legumes, vegetables, fruits, cereals), red meat (red and processed meat) or dairy (fluid milk products, cheese) are related to gut microbiota diversity (alpha-diversity), compositional differences (beta-diversity), and bacterial species abundances in Finnish adults.

Methods: We used data from the National FinDiet 2002 Study (n=1329, aged 25-65 years, 55% women). Diet was assessed with 48-hour dietary recalls. Gut microbiota was analyzed using shallow shotgun sequencing. Associations of microbial features (alpha/beta-diversity and species abundances) with dietary variables were analyzed using multiple linear regression, general multivariate regression models, and permutational multivariate ANOVAs. Analyses were adjusted for relevant confounders.

Results: None of the dietary variables were associated with microbial diversity (alpha-diversity, P>0.05). Plant-based foods (R^2=0.0015, P=0.012) and dairy (R^2=0.0013, P=0.037) but not red meat (R^2=0.0008, P=0.33) explained small but significant amounts of compositional variation between individuals' microbiotas (beta-diversity). In species-level analysis, plant-based foods were associated with 35 bacterial species, including positive associations with several butyrate producers e.g., *Coprococcus eutactus* and *Eubacterium eligens* and cellulolytic species e.g., *Ruminococcus flavefaciens*. Red meat was associated with eight species, including a positive association with *Clostridium disporicum*, previously demonstrated to have a

role in secondary bile acid production and a negative association with butyrate producer *Roseburia hominis.* Dairy products were associated with 34 bacterial species, including positive associations with several known lactic producing/probiotic species such as *Streptococcus thermophilus* and *Lactobacillus delbrueckii* and opportunistic pathogens including *Enterobacter cloaca* and *Citrobacter freundii*.

Conclusions: We found that plant-based foods and dairy were associated with compositional differences in terms of beta-diversity. We also found that plant-based foods, meat, and dairy were all associated with distinctive bacterial species. Plant-based food consumption, in particular, was associated with putatively beneficial bacterial species abundances. These findings confirm and extend previous evidence mainly from small-scale studies.

Keyword: Epidemiology, Gut microbiota, Nutrition, Public health, Sustainability

Conflict of Interest Disclosure The authors declare that there is no conflict of interest related to this study.

Mapping the functioning and identifying the needs of the baby friendly community Initiative in Kenya using a systems approach

Antonina Mutoro[1], Elizabeth Kimani-Murage[1], Calistus Wilunda[1], Milka Wanjohi[1], Antuela Tako[2], Thomas Jun[2], Patrick Waterson[2], Paula Griffiths[2]

1. African Population and Health Research Center (Kenya), 2. Loughborough University (UK)

Background and objectives: The Kenyan government has adopted the baby-friendly community initiative (BFCI) to promote and support optimal maternal and child nutrition (MCN) within communities primarily through community health volunteers (CHVs). The BFCI is being implemented in some communities amidst some challenges and is in the process of being scaled up nationally. We aimed to map and analyze the factors that influence the functioning of the BFCI system in Kenya and to identify the needs for its effective implementation in Kenya.

Methods: We used systems thinking tools to analyze the BFCI system which involved preliminary high-level analysis which included a strengths, weaknesses, opportunities, threats analysis; an in-depth systems mapping analysis using qualitative interviews, and identification of opportunities for further development of the BFCI. Stakeholders from government, non-governmental organizations and target communities were involved in the process. Linkages between the components of the BFCI system were mapped using influence diagrams to illustrate facilitators and barriers.

Results: Factors that influence the functioning of the Kenyan BFCI include: 1) A CHVs' level of interaction with the community which is associated with increased maternal knowledge on child feeding and access to health facilities was negatively impacted by a lack of meeting facilities, bad weather conditions and COVID-19; 2) CHV level of knowledge/competency about BFCI; and 3) funding available for BFCI activities including training and stipends for CHVs. In addition to system level factors, maternal factors were also important and included their engagement with the BFCI which enhanced their feeding practices, their opportunities for breastfeeding which were influenced by availability of breastfeeding spaces, cultural beliefs and practices, mother's time and availability; and access/referral to health facilities. Priority areas needed to enhance the BFCI system identified by stakeholders included financing, CHVs' knowledge/competency, and CHVs' level of interactions with the community.

Conclusion: The BFCI has potential to improve MCN and funding and appropriate CHV training programs are required for effective implementation. CHVs play an important role in the BFCI's implementation in Kenya and there is a need to both adequately compensate their time and improve their knowledge and competency through regular training and support supervision.

PAB(T6)-173
School feeding programmes in Malmesbury, South Africa: Does the national policy match what is on the plate?

Zarina Ebrahim[1], Marli Taljaard[1], Gunnar Sigge[1]

1. Stellenbosch University (South Africa)

Background and objectives: The National School Nutrition Programme (NSNP) is a nation-wide programme in South Africa that provides macro- and micronutrient-rich meals to all learners in primary and secondary schools daily. School-aged children experience an increase in motor skills, cognitive, social and emotional development. NSNP's can improve, promote and maintain healthy eating habits and assist in preventing nutritional deficiencies, excess weight gain and chronic diseases. The aim of this study was to investigate the implementation of the NSNP in primary schools in the Malmesbury area of the Western Cape, South Africa and determine the content of the served meals and whether it followed the predetermined menu guidelines; to evaluate the procurement, storage, preparation and serving conditions in the schools; and to observe whether a school food garden was established.

Methods: The study was a cross-sectional observational design. Data was collected at the selected primary schools, using an observational checklist and a self-administered questionnaire for the food handlers, NSNP coordinators and food gardener. Descriptive statistics were performed.

Results: The study area included twelve Quintile 1–3 primary schools in the Malmesbury district of the West Coast region. The findings of the study indicated that the schools implemented the NSNP well. Although the food served at the schools followed the predetermined menus, the recommended daily allowance (RDA) % for energy was not met according to the NSNP guidelines at any of the schools participating in the study. In terms of the food delivery system used, the procurement of raw materials was satisfactory and the storage conditions at the schools were clean and adequate. Preparation of meals was done by food handlers who all displayed a good sense of personal hygiene, and safe food-handling practices were observed. Food gardens at schools that had these were well maintained and the produce contributed toward the NSNP menu.

Keyword: School feeding programs, School menu, Food gardens at schools, National School Program, Nutrient intake in school children

Conclusion: The schools observed implemented the NSNP according to the guidelines, allowing the programme to reach its potential aims and have a positive impact on the learners attending school.

PAB(T6)-174
Food Step – development of a sustainable health-promoting model for food services and early childhood education and care

Maijaliisa Erkkola[1], Liisa Korkalo[1], Jelena Meinilä[1], Henna Vepsäläinen[1], Susanna Raulio[2], Sari Niinistö[2], Leena Forma[3], Merja Saarinen[4], Suvi Marjatta Virtanen[2,5], Food Step Study Group[1,2,3,4,5]

1. University of Helsinki (Finland), 2. Finnish Institute for Health and Welfare (Finland), 3. Laurea University of Applied Sciences (Finland), 4. Natural Resources Institute (Finland), 5. Tampere University (Finland)

Background and objectives: Transformation towards more climate friendly and healthy sustainable diets requires major changes in food systems. In Finland, early childhood education and care (ECEC) centres serve three meals per day. The Food Step project aims to develop a sustainable operating model that supports children's healthy diets and reduces the climate impacts of food provision in ECEC.

Methods: The Food Step project takes place in four Finnish municipalities. The content of a sustainable food system intervention is co-created together with municipal stakeholders and food service and ECEC professionals. The participating 23 ECEC centres were cluster-randomized or quasi-cluster-randomized (8 out of 23) into intervention and control centres. The 10-month intervention covers all the children in the intervention arm's centres. The aims for the intervention menus were to increase vegetables and fruit (particularly legumes) and sustainably sourced fish, to reduce red meat, and modestly reduce milk compared to the baseline menu. The intervention also includes advanced food education and activities to reduce food waste. We assess all stakeholders' knowledge, attitudes, and practices in relation to nutrition and the climate impacts of food by questionnaires. Thus far, we have analysed the food service managers' attitudes towards the planned changes at baseline. The impact of the intervention on the diet, costs of the food system, the climate impact of the diets, and food waste in the ECEC centres will be examined.

Results: At the baseline, the food service managers (n=9) had positive attitudes towards increasing fish and reducing red meat, but were slightly critical towards reducing milk on the menu. The food services of each municipality successfully developed intervention menus that are better aligned with the current recommendations than the previous menus. The intervention started and new menus were launched in March 2022. **Conclusion:**The project promoted all stakeholders' involvement in a sustainable food system through participatory design. We will demonstrate whether a systemic food reform in food services and ECEC would lead to benefits in environmental sustainability, nutrition, and cost-effectiveness. The national model will benefit policy-makers and professionals through concrete guidelines and action initiatives necessary for the sustainable food system reform.

PAB(T6)-175
The association between the EAT-Lancet planetary health diet and abdominal obesity in the Finnish adult population

Satu Männistö[1], Mirkka Maukonen[1], Niina Kaartinen[1], Anne-Maria Pajari[2], Tiina Suikki[1]

1. Finnish institute for health and welfare (Finland), 2. University of Helsinki (Finland)

Background and objectives: Nutrition is one of the key determinants of body weight maintenance and obesity. Furthermore, food production and consumption patterns are key factors of contributing to environmental burden. The EAT-*Lancet* Commission has recently launched the Planetary Health Diet (PHD) to consider both human health and environmental aspects. However, the association between the PHD and anthropometrics e.g., waist circumference, are examined only little so far. Therefore, our aim was to examine the association between the adherence to the EAT-*Lancet* PHD and abdominal obesity in the Finnish adult population.

Methods: We used data from the national FinHealth 2017 Study (n = 5123, aged ≧18 years, female 56%). The habitual diet

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

was assessed with a validated food frequency questionnaire. Based on the EAT-*Lancet* PHD, we developed a priori, energy-standardized (2500 kcal) dietary index score adapted for the Nordic food culture including 13 food and nutrient groups (score range 0–13 points) to evaluate diet quality. Waist circumference (WC) was measured by trained study nurses, and abdominal obesity was classified as WC ≧ 100cm for men or WC ≧ 90cm for women. Linear regression and multivariable logistic regression were used for the statistical analyses.

Results: Mean PHD score was 3,6 (SD 1,3) for men and 4,3 (SD 1,5) for women. In both men and women, 44% of participants were abdominally obese. In men, no significant association between the PHD score and WC was found (ß -0.28 with 95% CI -0.65, 0.10). In women, the PHD score was inversely associated with WC (ß -0.41 with 95% CI -0.73, -0.10). Furthermore, both men and women with higher PHD scores were less likely to have abdominal obesity although the associations were not statistically significant (men: OR 0.96 95% CI 0.90, 1.03; women: OR 0.94 95% CI 0.89, 1.00).

Conclusion: The adherence to PHD was relatively low in both Finnish men and women, however especially in women better adherence to PHD was associated with smaller WC. A diet following the EAT-*Lancet* PHD seemed to be beneficial in terms of maintaining normal WC particularly in women. However, further studies with different anthropometric measurements are warranted.

Importance of tailored technical assistance for sustaining high coverage of 2-dose vitamin A supplementation (VAS) in Nigeria: A case study of Katsina State

Deborah Benneth[3], Babatunde Ajidagba[4], Jacob Korir[2], Abdulhadi Abdulkadir[5], Titilola Abolade[3], Junaidu Sani[3], Caitlin Gomez[1], Banda Ndiaye[2], Alison Grieg[1]

1. Nutrition International (Canada), 2. Nutrition International (Kenya), 3. Nutrition International (Nigeria), 4. Nutrition International Consultant (Nigeria), 5. Katsina State Primary Health Care Development Agency (KSPHCDA) (Nigeria)

Background and objectives: Nigeria uses the biannual Maternal, New-born and Child Health Weeks (MNCHW) to deliver essential health and nutrition services, including VAS for children 6-59 months of age. Between 2014-2019, Katsina state received funding from the state government and financial and technical support from partners to implement the MCNHW. During this time, 2-dose VAS coverage in the state reached over 80%. VAS coverage in Katsina dropped to 0 in 2019, as the state was only able to provide one dose of VAS. This was due to multi-dimensional challenges, including loss of funding and support from partners, inadequate state nutrition leadership and lack of a clear sustainability plan to maintain the success of the MNCHW after partners exit. The objective of this ongoing project is to provide tailored technical and financial support to the Katsina State government to improve and sustain high 2-dose VAS coverage through effective, efficient planning and implementation of the MNCHW. **Methods:** In 2019, Nutrition International (NI) conducted a landscape analysis in Katsina to identify technical and programmatic gaps in the planning and implementation of the MNCHW. In response to the gaps identified, NI engaged a state-level consultant to provide technical support and guidance to the nutrition unit of the KSPHCDA. The tailored technical assistance focused on achieving and sustaining high VAS coverage while strengthening the capacity of the state government to implement the MNCHW. This support emphasized on improving demand creation for VAS, micro planning, coordination and supportive supervision. As part of NI's sustainability plan for the state, the technical assistance also included support for the development of 5-year costed plans for timely inclusion of the MNCHW into state annual health budgets. **Results:** Following NI's support to the state beginning in September 2020, VAS coverage improved to over 80% and this is expected to be sustained through the implementation of the 5-year plan developed with technical support from NI. **Conclusion:** The provision of tailored state-level technical and financial support is key for achieving high coverage of VAS. Technical assistance should include strategies that build resiliency and system strength to foster sustainability of the MNCHW and reduce reliance on partner support.

Nutritional knowledge and health, the Group of young students in physical education in Morocco

Mourad Oukheda[1], Khawla Bouaouda[1], Halima Lebrazi[1], Karima Mohtadi[1], Abdelfatah Derouiche[1], Rachid Saile[1], Hassan Taki[1]

1. University Hassan II Casablanca (Morocco)

Background and objectives: According to WHO, adolescence is the period of human growth and development that occurs between childhood and adulthood. It represents a critical transition period in life and is characterized by a significant rate of growth and change. A bad default or excess diet can distort this process over time. The changes that Morocco has experienced in recent decades with globalization reveal several behaviors affecting even the lifestyle of individuals and

family groups, including eating habits. The increasingly early manifestation of certain profile imbalances in young people, such as obesity or overweight, shows the importance of vigilance and education of children and adolescents in relation to lifestyle habits. However, our objective through this study is to evaluate the effect of education and nutritional knowledge of school children (n: 221) on their morphological and energy profiles (the energy balance in nutritional intake and energy expenditure) during a period of 20 weeks of study, in order to identify the eating behaviors and their effect on the physical activity of these young adolescents aged "15 to 18 years" made up mainly of pupils belonging to public schools in the city of Casablanca with an average physical practice of 2 to 3 hours per week.

Materials and methods: this is a sample of 221 school children including 120 girls and 101 boys aged (16 ± 0.8 years), height (1.67 ± 0.34 m), weight (65 ± 0. 12 kg), BMI (23). A self-administered dietary questionnaire was used to assess daily caloric intake, macronutrient distribution and antioxidant vitamin intake. Daily energy expenditure was evaluated by the factorial method. We studied nutritional knowledge using a Validated NSKQ questionnaire. As far as physical performance is concerned, several field-validated tests have been implemented to assess their motor skills and abilities (shuttle test for VO2max, 100 speed test and 1500 m endurance test).

Results: The results show that corpulence according to gender for girls (n=120) grade I undernutrition (n=9), grade II undernutrition (n=1), grade III undernutrition (n=1), normal (n=88), moderate Grade I obesity (n=3), overweight (n=18), And for boys (n=101): Grade I undernutrition (n=15), Grade II undernutrition (n =1), grade III malnutrition (n=2), normal (n=76), moderate Grade I obesity (n=2), overweight (n=5). Students who were of normal build achieved higher scores than those who were not ($p < 0.05$). The daily caloric intake is (2134.7 ± 1.4 kcal d^{-1}) and the macronutrient distribution (Carbohydrates: 53%, Proteins: 13%, Fats: 34%) while the energy expenditure is (3034, 5 ± 1.7 kcal.d^{-1}), with a deficit of 899.8 ± 1.3 kcal.d^{-1} is within the norms for moderate athletes, The analyses demonstrated significant associations between the level of performance and the energy intake ($P < 0.04$).

Conclusions: The students studied have an unbalanced diet in macronutrients with a high level of lipids. Similarly, these students suffer from a strong deficit in antioxidant vitamins A, E and D. Students nutrient intake should be monitored by their family or a nutrition professional. Each subject must have an individual diet. Nutrition education must be organized and the families of these students must be included in these training sessions.

Importance of well-trained health staff during pregnancy in semi-urban and rural surrounding of Bukavu, DR Congo

Damaris Elisabeth Beitze[1], Céline Kavira Malengera[2,3], Theophile Barhwamire Kabesha[2], Jan Frank[1], Veronika Scherbaum[1]

1. University of Hohenheim (Germany), 2. Université Evangélique en Afrique (Democratic Republic of the Congo), 3. Centre de Recherche en Sciences Naturelles/Lwiro (Democratic Republic of the Congo)

Background and objectives: Birth weight (BW) is influenced by maternal factors and health and nutrition during pregnancy as well as use of well-trained health services can play an important role. Within the scope of a nutrition study, it was aimed to compare health care during pregnancy and birth outcomes between semi-urban and rural areas around Bukavu, DR Congo.

Methods: At baseline of a cross-sectional follow-up study, 471 mother-infant pairs were recruited during the first week postpartum in two semi-urban and one rural hospital. BW was recorded by postpartum mothers and a structured questionnaire including retrospective information about health and nutrition during pregnancy as well as practicing family planning was applied. Descriptive statistics, chi-square-tests, Student's t-test, Mann-Whitney U-test, and multiple linear regression analysis were used. Practices related to health services are presented.

Results: BW was significantly lower in rural than in semi-urban areas (3004±468 g vs. 3263±444 g) along with a higher prevalence of low birth weight (10.7% vs. 2.7%). Maternal mid-upper arm circumference (MUAC) also differed significantly between rural and semi-urban mothers (23.8±2.1 cm vs. 26.9±3.1 cm). Compared to the semi-urban mothers, less rural women reported to have practiced family planning (3.1% vs. 17.1%), taken any medication during pregnancy (85.4% vs. 92.2%) which was most prominent for the use of deworming (24.6% vs. 88.3%) and antimalarial drugs (80.8% vs. 88.6%), taken nutritional supplements (81.5% vs. 89.3%), and have received information about nutrition by medical staff, a friend, or the mother (32.8%, 0.8%, 0.0% vs. 46.5%, 8.5%, 8.5%, respectively). Having experienced health problems during pregnancy and use of mosquito nets did not differ significantly between the study areas. In the rural hospital, breastfeeding was initiated less frequently within the first hour after birth (87.8% vs. 93.8%) as recommended by WHO/UNICEF.
Lower maternal MUAC, age, gestational age, primipara, female sex, and rural location were significantly associated with lower BW.

Conclusions: Poorer birth outcomes in rural areas might be partly mediated by maternal undernutrition and lower use of health services. Antenatal and perinatal care need to be strengthened especially in rural health facilities to benefit both maternal and newborns' nutrition and health status.

The estimated dietary and health impact of implementing the proposed 'high in' front-of-pack labelling in Canada: a macrosimulation modeling study

Nadia Flexner[1], Mavra Ahmed[1], Alena Ng[1], Jodi Bernstein[1], Anthea Christoforou[1], Jennifer Lee[1], Christine Mulligan[1], Neha Khandpur[2,3], Mary L'Abbe[1]

1. University of Toronto (Canada), 2. University of Sao Paulo (Brazil), 3. Harvard University (USA)

Background and objectives: Front-of-pack labelling (FOPL) has been identified as a cost-effective policy to promote healthier diets. In 2016, Chile was the first country to implement a mandatory 'high in' warning label (WL). Chilean consumer surveys report that between 30% and 60% of consumers choose products with less WL. Health Canada has similarly proposed a FOPL system mandating that packaged foods exceeding predetermined thresholds for sodium, total sugars, and/or saturated fat are required to display a 'high in' WL. The aims were to estimate the potential 1) dietary impact of substituting foods with similar foods that would carry at least one less WL, and 2) the number of diet-related noncommunicable disease (NCD) deaths that could be averted or delayed due to estimated dietary changes.

Methods: Baseline and counterfactual intakes of sodium, total sugars, saturated fats, and calories were estimated among Canadian adults (n=11,992) using both available days of 24h recall data from the 2015 Canadian Community Health Survey-Nutrition (CCHS). Using a Canadian branded food composition database, we identified similar foods to those reported in CCHS that would carry at least one less WL (n=272). Based on the Chilean experience, we substituted identified foods for 30% and 60 % (randomly selected) of CCHS respondents. Potential health impacts were estimated using the Preventable Risk Integrated ModEl (PRIME) macrosimulation model.

Results: Mean dietary reductions of 108 mg and 216 mg/d of sodium, 3.0 g and 5.7 g/d of sugars, 0.2 g and 0.3 g/d of saturated fats, and 16 kcal and 33 kcal/d of calories were estimated due to food substitution for 30% and 60% of CCHS respondents, respectively. Between 2,701 (95% CI 2,397-3,013) and 5,189 (95% CI 4,595-5,771) deaths due to diet-related NCDs, primarily from cardiovascular diseases (71%), could potentially be averted or delayed in a year by implementing FOPL in Canada.

Conclusions: Results suggest that FOPL could significantly reduce sodium and total sugar intakes among Canadian adults, the consequences of which could prevent or delay an important number of diet-related NCD deaths. These findings can inform policy decisions related to final approval and implementation of FOPL in Canada.

Niger's Climate Crises: Role of Food Security Responses and Nutrition Investments in Maternal and Neonatal Mortality Reduction

Shelley Walton[1], Nasreen Jessani[1], Nadia Akseer[1], Heather Ju-Wong[1], Elizabeth Hazel[1], Agbessi Amouzou[1], Rebecca Heidkamp[1], Assanatou Bamogo[1], Lamou Ousseini Youssoufa[2]

1. Johns Hopkins Bloomberg School of Public Health (USA), 2. Institut National de la Statistique du Niger (Niger)

Background and objectives: Niger has been plagued by high rates of poverty, environmental crises, food insecurity, and political instability, and ranks amongst the highest in the world in climate-vulnerability. Yet, it surpassed West African counterparts in greatly reducing newborn and maternal mortality over the past two decades. The study objective was to understand the climate-related food insecurity evolution in Niger and how the country's nutrition policy and programmatic focus in the most affected regions may have improved health and nutrition of mothers and newborns.

Methods: We used national household surveys from 1998, 2006, 2009 and 2012 to explore descriptive trends in maternal and newborn nutritional indicators (women's weight, anemia during pregnancy, and iron folate supplementation coverage, breastfeeding practices, child stunting and wasting). Through a desk review and in-depth key informant interviews we reviewed national and subnational nutrition policies and programs. **Results:** There were two severe food crises in 2005 and 2010 primarily impacting four regions in Niger. From 2010 to present, maternal, newborn, and child nutrition, food security, and resilience programs in Niger were increasingly implemented nationally or in the four most vulnerable regions. Each prioritized region saw major improvements in key indicators, above what was seen in other subregions. From 1998 to 2012, there were large improvements in anemia during pregnancy, improvements in iron supplementation coverage, early initiation of breastfeeding, and the birth disadvantage for wasting disappeared completely in several of the vulnerable regions. **Conclusions**: Results suggest that health and nutrition interventions in targeted regions played a large role in improving food security, maternal, fetal growth, and neonatal health. Policy and program efforts helped to offset any substantial rise in nutrition-related maternal and newborn mortality caused by repeated food crises in the hardest hit regions. Major drivers of food insecurity and malnutrition such as conflict, climate variability and extremes are expected to increase in the coming years and countries will need to prepare for future shocks. Similar methods can be replicated in other countries facing climate crises to understand the relationships between targeted nutrition and food security actions and reductions in maternal and neonatal mortality.

Assessment of Nutritional Status of Underweight Children aged 3 to 5 years old using Nutribun paired with Lipid-Based Nutrient Supplement (LNS) in Region IV-A

Christella ABrigo Inumerable[1], Lauren Lalaine Lao[1], Paul John De Leon[1], Gayle Urrera[1], Joyelli Anne Ramos[1]

1. Philippine Nutri-Foods Corporation (Philippines)

Background and objective: In 2018, 19.1% of Filipino children below 5 years old are underweight according to the World Bank Group. The Department of Social Welfare and Development (DSWD) implemented the Supplementary Feeding Programs (SFP) to diminish the growth of these numbers. A reformulated Nutribun paired with Enov' Nutributter Lipid-Based Nutrient Supplement (LNS) was given through this program. The reformulated nutribun comes in a smaller serving size - 80g vs. 160 g of the original formulation. It also uses skimmed milk and bread flour as the main sources of protein instead of soy fortified flour. It comes with LNS that can be used as a spread. When combined both will provide around 325 kcal and 10 g of protein. The main objective of this study is to assess the effect of nutribun paired with LNS in the nutritional status of underweight children in Region IV-A.

Methods: The study involved 12,985 underweight and severely underweight children as part of the feeding program in Region IV-A. The children were fed twice a day for 120 days with supplementary food, wherein Nutribuns with lipid-based nutrient supplement is served every two weeks and consumed in alternate days, along with other food items provided in the program. The improvement in the nutritional status of children was assessed by comparing their weight for age, based on the Child Growth Standards provided by the World Health Organization, prior to and after the feeding activity.

Results: 61.45 % of the total number of children had improvement in their nutritional status, provided that Nutribuns were consumed three to four times a week. The percent distribution of nutribun in the feeding program covers about 35% of the total program.

Conclusion: Nutribuns paired with LNS contributed effectively to the improvement of the nutritional Status of underweight children in Region IV-A. Nutribun with lipid-based nutrient supplement is an ideal option in feeding programs as it is both caloric and nutrient dense, enough to supplement for the daily requirement of the children.

Changes in the availability of ultra-processed foods offered in state-run public schools' meals in Brazil: evidence from a locally led intervention

Ana Clara Duran[1,2], Paula Pereda[2,3]

1. Center for Food Studies and Research, University of Campinas (Brazil), 2. Center for Epidemiological Studies in Nutrition and Health, University of Sao Paulo (Brazil), 3. Department of Economics, University of Sao Paulo (Brazil)

Background and objectives: School Feeding Programs (SFP) across the globe have been associated with better dietary and educational outcomes. Delivering a program that promote healthy eating while protecting students from the exposure to unhealthy foods, such as ultra-processed foods (UPF), can, however, be challenging. We explored whether a locally led intervention to optimize the implementation of the Brazilian National SFP "*Cozinheiros da Educacao*" was associated with changes in the proportion of UPF offered in state-run schools.

Methods: Longitudinal study that used publicly available data on 4,410 unique state-run school lunch and snack menus from from 645 municipalities between 2015 and 2019. We employed a two-way fixed effects model to assess yearly changes in the proportion of UPF (%) in school menus controlled for school- and municipality-level covariates and day of the week. We ran similar models to explore whether the *Cozinheiros da Educacao* program menus were associated with less UPF items for each school/year. This program had a staggered implementation from 2016 to 2019, when it was ended, and combined changes in the supply chain that allowed schools to receive unprocessed meats, inclusion of traditional local dishes and training provided to school cooks by a known local chef. Models were controlled for concomitant federal transfers to improve school lunch menus. Finally, we ran sensitivity analysis for state-run schools from the Sao Paulo Metropolitan Area, where the program had a wider reach.

Results: The overall proportion of UPF items in lunch menus decreased by 13.6 percentage points (p.p.) ($p<0.001$) between 2016 and 2018, with a slight increase in 2019. Similar trends were observed for breakfast and snack menus. *Cozinheiros da Educacao* Program was statistically associated with reductions in the proportion of UPF in lunch (-2.76; SE=0.94) and snack menus (-2.8 and 6.73; SE-2.01). Analyses restricted to the Sao Paulo Metropolitan Area provided similar results. **Conclusion**: We found that this locally led intervention aimed to replace UPF for unprocessed foods was associated with reductions in the proportion of UPF in school menus. Our findings can help inform further impact evaluation analyses and provide evidence to improve the quality of public schools' menus.

PAB(T6)-183
Resilience in the delivery of Vitamin A supplementation (VAS) during the COVID-19 pandemic: A case study in Kenya

Elijah Njeru Mbiti[1], Jacob Korir[2], Charles Ndiritu Mumbi[1], Banda Ndiaye[2], Jacqueline Kwamboka Kungu[2], Alison Greig[3], Caitlin Gomez[3], Joy Karimi Kiruntimi[1]

1. Nutrition International (Kenya), 2. Nutrition International (Kenya), 3. Nutrition International (Canada)

Background and objectives: Kenya's VAS policy specified routine health facility contacts, outreach and integration into campaigns to reach children 6-59 months with VAS. In 2017, the policy was revised to include distribution through community units (CUs) and Early Childhood Development centres (ECDs). Following this revision, Nutrition International (NI) conducted a demonstration project in Muranga county to systematically explore mechanisms to optimize VAS delivery through this expanded list of approaches. Using learnings from the demonstration project, NI further supported select county governments to optimize VAS delivery. This initiative demonstrated the immense potential of the CUs to improve VAS coverage. The COVID-19 pandemic caused severe disruptions to service delivery in Kenya, as well as increased hesitancy of community members to attend health facilities for fear of infection. As a result, VAS coverage was projected to drop by 30% in 2020. To minimize this, NI used lessons learned from the optimization project to support national and county governments to maximize coverage in the context of COVID-19.

Methods: The national VAS taskforce responded quickly to reduce the impact of the pandemic on the VAS program by developing operational guidelines for VAS during the pandemic, strengthening coordination mechanisms at national and sub-national levels, engaging and coordinating partners, building the capacity of CHVs to deliver VAS and adjusting budgets to accommodate task-shifting in service delivery. Lessons learned and VAS planning tools from NI's demonstration project were incorporated in the operational guide and disseminated to support VAS programming across the country.

Results: Two-dose VAS coverage in Kenya increased from 67% in 2019 (pre-covid) to 82% and 86% in 2020 and 2021, respectively, despite significant disruptions to the health system caused by the pandemic. This success was largely because VAS continued to be delivered in the community via the CHVs. In addition, NI's VAS microplanning tool was used across the country to facilitate efficient planning and resource allocation to reach all eligible children.

Conclusions: Diversifying VAS delivery approaches is critical for sustained coverage during disruptions to health systems, ensuring continuity when one platform is affected. Microplanning for VAS is an important tool, for sustained planning and delivery of VAS. Lastly, a robust community health strategy provides a resilient delivery platform for essential health and nutrition services as it did in Kenya during the COVID-19 pandemic.

Choline, docosahexaenoic acid, and diarrheal disease associated with growth faltering in a case control study

Jenna N Diaz[1], Sherlie Jean Louis Dulience[1], Noah Wolthausen[1], Xuntian Jiang[1], Emmanuel Gyimah[1], Francesca J. Marhône Pierre[2], Fredrick Matthew Kuhlmann[1], Lora L. Iannotti[1]

1. Washington University in St. Louis (USA), 2. Ministère de la Santé Publique et de la Population (Haiti)

Background and Objectives: Children with malnutrition are more susceptible to recurrent infectious diarrhea episodes and subsequent morphologic and functional enteric changes which may further compound growth faltering. DHA and choline status may influence these relationships given the role these biomarkers play in lipid metabolism, gut immunity, and inflammatory mediation. Here we aimed to examine the potential contributions of DHA, choline, and enteric damage in young children with diarrheal illness and the associated child growth outcomes.

Methods: We developed a longitudinal case-control study in children 6-36 months of age (N=195) living in Cap-Haitien, Haiti. Mother-child dyads were recruited from community health posts and cases were defined as having three or more liquid stools in the last three days. Child anthropometry, dietary intake, blood, and stool samples were collected at baseline and at the one-month follow-up. Plasma DHA, choline and betaine were measured using liquid chromatography tandem mass spectrometry methods (n=49). Intestinal fatty acid binding protein (I-FABP) completed by enzyme-linked immunoassay (n=183). Multivariate regression models were used, along with mediation analyses to examine these associations and adjust for confounding factors.

Results: Mean plasma DHA and choline concentrations were low in both cases and controls at baseline and follow-up visit. Mean plasma I-FABP levels were high in both groups, but significantly higher at one-month follow-up in cases compared to controls (3.20, 95% CI: 3.13, 3.27 and 3.34, 95% CI: 3.28, 3.40, respectively, p = 0.002). In multivariate regression models, higher plasma choline at one-month follow-up was protective (AOR 0.1, 95% CI: 0.011, 0.904, p= 0.04) against being underweight at follow-up. Higher plasma DHA at follow-up was associated with decreases in weight-age-z-score (p=0.016). Follow-up I-FABP was inversely correlated height-age-z-score (p=0.033). Mediation analyses were found to be non-significant.

Conclusions*:* This study found the children had low levels of plasma DHA and choline and high I-FABP concentrations which suggest high prevalence of malnutrition and enteric damage. Trends found in plasma choline and DHA indicate they may have a role in growth outcomes in this context.

PAB(T6)-185
A longitudinal assessment of rural food environments in Sri Lanka during Covid-19

Quinn Marshall[1], Dilini Hemachandra[2], Deanna Olney[3], Jessica Fanzo[4]

1. Johns Hopkins University, Bloomberg School of Public Health (USA), 2. University of Peradeniya, Faculty of Agriculture (Sri Lanka), 3. International Food Policy Research Institute, Poverty, Health, and Nutrition Division (USA), 4. Johns Hopkins University, Nitze School of Advanced International Studies (USA)

Background and objectives: Food environments are a critical determinant of diet quality, yet remain understudied in low-and-middle-income countries, especially in remote, rural communities. Sri Lanka has experienced a growing foreign exchange crisis during the Covid-19 pandemic, which has contributed to food price inflation and reports of food shortages. This study aims to assess how rural food environments, specifically the availability and cost of a healthy diet, have been affected.

Methods: Market surveys were conducted in open-air markets (n=16) and village retail shops (n=122) across 45 Grama Niladhari (GN) Divisions at 10 time points, from December 2020 to December 2021. Food availability was assessed according to the feasibility of sourcing sufficient variety of foods to meet national food-based dietary guidelines (FBDG). Cost was assessed as the minimum cost of adhering to FBDG (CORD). Secondary data was attained from Sri Lanka's national food price surveillance system to compare the trend in CORD in the study area, composed of rural communities, to the national average, which primarily reflects urban centers. CORD estimates were deflated by non-food price inflation. A generalized least squares model was used to test for difference in trajectories.

Results: In December 2020, 84% of the study GNs had sufficiently diverse foods for FBDG. However, by September 2021 only 62% had sufficiently diverse foods; supply of dairy products and fruit were particularly constrained. CORD was estimated at $2.63 (constant Dec.'20 LKR 155) per person per day in December 2020 and $3.32 (constant Dec.'20 LKR 196) in December 2021, an average GN-level increase of 25%. At its highest, nominal CORD represented 115% of household food expenditure. CORD increased at a significantly faster rate in the study area compared to the national average; though it was 20% lower in December 2020, by December 2021 the two were approximately equal.

Conclusions: Covid-19 and the macroeconomic pressures faced by Sri Lanka have seen an erosion in the availability and affordability of a healthy diet in the study area. The cost of a healthy diet may have increased more in rural parts of Sri Lanka, where market connectivity is relatively lower and food insecurity already high.

Is there an association between poor mental health and the nutritional status of Syrian refugee mothers and their children under five? A cross-sectional study in Greater Beirut, Lebanon

Joana Abou-Rizk[1], Theresa Jeremias[1], Georgiana Cocuz[1], Lara Nasreddine[2], Lamis Jomaa[2], Nahla Hwalla[2], Jan Frank[1], Veronika Scherbaum[1]

1. University of Hohenheim (Germany), 2. American University of Beirut (Lebanon)

Background and objectives: More than one out of four mothers were found to suffer from a form of depression and/or post-traumatic stress disorder (PTSD) among Syrian refugees in Greater Beirut, Lebanon. The objective is to examine the associations of socio-economic characteristics, nutritional inadequacies, nutritional status, and anemia of mothers and their children aged under five years with maternal mental health status.

Methods: A cross-sectional study was conducted among Syrian refugee mothers of children under five years from June-October 2018 in Greater Beirut, Lebanon (n=433). Data was gathered on socio-economic, maternal health, dietary intake (24-hour recalls), and anthropometric characteristics. Hemoglobin concentrations were measured using the HemoCue Hb301+ analyzer. Mental health was assessed using the Patient Health Questionnaire-9 (PHQ-9) for depression and the Mini International Neuropsychiatric Interview (MINI) for PTSD. Descriptive statistics, chi-square test and ANOVA were applied.

Results: Out of 432 mothers included in this study, 13.9% were found to suffer from moderate or severe depression, 6.9% from PTSD, and 6.2% from the co-occurrence of depression and PTSD. Being older in age, having a baby girl, a higher number of children under five in the household, a higher crowding index, lower use of micronutrient supplements, suffering from a flu or chronic disease, experiencing symptoms including headaches, dizziness, difficulty concentrating, undergoing a Caesarean section, and not having breakfast daily were found to be significantly associated with poor mental health among mothers. No associations were found between poor mental health and anemia, nutritional status, and nutritional inadequacy among mothers and anemia among children, except for maternal selenium intake. Proportions of nutritional inadequacy for selenium among mothers and of overweight/obesity (BMI-for age > +2) among children were significantly higher when mothers were suffering from PTSD or depression.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusion: Poor mental health is associated with various socio-economic and health characteristics among Syrian refugee mothers in Greater Beirut, Lebanon. It might play a crucial role in caregiving and impact the nutrition of offspring's, indicating the need to improve nutrition and mental health services for refugees. In-depth analysis is required to examine the determinants of poor mental health and its associations with maternal dietary patterns among refugees.

Food Models for Treatment of Children with Moderate and Severe Acute Malnutrition: A Narrative Review

Marian Abraham[1], Dr. Dripta Roy Choudhury[1], Dr. Satish B Agnihotri[1]

1. CTARA, IIT-Bombay (India)

i. Background & Objectives: The community-based management of acute malnutrition (CMAM) involves the provision of ready-to-use therapeutic foods (RUTF) or other nutrient-dense foods for the treatment for malnourished children without medical complications. Standard milk -peanut based RUTFs are expensive which impact the implementation of such programs on large scale. Instead, food-based alternatives to the standard RUTF formulations are practised by local community in CMAM programs. Thus, this study has attempted for a comprehensive review of the evidences on efficacy and appropriateness of such food-based strategies.

ii. Methods: The review compared different food models used in the treatment of severe and moderately acute (SAM, MAM) malnourished children of<5y. A computerised keyword search was conducted on databases such as PubMed, Cochrane and REFINE. A snowball method was also used to identify literature across set inclusion and exclusion criteria. The first part of analysis compared nutrition outcomes of different approaches to assess efficacy in addition to strength and limitations. The second part of the review focused on nutrition composition of the different food approaches.

iii. Results: The results for efficacy were mixed. Individual trials reported better recovery rates with standard RUTF compared to alternative RUTFs for SAM children however few also showcased that alternative formulations were not inferior. Some evidences showed better impact of certain alternative formulations to treat anaemia, very common among SAM children. The food analysis indicated two major concerns with the standard milk-peanut formulations i.e imbalance of omega 6:omega 3 ratio and high amount of added sugar. RUSF and LNS showed better outcomes for MAM children.

iv. Conclusion: Nutrient dense food-based models alternative to RUTF were observed to be a sustainable approach to manage malnourished children at community level.

BMI–for-age z-score between girls and boys of Mapuche ethnicity and descendants of Europeans living in rural and urban areas: A systematic review and meta-analysis

Jose Candido Fernandez-Cao[1], Claudia Troncoso[2], Catalina Avaria[1], Carlos Doepking[1]

1. University of Atacama (Chile), 2. Universidad Católica de la Santísima Concepción (Chile)

Background and objectives: A study reported significantly higher BMI-for-age z-score (BMIa-zs) in children of Mapuche ethnicity compared to those of European descent (Bustos 2009). This systematic review and meta-analysis aimed to compare the BMIa-zs between girls and boys of both groups living in urban and rural areas.

Methods: This systematic review and meta-analysis was recorded in Prospero (CRD42017069924), and the protocol can be consulted elsewhere (Fernandez-Cao 2018). The search was performed in PubMed/Medline, Scopus, Web of Science and SciELO until October 2020. Observational studies conducted on girls or boys of Mapuche ethnicity and descendants of Europeans living in urban or rural areas, separately; providing data on BMIa-zs; and published in English, Spanish were included. The selection process was performed first, from title and abstract, and then through the full text of relevant manuscripts. The global mean difference (GMD) and the 95% confidence interval (CI) were estimated using the generic inverse variance method applying random-effects models. Stratified analysis was conducted to examine the effect of sex on results. Heterogeneity was assessed by the Cochran Q-statistic and the I2 statistic, and the publication bias through the Egger's and Begg's tests. All analyses were performed with STATA 15.

Results: From 3,141 records initially identified, two were selected (Amigo 2010) (Fernandez 2019). No studies performed in rural areas were found. Stratified analysis based on the sex showed non-significant differences for BMIa-zs between girls of Mapuche ethnicity and descendants of Europeans living in urban areas (GMD= 0.10; 95% CI: -0.23, 0.42), and neither among children of both ethnic groups (GMD= 0.54; 95% CI: -0.16, 1.24). Consequently, the GMD for the BMIa-zs of children living in urban areas was 0.16 (95% CI: -0.13, 0.45), with a moderate heterogeneity (I2 = 38.3%). No evidence of publication bias was found.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: A limited number of studies with relevant information were found. No differences in the BMIa-zs between girls or boys of Mapuche ethnicity living in urban areas compared to European descent were observed. Further studies are needed to investigate possible differences in the BMIa-zs of children of both ethnic groups according to sex and the area of residence.

Keyword: BMI, children, urbanization, Mapuche, systematic review

PAB(T6)-189
Iron-folate supplementation coverage among pregnant women in federal capital territory, Abuja Nigeria

Clementina Ebere Okoro[1,2,3], Aloysius Nwabugo Maduforo[2,3]

1. FCT Primary Health Care Board Abuja (Nigeria), 2. University of Nigeria Nsukka (Nigeria), 3. Nutrition Society of Nigeria (Nigeria)

Background and objectives: Pregnant women in the Federal Capital Territory (FCT) Abuja, Nigeria receive iron and folic acid supplements routinely in the health facilities during antenatal as well as during the biannual maternal newborn and child health week (MNCHW). This study determined iron-folate supplementation coverage in FCT, the knowledge of the women on the benefits of the supplements, and the site they received the supplements.

Methods: A cross-sectional survey design was adopted in the study. Cluster random sampling technique was used to sample 849 respondents from 30 households in 30 communities in the six Area Councils of FCT. The questionnaire was used to elicit information from the respondents. The data were analyzed using descriptive statistics.

Results: Iron-folate coverage was 91.4% among the respondents, while 6.6% were not covered. The site majority (56%) of them received their supplements was at Primary Health Centre (PHC), 27% received it at Secondary and/or Tertiary Health Care Facilities and others received it at home (0.4%) and temporary health post (1.4%). Also, 251 respondents out of 849 did not know the benefits of iron-folate supplementations, only 73 (8.6%) knew that it could prevent birth defects and just 5.8% (49) knew that it could reduce mortality.

Conclusion: here is high coverage of iron-folate supplements among women in FCT, PHCs are the major supplementation site, but the knowledge on the various benefits of these supplements is low. Therefore, nutrition education among women should be increased on the benefits of iron-folate supplements to the pregnant woman and her foetus to stimulate self-motivation in the intake.

Valuation of wild edible plants in 3 regions in Morocco at different distances from the Mediterranean: Ethnobotanical Study.

Seloua Essaih[1]

1. Faculty of sciences, Ibn zohr university, Agadir, Morocco. (Morocco)

Our ethnobotanical study revealed the central importance of wild edible plants in several types of uses by the rural populations of the Casablanca-Settat region of Morocco. The study also reported that in this region, the elderly are the bearers of this cultural heritage, which must now be transferred to the younger generation to avoid the danger of their disappearance. In this framework, comes this present work; which is a logical continuation of our previous works. With a very particular accent on the characterization of traditional use of these plants with integration this time of a group of sellers of these last ones to give an outline on their modes of marketing within an informal sector threatened of disappearance.

The objective of this work was to inventory the uses and marketing of spontaneous edible plants among the survey population. In order to know the edible organ, its mode of consumption (recipe), the frequency, the type of use, its state of commercialization, their availability at the market, the plant organ sold, its average price, number and frequency of sellers for each species. An ethnobotanical survey consisted of interviews with consumers and traders of these plants using a pre-established questionnaire. The study reports a total of 78 plant species belonging to 36 families were identified, only plant species representing a use description or recipe were considered. 48 recipes were cited, of which 24 were for food use, 11 for medicinal use, 14 for food and medicinal use, and 2 for food and other use. Only one recipe for each of the following uses: food/medicinal/cosmetic, food/medicinal and other. Finally, 25 recipes for other uses in the locations studied. The most consumed plant parts were leaves (21.53%), followed by all the aerial part (18.46%), stems (16.92%), tubers or roots (15.38%), seeds (9.23%) , fruits (7.69%), flowers (4.61%), rhizomes (3.07%), fillets, stamens and receptacles (1.53%)

The results of this research contribute to document the modes of use of the identified wild edible plants which deserve to be valued in order to fight against their disappearance by their domestication.

Reporting of dietary patterns and implications for evidence synthesis and translation

Kate Wingrove[1], Mark A Lawrence[1], Sarah A McNaughton[1]

1. Deakin University (Australia)

Background and objectives: Dietary patterns evidence can be difficult to synthesise and translate into dietary guidelines when a quantitative description of the foods and nutrients contained with each dietary pattern is not provided, and when the dietary patterns are named using different criteria. The aims of this systematic review were to analyse the application and reporting of dietary pattern assessment methods, and the reporting of the dietary patterns that were analysed with health outcomes.

Methods: Three electronic databases were searched (Medline, Embase, and Global Health). Cohort and nested case control studies with dietary pattern exposures and health outcomes, published between 1980 and 2019 were eligible for inclusion. A narrative synthesis was conducted and descriptive statistics were used to summarise the data.

Results: This systematic review included 410 studies. Some studies used multiple dietary pattern assessment methods. In studies that used index-based methods (n=257), 463 distinct indices were used. Food and nutrient profiles were provided for 30.0% and 49.2% of indices respectively. Compared to Mediterranean diet indices and adaptations of the Healthy Eating Index, food and nutrient profiles were reported more frequently for Dietary Approaches to Stop Hypertension (DASH) indices. In studies that used factor analysis or principal component analysis (FA/PCA) (n=125) or cluster analysis (CA) (n=23), dietary patterns were frequently named using qualitative labels (e.g. healthy, western, Mediterranean, traditional) or based on the names of the foods that characterised the dietary pattern (e.g. vegetables pattern, meat pattern). In studies that used reduced rank regression (RRR) (n=26), basic labels were most commonly used (e.g. pattern 1, 2, 3), followed by the names of the intermediate variables (e.g. estrogen food pattern, c-peptide dietary pattern). Food profiles were reported for all the dietary patterns that were analysed with health outcomes in only 31.2% of FA/PCA studies, 46.2% of RRR studies, and 43.5% of CA studies. Nutrient profiles were reported for all dietary patterns in 50.4% of FA/PCA studies, 57.7% of RRR studies, and 47.8% of CA studies.

Conclusions: To ensure dietary patterns evidence can be synthesised and translated into dietary guidelines, standardised method-specific approaches for reporting dietary patterns may be needed.

PAB(T6)-192

A nutrition classification scheme combining level of processing and nutrient profiling predicts increased intake of critical nutrients and obesity prevalence in Australia

Sarah Dickie[1], Priscila Machado[1], Julie Woods[1], Mark Lawrence[1]

1. Deakin University (Australia)

Background and objectives: Nutrition policy actions such as food taxes, restrictions on marketing, and interpretive front-of-pack labelling (FOPL), are recommended to modify the food environment and promote healthy dietary behaviours. Nutrient-based nutrition classification schemes (NCSs) are often used to inform policy actions but do not account for level of processing. A prototype for a novel approach to NCS combining level of processing and nutrient profiling has been developed. The aim of this study was to examine the association between consumption of foods classified as 'unhealthy' by the prototype NCS and the intake of nutrients linked to non-communicable disease, and obesity in the Australian population.

Methods: A cross-sectional analysis of dietary and anthropometric data of 9,114 Australians aged >=19 from the National Nutrition and Physical Activity Survey 2011-2012 was conducted. Food and beverage items were classified by the prototype NCS. This involved classification by NOVA, and application of upper thresholds for sodium and free sugars, resulting in a binary output of 'healthy' (Group 1, group 2, and group 3 under nutrient thresholds) or 'unhealthy' (Group 4, and group 3 exceeding nutrient thresholds). The contribution of unhealthy foods to total energy intake and the mean sodium and free sugar intake over quintiles of unhealthy food consumption was examined. Adjusted linear and logistic regression models were used to analyse the association of the dietary share of unhealthy foods and obesity indicators (body mass index as continuous and categorised as >=30kg/m^2).

Results: Unhealthy foods (as classified by the prototype) contributed on average 49.7% of energy intake. A positive and statistically significant trend was observed between increasing quintiles of unhealthy food consumption and intake of free sugars (coef 2.37, p<0.001) and sodium (coef 0.13, p<0.001). In the multivariable regression analysis, those in the highest quintile of unhealthy foods consumption had significantly higher BMI (0.71 kg/m2; 95%CI 0.21, 1.21), and higher odds of having obesity (OR=1.53; 95%CI 1.22, 1.91) compared with those in the lowest quintile of consumption.

Conclusions: A NCS combining level of processing and nutrient thresholds predicts intake of free sugars and sodium, and prevalence of obesity in the Australian population.

CRESCER project- a cluster randomized controlled trial of the effectiveness of nutrition-sensitive and nutrition-specific interventions to prevent stunting in children under two in southern Angola: study design and baseline characteristics

Rocio Martin-Canavate[1], Maria Romay-Barja[1], Zaida Herrador[1], Isabel Aguado[2], Ferran Ramirez-Viaplana[2], Maria de Lourdes Faria[4], Ana Da Silva Gerardo[5], Sara Herran[3], Elena Trigo[2], Estefania Custodio[1]

1. Instituto de Salud Carlos III (Spain), 2. Hospital Universitario Vall d'Hebron (Spain), 3. Acción Contra el Hambre (Spain), 4. Fundo de Apoio Social-Instituto de Desenvolvimento Local (Angola), 5. Universidade Mandume Ya Ndemufayo (Angola)

Background and objectives: According to UNICEF, 7.3 million people in Angola face food and nutrition insecurity. Recurrent drought, reduced agricultural production, crop failures and the proliferation of infectious diseases are particularly compromising maternal and infant nutrition and health. Southern provinces are the most affected with high children malnutrition rates. Stunting prevalence reached 49.9% and 37.2% respectively in the provinces of Huila and Cunene. Implementing multi-sectoral interventions on the first 1000 days of life is key to prevent chronic malnutrition but evidence on the effectiveness of different options is limited. The CRESCER project aims to evaluate the impact and effectiveness of three interventions on stunting by implementing a community-based randomized controlled trial (c-RCT) in southern Angola.

Methods: This three-arm cluster randomized controlled trial of non-inferiority is set among FRESAN program communities in Huila and Cunene. We defined a control arm common to all arms as the standard of care (SOC) including health promotion activities, malaria prophylaxis, deworming and vitamin A supplementation. Pregnant women and their newborn children are target recipients of either arm: SOC, SOC+ nutrition supplementation with "Small-quantity lipid-based nutrient supplementation" (SQ-LNS) and family food ration, or SOC + unconditional cash transfers. Community and Health Development Agents (ADECOS) implement the interventions following Angolan government protocols. A total of 52 clusters will be randomized (13 clusters/arm). A minimum of 40 pregnant women per cluster are estimated. The primary outcomes are prevalence of stunting and mortality in children.

Results: Data collection and interventions implementation began in March 2022 and will end in October 2024. A total of 1440 pregnant women and their newborns, 480 in each arm, are enrolled to detect a 13% reduction in the prevalence of stunting among children aged 24 months. Primary efficacy analyses will be performed when participant's children have completed a total of 24 months of follow-up.

Conclusions: The findings of this trial will provide robust evidence on which intervention package can have the greatest impact on preventing stunting in children under two in Angola and improve comparability with other contexts.

PAB(T6)-194

Coverage of micronutrients needs of women and young children by diet and micronutrient interventions: cases study of Ghana and Benin

Jacques Berger[1], Valerie Greffeuille[1], Manta Dass[1], Jolene Nyako[2], Charles Torteo[2], Nadia Fanou-Fogny[3], Eunice Nago[3], Joseph Hounhouigan[3], Sonia Fortin[1], Frank T Wieringa[1]

1. IRD (France), 2. Food Research Institute, Council for Scientific and Industrial Research (CSIR) (Ghana), 3. Faculté des Sciences Agronomiques (FSA), Université d'Abomey-Calavi (UAC) (Benin)

Background and Objectives: In West Africa, widespread micronutrient deficiencies impact negatively the nutrition and health of the most vulnerable populations. To better understand pathways to improve micronutrient status, we estimated the contribution of diets, micronutrients interventions and specific foods to micronutrients needs of women of reproductive age (WRA) and young children in Ghana and Benin.

Methods: In both countries, scenarios of usual diets for WRA (15-49 yrs, non-pregnant and pregnant/lactating women), and breastfeeding and complementary diets for children (6-8, 9-12 and 13-24 months) in rural and urban settings were developed, based on literature, local surveys and meetings with national nutrition experts. Micronutrient intakes from usual diets were calculated as well as the potential contribution of four types of intervention: micronutrient fortification, micronutrient-enriched crops, micronutrient supplementation and locally available micronutrient-dense foods.

Results: Recommended Nutrient Intakes (RNIs) and Estimated Average Requirements (EARs) were not attained for most micronutrients by usual diets alone in WRA and children. Combination of supplementation and mandatory food fortification resulted in reaching the RNIs for pregnant/lactating women, while in non-pregnant/non-lactating women RNIs were only met for a few micronutrients, mainly in urban settings. Micronutrient coverage was lower in rural areas due to lower access to voluntary fortified foods products, and lower dietary diversity. In both countries, meeting the high micronutrient needs of children from 6 months remained a challenge. Breastmilk did not cover all micronutrient needs and the low diversity and frequency of the complementary diet did not fill the gap. Mass fortification strategies did not improve coverage as this is not adapted to young children. Specific complementary foods, dense in micronutrients, were the most efficient to improve the coverage of children's needs.

Conclusions: In women, better coordination of nutrition programs, including (bio-)fortification, supplementation and the promotion of nutrient-rich food, is warranted to reduce the high

prevalence of micronutrient deficiency while limiting the risk of overconsumption. In 6-23 mo children, quality and affordable first foods, complementary to breastfeeding, are essential to meet micronutrient needs and this supports the development of child-specific foods, based on micronutrient-rich available resources and efforts to increase dietary diversity particularly in the youngest children.

Keyword: Micronutrient deficiencies, West Africa, interventions, women, children

PAB(T6)-195
Evaluation criteria for flood monitoring portals: how to assess data quality and usability for nutrition and public health research?

Breanne Langlois[1], Katherine Berry[1], Leah Beaulac[1], Timothy Griffin[1], Erin Coughlan de Perez[1], Magaly Koch[2], Elena Naumova[1]

1. Tufts University (USA), 2. Boston University (USA)

Background and objectives: Flood identification using satellite imagery has improved in recent years, with many flood monitoring portals now in existence. These data can be linked to nutrition and health surveys using spatial and temporal dimensions to measure household exposure to floods. A recent review study of publicly available nutrition data dashboards defined a set of evaluation metrics based on principles of evidence, efficiency, emphasis, and ethics. Using these metrics, we identify a set of evaluation criteria for assessing quality and usability of flood monitoring portals for nutrition and public health research.

Methods: We reviewed a set of 48 previously defined evaluation metrics for nutrition data dashboards and applied them to flood monitoring data portals. These metrics were developed based on standards of data and visualization quality. We selected and described the metrics that were applicable to evaluation of flood monitoring portals. We then applied these criteria to the assessment of 7 flood monitoring portals.

Results: A total of 24 metrics were identified as applicable to the evaluation of flood monitoring portals. These evaluation metrics were related to goals and scope, data quality including integrity, standardization, and granularity, platform capability, visualization quality, platform accessibility, communication, and conflicts of interest and responsible conduct. Granularity appeared to be the most important criteria to evaluate usability of flood monitoring portals for measuring household exposure to floods. Flood monitoring data portals provide an opportunity for an objective measure of household flood exposure but risk misclassification.

Conclusions: The suggested criteria allow to compare and standardize assessment of flood monitoring data portals and facilitate usability for studying effects of floods on nutrition, food security, and health outcomes. Our next step is to apply these metrics to the assessment of 7 flood monitoring portals for a study of recurrent flooding and household food access in Indonesia.

PAB(T6)-196
The Japanese dietary pattern and nutrient density: A cross-sectional analysis of NHANES 2017-2018

Kotone Tanaka[1], Marin Aono[1], Saya Kojima[1], Kanna Tachikawa[1], Runa Watanabe[1], Yasutake Tomata[1]

1. Kanagawa University of Human Services (Japan)

Background and objectives: Several previous studies had shown that adhering to a Japanese diet is associated with better nutritional density. However, these previous studies were conducted only in Japan, and their generalizability is unclear. This study aimed to investigate the association between the Japanese dietary pattern and nutrient density among the US population.

Methods: Based on the National Health and Nutrition Examination Survey (NHANES) in 2017-2018, this study included 3,345 adults aged 20-80 years (1,556 men and 1,789 women) who were not pregnant or lactating women. Dietary intakes were assessed by the 24-hour recall method. The Japanese Dietary Index (JDI) score was calculated from 9 items (7 adhering items: rice, miso soup, fish, green and yellow vegetables, seaweed, pickles, green tea. 2 non-adhering items: coffee, beef and pork). The nutrient density (ND) index was calculated from 12 components of the Nutrient Rich Foods 9.3 Index based on "9 nutrients to encourage" (protein, fiber, vitamins A, C, E, calcium, iron, potassium, magnesium) and "3 nutrients to limit" (saturated fat, added sugar, sodium). We used the residual method to adjust the JDI score. Statistical analysis for correlations between items of JDI and ND index were performed using Spearman's correlation coefficients (ρ).

Results: The study sample included 1,253 (37%) non-Hispanic white, 744 (22%) non-Hispanic black, 750 (22%) Hispanic, 440 (13%) non-Hispanic Asian, and 158 (5%) non-Hispanic other. The JDI score was significantly correlated with the ND index (ρ = 0.155; p<0.001). The JDI score was positively correlated with all components in "9 nutrients to encourage" (range of ρ: 0.099 [vitamin E] to 0.376 [potassium]); p<0.001). The JDI score was negatively correlated with saturated fat and added sugar in "3 nutrients to limit" (ρ = -0.121 and -0.049; p = 0.005 and p<0.001), whereas the JDI score was positively correlated with sodium (ρ = 0.144; p<0.001).

Conclusion: The present findings suggest that adhering to a Japanese diet defined by the JDI score was associated with better

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

ND even among the US population. However, this dietary pattern also appears to be associated with high sodium intake as in previous studies of Japanese subjects.

Keyword: Cross-sectional study, Japanese diet, Nutrient density, Diet quality, Dietary pattern

PAB(T6)-197
What is the Iranian perception about genetically modified food? A content analysis study

Saeed Zare Bidaki[1], Arezoo Haghighian-Roudsari[2], Jalaleddin Mirzay Razaz[3]

1. National Nutrition and Food Technology Research Institute, School of Nutrition Sciences and Food Technology, Shahid Beheshti University of Medical Sciences (Iran), 2. National Nutrition and Food Technology Research Institute, School of Nutrition Sciences and Food Technology, Shahid Beheshti University of Medical Sciences (Iran), 3. National Nutrition and Food Technology Research Institute, School of Nutrition Sciences and Food Technology, Shahid Beheshti University of Medical Sciences (Iran)

Background and Objectives: Increasing global population and diversity in consumption patterns have increased food consumption and demand and raised concerns about food supply in recent years. New advances in science and technology have developed ways to solve this problem, one of which is genetically modified food (GM foods). The purpose of this study is to explain the perceptions and perceptions of consumers about GM food products. **Materials and methods**: This qualitative study was performed by maximum variety sampling. Thirty adults aged 20 to 70 years living in Tehran (capital of Iran) were recruited in the study using in-depth interviews and 15 people were included in the study through focus group discussion. The coding process begun from the first interview and continued simultaneously with subsequent interviews. The initial concepts were emerged and by constant comparative analysis, the saturation of the concepts was followed. Participants sampling continued until data saturation. Data analyzed by directed content analysis using MAXQDA10 software. **Results**: People awareness on GM foods is relatively low and limited. Their sources of information were mostly the Internet and television programs, and the most important types of GM food products were oils, fruits and corn, rice and soy. According to the participants' views, the lack of exact determination criteria and TV advertisements are the shortcomings of information about these products. Based on the consumers' interpretation, GM foods are products that are manipulated by genes, hormonal changes, grafting and changing the molecular structure of production and have a different taste and appearance compared to normal products. **Conclusion**</str: From consumers' point of view, one way to reduce their anxiety was to have a label or clear sign based on the transgenic products in the stores so that consumers have more choice. Thus, it is concluded that proper use of the ability of the mass media, especially television, as well as suitable food labeling can contribute to this information.

Nutrition of the oysters aqua-cultured in the ecosystem of the Hiroshima Regional Urban Area

Yumiko Nitta[1], Yumiko Miki[1]

1. Hiroshima Shudo University (Japan)

Research background: Could the ecosystem including oyster culturing area produce oyster meat with higher quality, sustain better human health and improve preventive medicine? The law, *Revision of the Law Concerning Special Measures for Conservation of the Environment of the Seto Inland Sea and Modification of the Basic Plan for the Conservation of the Environment of the Seto Inland Sea* acted in 20115. Evaluation of the oysters have been performed nutritionally. **Materials and Methods:** Study areas are in the Hiroshima Regional Urban Area and Hiroshima Bay, Japan. Amino acid components in oyster meat were examined. And, two heavy metals, Cd and Zn, were measured in the marine sediments, river sediments, oyster meat, and oyster shells. **Results:** The cultured oysters contained carbohydrate and Zn with high levels. The total concentration of glucogenic amino acids was 69.6% of the total amino acid when measured by molecular volume. The sediment below oyster culturing rafts of Hiroshima Bay contained Zn and Cd: the mean value of Zn exceeded the maximum limit of sediment acceptable, and that of Cd was as high as those of 9 years ago. Commercially available oysters contained Zn in meat with as high levels as those of 50 years ago, which were as those of sediment and in shell as one tenth of the sediment. Oyster shell waste contained 0.005~0.32 mg/kg of Cd, which were as high levels as those in their meat. **Conclusion:** The fundamental solution would be to regain the sediment of lesser concentrations of Zn and Cd, which would restore the healthy Hiroshima Bay for oyster culturing, decrease viral infections through oyster meat, and conserve the ecosystem with landscape level.

Keyword: Cd, Ecosystem, Glucogenic amino acids, Oyster, Zn

Use of food additives in the Chilean food supply after the implementation of the Chilean Labeling Law, 2020

Camila Zancheta Ricardo[1], Marcela Reyes[1], Camila Corvalán[1]

1. University of Chile (Chile)

Background and objectives: The use of additives in foods and beverages has increased with the growing participation of ultra-processed products in the diet worldwide. Despite regulations to set the maximum level of additives, there is concern that the increase and combination of additives might have health consequences in the long term. In 2016, Chile implemented a food labeling policy with improvements in the concentrations of sugars, saturated fats, and sodium in the packaged food supply. However, the food reformulation could also have increased the use of food additives. This study aimed to assess the distribution of food additives in the Chilean food supply.

Methods: We conducted a descriptive cross-sectional study with data from 14,038 packaged foods and beverages sold in the six largest supermarkets in Santiago, Chile, in 2020. We searched for all additives described by the Codex Alimentarius in the list of ingredients to identify their presence and describe the number of different additives per product.

Results: More than 70% of the foods products evaluated had at least one additive. The food categories with the highest proportion of items with additives were candies and confectionary (96.5%), bread and bakery products (90.3%), and dairy products (88.8%). A large part of the products used a combination of additives (61.6%). We found an average of 4.3 food additives per product, and 40.3% of them used a mix of five or more additives. Citric acid, lecithin, potassium sorbate, and sucralose were the most used additives, observed in more than 10% of the food items. Additives that change sensory aspects of the foods, a characteristic that defines a food product as ultra-processed, were prevalent in the Chilean market (67.1% of products). Emulsifiers were in 51.1%, flavoring agents in 46.8%, and colorants in 32.0% of the evaluated foods and beverages.

Conclusions: Food additives are widespread in packaged foods and beverages sold in Chile, and an important proportion of products use a mixture of different additives. Further analyses should explore the population consumption of food additives, and evaluate its association with health outcomes, especially metabolic disorders.

Keyword: Food additives, Ultra-processed foods, Chile

Overweight/obesity, hypertension, diabetes and dyslipidaemia among adults (>=18 years) from Maharashtra State, India

Indrapal Ishwarji Meshram[1], Arlappa Nimmathota[1], Hari kumar Rachakulla[1], Sreeramakrishna Kakani[1], Laxmaiah Avula[1]

1. National Institute of Nutrition, Hyderabad (India)

Background & Objective: Nonـcommunicable diseases are the important cause of morbidity and mortality globally, The study was undertaken to assess prevalence of overweight/obesity, hypertension, diabetes and dyslipidemia among adults, **Methods**: A community-based cross-sectional study was carried out in five cities including capital city of Maharashtra as part of National survey, Information was collected on household's socio-economic & demographic particulars. Anthropometric measurements such as height (cm), weight (kg), waist and hip circumferences, blood pressure, fasting blood sugar and lipid profile were measured on all the selected adults, Association between overweight/obesity, hypertension and diabetes with socio-demographic and other variables was tested using Chi-square and logistic regression was done, Total 6,933 adults were covered from 3,526 HHs. **Results**: The prevalence of overweight/obesity (BMI≧25) was 45.6% (M:38.5%, F:51.6%), hypertension was 38.8% [M:43.4% (41.7 - 45.1), F:34.9% (33.4 - 36.4)] (age adjusted 33.9% & 28.1%), diabetes 27.4%, [M:28.4% (26.6-30.2), F:26.5%, (24.9-28.1)], (age adjusted 19.6% & 19.9%) respectively, The prevalence of pre-hypertension was 38%, (men:39.6%; women:37.3%), The prevalence of hypercholesterolemia, & hyper-triglyceridemia was 27.6% & 35.7%. About 97% were aware of hypertension, 16% had past history of hypertension and all of them were on treatment, The prevalence of hypertension was observed high among elderly (66%) as compared to 18-35 years (16%), among men (43.4% vs 34.9%), belonging to high income group (45% Vs 35.5%), hyper-cholesterolemia (50.8%), hyper-triglyceridemia (50.3%), among diabetics (60%), and among overweight/obese (49%), On step-wise logistic regression, odds of hypertension was high among overweight/obese (OR:4.05; CI=1.87-8.76), with abdominal obesity (OR:1.37; CI=1.04-1.80), among diabetics (OR:1.70; CI=1.36-2.12), and among high cholesterol (OR:1.55; CI=1.24-1.95) while, the risk of diabetes was among high income groups (OR:1.52; CI=1.15-1.99), with abdominal obesity (OR:1.51; CI=1.17-1.95), among hypertensive (OR:1.68; CI=1.34-2.10) and with high triglyceridemia (OR:2.23; CI=1.78-2.78) **Conclusions**: The prevalence of hypertension and diabetes was high and was significantly associated with per capita income, overweight/obese, abdominal obesity and hyper-cholesterolemia and triglyceridemia. There is an urgent need to strengthen ongoing national program for prevention and control of cancer, diabetes, cardiovascular diseases and stokes (NPCDCS) for early screening for diagnosis and treatment and health & nutrition education may be strengthen for prevention & control of non-communicable diseases.

PAB(T6)-201

Effect of weight loss on improving laboratory test values by using health guidance in men with metabolic syndrome

Katsushi Yoshita[1,2], Sarasa Mori[1], Mika Nakagawa[1], Atsuki Sakai[1], Miki Yanai[2], Yumi Oouchida[2], Tomoe Fukumura[1,2], Masaji Tabata[3], Tomonori Okamura[4]

1. Osaka City University (Japan), 2. Osaka Metropolitan University (Japan), 3. Ishikawa Health Service Association (Japan), 4. Keio University (Japan)

Background and purpose: We examined the effect of weight loss by improving lifestyle habits in consideration of age.

Methods: Among individuals who underwent a health checkup at a specific medical institution in 2017 and 2019, 5,747 Japanese men, aged 19–72 years (i.e., baseline), who had no medication use, pre-existing illness, or data loss were included in the analysis. Between the weight gain group (n=2,930) and the weight loss group (n=2,844) who gained weight between 2017 and 2019, and the weight loss group (n=1,112) who achieved 3% or more of the weight loss group. Abdominal circumference, blood pressure, serum lipid between the non-3% or more weight loss achieved group (n=1,732), the weight loss group of 4 kg or more (n=620) and the non-4 kg or more weight loss achieved group (n=2,224). Changes in lipid-based test values were compared.

Results: The weight loss group had an improvement in or tended to have an improvement in the levels of triglyceride, high-density lipoprotein cholesterol, and low-density lipoprotein cholesterol, and blood pressure at the endpoint, compared to the baseline values. Furthermore, among the weight loss groups, the group that achieved a weight loss of 3% or more and the group that achieved a weight loss of 4 kg or more were significantly classified into the age groups of under 40 years, 40s, 50s, and 60 years old or older. An improvement was noted. Among these individuals, the findings also clarified that the younger the age, the more remarkable was the improvement.

Conclusion: The younger the population, the stronger was the improvement in laboratory test values in association with weight loss. If a person is judged as having metabolic syndrome, based on health checkup findings, then promoting weight loss measures by improving lifestyle habits as early as possible is necessary.

Keyword: weight loss, health guidance, metabolic syndrome, Japanese men

PAB(T6)-202

Relationship between dietary patterns with subjectively measured physical activity in 85+ years older.

Tao Yu[1], Yuko Oguma[1], Keiko Asakura[2], Yukiko Abe[1], Yasumichi Arai[1]

1. Keio University (Japan), 2. Toho University (Japan)

Background and objectives: It is defined as healthy behaviors (Hbs) such as a better-quality diet and exercising regularly. HBs are associated with many health outcomes and are expected to improve quality of life and increase life expectancy. While the maintenance of HBs is essential in an aging society, the relationship between dietary patterns (DPs) and physical activity (PA) is less known. Furthermore, there is no knowledge of the relationship between the two in the population aged 85 years and older, so this study was a cross-sectional investigation of the relationship between both.

Methods: This study used baseline data from The Tokyo Oldest Old survey on Total Health (TOOTH) Study conducted in 2008 – 2009, JAPAN. The Diet survey used brief-type self-administered diet history questionnaire (BDHQ) to estimate the intake of 55 foods. After energy adjustment, principal component analysis (PCA) was performed to identify major DPs. PA was using a questionnaire that has been validated for this age group. This study used three outcomes: walking, exercise (e.g., calisthenics and resistance training), and PA index (PAI, the sum of these activities, METs*hour/week). The association between DPs and PA were examined in a general linear model, considering various confounders.

Results: A total of 519 subjects (median age: 87.3 years; male: 42.2%) were included in the analysis, excluding those with missing BDHQ. Three major DPs (DP1: various plant foods, DP2: fish and mushrooms, DP3: cooked rice and miso soup) were identified from PCA. DP1 was similar to DPs previously named "healthy" or "prudent". A positive association was observed between the trend of DP1 and higher PAI (1.41, 0.33 – 2.48 (B, 95%CI)). The results also suggested a relationship with exercise but not walking.

Conclusion: This study observed the implementation of HBs even among those aged 85 years and older, suggesting that a trend toward a healthier, more food-diverse DP is associated with higher PA. Future studies should examine the outcomes of the implementation of HBs.

PAB(T6)-203

Association between screen time, including that for smartphones, dietary habits, and overweight/obesity among children in Japan.

Izumi Ikeda[1], Kazuya Fujihara[1], Sakiko Y Morikawa[1,2], Yasunaga Takeda[1], Mayuko H Yamada[1], Chika Horikawa[1,3], Yasuhiro Matsubayashi[1], Takaho Yamada[1], Yohei Ogawa[4], Hirohito Sone[1]

1. Niigata University (Japan), 2. Tokushima Bunri University (Japan), 3. University of Niigata Prefecture (Japan), 4. Niigata University Medical and Dental Hospital (Japan)

Background and Objectives: The association between screen time (ST), including that for smartphones, and overweight/obesity in children was examined separately for boys and girls, considering the influence of lifestyle factors including diet, physical activity, and sleep time.

Methods: A cross-sectional study was conducted in 2242 Japanese children (1278 girls) aged 10-14 years. Overweight/obesity was defined by the International Obesity Task Force. Lifestyle habits such as ST, sleep time, physical activity and dietary habits were surveyed using a questionnaire.

Results: Logistic regression analysis showed that only for girls, total ST (≧4h), smartphone ST (≧3h) and non-smartphone ST (≧2h) were all independently and significantly associated with overweight/obesity compared to <2h total ST, non-use of smartphones, and <1h non-smartphone ST. The latter two were additively associated with overweight/obesity at ST ≧3h and ≧2h, respectively. In other words, girls having smartphone ST ≧3h and non-smartphone ST ≧2h were 6.80 times (95% CI: 3.11-14.84) more likely to be overweight/obesity than girls with less usage of both devices. In girls, compared to total ST <4h, smartphone ST <3h, and non-smartphone ST <2h, ≧4h, ≧3h, and ≧2h had significantly more beverage consumption and breakfast skipping in common, and the former two were significantly more likely not to eat breakfast or dinner with their families. In addition, none of these associations were significant in boys.

Conclusions: In Japanese girls, smartphone ST, non-smartphone ST, and total ST were all significantly associated with overweight/obesity. In addition, those with shorter ST had fewer dietary habits that could contribute to overweight/obesity. To avoid overweight/obesity, it is suggested to keep smartphone ST, non-smartphone ST, and total ST to <3h, <2h, and <4h.

Biofortification scale-up as a strategy to mitigate food shortages and increase nutrient intake during COVID-19 in a maternal and child health and nutrition program in Bangladesh, Kenya, Myanmar and Tanzania.

Asrat Dibaba Tolossa[1]

1. World Vision Canada (Canada)

Background and Objectives: ENRICH-MNCH project targeted 4.1 million individuals including 1.8 million women and adolescent girls 10-49 years, through gender-responsive efforts to slow and contain the spread of COVID-19 while mitigating aftershocks and secondary nutrition, health and social impacts in the target areas of Bangladesh, Kenya and Tanzania. The project scaled up the ongoing biofortification promotion to address food shortages and inadequate nutrient intake exacerbated by the COVID-19 pandemic. The initiative also complemented the Ministry of Health and other line ministries'COVID-19 preparedness activities, including stockpiling of the necessary medicine, equipment and supplies, orientation, and training of health workers, identifying isolation facilities, conducting community sensitization and engagement, strengthening of national and regional laboratories, infection prevention and control, and surveillance in the communities.

Methods: The project strengthened community-based social services and structures to minimize the gendered impact of the pandemic on nutrition and health systems, social services, and economic activity, particularly for women and girls.

Results: Biofortified crops were promoted in in the target countries with support from HarvestPlus and local organizations. In Bangladesh, five varieties of zinc-fortified rice were introduced through 6,155 demonstration plots and 581 farmers received training. Due to COVID-19 public health measures, small neighbourhood meetings were used to reach farmers. The project distributed 427.9 metric tonnes of zinc rice seeds to 115,774 families in Bangladesh. In Kenya 70 metric tons of seeds of high-iron beans was distributed to households with children under two years of age. In Tanzania, 10 million Orange Fleshed Sweet Potato (OFSP) vines of were distributed to households with pregnant women and children under two years of age. Overall, 41,087 families were reached with beans while 24,976 were reached with OFSP in Kenya, and 23, 476 families were reached with OFSP in Tanzania.

Conclusion: Promotion of biofortified crops is one of the strategies which can be scaled up to address food shortages and inadequate nutrient intake during emergency situations.

Reducing red meat consumption for climate mitigation: is the US population making the cut?

Shauna Downs[1], Joachim Sackey[2], Yanhong Jin[3], Elizabeth Fox[4], Rebecca McLaren[5], Jessica Fanzo[5]

1. Rutgers School of Public Health (USA), 2. Rutgers School of Health Professions (USA), 3. Rutgers School of Environmental and Biological Sciences (USA), 4. Cornell University College of Veterinary Medicine (USA), 5. Johns Hopkins Berman Institute of Bioethics (USA)

Background and objectives: Reducing meat consumption was identified in the Intergovernmental Panel on Climate Change Sixth Assessment Report as a key response option for climate change mitigation, given its high environmental footprint. The US has among the highest meat intakes globally. Reducing red meat consumption should be a priority in the US, yet little is known about what influences people to consume less. The objective of this study was to examine factors that influence consumers to shift red meat consumption in the US.

Methods: We conducted an online survey (n=1224) in July-September 2021 with a representative sample of the US population. The survey included questions about socio-demographics, frequency of both unprocessed and processed red meat consumption in past 7 days and changes to red meat consumption patterns over the previous year. Participants who reported reducing their meat consumption were asked to identify factors that influenced those changes. We report multivariable binary logistic regression results about unprocessed/processed red meat consumption and utilized survey weights to represent the US population.

Results: Most participants reported consuming red meat (78% unprocessed; 74% processed) 1-4 times per week. Overall, 68% of participants reduced consumption of unprocessed, and 62% reduced consumption of processed, red meat. Twenty-seven percent of participants ≧65 years were unprocessed/processed red meat reducers, as compared to 5-6% of participants 18-24 years old. Participants who did not report eating red unprocessed/processed meat at all and those consuming unprocessed meat 1-4 times in the past 7 days had higher odds of being meat reducers compared to those consuming unprocessed/processed red meat ≧5 times in past 7 days. Health was the most identified factor influencing red meat reduction (66% unprocessed; 63% processed), followed by price (32% unprocessed; 23% processed). Only 6% reported reducing unprocessed/processed red meat due to environmental sustainability concerns.

Conclusions: Our findings suggest that a significant proportion of the US population may be reducing their red meat consumption but that it is primarily driven by health rather than environmental concerns. Emphasizing the health aspects of red meat reduction among the US population may increase the likelihood of shifting food choices towards more sustainable diets.

Regional difference in effect of food store accessibility on vegetable and fruit acquisition and healthy eating behaviors for older adults

Seulgi Lee[1], Dong Eun Lee[1], Jisoo Hong[1], Kirang Kim[1]

1. Dankook University (Korea)

Background and objectives: Since the regional contextual environment of urban and rural areas is different, the effect of the food environment in these areas on dietary intakes would be different. This study aimed to examine whether accessibility-based food environmental factors influence on vegetable and fruit acquisition and healthy eating behaviors in different areas, using a nation-wide data set.

Methods: This study is based on the data from the 2019 Consumer Behavior Survey for Food (CBSF) provided by the Korea Rural Economic Institute (KREI). The subject is older adults aged ≧ 65 years (n 830) who participated in the CBSF. Food environment was assessed by perceived food store accessiblity questionnaires. The vegetable and fruit acquisition included frequency of daily purchases and non-purchased sources and healthy eating behaviors were evaluated by three items of moderation, variety and eating healthy foods. **Results:** Insufficient food store accessibility was related to low vegetable and furit acquisition and poor healhty eatign behvaiors. Amogn food store accessibility, specifically, rural older adults who perceived insufficient physical accessibility were more likely to have low vegetable and furit acquisition (OR: 2.34 95% CI: 1.27-4.32 for vegetable and 1.96, 95% CI: 1.02-3.75 for fruit). OR: 2.34 95% CI: 1.27-4.32). For those who perceived that only one of the two accessibility is insufficient, the urban older adults were less likely to have various and healthy food eating when they perceive insufficient economical accessibility acquisition (OR: 0.47, 95% CI: 0.25-0.90 for variety and 0.23, 95% CI: 0.11-0.46 for eating healthy foods) but rural older adults were less likely to have when they perceive insufficient physical accessibility (OR: 0.49, 95% CI: 0.21-0.97 for variety and 0.28, 95% CI: 0.13-0.63 for eating healthy foods).

Conclusions: The food store accessibility environment affected healthy food acquisition and healthy eating behaviors in older adults. The dimentsion of food store accessibility that affected food acquisition and eating behaviors was different by region.

Keyword: Food store accessibility, Region, Vegetable and fruit acquisition, healthy eating behavior, Older adults

Access to sufficient and safe drinking water and health outcomes in Ghana: Results from UNICEF-MICS6 survey

Jigna Morarji Dharod[1], Seth Armah[1], Carole Debora Nounkeu[2], Husein Mohammed[3]

1. University of North Carolina-Greensboro (USA), 2. Limbe Regional Hospital (Cameroon), 3. University of Ghana (Ghana)

Background and objectives: Water is an essential nutrient. It is also a critical component in maintaining food production, access, and utilization. However, according to the WHO/UNICEF 2021 report, about 2 billion people globally lack access to safe drinking water. Most of these people are living in Sub-Sharan Africa and Asia. Ghana has made significant progress in expanding water services, but still a significant proportion of the country's population use unimproved drinking water source. Hence the objectives of this study were to 1) Examine sociodemographic predictors of drinking water quality in rural and urban households, and; 2) Determine the relationship between water quality and incidence of diarrhea among u children.

Methods: A secondary data analysis was carried out using the Ghana UNICEF-MICS6 survey. Data were analyzed using R software. The survey package in R took into consideration the strata, principal sampling units, and sampling weights. Bivariate and multivariate analyses were carried out using the statistical significance of $p \leq .05$.

Results: Among the 12,886 households interviewed, 88.4% used improved source of drinking water including piped water, tube well or borehole and packaged/delivered water. Contamination of drinking water with *Escherichia coli* (*E. coli*) was significantly higher among rural compared to urban households irrespective of the source of water (improved vs unimproved, β±SE: 6.1±2.3, p = 0.008). By wealth index, the highest quintile households were associated with lower *E. coli* count in drinking water compared to the poorest quintile (β ± SE: -9.3±4.4, p = 0.03). After controlling for potential cofounding variables, child diarrhea incidence was predicted by maternal/caretaker education and age of child, but not water quality.

Conclusions: In Ghana, rural and poor households are significantly affected by poor water quality. In future, an in-depth investigation on water fetching, storage, handling and frequency of hand washing, and sanitation services is warranted to examine pathways through which fecal contamination is likely to occur and what behavior change and interventions are critical to meet the SDG 6 target of ensuring safe and clean drinking water at the household level.

PAB(T6)-208

The association of sunlight exposure with sleep quality among pregnant women in Kuala Lumpur, Malaysia.

Ee Yin Kok[1], Wan Ling Chew[1], Satvinder Kaur[1]

1. UCSI University (Malaysia)

Background and objectives: Sleep quality deteriorates during pregnancy due to physical and hormonal changes in the body. Previous studies have found that sunlight exposure is beneficial for emotional wellbeing and sleep health. This study aims to determine the role of sunlight exposure on sleep quality of pregnant women in Kuala Lumpur.

Methods: This cross-sectional study was conducted in 9 randomly selected government maternity clinics in Kuala Lumpur. Healthy women aged 19-39 with single pregnancy were recruited using convenience sampling. The participants were required to wear a UVB dosimeter pinned on their shoulders for 2 weekdays and 1 weekend day to determine sunlight exposure. Sunlight exposure was expressed in standard erythemal dose (SED). Sleep quality was self-reported using the Pittsburgh Sleep Quality Index (PSQI).

Results: A total of 86 pregnant women participated in this study with average age of 27.74 ± 3.17 years. The total SED was 0.04 (IQR=0.10). Prevalence of participants with poor sleep quality was 62%, with mean sleep duration of 6h 56m ± 1h 33m. Sunlight exposure was negatively correlated with global PSQI scores (ρ=-0.311 p=0.004), subjective sleep quality (ρ=-0.256, p=0.017), sleep latency (ρ=-0.258, p=0.017) and sleep disturbance (ρ=-0.247, p=0.022). Adjusted multiple linear regression revealed that higher sunlight exposure was associated with good sleep quality (β= -0.332, p=0.003), higher subjective sleep quality (β= -0.297, p=0.009), and lower sleep latency (β= -0.232, p=0.039).

Conclusion: From this study, participants who had low sunlight exposure were found to have poor sleep quality. Sunlight exposure is closely related to sleep quality during pregnancy. The study findings may act as a guide for future interventional studies to improve sleep quality among pregnant women by controlling sunlight exposure for favourable mother and infant health outcomes.

Keyword: Sunlight exposure, Sleep quality, Pregnancy, Sleep duration, UVB light

PAB(T6)-209
Spatial Distribution and Correlates of Child Nutrition in Gujarat, India

Suneeta Chandorkar[1], Surabhi Pareek[1], Payal Meghani

1. The M. S. University of Baroda (India)

Background and Objectives- Although the recently released National Family Health Survey -5 (NFHS-5, 2019-2020) data show a significant improvement in maternal nutrition and health indicators, India continues to suffer from a high prevalence of child undernutrition. Gujarat is a progressive state, but its maternal and child nutrition and health indicators are poor. The goal of this study was to look at spatial heterogeneity, factor clustering associated with maternal, and child health indicators at the district level in Gujarat, India. **Methodology** - Secondary source data on child undernutrition indicators and associated maternal factors were used at the district level from NFHS 4 (2015-16) and NFHS 5 (2019-2020). Spatial thematic mapping in Arc GIS was used to map the spatial distribution of indices from 2015-16 to 2019-2020. To investigate the factors associated with these indices, Pearson's Correlation Model was used. **Results** - The findings indicate that districts in the north-western geographical region have improved maternal indicators such as antenatal care (ANC), whereas districts in central Gujarat experienced decline or stagnation. Institutional births increased significantly in almost all regions of Gujarat, except for Dangs, a tribal district. The prevalence of diarrhea and acute respiratory infection have shown a marginal decrease. The western region made strides in terms of breastfeeding initiation. Prevalence of stunting, wasting, and being underweight among children under the age of five has remained unchanged in Gujarat from 2015-to 16. The prevalence of wasting, underweight, and anemia in children (6-59 months) increased in the northeastern districts. The Geographically Weighted Regression shows a significant association between female literacy, women's nutritional status (low BMI, overweight/obesity), maternal anemia, sanitation and drinking water sources, institutional births, and antenatal care with undernutrition in children (6-59 months). The weighted sum analysis identified clusters with a high burden of undernutrition in the southeast region and clusters with a low burden in the northwest region of the state.

Conclusion- Spatially targeted District level strategies to improve literacy among women, reduce maternal under-nutrition and anemia, and promote sanitation and hygiene will improve the maternal and child health indicators in high burden districts of Gujarat.

PAB(T6)-210
Association of spot urine sodium-to-potassium ratio with dietary salt and intake of vegetables in male Japanese bus drivers

Tomoe Fukumura[1], Megumi Okabayashi[1], Katsushi Yoshita[1], Masaji Tabata[2]

1. Osaka City University Graduate School of Human Life Science (Japan), 2. Ishikawa Health Service Association (Japan)

Background and objectives: The aim of this study was to examine the association of the spot urine sodium-to-potassium (Na⁄K) ratio with dietary salt and intake of vegetables in male Japanese bus drivers.

Methods: A cross-sectional study was performed in 492 male Japanese bus drivers (19-70 years old) working at a transportation company in Ishikawa Prefecture. The 24-h urinary Na⁄K ratio was estimated from a formula using collected spot urine. A self-administered questionnaire was used to assess daily intake of vegetables and a salt check sheet was developed by Tsuchihashi et al. during health examinations in the summer of 2020. The participants were grouped into four categories based on their 24-h urinary Na⁄K ratio: Group I, n=73, <3; Group II, n=218, ≧3 to <4; Group III, n=146, ≧4 to <5; and Group IV, n=55, ≧5. Associations of laboratory test results, health-related behaviors, and dietary salt and vegetable intake with the four 24-h urinary Na⁄K ratio categories were examined. This study was approved by the ethics committee of Osaka City University Graduate School of Human Life Science.

Results: There were no significant differences (at the 5% level) in age, height, body weight, and diastolic blood pressure among the groups. In the JSH2019 blood pressure classification, the percentage of participants with high blood pressure, including those taking medication, was highest in Group IV, although this difference was not significant. The estimated 24-h urinary sodium and salt excretion and the salt check sheet score were significantly higher and the estimated 24-h urinary potassium excretion was significantly lower in Group IV compared to the other three groups. Daily intake of vegetables did not differ significantly among the groups, but was significantly higher at dinner than at breakfast and lunch.

Conclusions: These results indicate that a high urinary Na⁄K ratio has a high risk of hypertension. This suggests that there is a need to provide dietary guidance to increase vegetable intake while reducing salt.

Keyword: spot urine Na/K ratio, vegetables, salt

PAB(T6)-211
Examination of the relationship between abdominal circumference and BMI in Japanese women

Mika Nakagawa[1], Katsushi Yoshita[1], Atsuki Sakai[1], Eri Uezu[2], Miki Yanai[2], Yumi Oouchida[2], Tomoe Fukumura[1], Masaji Tabata[3], Tomonori Okamura[4]

1. Osaka City University (Japan), 2. Osaka Metropolitan University (Japan), 3. Ishikawa Health Service Association (Japan), 4. Keio University (Japan)

Background and Purpose: In Japan, medical checkups focusing on metabolic syndrome are conducted. The standard for women uniformly is an abdominal circumference of ≧90 cm or a body mass index (BMI) of ≧25 kg/m². We examined the relationship between abdominal circumference and BMI in Japanese women, based on age group and height group.

Methods: The study participants were 28,598 women, aged 30-59 years, who had undergone a medical examination in 2019, were not on medication, and did not have a medical history or missing data. Using the values of abdominal circumference, height, and BMI, the patients were classified according to age group and height group. The criteria for abdominal circumference was <90 cm or ≧90 cm and the criteria for BMI was <25 kg/m² or ≧25 kg/m². Height was classified into four groups: <150 cm, ≧150 and <160 cm, ≧160 cm and <170 cm, and ≧170 cm.

Results: At all ages, the percentage of women with an abdominal girth of ≧90 cm tended to increase with increasing height group. The percentage of women with an abdominal girth of ≧90 cm and a BMI of ≧25 kg/m² similarly increased with a marked increase among women in their 50s. However, the percentage of women with an abdominal circumference of <90 cm and a BMI of ≧25 kg/m² decreased. Among women in their 30s and 40s, the percentage of women with an abdominal circumference of <90 cm and a BMI of <25 kg/m² increased with increasing height. Furthermore, even within the same height group, the proportion of women with an abdominal girth of ≧90 cm increased with increasing age.

Conclusion: The relationship between abdominal circumference and BMI, based on height, was similar in all age groups but was more pronounced in women in their 50s. When Japanese women age from their 40s to their 50s, clinicians and dietitians should be aware that abdominal circumference and BMI increase rapidly, especially among women whose height is ≧170 cm.

Keyword: Japanese women, medical checkup, abdominal circumference, BMI

PAB(T6)-212
Nutrient Profiling and Environmental-Impact Profiling in Processed Food Products: An exploratory analysis of Nutri-Score, Thailand Healthier Choice and Eco-Score

Hung Nguyen Ngoc[1], Wantanee Kriengsinyos[1]

1. Mahidol University (Thailand)

Background and objectives: The sustainability of food systems turns out to be a highly critical question with various nutritional and environmental challenges. Regarding food and nutrition, nutrient profiling for front-of-pack (FOP) nutritional labeling aims to classify food healthiness by its nutrient composition. Besides, environmental-impact profiling purposes to capture and differentiate the environment-friendliness by the environmental footprint of food products. This study aims to investigate the association between nutrient profiling (as assessed by Nutri-Score and Thailand Healthier Choice) and environmental-impact profiling (as assessed by Eco-Score) in processed food products.

Methods: The database was obtained from the Open Food Facts database. The ultimate of 84,455 processed food products were incorporated into this investigation. 'Healthier' and 'Less healthy' products were independently analyzed by the algorithm of Nutri-Score and THCL. Especially, 'Healthier' products were interpreted as receiving grade A, B, and C (by Nutri-Score) or passing the nutrient threshold of saturated fatty acids, trans-fatty acids, sodium, sugars, energy, and fiber (by Thailand Healthier Choice), whereas 'Less healthy' items were defined of carrying Nutri-Score grade D and E or disqualified with the THCL nutrient criteria. Eco-Score points for each food were computed with a Life Cycle Assessment and were available in the database. The association and relationship between the two systems was carried out using Mann-Whitney tests and simple correspondence analysis appropriately.

Results: The majority of surveyed products had an Eco-Score of grade D (37.2%), followed by grade B (27.4%), and grade C (23.3%). The median and interquartile of Eco-Score points in investigated products were 41.0 (31.0-62.0). 'Healthier' products classified by both Nutri-Score and Thailand Healthier Choice criteria were significantly associated with a lower environmental footprint ($p<0.001$), rating ranging from 44 to 54% in Eco-Score category B, 21 to 26% in category C, and 26 to 30% in category D depend on the distinct scheme.

Conclusions: Among our investigated products, 'Healthier' products classified by either Nutri-Score or Thailand Healthier Choice nutrition labeling scheme presented a lower environmental footprint, compared to less healthy items. This exploratory study highlights the need for further studies and focuses on the evaluation of the sustainability of FOP nutrition labeling as well as the industrial food system in order to achieve a win-win solution in environmental and nutritional improvements.

Quality of Beverage Intake and Cardiometabolic and Kidney Outcomes: Insights From the STANISLAS Cohort

Sandra Wagner[1], Thomas Merkling[1], Nicolas Girerd[1], Axelle Hoge[3], Michèle Guillaume[3], Simon N Thornton[4], Jean-Marc Boivin[1], Martine Laville[2], Patrick Rossignol[1], Julie-Anne Nazare[2]

1. University of Lorraine, INSERM CIC 1433, Nancy CHRU, Inserm U1116, FCRIN INI-CRCT (France), 2. Centre de Recherche en Nutrition Humaine Rhône-Alpes, Univ-Lyon, CarMeN Laboratory, Université Claude Bernard Lyon1, Hospices Civils de Lyon, F-CRIN/FORCE Network (France), 3. Département des Sciences de la Santé Publique, Université de Liège (Belgium), 4. Université de Lorraine, Inserm, DCAC (France)

Background and Aims: Beverages are an important aspect of diet, and their quality can possibly affect health. The Healthy Beverage Index (HBI) has been developed to take into account these effects. This study aimed to highlight the relationships between health and beverage quality by assessing the association of the HBI and its components with kidney and cardiometabolic (CM) outcomes in an initially healthy population-based familial cohort.

Methods: This study included 1,271 participants from the STANISLAS cohort. The HBI, which includes 10 components of habitual beverage consumption, was calculated. Associations of the HBI and its components with estimated glomerular filtration rate (eGFR), albuminuria, hypertriglyceridemic waist (HTG waist), metabolic syndrome (MetS), carotid-femoral pulse wave velocity (cfPWV), carotid intima-media thickness (cIMT), and left ventricular mass (LV mass) were analyzed using multivariable linear or logistic regression models.

Results: The median HBI score was 89.7 (78.6–95) out of 100 points. While the overall HBI score was not significantly associated with any of the studied outcomes, individual HBI components were found differently associated with the outcomes. cfPWV and cIMT were lower in participants who did not meet the full-fat milk criteria (p = 0.03 and 0.001, respectively). In men, higher cfPWV was observed for the "low Fat milk" (p = 0.06) and "alcohol" (p = 0.03) non-adherence criteria. Odds of HTG waist were higher with the non-adherence to sugar-sweetened beverages criteria (p < 0.001). eGFR was marginally higher with non-adherence to the coffee/tea criteria (p = 0.047).

Conclusions: In this initially healthy population, HBI components were differently associated with kidney and cardiometabolic outcomes, despite a good overall HBI score. Our results highlight specific impacts of different beverage types and suggest that beverages could have an impact on kidney and cardiometabolic health

Association of Dietary Na/K Ratio with Intake of Nutrients in Japanese Children Aged 3-5 Years Old

Eri Uezu[1], Tatsuya Koyama[2], Ruriko Sasaki[3], Hiromi Ishida[4], Katsushi Yoshita[1]

1. Osaka Metropolitan University (Japan), 2. Aomori University of Health and Welfare (Japan), 3. Miyagi Gakuin Women's University (Japan), 4. Kagawa Nutrition University (Japan)

Background and Objectives: Several studies in Japanese adults have suggested that a high dietary Na/K ratio increases the prevalence of stroke. However, there have been few reports of the dietary Na/K ratio in Japanese children. The aim of this study was to examine the association of dietary Na/K ratio (high or low) with the intake of energy and nutrients in Japanese children. **Methods:** The participants were 225 Japanese nursery school children (126 boys, 99 girls; age 3-6 years). A dietary survey was conducted over three non-consecutive days comprising two days with a school lunch (i.e., weekdays) and one day without a school lunch (i.e., a holiday) in each season (i.e., 12 days in total in one year) using the semi-weighted dietary record method. Participants were divided into groups based on their Na/K ratio (high or low, using the median as a cutoff), with different pairs of groups established based on gender and for weekdays and holidays. Intake of energy and nutrients were compared in these groups. **Results:** For boys, the mean Na/K ratios in the low and high groups were 2.08 and 2.84 on weekdays, and 2.36 and 3.55 on holidays, respectively. The low group had significantly higher mean intake of energy, protein, calcium, iron, vitamin B_1 and dietary fiber on weekdays, and of vitamin A and vitamin C on holidays. For girls, the mean Na/K ratios in the low and high groups were 1.99 and 2.82 on weekdays, and 2.15 and 3.30 on holidays, respectively. The low group had significantly higher mean intake of energy, carbohydrates, calcium, vitamin A, vitamin B_1, vitamin B_2, vitamin C and dietary fiber on weekdays, and of calcium, vitamin A, vitamin C and dietary fiber on holidays. **Conclusions:** Children with a lower Na/K ratio generally had significantly higher intake of vitamins and minerals. These findings suggest that maintenance of a low dietary Na/K ratio leads to desirable nutrient intake.

Keyword: Na/K ratio, nursery, Japanese children, dietary survey

PAB(T6)-215

Cardiometabolic risk of women caregivers living in fishing communities along the four coastal regions of Ghana.

Richard Stephen Ansong[1], Marian Kjellevold[2], Agartha Ohemeng[1], Matilda Steiner Asiedu[1]

1. University of Ghana (Ghana), 2. Institute of Marine Research (Norway)

Background and Objectives: Cardiovascular disease and diabetes continue to increase globally. This study assessed the cardiometabolic risk of caregivers living along the four coastal regions (Greater Accra (GAR), Volta (VR), Central (CR), and Western (WR)) of Ghana using simple anthropometric and body composition indicators.

Methods: 1120 women caregivers between 15 and 49 years were recruited from 16 communities (4 per region). Anthropometric measures of height, weight, hip, and waist circumference (WC) were obtained and used to determine body mass index (BMI), waist to hip ratio (WHR), and waist to height ratio (WHtR). Percent body fat (PBF), visceral fat (VF), skeletal muscle (SM), and resting metabolism (RM) were determined using a body composition scale. All measures and indicators were compared across regions at a significance level of $p < 0.05$.

Results: 1001 caregivers completed the assessment. Significant differences were observed across regions for WC, BMI, PBF, VF, SM, WHR and WHtR. Many caregivers were at an *increased risk of metabolic complication* (WC > 0.80) – GAR=73.1%, VR= 71.5%, CR= 64.3%, WR= 64.6%. Whereas majority had a *substantially increased risk* of cardiovascular disease (CVD) and diabetes, (WHR > 0.85) – GAR= 63.8%, VR= 57.0%, CR= 51.4%, WR= 54.8%, more than a third had an *increased risk* (WHtR ≧ 0.5 and < 0.6) – GAR= 43.8%, VR= 46.8%, CR= 51.4%, WR= 54.8%. Over a third had a *normal* BMI (BMI ≧ 18.5 and ≦ 24.9kg/m^2) – GAR=38.8%; VR= 46.4%, CR= 47.8%, WR= 41.4%. However, a large majority had a *normal* VF (VF ≦ 9%) – GAR= 82.7%, VR= 85.5%, CR= 96.1%, WR= 94.1%.

Conclusions: Most caregivers living in fishing communities along the four coastal regions of Ghana were at risk of cardiovascular diseases and diabetes. Culturally appropriate interventions are required to reduce cardiometabolic health risks and improve quality of life.

Skin carotenoid levels and metabolic syndrome in a general Japanese population: the Hisayama Study

Yasumi Kimura[1,2], Jun Hata[2], Takanori Honda[2], Mao Shibata[2], Satoko Sakata[2] , Yoshihiko Furuta[2], Toshiharu Ninomiya[2]

1. Hiroshima Shudo University (Japan), 2. Kyushu University (Japan)

Background and objectives: A higher vegetable intake is being promoted as an initiative to prevent lifestyle-related diseases such as obesity and metabolic syndrome. Carotenoids are yellow or red pigment components and are widely present in plants, mainly included in vegetables. Since ingested carotenoids accumulate in the skin, skin carotenoid levels are a good indicator of vegetable intake. Recently, a non-invasive optical sensor for assessing skin carotenoid levels has been developed and its measured values have been verified to be highly correlated with serum carotenoid levels. Herein, we examined the association of skin carotenoid levels estimated by the noninvasive optical sensor with the presence of metabolic syndrome.

Methods: A total of 1,619 individuals (604 men and 1,015 women) aged ≧40 years (mean age 63.1 years) participated in the study. Skin carotenoid levels were measured by the optical sensor based on multiple spatially resolved reflectance spectroscopy. The definition of metabolic syndrome was based on the Joint Scientific Statement by six international scientific societies (Alberti KG, et al. Circulation. 2009;120:1640-1645). The multivariable-adjusted logistic regression models were used to analyze cross-sectional association between skin carotenoid level and the presence of metabolic syndrome.

Results: The prevalence of metabolic syndrome was 31.3 % (n = 506). Higher skin carotenoid levels were associated remarkably with lower likelihood of metabolic syndrome after adjusting for confounders (*P*-trend <0.001). Multivariable-adjusted odds ratio for the presence of metabolic syndrome in individuals with the highest quartile of skin carotenoid level was 0.39 (95 % confidence intervals 0.28-0.55) compared to those with the lowest quartile. With regard to each component of metabolic syndrome, the odds ratios for the presence of abdominal obesity, hypertriglyceridemia, elevated blood pressure, elevated blood glucose decreased significantly with higher levels of skin carotenoids (all *P*-trend <0.001).

Conclusions: Our findings suggest that higher skin carotenoid levels are significantly associated with lower likelihood of metabolic syndrome and its components in a general Japanese population. Skin carotenoid levels estimated by the noninvasive optical sensor may be useful in the assessment of the daily vegetable intakes and the dietary guidance for individuals to prevent metabolic syndrome.

Keyword: skin carotenoids, metabolic syndrome, non-invasive measurement, cross-sectional study, vegetable intake

Barrners and enablers to healthy and sustainable food systems in Ethiopia: Qualitative study

Samson Gebremedhin Gebreselassie[1], Seifu Hagos Gebreyesus[1], Fikadu Reta Alemayehu[2], Alemtsehay Sergawi[3], Mesret Zelalem Tadesse[4]

1. Addis Ababa University (Ethiopia), 2. Hawassa University (Ethiopia), 3. Ministry of Agriculture (Ethiopia), 4. Ministry of Health (Ethiopia)

Background and objective: Healthy and sustainable food systems is indispensable for combating the triple burden of malnutrition. Without improving the food systems, the efforts to control multiple forms of malnutrition would be undermined. The purpose of this study is to identify the barriers and enablers for healthy and sustainable food systems in Ethiopia.

Methods: A qualitative study was used to explore the barriers and enablers of various sub-components of the food systems. The study was designed in such a way that the perspectives of rural and urban dwellers and agrarian and pastoral livelihoods of Ethiopia are represented. The study captured the views federal and regional level informants as well. Data were gathered through Focus group discussions (FGDs) and key informant interview (KIIs). More than 60 KIIs with decision makers, researchers and academicians were conducted. Twelve FGDs were organized with urban consumers, farmers, youth and women's group.

Results: The major enable to the national food systems is the presence of comprehensive policy environment. Nutrition is also enjoying increasing attention by various stakeholders. Currently multisectoral nutrition interventions including Nutrition Sensitive Agriculture and social protection programs are being implemented at scale. The government has adopted promising strategic directions, including cluster farming and lowland wheat initiative for boosting production. The Integrated Agro-industrial Parks initiative helps to modernize the value chain and reduce food loss. Presence of the Health Extension Program platform offers a special opportunity for promoting nutrition literacy and implementing nutrition programs at grassroots level. However, the food systems is constrained by multiple barriers including: lack of political stability, uncontrolled population growth, subsistence rain-fed agriculture, lack of support to large-scale farming, weak agricultural cooperatives, uncontrolled food price, uncontrolled export of healthy foods, food safety irregularities, low nutrition literacy, and demotivation of frontline health and agriculture workers.

Conclusion: Efforts to transform the agriculture system must be accelerated. Supporting large-scale farming and scaling up initiatives of cluster and market-led farming, and lowland wheat production should be maintained. However, the initiatives need to mainstream production diversification as well. Building agricultural cooperatives' capacity, directly linking them with consumer cooperatives, and strengthening Consumer Protection Agency, are vital.

"Smart meal" certification of employee canteens under the Healthy Meal and Food Environment Certification System for the promotion of Health and Productivity Management

Junko Tamaru[1], Akiko Kuwabara[2], Tomoko Koda[3], Takako Takahashi[2], Tadashi Akao[4], Jun Uda[5], Yoko Ichikawa[6]

1. Kobe Gakuin University (Japan), 2. Osaka Metropolitan University (Japan), 3. Doshisha Women's College of Liberal Arts (Japan), 4. Osaka Shoin Women's University (Japan), 5. Jikei University of Health Care Sciences (Japan), 6. University of Shizuoka (Japan)

Background and objectives: The Healthy Meal and Food Environment (HMFE) Certification System that was launched in 2017 certifies restaurants and food service facilities that provide well-balanced meals (smart meals (SM)) and environments that are beneficial for employee health. In workplaces, certification is awarded as part of a Health and Productivity Management initiative. This study examined the SM certification status of employee cafeterias and clarified future challenges. Methods: Of the 386 offices that received SM certification (i.e., 5th certification) by 2021, consent to participate in this study was received from 361 (93.5%). The items considered included: number of meals during lunch (NM): number of SM provided (SM-P); certification status of optional items (OPTN), i.e., development of SM (D-SM) and promotion of a food environment (P-FE); and availability of registered dietitians (RD) and dietitians in the employee canteen. The SM provision rate (SM-PR) was calculated by dividing the SM-P by the NM. Results: The median NM in the analyzed facilities was 300 (25^{th} and 75^{th} percentiles: 125, 650) and the median SM-PR was 0.14 (0.07, 0.25). The percentage of canteens with an assigned RD was 47.6%, and no differences were observed according to the level of certification. However, the percentage of dietitians assigned in the first year (31.2%) increased to 50.0% by the fifth level of certification (chi-squared test, $p < 0.05$). Of 18 possible OPTNs, less than five were available at numerous facilities with level 1 and 2 certification, but more than five OPTNs were available at canteens with level 3 certification (2019; chi-squared test, $p < 0.05$). High mean OPTN percentages at canteens with level 5 certification were attributed to cereals (69.0%), nutritional information labels (energy, protein, fat, carbohydrates and salt equivalent) under D-SM (88.7%), reduced-salt seasoning (73.3%), not placing seasoning on tables (65.4%), and holding regular meetings as part of P-FE (70.7%). Conclusions: Office lunches are important tool for promoting employee health. However, relatively few offices are SM certified and the SM-PR is only about 10%. Future challenges to promoting employee health involve popularizing SM and increasing the quality of HMFE by increasing the percentage of optional items certified.

PAB(T6)-219

An economic analysis of food consumption and implications for the transition to sustainable diets in Ireland

Laura B. Kirwan[1], Janette Walton[2], Albert Flynn[3], Anne P. Nugent[1,4], John Kearney[5], Breige A. McNulty[1]

1. University College Dublin (Ireland), 2. Munster Technological University (Ireland), 3. University College Cork (Ireland), 4. Queens University Belfast (UK), 5. Technological University Dublin (Ireland)

Background and objectives: Food security and dietary cost has become a prominent focus of public health in recent years. Equity and nutrition security are considered central to a sustainable food systems transformation. However, research on dietary costs is limited, and an improved understanding of the economic impact of dietary changes has been identified as necessary to a transition to more sustainable diets. The objective of this analysis was to quantify the cost of diets reported in the Irish food consumption surveys and to investigate the relationship between dietary expenditure, food intake, demographic, and environmental factors. **Methods:** Diets reported in the National Adult Nutrition Survey (NANS; 2008–2010), National Teens Food Survey II (NTFSII; 2019–2020) and National Children's Food Survey II (NCFSII; 2017–2018) were analysed with under-reporters removed. A national food price database was compiled for 6,251 food codes and multiplied by consumed amounts. Diet quality was assessed using five diet quality indices and environmental impact was assessed using data on blue water use, GHGe, cropland, nitrogen, and phosphorous use. Multiple linear regressions, Spearmann correlations, ANOVAs with Bonferroni corrections and principal component analyses were used to evaluate dietary expenditure against additional factors. All analyses were completed using RStudio software (version 4.1.1). **Results:** Median daily expenditure was €4.07 (range €2.58 - €6.37) for children, €4.29 (range €2.65 - €7.34) for teenagers and €7.29 (range €3.57 - €21.18) for adults. Higher dietary expenditure was significantly associated with males across all population groups, a higher educational status and a more urban location in children and adults; higher social class in teenagers and; a higher BMI in children. Contribution of foods to dietary expenditure differed between population groups, however 'meat and alternatives'; 'eggs, dairy, and alternatives'; and 'starchy staples' constituted almost half of all dietary expenditure for all groups. Healthier and less sustainable diets were associated with a higher dietary cost. **Conclusions:** Dietary expenditure is relative to life stage, and influencing factors are inconsistent across population groups. Future interventions and policies should be socially inclusive by considering factors such as socio-economic status, and while healthier diets are more expensive, a transition to sustainable diets may reduce dietary cost.

Keyword: Sustainability, Food Consumption, Dietary Cost, Food Security, Sustainable Diets

Alkaline Water Improves Sleep Quality, Muscle Strength and Selected Metabolic Risks Among Postmenopausal Women in Malaysia

Yoke Mun Chan[1], Zalilah Mohd Shariff[1], Yit Siew Chin[1], Sazlina Shariff Ghazali[1], Ping Yein Lee[1], Kai Sze Chan[1], Poh Ying Lim[1]

1. Universiti Putra Malaysia (Malaysia)

Background and Objectives: Much have been claimed on the health benefits of alkaline water including metabolic syndrome (MetS) and its features with scarcity of scientific evidence. This cross-sectional comparative study was conducted to determine whether regular consumption of alkaline water confers health advantage on blood metabolites, anthropometric measures, sleep quality and muscle strength among postmenopausal women in Malaysia.

Methods: A total of 304 community-dwelling postmenopausal women were recruited with comparable proportion of regular drinkers of alkaline water and non-drinkers. Participants were ascertained on dietary intake, lifestyle factors, anthropometric and biochemical measurements. Multivariate analysis of covariance (MANCOVA) was performed to determine whether alkaline water consumption augments metabolic risks (fasting plasma glucose, systolic and diastolic blood pressures (BP), low density lipoprotein (LDL), triglycerides / HDL-C ratio), anthropometric measures (waist circumference, body weight), sleep duration and handgrip strength, with age and physical activity as the covariates of the model.

Results: A total of 47.7% of the participants met MetS criteria, with a significant lower proportion of MetS among the alkaline water drinkers. The observed lower fasting plasma glucose ($F(1,296) = 24.20$, $p=0.025$), triglyceride/HDL-C ratio ($F(1,296) = 21.06$, $p=0.023$), diastolic BP ($F(1,296) = 7.85$, $p=0.046$) and waist circumference ($F(1,296) = 9.261$, $p=0.038$) in the alkaline water drinkers could be considered as favourable outcomes of regular consumption of alkaline water. In addition, water alkalization improved duration of sleep ($F(1,296) = 32.07$, $p=0.007$) and handgrip strength $F(1,296) = 27.51$, $p=0.011$). Body weight ($F(1,296) = 27.51$, $p=0.011$), LDL-C ($F(1,296) = 1.772$, $p=0.287$), and systolic BP ($F(1,296) = 1.656$, $p=0.301$) were comparable between the two different water drinking behaviours.

Conclusion: Drinking adequate of water is paramount for public health with access to good quality drinking water remains a critical issue. While consumption of alkaline water may be considered as a source of easy-to implement lifestyle to modulate metabolic features, sleep duration and muscle strength, further studies are warranted for unravelling the precise mechanism of alkaline water consumption on the improvement and prevention of MetS and its individual features, muscle strength and sleep duration as well as identification of full spectrum of individuals that could benefit from its consumption.

Keyword: Alkaline water, metabolic risks, sleep quality, muscle strength, postmenopausal women

Development of a technical file to reduce, replace or eliminate trans fatty acids (TFA) in foods

Amina El Hajjab[1], Mohammed Rahmani[1], Houria Lahmam[1], Hasnae Benkirane[1], Khalid El Kari[1], Ayoub Al Jawaldeh[2], Laila El Ammari[3], Hasnae Gamih[3], Abdelhakim Yahyane[3], Hassan Aguenaou[1]

1. Ibn Tofaïl University-CNESTEN, Joint Research Unit in Nutrition, Health and Environment, RDC-Nutrition AFRA/IAEA, Laboratory Biology and Health, Rabat-Kénitra, Morocco (Morocco), 2. WHO Regional Office for the Eastern Mediterranean, Cairo (Egypt), 3. Ministry of Health, Morocco (Morocco)

Background and objectives: The objective of this study is to determine the dietary sources of trans fatty acids in the Moroccan diet, with the aim of establishing a technical file to reduce, replace and eliminate *Trans* Fatty Acids (TFA) of industrial origin and to align with the World Health Organisation (WHO) recommendations. Knowing that mortality from Non-Communicable Diseases (NCDs) in Morocco is the main cause of death. It is estimated at 80% according to the WHO and premature mortality is estimated at 12%. Indeed, according to the national survey on the identification of risk factors for NCDs, among people aged 40 to 69 years, 4.9% had a cardiovascular risk ≧ 30%. This risk increased with age, it was 7.6% in people aged 55-69 compared to people aged 40-54 for whom this risk was estimated at 3.2%. Trans fatty acids contribute closely to this epidemiological picture because excessive consumption of TFA (intake greater than 2% of the TEA) is associated with an increase of 23%. % of cardiovascular risk. **Methods**: First of all, we wanted to determine the main dietary sources of trans fatty acids, these are, Edible oils (edible oil, frying oil, sunflower oil, partially hydrogenated palm and palm kernel oils) Shortenings, Margarines (pastry and spread), Chips, Cold cuts, Butter, Biscuits, Breakfast cereals, Yoghurts, creams and chocolate spreads. **Results**: The reduction and / or elimination of TFA requires the collaboration of three stakeholders, namely the government (represented by the Ministry of Health and the National Office for the Sanitary Safety of Food Products (ONSSA), by setting a limit for the content of TFA, making the mention of TFA obligatory on the labels and regulation the use of frying oils. The agro-industries food who can contribute by controlling oil production procedures. Finally, the consumers must be aware of TFAs risks and improve their food choices. **Conclusion**: This study will support the technical file that will be delivered to the authorities responsible to make regulations to reduce, replace and eliminate TFA.

Keyword: Trans fatty acids, reformulation, reduction, elimination

Combatting Iron Deficiency in Morocco : case of iron bioavailability of NaFeEDTA

Hassan Aguenaou[1], Meryem Lazrak[1], Nisrine El Mir[1], Asmae El Hamdouchi[1], Hasnae El Hamdouchi[1], Ayoub Al Jawaldeh[2], Abdelhakim Yahyane[3], Cornelia U. Loechl[4], Amina Barkat[5]

1. Ibn Tofaïl University-CNESTEN, Joint Research Unit in Nutrition, Health and Environment, RDC-Nutrition AFRA/IAEA, Laboratory Biology and Health, Rabat-Kénitra, Morocco (Morocco), 2. WHO Regional Office for the Eastern Mediterranean, Cairo, Egypt. (Egypt), 3. Ministry of Health, Morocco (Morocco), 4. International Atomic Energy Agency, Division of Human Health, Vienna International Center, Vienna, Austria (Austria), 5. Health and Nutrition Research Team of the Mother-Child Couple, Faculty of Medicine, Mohammed 5th, University. 10100. Rabat. Morocco (Morocco)

Background: As part of the fortification of staple foods. The NaFeEDTA complex is 2 to 3 times more bioavailable than ferrous sulfate and other fortifiers. It is known for its protective power of iron against various inhibitors such as phytates and polyphenols.

Objectives: Identification and evaluation of the bioavailability of iron from NaFeEDTA in anemic and non-anaemic women with or without consumption of green tea.

Methods: 46 childbearing age women were divided in 2 groups; non-anaemic group (NAG; n=25, age 18-41y) and anaemic group (AG; n=21, age 19-39y). Each group was used as self-control by using two different iron isotopes; 6mg of Fe57 (bread fortified with Na57FeEDTA) and 6mg Fe58 (bread fortified with NaFe58EDTA). Iron absorption was measured by the erythrocyte incorporation of isotopes after 14 days by ICP-MS analysis.

Results: The mean fractional absorption (MAF) of iron NaFeEDTA was 36.7% (range: 24.2-39.8) in AG and 16.7% (range: 9.2-24 ,2) in NAG ($p < 0.001$) from a test meal consumed with water and 4.1% (2.8-6.1) in AG and 1.4% (0 ,8-2,9) in NAG from a test meal consumed with tea. The mean inhibition was almost equal to 87.5% and 86.2% respectively in AG and NAG. The AFM was 2 times greater in case of iron deficiency anemia.

Conclusion: 18.88% of the 1.43 mg iron requirement per day would be covred with a test meal fortified with 6 mg of iron NaFeEDTA and consumed with tea in AG. The use of NaFeEDTA as a wheat flour fortifier can largely solve the problem of iron deficiency anemia in Morocco and a solid communication strategy which recommends the consumption of the tea one hour before or after the meal is still necessary.

Child nutritional intake in rural Cambodia: Application of Food Frequency Questionnaire and comparison with 24-h recall data

Makiko Sekiyama[1], Saiko Shikanai[2], Takuya Furukawa[3], Makoto Ehara[3], Sivleng Voeun[4], Koung ry LY[4], Naven Hon[5], Jackson Frechette[5], Ith Sreyoun[6], Norint NET[7]

1. National Institute for Enviornmental Studies (Japan), 2. Aomori University of Health and Welfare (Japan), 3. Forestry and Forest Products Research Institute (Japan), 4. ANFRC (Cambodia), 5. Conservation International (Cambodia), 6. Royal University of Phnom Penh (Cambodia), 7. Ministry of Environment (Cambodia)

Background and objectives: The nutritional status and nutrient intake of school-aged children in rural areas in Cambodia is largely unknown. This study aimed to assess the nutritional status and nutrient intake of school-aged children in rural Cambodia.

Methods: In February 2020, anthropometric measurements (height and weight), dietary surveys, and questionnaire surveys of household socioeconomic status were conducted, targeting 161 school-aged children in four rural communities in Stung Treng Province in Cambodia, in which forest is disappearing at the fastest rate in Southeast Asia. For the dietary survey, we applied the following two methods: 1) 56-item Food Frequency Questionnaire (FFQ) developed for use with Cambodian school children nationwide (including both urban and rural areas), and 2) 1-day 24-h dietary recall.

Results: The mean age of the children was 7.2 (± 1.0) years old, and 45.0% and 55.0% of the children were boys and girls, respectively. The prevalence rates of stunted and underweight children were 26.1% and 25.5%, respectively, which was higher than that reported in previous study in Cambodia. Overall, the energy and nutrient intake estimated by the two methods did not meet the recommended dietary allowance for Cambodian children. The energy and nutrient intake estimated by the FFQ was lower than the average intake reported in 24-h recall. The mean difference between FFQ and 24-h recall results ranged from 15.3% (carbohydrate) to 29.2% (energy and protein). Pearson's correlation coefficients for log-transformed energy and nutrient intake ranged from 0.157 (fat) to 0.367 (carbohydrate). Cross-classification analysis revealed that 36.0% (Ca) to 49.7% (carbohydrate) of participants were classified into the same tertile.

Conclusions: The energy and nutrient intake did not meet the recommended dietary allowance for Cambodian children, highlighting the necessity of nutrition improvement in the study area. The 56-item FFQ is moderately useful for correct classification of individuals in the population, although it underestimates the energy and nutrient intake.

Keyword: Cambodia, school-aged children, nutritional intake

Optimal vitamin D intake level for preventing serum 25–hydroxyvitamin D insuffciency in young Korean women

Hye Ran Shin[1], Sun Yung Ly[1]

1. Chungnam National University (Korea)

Background and objectives: Vitamin D deficiency is prevalent but is particularly severe in young women. Vitamin D requirement is critical at a young age (18–25 years old) since peak bone mass is achieved at this stage. This study aimed to determine an optimal level of vitamin D intake for maintaining a healthy serum 25–hydroxyvitamin D(25(OH)D) level based on the season in young Korean women.

Methods: Based on the sunlight amount affecting serum 25(OH)D, December–April was designated as wintertime(WT) and June–October as summertime(ST). The recruited participants (WT, n=103; ST, n=117) underwent a lifestyle survey, 6-day dietary record, bone mineral density (BMD) test, and blood and urine tests. Multiple linear regression was performed to identify seasonal factors impacting serum 25(OH)D, and vitamin D intake for maintaining the 25(OH)D threshold was calculated using receiver operating characteristic curve analyses. The Chungnam National University Institutional Review Board approved this study.

Results: The serum 25(OH)D level was higher in the ST than that in the WT (15.2 ng/mL vs. 17.87 ng/mL, p<0.01). Intact parathyroid hormone level was lower in the ST than that in the WT (33.78 pg/mL vs. 43.54 pg/mL, p<0.001). However, no seasonal difference in BMD was noted. Serum 25(OH)D was influenced by vitamin D intake and income in WT and by vitamin D intake, UV exposure time, number of sunscreens and/or sunshade tools, and smoking in ST. Vitamin D intake was significantly associated with serum 25(OH)D, and a 1 µg/1000 kcal increase in intake increased the 25(OH)D levels by 0.155 ng/mL in WT and 0.072 ng/mL in ST (p<0.01). The vitamin D intake threshold for maintaining 25(OH)D levels at 20 ng/mL or higher was ≧ 10.97 μg/day.

Conclusions: The 2020 Dietary Reference Intakes for Koreans recommend a vitamin D intake of 10 µg/day for Korean adults aged 19–64 years. Vitamin D intake should be increased to maintain a serum 25(OH)D level of 20 ng/mL for bone health in young women.

A meal quality score based on Japanese healthy meal guidelines and its association with nutrient intakes in adult men and women

Mariko Takano[1], Fumi Hayashi[1], Yukari Takemi[1]

1. Kagawa Nutrition University (Japan)

Background and objectives: To promote health and prevent lifestyle-related diseases, the Ministry of Health, Labour, and Welfare of Japan has proposed standards for a healthy meal. This study aimed to develop a meal-based diet quality score based on adherence to the standards and examine associations of the score with nutrient intakes in adult Japanese men and women.

Methods: This cross-sectional study involved a secondary analysis of data from the 2017 Saitama Prefecture Nutrition Survey. We analyzed data obtained from a questionnaire and 2-day dietary records of 548 men and women aged 30–65 years with nutrient intakes within 0.5–99.5 percentile. The score for each meal (breakfast, lunch, and dinner), excluding eating out and alcoholic beverages, was calculated for six components based on the standard: grain dishes (amount of carbohydrate from grains), vegetable dishes (amount of vegetable, potato, mushroom, and seaweed intake), fish and meat dishes (amount of protein from seafood, meat, eggs, and soybeans), milk and dairy products, fruits, and salt equivalent. The scores for the first three components were adjusted based on the following sub-components: whole grain, green and yellow vegetable, red meat, and fish and soybean intakes. Each component was scored on a 10-point scale and 10 points were allotted if it met the criteria; otherwise, points were deducted and summed up to total scores (range 0–60 points) to examine associations with energy-adjusted nutrient intakes (per 650 kcal) for each meal using linear regression analysis controlled for age and sex.

Results: The median total scores were 26.1 (21.2, 32.1) points for breakfast (n=540), 24.8 (19.8, 28.6) for lunch (n=360), and 27.8 (23.6, 31.8) for dinner (n=507). Some nutrients, such as dietary fiber and vitamin A, were positively associated with the total score across all meals, but fewer were associated with dinner than with breakfast and lunch. However, the total score was positively associated with better macronutrient balance and lower salt intake at dinner.

Conclusions: The meal quality score developed in this study is efficacious for evaluating the quality of breakfast and lunch. However, further modification of the score is needed to evaluate the quality of dinner.

Double and triple-duty actions for addressing the global syndemic of obesity, undernutrition and climate change in childhood: a scoping review

Carolina Venegas Hargous[1,2], Claudia Strugnell[1], Steven Allender[1], Liliana Orellana[3], Camila Corvalan[4], Colin Bell[1,2]

1. Global Obesity Centre (GLOBE), Deakin University (Australia), 2. School of Medicine, Deakin University (Australia), 3. Biostatistics Unit, Deakin University (Australia), 4. Institute of Nutrition and Food Technology (INTA), University of Chile (Chile)

Background and objectives: Obesity, undernutrition, and climate change constitute a global syndemic that disproportionately affects vulnerable populations, including children. Actions that simultaneously address these pandemics are urgently needed to avoid further health, economic, and environmental consequences. Compiled evidence on double and triple-duty interventions (targeting two or the three pandemics simultaneously) is lacking. This review aimed to summarize data on the design, implementation and evaluation of whole-of-population interventions designed or adapted to be double or triple-duty and describe their effects on childhood.

Methods: Six academic databases were searched (January 2015 - March 2021) using terms related to 'children', 'interventions', 'nutrition', 'physical activity', and 'climate change'. Study protocols and peer-reviewed articles describing interventions designed or adapted to address any form of malnutrition and mitigate or adapt to climate change we included, as were those describing existing interventions that were assessed to see if they do no harm to other forms of malnutrition or the environment. Two independent reviewers conducted relevant article screening and data extraction.

Results: The search yielded 15,475 articles after duplicates were removed. Data were extracted from 43 studies, including 6 randomized controlled trials (RCTs). In total, we found 33 triple-duty, 8 double-duty, and 2 single-duty actions. Most studies described policies, programs or regulations, targeting the food system in the school setting. Evidence of community engagement was reported in 53% of studies. Out of the 43 interventions, 31 measured outcomes related to at least 2 components of the global syndemic. Dietary intake and food-related attitudes were the most common health-related outcomes while greenhouse gas emissions and food waste were the most measured climate change-related outcomes. Overall, 19 interventions (3 RCTs) showed positive double or triple-duty effects. Modelling studies indicate that strengthening the environmental sustainability of dietary guidelines is a cost-effective triple-duty action.

Conclusions: We found promising double and triple-duty actions for addressing the global syndemic in childhood. Highest quality studies point to food-related policies and programs that expose children to healthy and sustainable foods. Future research should ensure consistency in the type of outcomes measured to enable comparison with published studies and prioritise the evaluation of double and triple-duty effects.

Keyword: Triple-duty actions, Obesity, Undernutrition, Climate change, Childhood

PAB(T6)-227

Changes in dietary consciousness throughout the coronavirus infectious disease 2019 pandemic among Japanese adults

Fumi Hayashi[1], Yukari Takemi[1]

1. Kagawa Nutrition University (Japan)

Background and Objectives: The coronavirus infectious disease 2019 (COVID-19) has impacted the individuals' health concerns and behaviors. This study aimed to understand the changes in individuals' dietary concerns throughout the COVID-19 pandemic and examine the factors associated with these changes.

Methods: A web-based survey was conducted in July 2020 and September 2021. Participants were aged 20–69 years residing in 13 prefectures where COVID-19 regulations had been implemented in April 2020 and bought groceries and prepared meals ≧2 times a week. A total of 661 men and 678 women who completed both surveys were included the analysis. Dietary consciousness was measured using a validated questionnaire divided into two subscales; importance of diet (seven items) and precedence of diet (five items). Changes in dietary consciousness from 2020 to 2021 were categorized according to the median score of each subscale at each survey period: “low/low,” “low/high,” “high/low,” and “high/high.” Demographic and socioeconomic variables at baseline and follow-up were compared among four groups using chi-squared tests and residual analysis.

Results: The rates of participants in each category were 37.7%, 10.6%, 12.1%, and 39.6%, respectively, for the importance, and 6.4%, 38.8%, 31.3%, and 23.5%, respectively, for the precedence; therefore, changes in the precedence were observed in many participants. The participants who lowered the precedence of diet throughout (“low/high”) were more likely to be men, aged 30–39 years, unmarried, full-time workers, had household incomes of 4 to 6 million yen, and low subjective living status upon the survey and pre-pandemic. Conversely, those who raised the precedence of diet (“low/high”) were more likely to be women, aged 60–69 years, housewives, had household incomes of ≧6 million yen, and high subjective living status upon the survey and pre-pandemic.

Conclusions: Changes in the precedence of diet throughout were noted in approximately 70% of the participants, but only 20% have changed their importance of diet. The study reveals some demographic and socioeconomic characteristics related to the changes in dietary consciousness during the COVID-19 pandemic. It is important to consider the living conditions of the targeted population to develop a comprehensive approach for dietary behavior modification.

Keyword: vulnerable population, COVID-19, dietary habits, attitudes, Japanese

Attempts to prepare food for disasters with consideration for nutrition and water conservation.

Ikuko Shimada[1], Kaori Aoki[1], Chikako Shimamura[1], Yuka Kumamoto[1], Maya Nishimura[1], Noriko Sudo[2], Nobuyo Tsuboyama Kasaoka[3], Keiichi Sato[4]

1. University of Kochi (Japan), 2. Ochanomizu University (Japan), 3. National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 4. Senshu University (Japan)

Background and objectives; It has been pointed out that, in the event of a disaster, the food supplied in shelters and other places is subject to nutritional over- or under-supply. In addition, it is assumed that this is done with limited resources. The aim of this research was to develop a menu for a soup kitchen that can solve these nutritional problems and is also practicable in terms of work and hygiene. **Methods;** 1) Based on the immediate target nutritional reference amounts (Ministry of Health, Labour and Welfare) for planning and evaluating the provision of meals in evacuation centres. 2) Dried foods (1 fruit, 3 mushrooms, 3 vegetables, 2 seaweeds and 1 bean) used in the prepared menus were returned for 50 people each, and the return rate and the amount of water required, etc. were investigated. The amount of water required, etc., was investigated. In addition, the study investigated whether using plastic bags to return dry goods would save water. **Results;** 1) In menus without raw meat, the amount of protein was very high (more than 80 g) because the B vitamins were supplemented with canned mackerel and fish sausages. When nutritionally adjusted foods were added to the menu, the vitamin B group could be met with less than 80 g of protein. 2) One to two staff were required for each task, including measuring, cutting, cooking and distributing the food. Aubergine chips, dried shiitake mushrooms and chopped kelp, which have a low water absorption rate in the 10% range, were found to have a high water saving rate of more than 60% when returned in plastic bags. All but the lowest-use dry goods could be returned in a bowl with an inner diameter of 36.0 cm. The use of plastic bags was possible with widths from 260 mm to 650 mm. **Conclusions;** It is clear that menus and processes that consider nutritional, hygienic and environmental aspects can be envisaged in advance during a disaster, and that the use of dried food can also lead to water savings, which could be used during cookouts.

Effects of dairy beverages fortified with protein and micronutrients on the risk of early-stage undernutrition and frailty in community-dwelling older adults: A randomized, controlled trial

Miki Narita[1], Shoji Shinkai[2], Yuri Yokoyama[1], Akihiko Kitamura[1], Hiroki Inagaki[1], Yoshinori Fujiwara[1], Shuichi Awata[1]

1. Tokyo Metropolitan Institute of Gerontology (Japan), 2. Kagawa Nutrition University (Japan)

Background and objectives: This study aimed to test the hypothesis that an intervention program that adds regular exercise and a dairy beverage fortified with protein and micronutrients further improves the risk of early-stage undernutrition and frailty in older adults.

Methods: A total of 74 community-dwelling older adults (mean age, 76.8 years) were randomly allocated to four groups; group A were supplemented with 400-kcal energy, 15-g dairy protein and micronutrients, group B with a 15-g dairy protein, group C with no supplementation but given nutritional education, and group D without any intervention (controls). Each group, except group D, performed the same resistance exercise program every other week for 28 weeks. Early-stage Undernutrition Score (EUNS), Mini Nutritional Assessment–Short Form, frailty (CL-15), mental health (WHO-5), Simplified Nutritional Appetite Questionnaire, weight, body mass index, fat-free mass index (FFMI), handgrip strength, and five-repetition chair stand test were measured before and after the intervention period. Two-way analysis of variance (ANOVA) was used to compare changes in all outcomes between groups, with sex and age treated as covariates. Similarly, a one-way ANOVA was used, with sex and age as covariates, for changes within groups. The Friedman test was used for multiple comparisons.

Results: Groups A and B showed decreased EUNS (changes over time: −0.95 ± 0.35 and −0.45 ± 0.36, respectively), but group D showed increased CL-15 score (0.45±0.29). Group A gained weight and showed increased muscle mass (FFMI: 0.32±0.10 kg/m^2), increased handgrip strength (1.11±0.39 kg), and improved WHO-5 (0.76±0.75), although they showed a decreased appetite compared to the other groups. Group B had improved muscle mass (FFMI: 0.17±0.10 kg/m^2) and handgrip strength (0.53±0.40 kg) and decreased five-repetition chair stand time (−0.57±0.36 s), although their body weight decreased. However, no significant group-by-time interactions were found in any outcomes.

Conclusions: The intervention groups showed a trend toward improved risks of early-stage undernutrition and frailty compared to the control group. Dairy protein supplementation during resistance exercise increased muscle mass and improved physical performance in older adults. These changes were greater in the group with energy and micronutrients supplimentation in addition to milk protein.

Relationship between Weight Gain and Stress Factors among Working-age People in Yugawara Town, Kanagawa Prefecture, Japan: A Cross-sectional Study.

Rina Kurasawa[1], Kenji Watanabe[2], Yoshihisa Watanabe[3], Ryoji Hirota[1]

1. Matsumoto University (Japan), 2. Keio University School of Medicine (Japan), 3. Tokai University School of Medicine (Japan)

Background and objectives. The aim of study was to determine the sociodemographic and lifestyle factors associated with weight gain among working-age people living in Yugawara town, Japan.

Methods. A cross-sectional study was carried out among Japanese citizens aged 19-64 years, living in Yugawara town in Kanagawa prefecture, Japan. Data were collected between February and March 2015 through a household survey exploring sociodemographic characteristics and lifestyle patterns of the participants. For statistical analysis of the study data, mean (SD) values were determined and a bi-variate logistic regression model was performed to determine the factors associated with overweight status. The level of statistical significance was set at $p < 0.05$.

Results. In total, there were 796 participants; based on their answers on weight and height on the survey sheet, body mass index (BMI) was calculated. Then, participants were stratified into three subgroups as follows: “underweight” for participants with a BMI < 18.5 kg/m^2, “normal weight” for those with a BMI between 18.5-24.9 kg/m^2, and “overweight” for those with a BMI > 25.0 kg/m^2. There were 137 (17.2%) overweight and 659 (82.8%) participants with either normal weightor low BMI. “Overweight status” was positively associated with "being unable to manage stress" (OR: 1.66; 95% CI: 1.10-2.51; p=0.015), "stress relief by eating" (OR: 1.63; 95% CI: 1.03- 2.57; p=0.036),"stress relief by watching TV" (OR: 1.70; 95% CI: 1.09-2.66; p=0.020) ,"feeling unhealthy" (OR: 1.95; 95% CI: 1.16-3.25; p=0.011) , "eating dinner alone" (OR: 1.58; 95% CI: 1.03- 2.44; p=0.038), "lower frequency of drinking alcohol" (OR: 2.16; 95%CI: 1.41-3.32; p<0.001).

Conclusions. Findings from this study suggest that weight gain is influenced by stress factors in a sample of working-age Japanese people living in Yugawara town, suggesting the importance of good stress management approach to prevent obesity and related health problems.

PAB(T6)-231

Intervention strategies and effectiveness of health-related interventions to reduce obesity and unemployment in adults.

Sophia Doyo Amenyah[1], Diane Waters[1], Wen Tang[1], Lee-Ann Fenge[1], Jane L Murphy[1]

1. Bournemouth University (UK)

Background and objectives: Obesity and unemployment are interconnected, complex social and health issues with devastating effects on mortality, health, wellbeing and quality of life. While there is clear research evidence on the interrelations between unemployment and obesity, there is lack of holistic approaches to addressing unemployment and obesity using common strategies. The objective of this study was to conduct a systematic realist synthesis to investigate the interrelation between unemployment and obesity and understand the effectiveness of health-related interventions designed to reduce overweight, obesity and unemployment.

Methods: Systematic literature searches were conducted in 6 electronic databases including Cochrane library, Medline, SocIndex, Cumulative Index to Nursing and Allied Health Literature (CINAHL), Scopus, and PsychInfo. Studies were screened using predefined exclusion criteria followed by subsequent data extraction from included studies. Extracted data was coded for Context-Outcome-Mechanism configurations (CMOcs). Data synthesis and analysis was conducted using a realist approach to thematic analysis to identify common intervention strategies, outcomes and effectiveness and to refine the final program theory. Results are presented using a narrative synthesis.

Results: A total of 83 out of 11495 studies screened met the inclusion criteria and assessment for relevance and rigour and were included in the final data synthesis. Seven common strategies were identified to be highly effective in both health-related unemployment and obesity interventions. These included knowledge and skill building to enable behaviour change, increasing motivation, cognitive behaviour therapy/positive psychology, improving self-efficacy, confidence and self-esteem, building resilience and emotional competency, hands-on practice of behaviour, knowledge and skill building on goal-setting, identification of barriers to achieving goals, and self-monitoring. Multicomponent interventions, combining more than two strategies and tailored to participants' unique circumstances were more effective and resulted in positive outcomes.

Conclusions: This study provides the first realist evidence on complex health-related interventions and novel insights into holistic approaches to address unemployment and obesity. The findings contribute to an emerging field in systematic review and highlights overlooked perspectives which should be considered in future research.

Daily fruit and vegetable consumption habits during COVID-19 pandemic: A cross-sectional study

Seyma Kalkuz[1,2], Zeynep Goktas[2]

1. Kirklareli University (Turkey), 2. Hacettepe University (Turkey)

Background and objectives: Although the effects of COVID-19 are still not fully understood, its relationship with the immune system is outstanding. A healthy diet is an integral part of the immune system. Adequate consumption of fruits and vegetables boosts immunity due to their vitamin and antioxidant content. Therefore, we aimed to investigate daily fruit and vegetable consumption habits during COVID-19 pandemic.

Methods: This study was conducted as an online survey between June and December 2021. Inclusion criteria were as follows: (1) being 18 to 65 years old, (2) using social media, and (3) being able to understand Turkish. Besides socio-demographic characteristics and COVID-19 status of participants, study questionnaire involved a food frequency questionnaire aimed to assess fruit and vegetable consumption. In addition, participants' beliefs regarding the efficacy of fruits and vegetables on COVID-19 were investigated.

Results: A total of 1767 individuals participated in this cross-sectional study. Most of the respondents were women (76.9%). The mean age was 29.07±11.50 years. Daily fruit consumption was reported by 37.7% of the participants and they consumed 1.99±0.69 portions a day. Daily vegetable consumption was reported by 30.1% of the participants and they consumed 2.17±0.82 portions a day. There was no difference in fruit and vegetable consumption habits between COVID-19 (+) and COVID-19 (-) participants (fruits: 40.7%, 2.05±0.7 portions/day and 36.8%, 1.97±0.68 portions/day, vegetables: 32.7%, 2.20±0.75 portions/day and 29.3%, 2.15±0.85 portions/day respectively). However, when the participants were asked whether they consumed adequate amounts of fruits and vegetables, 50.4% claimed adequate fruit consumption and 36% claimed adequate vegetable consumption. COVID-19 (+) participants claimed a higher consumption ratio compared to COVID (-) participants. Overall, 76.9% of participants believed that fruits and vegetables have a role in treatment and protection against COVID-19.

Conclusions: This study demonstrated that most of the participants did not consume adequate amounts of fruits and vegetables.

Keyword: COVID-19, fruits, vegetables, immunity

Overweight and social marginalization among preadolescent children in Taiwan

Tan-Wen Hsieh[1], Hsin-Jen Chen[1], Yen-Sheng Chiang[2], Chuan-Yu Chen[1,3]

1. Institute of Public Health, National Yang Ming Chiao Tung University (Taiwan), 2. Institute of Sociology, Academia Sinica (Taiwan), 3. Center for Neuropsychiatric Research, National Health Research Institutes (Taiwan)

Background: Weight-related stigma may exert adverse effects on psychosocial health of children and adolescents, yet possible underlying mechanisms have been less delineated. The present study aims to examine the extent to which overweight status was associated with peer relations and network positions among preadolescent children.

Methods: Data were obtained from a 2017 cross-sectional survey conducted in Taiwan's Keelung City, with the study population comprising the fourth graders (9-11 years old) in 42 public schools (n= 2,333, response rate= 97.3%). Body mass index (BMI) was ascertained by self-reported weight and height. Children's school-wide social networks and status (i.e., marginalization and isolation) were assessed by child's peer nomination (maximal five). Linear and generalized mixed-effect models were applied to examine the risk of having few nominations and being isolated by weight status.

Results: Overweight children were found to have fewer indegree nominations (4.07 ± 2.83 vs. 3.00 ± 2.42, p<0.0001) and reciprocal ties (1.93 ± 1.45 vs. 1.43 ± 1.31, p<0.0001) as compared with their non-overweight peers. After adjustment for socioeconomic characteristics, participation in school activities, school-level network features (network size, density), and school average BMI, overweight preadolescents received 1.10 fewer nominations (p<0.0001) and were more likely to have 0 indegree nomination (OR: 1.75, 95% confidence intervals [CI]: 1.28-2.39). Overweight may elevate the risk of having a marginal or isolated position in the school-based social network by 71% (95% CI: 1.38-2.12). Gender-stratified analysis indicated that overweight-related increased risk of social isolation was more prominent in girls (OR: 2.63, 95% CI: 1.85-3.74) than in boys (OR: 1.34, 95% CI: 1.01-1.77).

Conclusion: Overweight in preadolescence appeared associated with having fewer friends and being marginalized/isolated in school, especially girls. Targeted efforts are needed to ameliorate weight-based social marginalization/isolation and to avoid spiral-down effects throughout adolescence.

Keyword: Body mass index, social marginalization, social network analysis, network position, peer relation

Prevalence and determinants of Hypertension and Diabetes among different Indian populations groups: Findings of the National Nutrition Monitoring Bureau surveys

Avula Laxmaiah[1], Arlappa Nimmathota, Meshram I Indrapal, Sree Ramakrishna K, Neeraja G

1. ICMR-National Institute of Nutrition, Hyderabad and National Secretary, Nutrition society of India (India)

Background and Objectives: Non-communicable diseases (NCDs) are leading causes of mortality globally and are collectively responsible for almost 70% of all deaths and the causes could be due to combination of genetic, physiological, environmental and behavioural factors. The objective of the current communication is to determine the strength of association between overweight/obesity, diet, demographic factors and hypertension & diabetes among tribal, rural and urban populations in India as available data accessed from the large epidemiological diet and nutrition survey carried out by the National Nutritional Monitoring Bureau.

Methods: The NNMB repeat surveys were carried out periodically every decade in 120 randomly selected villages each state, from 10 major states in India among tribal (2008-09), rural (2011-12) and urban (2015-16) population by adopting multistage stratified sampling procedure.

Results: A total of 70,525, 56,425, and 1,23,175 adults 18years and above were participated from tribal, rural and urban areas, respectively, for the survey. The prevalence of overweight and obesity (34-44%), hypertension (24-25%) and diabetes (19-22%) was significantly high among urban population as compared to the rural (10-14%, 23-25%, 7-8%%) and tribal (3-4%, 22-23%) population, respectively. Regression analysis showed that general, abdominal and central obesity, diet, age, gender are important risk factors for hypertension & diabetes among all the population groups. A principal component analysis revealed that the predominant contribution for obesity was unhealthy diet and ultra processed food consumption.

Conclusions A multi-component extensive health and nutrition education intervention program is the need of the hour to control the epidemic increase of all non-communicable diseases in the low and middle income countries like India.

Feasibility testing of Food-Based Dietary Guidelines recommendations in Ghana

Richmond Nii Okai Aryeetey[1], Sawudatu Zakaria[1]

1. University of Ghana (Ghana)

Background and Objecitives: Ghana is developing its first food-based dietary guidelines. The proposed technical recommendations that have been developed were field tested to determine comprehension and feasibility among male and female adults.

Methods: Seventy-two focus group discussions were held in x communities across the three main ecological zones of Ghana between February and March of 2022. Participants were adults (18 years+) or adolescents (12-17 years) selected to be representative of rural- and urban communities in Ghana. For each ecological zone, discussion guides were pretested and used to guide 12 group discussions involving between eight and twelve participants. The questions were intended to determine respondent understanding and comprehension of the technical recommendations, willingness to adopt the recommendations, anticipated barriers to adoption, and implications of adoption. In addition 12 focus groups were held in each ecological zone to test feasibility of images designed to facilitate communication of the recommendations. These focus groups asked questions to determine clarity and legibility of the images and their suitability in communicating the associated recommendation.

Results: Generally, the recommendations were comprehensible to participants in the discussion groups across all ecological zones. Because many of the respondents were not literate, comprehension of the recommendations was only possible if the messages (originally constructed in English) were translated into local languages. There was also high interest and willingness to adopt the recommendations. However, in some communities, there was recognition that the adopting the recommendations will increase the cost of diets. This was especially linked to the cost of fruits and vegetables. The images were generally recognizable regarding the messages intended. However, the images were fully comprehensible when they were accompanied with explanation.

Conclusions: The technical recommendations for Ghana's Food-based Dietary Guidelines and the accompanying images are generally well understood and require only minor edits based on feedback from focus group participants.

Associations of gender with BMI and dietary intakes in a cohort of children in Northern Ireland

Lauren D Devine[1], Alyson J Hill[1], Alison M Gallagher[1], Chris Patterson[2], David R McCance[3]

1. Nutrition Innovation Centre for Food and Health, School of Biomedical Sciences, Ulster University (UK), 2. Centre for Public Health, Queen's University (UK), 3. Regional Centre for Endocrinology and Diabetes, Royal Victoria Hospital (UK)

Background and objectives: Childhood obesity is a major public health concern in the UK, affecting both males and females. A combination of lifestyle, dietary and environmental factors contribute to the aetiology. The aim of this study was to investigate whether differences exist between boys and girls in Northern Ireland (NI) for dietary intake and anthropometry in children.

Methods: Participants were offspring of healthy pregnant mothers recruited within the third trimester as part of the Belfast cohort of the Hyperglycaemia Adverse Pregnancy Outcome (HAPO) study, a prospective observational study examining maternal glycaemia and pregnancy outcomes. Participants (n=706) attended one follow-up visit between 2011-2016 (~12 year follow up) for metabolic investigations where dietary, anthropometry and lifestyle data were collected. 3-day semi-quantitative dietary intake at the study visit was analysed using Nutritics Nutritional Analysis Software (v5.74 RE) to provide quantitative nutrient data. Level of deprivation was categorised from postcodes. BMI z-scores were calculated to categorise children as underweight (<-2SDs), normal weight (>-2-0.99SDs), overweight (>1-<2SDs) or obese (>+2SDs) (WHO, 2007).

Results: Participants were mean age 12.0 years (range 10.1-13.8, SD 0.862) with 49.6% boys (n=348) and 50.4% girls (n=353). More girls were classified as overweight/ obese (35%) than boys (23%). Mean energy intake (EI) was higher for boys (7429kJ) than girls (6669kJ). Those with a higher BMI (boys and girls) were found to self-report lower EI (p=0.005), with two thirds of under-reporters overweight/ obese. No difference in % EI from protein, carbohydrate or fat between BMI categories was observed for boys or girls when including or excluding mis-reporters. Children from more deprived areas had a higher BMI (p=0.003). Boys had higher fibre intakes (mean 16g/d) than girls (mean 14g/d) (p<0.001).

Conclusions: More girls were overweight and obese than boys, however, overall EI of girls did not differ from boys although increased levels of mis-reporting of EI was observed at higher BMIs. Differences were observed between children's deprivation level and BMI. No differences were noted between BMI and dietary intakes. Further studies are required to explain gender differences in BMI observed in children to assist in developing targeted interventions aimed at reducing obesity risk.

Adopting a Gender Transformative Approach to Increase Participation in Income Generating Activities and Dietary Diversity of Women of Reproductive Age: Evidence from Suchana -a Multi-Sector Initiative in Bangladesh

Md Amin Uddin[1], Chowdhury Abdullah Al Asif[1], Md Abul Kalam[1]

1. Helen Keller International (Bangladesh)

Background and objectives: Helen Keller Intl's gender transformative approach (GTA), the Nurturing Connections (NC)© curriculum, was streamlined into a six-year multi-sector initiative, Suchana, that aims to prevent child undernutrition of the poor and very poor in the first 1,000 days of their lives in the Sylhet Division of Bangladesh. The GTA curriculum was integrated into the technical trainings for agriculture, nutrition, and market development to challenge gendered barriers related to agriculture, health, and nutrition behaviors. This study explores the association between women's participation in critical household decisions and their own dietary diversity and participation in income. **Method:** We use a recent primary dataset of present participant households from Suchana. Data were collected using a seasonal cross-sectional cluster random survey in each season of food production. This study analyzes data from Suchana's first implementation phase (2017-2018) during which four rounds of data were collected from November 2017 to December 2018 from 300 villages for a total of 1,487 respondents. Adjusted logistic regression analysis was conducted to examine the relationship between women's participation in critical household decisions and dietary diversity scores. **Results:** During the implementation period being examined, the proportion of women consuming an inadequate diet (fewer than 5 of 10 food groups) reduced (31%-27%) with increased participation in all critical household decisions including own income, own healthcare, child healthcare, major household purchases, daily food purchases, food preparation, and visiting family (27%-32%). Adjusted logistic models reveal that the average dietary diversity score of women associated with greater odds of participation in all critical household decisions (AOR .754, CI 0.66,0.86, p<0.00). Controlling other household level variables, women's age (AOR 1.07, CI 1.03,1.10, p<0.00), selling vegetables (AOR 1.07, CI 1.003,1.14, p<0.038), selling poultry birds (AOR 1.79, CI 1.06,3.03, p<0.029), and support in-laws in homestead gardening (AOR 1.2 CI 0.52,2.77, p<0.009) was also associated with participation in household decisions. **Conclusion:** Women's participation in critical household decisions positively impacts women's dietary diversity and participation in income generating activities. Integrating GTA, across technical implementation areas can be an effective way to addressing gender inequality and support household members to work together for better nutrition outcomes for women.

Association between recommended Japanese dietary patterns and the source of salt intake among middle-aged Japanese adults: Analysis of food grouping based on NOVA system

Kaori Koiwai[1], Yukari Takemi[1], Keiko Ozawa[2], Akiko Kubo[1]

1. Kagawa Nutrition University (Japan), 2. Junior College of Kagawa Nutrition University, (Japan)

Background and objectives: The government food and nutrition policy and guidelines in Japan recommend meals comprising staple, main, and side dishes (SMS meals). No study has examined the relationship between consumption of SMS meals and the source of salt intake. Therefore, we aimed to evaluate the association between consumption of SMS meals and the source of salt intake among middle-aged Japanese adults based on the degree of food processing (NOVA system).

Methods: A cross-sectional study was conducted using data of 153 men and 195 women from the Saitama Prefecture Health and Nutrition Survey 2011. Dietary intake was assessed using 2-day dietary records. We calculated consumption of SMS meals based on the serving data from Japanese Food Guide Spinning Top: the number of servings per dish was calculated per plate, and the number of servings per dish per meal was summed every breakfast, lunch, dinner, and between meals. We calculated the total number of servings per day. Finally, we calculated the average of 2 days. The frequency of SMS meals was classified into <1,≧1 and <2,≧2. Food items were classified according to the NOVA system into the following four groups: unprocessed or minimally processed foods (UMPF), processed culinary ingredients (PCI), processed foods (PF), and ultra-processed foods (UPF). Analysis of covariance adjusted for age, family structure, income, and total energy and was used to analyze the association between consumption of SMS and the source of salt intake.

Results: The proportion of single men was significantly the highest among subjects who consumed SMS meals at least once a day. In men and women, salt intake (%) from PCI, such as soya sauce and miso was significantly higher as the consumption of SMS increased. However, salt intake (%) from UPF, such as store-bought rice ball, sweets, fatty or salty snacks was significantly higher as the frequency of SMS decreased.

Conclusions: Salt intake from PCI was high among participants who consumed SMS meals more than twice a day, whereas salt intake from UPF was high among those who consumed SMS meals less than twice a day. Thus, the salt reduction countermeasure should be modified considering the consumption of SMS.

Associations between types and sources of dietary carbohydrates and liver fat: a UK Biobank study

Josefina Orliacq[1], Aurora Pérez-Cornago[1], Rebecca Kelly[1], Siôn Parry[1], Jennifer Carter[1]

1. University of Oxford (UK)

Background and objectives: Excessive liver fat can lead to non-alcoholic fatty liver disease (NAFLD). Evidence on the associations between dietary carbohydrates and liver fat remains unclear. This study aimed to examine the associations between types and sources of dietary carbohydrates and liver fat.

Methods: The study included UK Biobank participants with no pre-existing diabetes, liver disease or cardiovascular disease. Dietary intake of types and sources of carbohydrates (total carbohydrates, total sugars, free sugars, non-free sugars, total starch, starch from whole grains, starch from refined grains, and fibre) was measured using at least two 24-hour dietary assessments. In a cross-sectional analysis (n=27,272), the Hepatic Steatosis Index (HSI) was calculated at baseline (2006-2010). A score of 36 or higher defined cases of 'high liver fat'. Odds ratios (OR) of high liver fat by quintiles of carbohydrate intakes were estimated using multivariable logistic regression models. In a prospective analysis, a second sample (n=3,915) had liver proton density fat fraction (LPDFF) measured by magnetic resonance imaging (2014-2020). Multivariable linear regression models estimated geometric means of LPDFF (%) by quintiles of carbohydrate intakes. All models were adjusted for confounders, including total energy intake.

Results: In cross-sectional analyses, 8,823 cases of high liver fat were identified. Inverse associations between intakes of fibre (OR of highest vs. lowest quintile 0.47 [95% CI: 0.44-0.51]), non-free sugars (0.66 [0.62-0.70]) and starch from whole grains (0.53 [0.50-0.58]), with liver fat were observed. Positive associations between starch from refined grains and liver fat were observed (1.25 [1.18-1.32]). Free sugars showed no significant associations with liver fat. In prospective analyses, inverse associations with LPDFF (%) were observed for intakes of fibre (-0.74 geometric mean difference between highest and lowest quintile of intake [-0.85 to -0.62]), non-free sugars (-0.73 [-0.67 to -0. 78]) and starch from whole grains (-0.53 [-0.49 to -0. 58]). Free sugars and starch from refined grains were positively associated with LPDFF (0.33 [0.30 to 0.36]) and (0.31 [0.17 to 0.46]), respectively.

Conclusion: This study suggests that different carbohydrate types and sources, as opposed to overall carbohydrates, have varying associations with liver fat, which may be important for NAFLD prevention.

Keyword: NAFLD, hepatic steatosis, sugar consumption, dietary carbohydrates, dietary fibre

PAB(T6)-240
Degree of food processing and risk of head and neck and oesophageal cancers in the European Prospective Investigation into Cancer study

Fernanda Morales-Berstein[1], Carine Biessy[2], Nathalie Kliemann[2], Manon Cairat[3,2], Jessica Blanco Lopez[2], Aline Al Nahas[2], Christopher Millett[4], Marc Gunter[2], Caroline Relton[1], Inge Huybrechts[2]

1. University of Bristol (UK), 2. International Agency for Research on Cancer (France), 3. Paris-Saclay University (France), 4. Imperial College London (UK)

Background and objectives: Evidence suggests that food processing may be associated with cancer risk. Associations between different degrees of food processing and head and neck cancer (HNC) and oesophageal cancer (OC) have not been fully explored. We aimed to investigate these associations in the European Prospective Investigation into Cancer (EPIC) cohort.

Methods: EPIC recruited 521,323 adult participants across 10 European countries between 1992 and 1998. Our study included 450,111 EPIC participants, of which 814 and 409 were incident cases of HNC and OC, respectively. Food frequency questionnaires were used to obtain dietary data at baseline and the NOVA classification was used to categorise foods into four groups according to their degree of processing. We used Cox proportional hazard models to investigate associations between the consumption of unprocessed/minimally processed foods (NOVA 1), processed foods (NOVA 3) and ultra-processed foods (NOVA 4) and the risk of HNC and OC.

Results: A 10% increase in the proportion of grams of ultra-processed food in the diet was associated with an increase in the risk of HNC (HR=1.16, 95%CI 1.07–1.27, events=814) and oesophageal adenocarcinoma (HR=1.25, 95%CI 1.06–1.48, events=215). Among HNC subtypes, a strong positive association was found for pharynx cancer (HR=1.25, 95%CI 1.09–1.44, events=264) and larynx cancer (HR=1.20, 95%CI 1.04–1.38, events=310), but not for oral cancer (HR=0.97, 95%CI 0.81–1.15, events=277). Similarly, a 10% increase in the proportion of processed food was associated with a higher risk of HNC (HR=1.26, 95%CI 1.19–1.34; pharynx cancer HR=1.23, 95%CI 1.10–1.37; larynx cancer HR=1.23, 95%CI 1.12–1.35; oral cancer HR=1.30, 95%CI 1.17–1.45) and oesophageal squamous cell carcinoma (SCC) (HR=1.77, 95%CI 1.58–1.98, events=194). In contrast, a 10% increase in the proportion of unprocessed/minimally processed food was associated with a lower risk of HNC (HR=0.73, 95%CI 0.69–0.78; pharynx cancer HR=0.77, 95%CI 0.70–0.85; larynx cancer HR=0.77, 95%CI 0.71–0.85; oral cancer HR=0.82, 95%CI 0.74–0.91) and oesophageal SCC (HR=0.66, 95%CI 0.59–0.74).

Conclusions: Reducing the intake of processed and ultra-processed foods in favour of unprocessed/minimally processed foods may confer protection against HNC and OC. Further research is required to uncover the mechanisms underlying our findings.

The effect of important food sources of fructose-containing sugars on adiposity: a systematic review and meta-analysis of controlled feeding trials

Laura Chiavaroli[1,2], Annette Cheung[1,2], Sabrina Ayoub-Charette[1,2], Amna Ahmed[1,2], Danielle Lee[1,2], Rodney Au-Yeung[1,2,3], XinYe Qi[1,2], Songhee Back[1,2], Tauseef A Khan[1,2], John L Sievenpiper[1,2]

1. University of Toronto (Canada), 2. St. Michael's Hospital (Canada), 3. INQUIS Clinical Research Ltd (Canada)

Background and Objective: The effect of various food sources of sugars, other than sugar-sweetened beverages (SSBs) providing excess energy, on weight gain is unclear. We conducted a systematic review and meta-analysis of controlled trials on the effect of different food sources of fructose-containing sugars on body weight and markers of adiposity at different levels of energy control.

Methods: MEDLINE, Embase, and the Cochrane Library were searched through April 2022 for controlled trials ≧2-weeks. Four trial designs were prespecified by energy control: substitution (energy matched replacement of sugars); addition (excess energy from sugars added to diets); subtraction (energy from sugars subtracted from diets); and ad libitum (energy from sugars freely replaced). The primary outcome was body weight. Secondary outcomes included other markers of global and abdominal adiposity. Independent reviewers extracted data and assessed risk of bias. GRADE assessed certainty of evidence.

Results: We identified 169 controlled trials (255 trial comparisons, N=10,357) assessing 14 food sources at 4 levels of energy control. Total fructose-containing sugars increased body weight and BMI in addition trials; decreased body weight, waist circumference and waist-to-hip ratio in subtraction trials; and had no effect in substitution or ad libitum trials. There was evidence of interaction/influence by food source: substitution trials (fruit decreased and added nutritive sweeteners and mixed sources (with SSBs) increased outcomes); addition trials (dried fruit, honey, and 100% fruit juice (≦10%E) decreased and SSBs, fruit drink, 100% fruit juice (>10%E) and mixed sources (with SSBs) increased outcomes); subtraction trials (removal of mixed sources (with SSBs) decreased outcomes); and ad libitum trials (mixed sources (with SSBs or without SSBs) increased outcomes). The certainty of evidence was moderate to low for most comparisons.

Conclusions: Energy control and food source appear to mediate the effect of fructose-containing sugars on adiposity. The evidence provides a good indication that excess energy intake from SSBs, other sugary beverages, and mixed sources (with SSBs) increase adiposity, whereas removal of energy from mixed sources (with SSBs) decrease adiposity. Most other food sources have no effect with some sources (fruit, 100% fruit juice (≦10%E), dried fruit, honey) showing decreases irrespective of energy control.

Designing interventions to address factors impacting maize flour fortification compliance among small and medium scale millers in Kenya

Mary Wanjiru Kihara[1], Peter Kahenya[2], Manpreet Chadha[3], Jacqueline Kungú[4], Martha Nyagaya[1], Joy Kiruntimi[1]

1. Nutrition International (Kenya), 2. Jomo Kenyatta University of Agriculture and Technology (Kenya), 3. Nutrition International, Headquarter (Canada), 4. Nutrition International Africa Region (Kenya)

Background and objective: Large-scale food fortification is one of the strategies adopted by the Government of Kenya to address high prevalence of micronutrient deficiencies. Kenya has mandatory fortification of packaged maize and wheat flour, edible oils and salt. However, maize flour fortification compliance to regulatory standards remains low (28%), due to poor technical and financial capacity of small, medium-scale millers. Nutrition International (NI) supports government and millers in increasing production and availability of adequately fortified maize flour. In 2020 and 2021, NI conducted two rounds of rapid appraisal of millers to determine factors impacting compliance to fortification standards and design targeted capacity-development interventions.

Methodology: Rapid appraisals included: (i) quantitative data collection; (ii) observation of fortification processes; (iii) iron spot test (IST) of flour samples. In the 2020 round, 18 out of 20 millers who NI was supporting were selected using a predetermined criterion: (i) mills operational at the time of assessment; (ii) voluntary participation; (iii) consent to conduct IST. In 2021, NI expanded the program to cover more millers across six millers' associations. 62 of 280 millers (22%) were selected mainly using the same criteria, in addition to including those had received NI's support. A total of 56 flour samples were tested for compliance.

Results: High maize grain prices (by 38% in 2020, 28.2% in 2021) and aflatoxin levels (by 19.1% in 2020, 34% in 2021) were reported as major challenges. In 2020, COVID 19 had a significant effect on millers' business performance; millers reported operating at less than half of their installed capacity. In 2020, 35% mills reported shortage of premix due to COVID-19 restrictions, in 2021, high costs and poor quality were premix-related challenges reported by 27.4% and 15.1% respectively. While majority (>90%) owned microdosers, weekly calibration of microdosers was done by <30% mills.

Conclusion: It is important to identify issues that impact fortification compliance and design specific capacity-development/ intervention packages for millers to improve QA/QC procedures, technology and adherence to standards. NI-supported implementation of interventions contributed to improvement in compliance of production of adequately fortified maize flour from 28% in 2020 to 39% in 2021.

Impact of urbanization on food systems and nutrition leading to metabolic syndrome in Low- and Middle-Income Countries: A systematic review and Meta-analysis

Phenias Nsabimana[1], Olivier Sombier Ouahamin[2], Nele Pauwels[4], Hilda Vasanthakaalam[3], Stefaan De Henauw[4], Souheila Abbeddou[4]

1. Ghent University (Belgium), 2. Institut de Recherche en Sciences de la Santé (IRSS) (Burkina Faso), 3. University of Rwanda (Rwanda), 4. Ghent University (Belgium)

Background and objectives: The prevalence of metabolic syndrome (MetS) is on the rise in an urbanizing world. Urbanization is likely associated with the reduced access to healthy food patterns. An understanding of health effect of this process is needed for effective interventions and policies. The study objective is to review the impact of urbanization on food systems and nutrition leading to the development of MetS in Low- and Middle- Income Countries (LMIC).

Methods: A comprehensive search of five databases (PubMed, Web of Science, Scopus, Embase and Cochrane Library) was performed from November 2021 to January 2022. Following to the Preferred Reporting Items for Systematic Reviews and Meta- Analysis (PRISMA) guidelines, peer-reviewed studies conducted from 1954 to January 2022 and published in English were included in the present systematic review. Appropriate search terms were used for the main concepts which are MetS, dietary patterns and urbanization in LMIC. Study selection was done in two stages an in duplicate.

Results: 34 studies out of 8,875 identified studies met the eligibility criteria. The rate of MetS varied from 11.0% to 57.8% depending on sex, age and region. The highest rate (57.8%) was observed among the Egyptian urban residents in Alexandria. The lowest rate (11.0%) was reported in northwest Chinese adults. A difference in prevalence of MetS between urban and rural resident was found in the majority of studies. Fifteen studies reported a significant association between dietary patterns and the prevalence of MetS. Similarly, seventeen studies showed a significant association between urbanization and MetS.

Conclusions: This systematic review identified possible association between low access to healthy food and the high prevalence of MetS in urban residents.

Food Consumption Data Collection in the Balkan Region According to the EFSA EU Menu Methodology Standards and its further applications in project FNS-Cloud

Maria Glibetic[1], Jelena Milesevic[2], Milica Zekovic[3], Marija Ranic[4], Agnes Kadvan[5], Mirjana Gurinovic[6]

1. University of Belgrade, Institute for medical research (Serbia), 2. University of Belgrade, Institute for medical research (Serbia), 3. University of Belgrade, Institute for medical research (Serbia), 4. University of Belgrade, Institute for medical research (Serbia), 5. Capacity Development Network in Nutrition in Central and Eastern Europe, CAPNUTRA (Serbia), 6. Capacity Development Network in Nutrition in Central and Eastern Europe, CAPNUTRA (Serbia)

Background and Objective: Initiatives in the Capacity Development in Nutrition Research in the Balkan region in the last decade have focused on developing Research Infrastructure (RI) compliant with European standards to overcome the evident lack of comparable and harmonized food consumption and food composition data in the region. This study presents a process implementation of the European Food Safety Authority (EFSA) EU Menu methodology during the EFSA support projects for Food consumption data collection in four countries (Serbia, Montenegro, Bosnia and Herzegovina, and North Macedonia) in a synchronized way. The study also explores how the data is employed on an open-access pan-European platform like the H2020 project called FNS-Cloud.

Methods: The EU Menu methodology in Balkan countries was made possible by applying an innovative tool for standardized food consumption data collection and dietary intake assessment, the DIET ASSESS & PLAN (DAP). DAP operates with the Balkan food platform (Serbian food composition database (FCDB) and Regional FCDB), compliant with European Food Information Resource (EuroFIR™) standards. It includes computerized food consumption, anthropometric measurements, physical activity questionnaires, a validated food picture book, and a FoodEx2 exposure hierarchy with sets of facet descriptors of the interest. FoodEx2 and LanguaL coding systems enable flexibility in data utilization and facilitate the food matching process and international data comparability. To enable harmonized data collection, methodology required the development of study protocol, extensive education and training of study personnel, and process surveillance by internal and external coordinators.

Results: Food consumption data from the Balkan region are cataloged and matched with their datasets from Europe within EC H2020 project FNS-Cloud, creating a platform for interconnected food databases and research tools for various research in food composition and consumption, nutrition, and other related topics.

Conclusions: The collection of food consumption and composition data in the Balkan region presents evidence for further nutrition research, provides infrastructure for policy-making lacking in public health nutrition in the region, and has a long-term effect on developing a sustainable food system. Harmonization with European standards categorizes these datasets as adequate for joining the international research arena for further exploitation.

PAB(T6)-245

Association between chewing habit and risk of excess gestational weight gain

Eri Abe[1,2], Minatsu Kobayashi[1,2], Kohei Ogawa[2], Naho Morisaki[2], Hisako Tanaka[2], Reiko Horikawa[2]

1. Otsuma womens university (Japan), 2. National Center for Child Health and Development (Japan)

Objective: Achieving appropriate gestational weight gain (GWG) during pregnancy is essential for maternal and child health. It has been reported that those who chew more often have a lower risk of obesity, but few studies have examined GWG during pregnancy and mastication. Therefore, this study aimed to clarify the relationship between mastication habits and the risk of excess gestational weight gain among Japanese women.

Methods: This study analyzed data from a prospective cohort study conducted from May 2010 to November 2013 at National Center for Child Health and Development, a hospital in an urban area (Tokyo, Japan), which included 1246 pregnant women. Participants fulfilled a questionnaire about dietary habits during 26–40 weeks' gestation. We categorized participants into three groups based on responses to the question "Do you chew your food well?": Group 1, "never" or "rarely"; Group 2, "sometimes"; and Group 3, "usually" or "always". We assessed GWG using the Optimal Weight Gain Chart for Pregnancy from the Japanese Ministry of Health, Labor and Welfare; participants' weight gain was classified as "excess" if it exceeded the criteria. We performed multivariate logistic regression analysis to examine the relationship between the risk of excess GWG and chewing habits.

Results: Of the 1246 participants, 137, 434, and 675 were classified into Group 1, Group 2, and Group 3, respectively. While there were no significant differences in age, pre-pregnancy BMI, or energy intake among the three groups, a significant difference in gestational weight gain (Group 1: 10.5 kg ± 3.8, Group 2: 10.1 kg ± 3.7, Group 3: 9.5 kg ± 3.5, p = 0.004) was found. The current study found pregnant women in Group 3 had a higher risk of excessive GWG compared with those in Group 1 (OR: 0.512, 95%CI: 0.348–0.755), albeit non-significant difference between Group 1 and Group 2.

Conclusions: Pregnant women who regularly chew their food well had a lower risk of excess GWG.

Keyword: Pregnancy, Gestational weight gain, Dietary habit

Greenhouse Gas Emission from Food Consumption; Results from the Icelandic National Dietary Survey 2019-2021

Ragnhildur Gudmannsdottir[1], Steina Gunnarsdottir[1], Johanna Eyrun Torfadottir[2], Holmfridur Thorgeirsdottir[2], Olof Gudny Geirsdottir[1], Maria Gudjonsdottir[1], Ingibjorg Gunnarsdottir[1], Bryndis Eva Birgisdottir[1], Olafur Ogmundarson[1], Thorhallur Halldorsson[1]

1. University of Iceland (Iceland), 2. Directorate of Health (Iceland)

Background and objectives: Food is one of the main drivers of global greenhouse gas emission. It is important to investigate the environmental impact of food choices in relation to health. The dietary carbon footprint (DCF) based on results from the National Dietary Survey have not been examined for Iceland before. The objective was to estimate the DCF of dietary habits of Icelandic adults. This was done by using three independent food databases from different countries, due to a lack of local data for the carbon footprint of food consumed in Iceland.

Methods: A carbon footprint calculator was implemented, using data from three different food databases from Denmark, the US, and France, which all include the carbon footprint of the presented food items. The DCF was calculated using results from the latest National Dietary Survey, including data from 2019-2021. This was a random study sample of 18-80 years old Icelanders including 822 participants, 428 (52%) females and 394 (48%) males. The participation rate in the National Dietary Study was 51%. In addition to background data, two non-consecutive 24-hour recalls of food intake, and a food frequency questionnaire were used to evaluate dietary intake.

Results: Total DCF from the three databases was on average 7.4 kg $CO_{2\ eq}$. The highest DCF emission originated from the consumption of meat and meat products (39%) (median 800g/week) and dairy products (16%) (median 250g/d), while DCF emission from the consumption of seafood (median 300g/week) had a wider range (6-17%). Beverages also contributed to a significant portion (13%), while other food groups contributed less than 10% to the DCF in all the databases.

Conclusion: The main driver for the DCF of Icelandic food consumption, as identified by the three databases, was considerable meat and dairy consumption, contributing to an average of 55% of the total DCF. The consistent results obtained suggest that uncertainties in estimating DCF from different foods using the three databases are not critical in terms of identifying key drivers of greenhouse gas (GHG) emissions.

The estimated health impact of the World Health Organization global sodium benchmarks for packaged foods in Australia: a modelling study

Kathy Trieu[1], Daisy Coyle[1], Emalie Rosewarne[1], Maria Shahid[1], Rain Yamamoto[2], Chizuru Nishida[2], Feng He[3], Matti Marklund[1,4], Jason H Y Wu[1]

1. The George Institute for Global Health, University of New South Wales (Australia), 2. The World Health Organization (Switzerland), 3. Wolfson Institute of Population Health, Barts and The London School of Medicine and Dentistry, Queen Mary University of London (UK), 4. Johns Hopkins Bloomberg School of Public Health (USA)

Background and objectives: In 2021, the World Health Organization (WHO) set global sodium benchmarks for 58 packaged food categories, to help countries put in place feasible and effective sodium reformulation programs for lowering sodium intake and preventing related diseases. We modelled the potential dietary and health impact of achieving the WHO's global sodium benchmarks in Australia and compared it to the potential impact of the Australian government's 2020 sodium reformulation targets.

Methods: We used nationally representative data on food and sodium intake, sodium levels in packaged foods, and food product sales volume to estimate sodium intake pre- and post-implementation of the WHO sodium benchmarks and the Australia's current sodium reformulation targets, for 24 age-sex groups (>24 years). Using data from the Global Burden of Disease Study and comparative risk assessment models, we estimated the potential deaths, incidence, and disability-adjusted life years (DALYs) averted from cardiovascular disease (CVD), chronic kidney disease (CKD) and stomach cancer based on the reductions in sodium intake.

Results: Full compliance with the WHO's global sodium benchmarks for packaged foods in Australia could lower average adult sodium intake by 404mg/day, corresponding to a 12% reduction. This could prevent about 1,770 deaths/year (95% uncertainty interval 1,168 to 2,587), corresponding to 3% of all CVD, CKD and stomach cancer deaths in Australia, and prevent some 6,900 (4,603 to 9,513) new cases, and 25,700 (17,655 to 35,796) DALYs/year from CVD, CKD and stomach cancer. Full compliance to the Australian government's current sodium reformulation targets was estimated to reduce sodium intake by 3% (or 107mg/d) and avert around 510 deaths/year (335 to 757). By adopting WHO's sodium targets for packaged foods instead of Australia's targets, this could avert around 1260 *more* deaths (95% UI 740 to 1,950) each year.

Conclusion: Achieving the WHO global sodium benchmarks for packaged foods in Australia could avert around 1,770 deaths/year – more than triple the number of deaths that could be averted through Australia's current sodium reformulation program. The Australian government could strengthen its current reformulation program to have substantially more health impact by adopting WHO's more strict and comprehensive sodium targets for packaged foods.

Comparison of eating behaviors, self-rated health and food intake of college students pre- and post-COVID-19

Tomoko Osera[1,2], Anna Oue[1], Yasuhiro Iimura[1], Airi Sekine[1], Saki Maruyama[2], Yukiko Segawa[3,2], Hiroko Hashimoto[3,2], Nobutaka Kurihara[2]

1. Toyo University (Japan), 2. Kobe Women's Univirsity (Japan), 3. Osaka Seikei College (Japan)

Background and objectives: The coronavirus disease 2019 (COVID-19) pandemic has had several impacts on human lives. In 2020, Japan underwent measures close to lockdown for several months. In 2021, life was gradually returning to normal but eating out, including alcohol drinking, remained restricted in Japan. Many other things, including increased stress and lack of exercise, have been reported. In this study, we examined the presence or absence of lifestyle changes, self-rated health (SRH) status and eating habits of pre- and post-COVID-19 Japanese university students.

Methods: A cross-sectional survey was conducted among Japanese adolescents in 2019 and in 2021. The self-administered SRH and food frequency questionnaires distributed to the students contained 18 items. The change variables were analyzed using t-test and Fisher's exact test. P<0.05 was considered statistically significant.

Results: The participants (n=193) were mostly female (75.1%), aged at 20.0±0.9 y.o. and had a self-reported BMI of 21.3±3.6 kg/m^2. Regarding eating behaviors, the proportion of participants “shopping for dinner”, “helping with meals”, “have conversation during meals” and “concerned about food” was higher in 2021 than in 2019 (P<0.05). Regarding food intake frequency, the vegetable intake of the participants was higher in 2021 than in 2019 (86±89 (2019) vs 194±119 (2021) g/day, P<0.05). Intake of the nutrients β-carotene (2309±1302 vs 2864±1525 µg/day), vitamin K (171±83 vs 209±90 µg/day), vitamin C (58±28 vs 97±35 mg/day) and dietary fiber (9.8±3.3 vs 11.4±4.1 g/day) was higher in 2021 than in 2019 (P<0.05). There were no significant differences in SRH between 2019 and 2021.

Conclusions: Comparing the participants in 2021 and in 2019, their eating behaviors improved and vegetable intake increased. The increased may be due to restriction on eating out. Nutrients derived from vegetable were also increased. Thus, in these 2 years, eating behaviors changed, but SRH did not change.

Associations of carbohydrate quantity and quality with all-cause and cause-specific mortality in a prospective cohort study

Hyun Jeong Cho[1], Woo-kyoung Shin[1], YoonJu Song[2], Jong-Koo Lee[1], Daehee Kang[1], Jung Eun Lee[1]

1. Seoul National University (Korea), 2. The Catholic University of Korea (Korea)

Background and objectives: The long-term effects of low carbohydrate diets on health outcomes are controversial and inconclusive. We aimed to examine the associations of carbohydrate quantity and quality with mortality from all-cause, cancer, and cardiovascular disease (CVD) mortality among Korean adults.

Methods: We included 113,043 participants aged 40-69 years who did not report extreme caloric intake after excluding those who died within three years from the baseline in the Health Examinees-Gem (HEXA-G) study in Korea. Participants' dietary intake was recorded using a validated semi-quantitative food frequency questionnaire. We used Cox proportional hazards regression model to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) for all-cause, cancer, and CVD mortality.

Results: During an average follow-up of 9.2 years, a total of 2,009 deaths (1,035 deaths from cancer and 304 deaths from CVD) were documented. After multivariable adjustment, <55% of energy intake from carbohydrates was significantly associated with increased risks of all-cause and CVD mortality compared to 55-65% of energy intake from carbohydrates when total fat was replaced with carbohydrate; HRs (95% CIs) were 1.43 (1.02-2.02) for all-cause mortality and 3.41 (1.53-7.63) for CVD mortality. However, we did not find any association with cancer mortality [HR (95% CI) = 1.08 (0.65-1.79) for <55% vs. 55-65% of energy from carbohydrates]. When we examined the association of dietary glycemic index (GI) and glycemic load (GL) with mortality, we did not find significant associations.

Conclusions: The data from the HEXA-G study indicated that <55% energy intake from carbohydrates was associated with an increased risk of mortality from all-cause and CVD among populations with high carbohydrate intake.

Research on the actual nutritional status and the development of nutritional tools for older adults participating in Kayoinoba

Keiko Motokawa[1], Mananori Iwasaki[1], Maki Shirobe[1], Yuki Ohara[1], Ayako Edahiro[1], Yutaka Watanabe[2], Shuichi Obuchi[1], Yoshinori Fujiwara[1], Hirohiko Hirano[1]

1. Tokyo Metropolitan Institute of Gerontology (Japan), 2. Hokkaido University (Japan)

Background Japan urgently required policies for managing an expected increase in the number of older adults in need of long-term care in the near future. Current approaches have included the expansion of Kayoinoba (community-based salon for the older adults) that can contribute to prevention of disability and dependency. With regard to nutrition, Kayoinoba activities such as shared meals are expected to address undernutrition; nevertheless, evidence of specific outcomes is limited. Therefore, this study aimed to examine physical and nutritional status among older adults participating in Kayoinoba and create a nutritional support tool based on results that can be utilized in this setting.

Methods The current study included 651 adults who participated in a Kayoinoba that provided meals. The survey items included nutritional status assessment using the Mini Nutritional Assessment - Short Form (MNA®-SF); an oral examination; grip strength and anthropometric measurements; and body composition measurement using In Body S10. We also administered a self-assessment questionnaire including a basic frailty assessment checklist. We described health characteristics of Kayoinoba participants. Then, we developed support tool consisting of the specific contents of basic frailty assessment checklist. The predictive validity of this tool was determined by calculating sensitivity and specificity.

Results Based on MNA®-SF, participants' nutritional status was categorized into risk of malnutrition (22.1%), and malnourished (1.7%). The prevalence rate of frailty based on basic checklist was 22.4%. Developed tool has 4 questions regarding nutrition and oral health. The cut-off to best differentiate between individuals with risk of malnutrition and malnourished was 1 with a sensitivity of 72% and specificity of 51%. The screening score based on only the question of nutrition has lesser predictive validity.

Discussion and conclusion the percentage of Kayoinoba participants with undernutrition was small, many were at risk; the frailty rate was about double that of in previous studies. This suggests a need for measures that enable the early discovery of undernutrition and frailty at Kayoinoba. Based on these results, we created a simple nutritional support tool that can be used in Kayoinoba. We plan to disseminate and teach people about the tool for use in the future.

Keyword: older adults, undernutrition, oral function, community-based salon, nutritional support tool

PAB(T6)-251

Food Environmental Interventions Using Nudge Tactics in a Hospital Convenience Store is Cost-Effective

Teruko Kawabata[1], Masakazu Nakamura[1], Yukari Takemi[2], Fumi Hayashi[2], Takashi Yamada[1]

1. Japan Association for Development of Community Medicine (Japan), 2. Kagawa Nutrition University (Japan)

Background and objectives: During the COVID-19 pandemic, protecting healthcare workers' wellbeing has become even more essential than before. A food environment intervention was conducted in a hospital convenience store in Tokyo to improve employees' eating habits. The objectives of this study were to evaluate increased store sales and the cost-benefit of the intervention.

Methods: This strategy incorporated nudge tactics, a behavioural economics technique that entails increasing healthy options as well as easy-to-pick-up placement, eye-catching information and price incentives. Sales were examined by means of a quasi-experimental design. The control store was of the same company inside another hospital in Tokyo. The results were compared for five months, i.e. from April to August 2019. The primary outcome of this strategy was an improvement in overall sales, whereas the sub-outcomes entailed increased sales of the targeted products and an increased number of bowl noodles sold by salt content. All sales were evaluated using a sample *t*-test, whereas the number of bowl noodles sold was evaluated using the Mann–Whitney *U* test. The costs and benefits were analysed for one year, i.e. from April 2019 to March 2020. Costs were defined as the increased expenses required for the intervention, including point-of-purchase advertising production costs, decreases in revenue due to price discount, the costs of implementation specialists and others. Benefits were defined as increases in total sales. The evaluation indices used were the cost-benefit ratio and net benefits.

Results: At the intervention store, total sales relative to average sales for the same period of the previous year increased by 106% ($p < 0.001$); furthermore, targeted product sales for salads, sugar-free beverages and others increased between 120% and 146%. Number of bowl noodles sold decreased significantly for high-salt items ($p < 0.001$). The control store showed no such changes. The total cost of the intervention was ¥1,188,388, and the profit earned was ¥3,001,436. Therefore, the cost-benefit ratio and net benefit were 2.5 and ¥1,813,048, respectively.

Conclusions: The results indicate that this food environmental intervention in the hospital's convenience store by means of nudge tactics was cost-beneficial and contributed to increasing the store's sales.

Can an Enhanced Homestead Food Production (EHFP) Program Improve a Household's Resilience to the COVID-19 Pandemic: Evidence from Rural Bangladesh

Aminuzzaman Talukder[1], Md Abul Kalam[1], Archis Banerjee[1], Md. Amin Uddin[1], Mehedi Hasan[1], Chowdhury Abdullah Al Asif[1]

1. Helen Keller International (Bangladesh)

Background and objectives: This study investigates the impact of an Enhanced Homestead Food Production (EHFP) approach (to produce plant and animal-based foods at home for consumption and income generation) on household food consumption, women's dietary diversity, and household food security following shutdowns due to the COVID-19 pandemic in Bangladesh. To examine a potential causal link, we use a recent primary dataset of former and present participant households of a six-year, multi-sector initiative in Sylhet Division, SUCHANA, that aims to prevent child undernutrition of the poor and very poor in the first 1,000 days of their lives.

Methods: Data were collected using a seasonal cross-sectional cluster random survey in June-July 2020 using a structured questionnaire from 1,464 participant households randomly selected from four project implementation phases that took place between 2017-2020. Households were divided into former (six months since exited), active (18-30 months since starting the program), and newly enrolled (not started EHFP) households. To measure the impact of EHFP in terms of exposure duration, we compared the newly enrolled households with former and active households. Level of production, consumption from HFP, household food security, and women's dietary diversity were assessed and compared.

Results: Former and active households significantly ($p<0.00$) produced more vegetables (43% and 79%, respectively), eggs (79% and 150%), and poultry (71% and 90%) compared to newly enrolled households. Severe food insecurity was 4% and 7% less prevalent among former and active households compared to the newly enrolled group. Former and active households were 15% and 1.5% respectively less likely to have suffered from food scarcity or decreased food consumption compared to newly enrolled households. Minimum dietary diversity was higher for women in the former (11%) and active (21%) groups compared to the newly enrolled group.

Conclusions: From 1999 to 2016, Bangladesh has developed national policies that identify HFP as a pathway to resilience and poverty reduction, in part by involving women in agriculture. Our research suggests that rural poor households' ability to cope with the protracted crises, the associated restrictions, and disruption

PAB(T6)-253

Effects of the COVID-19 pandemic on the diet of Chilean elderly people.

Carlos Marquez[1], Lydia Lera[1], Rodrigo Saguez[1], Ximena Diaz[2], Natalia Bello[2], Cecilia Albala[1]

1. INTA, Universidad de Chile (Chile), 2. Universidad del Bio Bio (Chile)

Background and objectives: Chile is experiencing an advanced demographic transition characterized by an increase in life expectancy accompanied by an accelerated population aging. The COVID-19 pandemic placed a burden on the health system, the economy, and people's quality of life. Older people are one of the groups that has been most affected due to this situation, among other things they have difficulties to carry out their activities of daily living. Our research objective is to characterize the food access of Chilean elderly people during the Covid-19 pandemic and its association with different factors.

Methods: A cross-sectional study was carried out in a sample of older adults from two regions of Chile (Central and South of the country), a questionnaire was applied via telephone to assess the impact of the pandemic on their daily lives. We used chi squared test to compare differences in the consumption of multiple groups of foods between sexes. we carry out logistic models adjusted for sex, age, region of origin and depression, to evaluate the association of the difficulty of access to food in the context of a pandemic.

Results: The total sample is 374 participants, 59.4% from the central zone, 73% are women, the average age is 74.2$\pm$7.6 years. In relation about having difficulty accessing the purchase of food, 15.5% declares having some or many problems, when observing differences between the sexes, statistically significant differences can be observed 21.8% in men vs 13.2% in women $p<0.05$. When we asked about the consumption of fruits and vegetables, 11.3% of the participants declared to have decreased their consumption due to social isolation, without differences according to sex. In the logistics models we found significant associations between sex (Women) (OR:0.43 CI95%:0.21-0.88), Region (South) (OR:59 CI95%:13.16-264.76) and depression assessed by GDS-5 (OR:2.44 IC95%:1.12-5.32) with the access to fruits and vegetables.

Conclusions: The social isolation caused by the pandemic has affected the diet of the elderly, making it difficult to access healthy foods such as fruits and vegetables and this could impact their nutritional and general health status.

Keyword: Aging, Diet, COVID-19

Barriers and enablers towards achieving effective coverage of key nutrition interventions in LMICs

Megan Parker[1], Elan Ebeling[1], Kiersten Israel-Ballard[1], Carrie Hubbell Melgarejo[1], Debjeet Sen[2], Laura Meyer[1], Sadaf Khan[1], Jessica Shearer[1], Katharine Shelley[1], Kimberly Mansen[1]

1. PATH, USA (USA), 2. PATH, South Africa (South Africa)

Background and objectives: Nutrition related factors contribute to 45% of under five deaths. Successful scale up of evidence-based nutrition interventions remains challenging. To inform future strategies, the Asset Tracker project sought to identify and understand barriers and enablers to scale across key nutrition interventions: IFA (iron-folic acid), MMS (multiple micronutrient supplementation), EIBF/EBF (early initiation and exclusive breastfeeding), FSSN (feeding of the small and sick newborn), BEP (balanced energy protein), and MgmtAM (management of acute malnutrition).

Methods: The Asset Tracker 6-stage scale-up framework toward effective coverage—global guidelines and market availability, national policy adoption, system integration and readiness, implementation and service delivery, availability, and coverage—anchored data collection, analysis, and synthesis across a multistep approach for each intervention. This included a literature review on barriers, enablers, and implementation; 41 global and 53 country key informant interviews across five countries (Burkina Faso, Ethiopia, India, Kenya, and Nigeria); compiling 99 nutrition indicators relevant to our six assets from DHS, SPA, SARA, HMIS, ENAP, and WHO Policy Survey; and reviewing 277 policy documents, budgets, guidelines, and training curriculums. Tableau data visualizations were created to aid interpretation and presentation as an interactive Global Good.

Results: The six interventions were categorized into three subgroups relating to barriers, enablers, and implementation reach along the framework towards effective coverage. Subgroup 1 (new and donor-dependent) for BEP, MMS, and FSSN; subgroup 2 (complex and for specific cases) for MgmtAM; and subgroup 3 (available/supported by not equitable) for IFA and EIBF/EBF. All six assets had a global policy available, only three (IFA, EIBF/EBF, MgmtAM) had a national policy in the five countries. Two of six assets (IFA, EIBF/EBF) reached the last data milestone representing effective coverage. IFA:5-50% of pregnant women took >90 IFA tablets. EIBF/EBF:42-73% of infants were put to the breast within the first hour of life; 29-61% of children <6 months are EBF in priority countries.

Conclusion: Data availability is lacking for most assets to complete the scale-up story. Gaps across the implementation framework prevent effective coverage. Tailored strategies by subgroup could be utilized to address implementation barriers along the framework and accelerate uptake, implementation, and effective coverage.

The effects of the active education combined with weekly taking iron supplements to increase the nutritional status and anemia of the reproductive Tay ethnic women in Vietnam

Van Thi Hong Tran[1], Huong Thi Le[3], Eiko Yamamoto[2], Ham Van Do[1], Tam Thi Thanh Nguyen[1,2]

1. Thai Nguyen University of Medicine and Pharmacy (Viet Nam), 2. Nagoya University Graduate School of Medicine (Japan), 3. Ha Noi University of Medicine (Viet Nam)

Background and objectives: Anemia is a common disease among reproductive Vietnamese women, especial in minor ethnics. This study aims to evaluate the effect of positive communication in raising awareness combined with weekly taking iron tablets on the nutritional status and anemia among Tay ethnic reproductive women.

Methods: A non-randomized quasi-experimental, controlled before-after study was conducted in two wards in Phu Luong District, Thai Nguyen Province, in 2017-2018. The participants were 188 Tay ethnic women aged 20-35 years. They had no hematologic diseases or pregnant. All participants were divided into the intervention group (n=96) and the control group (n=92). Both groups were performed the anthropology and blood testing at the enrollment and the end of study. The intervention group were given as following interventions: health workers'home visits to access their nutrition condition to provide consultations about anemia; joining an outstanding communicator competition in anemia in reproductive women; taking an iron supplement Fumafer-B9 Corbiere 200mg (66mg iron+1mg folic acid) every Sunday for 6 months. Healthcare workers monthly monitored by meeting the intervention group. The control group did not receive medicine, monitoring, or consultations. Chronic energy deficiency (CED) was defined as BMI<18.5kg/m^2. Anemia was defined as hemoglobin (Hb)<12.0g/dL and ferritin<15µg/L. The data were analyzed by STATA13.0, one-sample T-Test and paired-sample T-test were used.

Results: The study outcomes were evaluated after 6 months. The CED proportion in the intervention group decreased to 13.6%, compared with 3.3% of the control group. Hb and serum ferritin increased by 5g/l and 19.2g/l, respectively in the invention group. The control group showed no change in the Hb level and an increase of 1.7mg/L of the serum ferritin level. Regarding the proportion of anemia, the intervention group showed a decreased to 15.6%, the control group increased to 1.1%. The iron storage depletion reduced by 10.4% in the women

using medicine, and 2.2% in the control group. The statistical analysis was significant difference.

Conclusions: Intervention by positive communication combined with taking iron tablets weekly has improved nutrition and anemia situation in the 20-35 aged women of Tay ethnic.

Galvanizing Community Actions and Male involvement to address Stunting in Shefa and Sanma Provinces in Vanuatu.

Leiwaku Noah, Adaeze Oramalu-Ogwuche, Jennifer Weiss, Carolyn O'Donnell, Anne Crawford, Adele Harmer

Background and objectives: Globally, chronic malnutrition, which is evident by stunting, has declined steadily since 2000 – but faster progress is needed to reach the 2030 Social Development Goals target. According to the 2021 Global Nutrition Report, stunting rates in Vanuatu increased from 25.7% to 28.9% between 2008 and 2013 and the prevalence of anemia among women of reproductive age increased from 24% in 2010 to 25% in 2016. Various factors affect nutrition practices and behaviour change such as traditional norms, influence of fathers & older women in the household. Save the Children (SC) implemented the ***First 1,000 Days Program*** in 22 selected Communities in Shefa and Sanma Provinces of Vanuatu from 2017 to 2021 with the aim of contributing to the reduction of stunting in Children under 2 by increasing coverage of evidence-based health and nutrition practices among pregnant and lactating women (PLW) and caregivers.

Methods: **SC used the Community Action Planning (CAP)** approach to establish Development Committees, develop community-led solutions, and strengthen community engagement for the adoption of appropriate MCHN behaviours. This approach resulted in stronger engagement of Men for the promotion and prioritization of maternal and child health and nutrition (MCHN) behaviours. SC used the ***Peer Support Group Approach*** to deliver preventive nutrition interventions directly to beneficiaries including promotion of maternal and child health and nutrition (MCHN) practices among PLW, older women in the households and men.

Results: Endline evaluation among beneficiaries showed stunting rates reduced from 20.8% to 13.8%, minimum acceptable diet increased from 35.7% to 54.2%. Also, knowledge of key MNCH practices increased significantly among women (84.9%) and men (81.8%), increase consumptions of grains/roots, dairy, flesh foods and vitamin A-rich fruits & vegetables for children 6-23 months and women of reproductive age. Women who reported they could make decision for their own and child's health and nutrition increased to 40% while 77% of men agree that decisions on the health and nutrition of mother and child should be jointly made.

Conclusions: Effective engagement of men in programme implementation creates conducive environment for the adoption of appropriate health and nutrition behaviours in the household.

PAB(T6)-257
Using co-design to change attitudes towards food waste and healthy eating in adolescents

Eva L Jenkins[1], Linda Brennan[2], Tracy A McCaffrey[1]

1. Monash University (Australia), 2. RMIT University (Australia)

Background and objectives: One-third of food produced globally is lost or wasted, having severe impacts on greenhouse gases. One major cause of food waste at the consumer level is leftovers, which are often seen as unappealing and are often thrown out. Adolescents are a key age group to target with behaviour change interventions as they are developing their life-long beliefs and behaviours. The aim of this intervention was to increase awareness of food waste and healthy eating, build adolescents' capacity for preparing and cooking food.

Methods: An 8-week co-design intervention (Re-licious) was piloted in a secondary school during Food Technology classes. Students watched videos on food waste and healthy eating based on information from the dietary guidelines. Students worked in small groups to identify leftover ingredients at home, and repurposed them to create a delicious meal suited to their needs. Students co-created criteria focussing on the question 'what is important to you in a recipe?' to ensure relevancy of recipes. Pre-and post-intervention questionnaires about food skills, food waste attitudes, and motivation and interest in health and healthy eating.

Results: 40 students aged 13 (n=16) or 14 years old (n=24) participated. Factors identified in the co-creation activity were: time taken to cook, difficulty level, healthiness e.g. inclusion of fruit or vegetables, and sustainability of ingredients. There was an increase in intention to reduce food waste ($p=0.007$), resourcefulness i.e. creating recipes with limited ingredients ($p<0.001$), and a change in personal norms, with students more likely to feel guilty when wasting food post-intervention ($p=0.048$). Re-licious reduced the number of students with low motivation and interest in health and healthy eating (n=6 to n=1) and increased those with high interest (n=11 to n=23).

Conclusions: Re-licious was successful in changing students' attitudes towards food waste and increasing students' motivation and interest in health and healthy eating. Re-licious holds promise in promoting sustainable lifestyles and should be scaled up in different age groups and populations.

Determinants of Receiving Anti-helminth Medication Among School-Age Children during National Deworming Week in the Chittagong Hill Tracts of Bangladesh

Afsana Habib Sheuly[1], Abdul Kader[2], Chowdhury Abdullah Al Asif[3], Zaman Talukder[4]

1. Helen Keller International (Bangladesh), 2. Helen Keller International (Bangladesh), 3. Helen Keller International (Bangladesh), 4. Helen Keller International (Bangladesh)

Background and Objectives: Soil-transmitted helminth (STH) infections are common chronic infections resulting in lower levels of key micronutrient adequacy, including vitamin A, iron, copper, selenium, cobalt, and zinc. To address this challenge, Helen Keller Intl, in collaboration with the Bangladesh Ministry of Health & Family Welfare, and with funding support from Johnson & Johnson, initiated a project to control STH in Bandarban District of the Chittagong Hill Tracts of Bangladesh. We explore the determinants of receiving anti-helminth medication among school-age children during the National Deworming Week (NDW). **Methods:** Data were obtained from a repeated cross-sectional post-coverage survey, one month after distribution of preventive chemotherapy during NDW in October 2018 from 1159 randomly selected households in 168 villages across the sub-district of Bandarban Sadar. Our analysis includes 1705 children aged 5 to 16 years. We undertook multivariate logistic regression analysis to better understand the characteristics associated with the receipt of medication. **Results:** During the NDW, 87% of school-aged children received deworming tablets. Multivariate logistic regression indicates older children (AOR 1.08, 95% CI 1.02-1.15, p<0.01), school-going children (AOR 31.58, 95% CI 18.48-52.92, p<0.00, and parents with a greater knowledge score on helminth infections (AOR 1.25, 95% CI 1.12-1.41, p<0.00) have a positive correlation with receiving medication. Distance of households from primary and secondary schools was not significantly related to receipt of medication. Controlling these factors, the education level of the household heads was not positively correlated with the receipt of anti-helminth medication. **Conclusions:** This study shows that parents' knowledge on helminth infections may be one of the key drivers that motivate children to receive medication, regardless of the education level of household heads. Awareness-raising campaigns on this topic should be reinforced.

Effect of underweight and anaemia in pregnancy on birthweight among rural pregnant women in Tamil Nadu

Vigneswari Aravindalochanan[1], Yunyun Chen[2], Sarada S Garg[1], Thangavel Gurusamy[1], Sheela Sinharoy[2], Usha Ramakrishnan[2], Kalpana Balakrishnan[1], Lance A Waller[2], Thomas Clasen[2], Jennifer Peel[3]

1. SRIHER, Chennai, Tamil Nadu (India), 2. Emory University, Atlanta, Georgia (USA), 3. Colorado State University (USA)

Background and objective: Low birthweight (LBW) is the leading cause of neonatal deaths and poor growth in children in India. Poor maternal malnutrition before and during pregnancy is an important risk factor for adverse pregnancy outcomes. Aim of this study is to estimate the combined effects of anaemia and underweight in rural pregnant women on the risk of delivering LBW infant in two sites of Tamil Nadu state in South India from Household Air Pollution Intervention Network (HAPIN) study **Methods:** 779 women with singleton pregnancies who were eligible and consented to participate were recruited <20 weeks of gestation with ultrasound confirmation. Maternal weight, height, haemoglobin and sociodemographic characteristics were obtained at baseline (BL). Birth weights were obtained within 24 hours of delivery (n=773 livebirths). Women were classified based on their Body Mass Index (BMI) and haemoglobin (Hb) levels at BL into 4 groups: G1-only underweight (BMI<18.5kg/m^2), G2-only anaemic (Hb<11g/dl), G3-anaemic & underweight and G4-neither anaemic nor underweight. Binomial logistic regression analyses were performed to assess the combined effect of anaemia and underweight on LBW (<2500gm) after adjusting for age, height, education, wealth index, gestational age (GA) at BL, parity, birth spacing, household food insecurity, dietary diversity, change of fuel use in pregnancy. **Results**: Mean maternal age, height, BMI, Hb and GA at BL were 23.9±4y, 151±1.4cm, 19.8±3.2kg/m^2, 10.4±1.3g/dl and 16±3 weeks, respectively. The mean GA at birth was 38.9±1.5 w. Mean birthweight of infants was 2591±393g. The prevalence of LBW was 49.5%, 29.6%, 50.9% and 36.8% in G1(n=91), G2(n=307), G3(n=212) and G4(n=163), respectively; 53.8% of new-borns were male. Compared to women in G4, the crude odds ratio (OR) for having LBW babies in G1, G2 and G3 were 1.6(95% CI 0.9-2.7:p=0.10), 0.7(0.5-1.1;p=0.11) and 1.8(1.2-2.7;p=0.007). The adjusted ORs for G1, G2 and G3 were 1.6(0.9-2.7;p=0.1), 0.7(0.4-1.0;p=0.05) and 1.7(1.1-2.7;p=0.015), respectively. **Conclusions:** BL underweight in women was the major contributor to LBW. The co-existence of anemia and underweight at BL was linked with significantly increased risks of LBW. Better outcomes in only anemic group may be due to the timing of Hb measurement, and possible prospective corrective measures taken during pregnancy course.

ssociation between Dietary Patterns, Anthropometric status, Lifestyle, and Bone Mineral Density among Postmenopausal women in Taiwan: A Cross-sectional Study

Narantsetseg Jargalsaikhan[1], Chien-Yeh Hsu[2], Hsiu-An Lee[3], Jane C.-J. Chao[1]

1. Taipei Medical University (Taiwan), 2. National Taiwan University (Taiwan), 3. National Health Research Institute (Taiwan)

Title: Association between dietary patterns, anthropometric status, lifestyle, and bone mineral density among postmenopausal women in Taiwan: a cross-sectional study **Background and objectives:** Dietary patterns influence bone health status. Decreased bone density often occurs in the postmenopausal women because of estrogen deficiency. The aim of this study was to investigate the association between dietary patterns, anthropometric status, lifestyle, and bone mineral density among postmenopausal women in Taiwan. **Methods:** A total of 10,451 postmenopausal women aged between 45 and 94 years who measured bone mineral density were recruited from Mei-Jau Health Institution from 2001 to 2015. The sociodemographic data, lifestyle, medical history, and dietary habits were collected by self-report questionnaires. Anthropometric data including body mass index (BMI), waist-to-hip ratio, and body fat were measured. Dietary intake was assessed using a validated food frequency questionnaire composed of 85 closed-ended questions, and intake frequency was identified for 22 food groups. Principal component analysis (PCA) was used to identify the dietary patterns. Multinomial logistic regression analysis was performed to determine the association between dietary patterns, anthropometric status, lifestyle, and bone mineral density.; fired-processed dietary pattern, vegetables dietary pattern, and dairy-grain dietary pattern. **Results:** Three dietary patterns including fired-processed, vegetables, and dairy-grain dietary patterns were derived by PCA. After full adjustments for confounders, participants who were awakened easily or hard to sleep were associated with a higher risk of osteoporosis by 22% (OR=1.22, 95% CI 1.07, 1.18) or 34% (OR= 1.34, 95% CI 1.15, 1.56), respectively. Underweight was significantly correlated with higher odds of osteoporosis (OR=2.02, 95% CI 1.57, 2.60) compared with normal BMI. Central obesity was negatively associated with the risk of osteoporosis (OR=0.59, 95% CI 0.51, 0.68). Participants in the higher quintile (Q4) of the dairy-grain dietary pattern were less likely to have the risk of osteoporosis (OR=0.73, 95% CI 0.60, 0.90) compared with those who were in the reference group (Q1). **Conclusions:** The dietary pattern with high intakes of milk, dairy products, and grains is inversely associated with a risk of osteoporosis. Furthermore, the incidence of osteoporosis is positively associated with underweight and poor sleep quality.

The South East Asian Nutrition Surveys (SEANUTS) Malaysia: Changes in eating habits of Malaysian primary schoolchildren aged 6-12 years over a decade

Giin Shang Yeo[1], Shoo Thien Lee[1], Nik Shanita Safii[1], Jyh Eiin Wong[1], Ilse Khouw[2], Bee Koon Poh[1], on behalf of the SEANUTS II Malaysia Study Group

1. Universiti Kebangsaan Malaysia (Malaysia), 2. FrieslandCampina (Netherlands)

Background and objectives: Accelerated modernisation and urbanisation in developing countries nurtures unhealthy eating habits in populations. Unhealthy eating habits, including meal skipping, are linked with poorer diet quality and central adiposity. Thus, this study aims to investigate the changes in eating habits, in terms of main meal intake and snacking habits by socioeconomic factors amongst Malaysian primary schoolchildren over a decade (years 2010-2020).

Methods: A total of 1429 children aged 6-12 years (SEANUTS I) from the entire Malaysia and 1183 children (SEANUTS II) from Peninsular Malaysia were included. Questionnaires were used to identify socioeconomic characteristics and eating habits. Complex sampling Pearson chi-square test was performed to determine the changes in eating habits.

Results: Approximately one-half and two-thirds of schoolchildren had three main meals [SEANUTS I 54.0% (95%CI 50.5-57.5); SEANUTS II 50.5% (95%CI 46.9-54.1)] and breakfast [SEANUTS I 64.4% (95%CI 61.0-67.8); SEANUTS II 66.2% (95%CI 62.7-69.5)] daily, respectively. Lower consumption of lunch [84.7% (95%CI 82.0-87.1) to 79.2% (95%CI 76.2-81.9), p<0.01] and dinner [80.8% (95%CI 77.8-83.4) to 73.8% (95%CI 70.5-76.9), p<0.01] were observed in 2020. A reduction trend was demonstrated in the daily three snacking habits which decreased from 19.6% (95%CI 16.7-22.7) in 2010 to 6.7% (95%CI 5.1-8.6) in 2020 (p<0.001). Less children consumed morning tea (29.7% 95%CI 26.6-33.0) and supper (16.5% 95%CI 14.0-19.4) daily as compared to 2010 [morning tea: 44.3% (95%CI 40.9-47.8), p<0.001; supper: 27.5% (95%CI 24.3-30.8), p<0.001]. A drastic decrease in the proportion of regular main meals consumption was observed amongst those living in rural areas [52.8% (95%CI 46.8-58.8) to 40.0% (95%CI 33.7-46.7), p<0.01], lower household income [49.4% (95%CI 44.2-54.5) to 34.1% (95%CI 27.4-41.6), p<0.01] and paternal secondary education [51.9% (95%CI 47.5-56.2) to 43.7 (95%CI% 38.8-48.6) p<0.001]. Lower proportion of three snacks, morning tea and supper consumption in 2020 were associated with all socioeconomic factors.

Conclusions: Over the past decade, irregular main meal consumption has worsened amongst Malaysian primary schoolchildren. Meal skipping is increasingly observed among children in rural areas, lower household income, and those whose father had secondary education. There is an urgent need to continuously promote healthy eating habits to children and their parents.

A study of the association between depression, diet quality, and metabolic syndrome in Korean adults

In Seon Kim[1], Sung-Min Yook[1], Ji-Yun Hwang[1]

1. Sangmyung University (Korea)

Background and objectives: Several previous studies suggested the possibility that has a relationship between depression and metabolic syndrome (MetS) based on having an unhealthy lifestyle such as low diet quality or sharing a physiological mechanism. Thus, this study investigated associations between depression, diet quality, and MetS, and whether diet quality modifies or interacts with an association between depression and MetS.

Methods: We analyzed using the data from 13,539 Korean adults aged 19 to 80 in 2014, 2016, and 2018 Korea National Health and Nutrition Examination Survey (KNHANES). Participants were divided into three subgroups according to depression severity levels (normal, mild, moderate to severe) based on the PHQ-9 (The Patient Health Questionnaire-9) score and overall diet quality to the KHEI (Korea Healthy Eating Index) score. We used complex sample multiple logistic regression to estimate ORs and 95% Cis. Diet quality levels further stratified models to explore whether diet quality modifies the association between depression severity and metabolic syndrome.

Results: Depression severity was significantly associated with the risk of MetS (p trend=0.006). However, an association did not exist between diet quality and MetS (p trend=0.064) after adjustment for age, sex, drinking status, education level, energy intake, and physical activity. The moderate to severe group showed a higher risk of MetS (OR: 1.723, 95% CI: 1.238-2.398) and abdominal obesity (OR: 1.699, 95% CI: 1.028-2.808) compared with the normal group only in the lowest diet quality group (T1). The associations between depression severity and MetS disappeared in the second (T2) and third (T3) tertiles of diet quality groups.

Conclusions: Our results suggest that a healthy diet could offset the increased risk of MetS for those with moderate to severe depression in the general Korean adult population.

Associations of MIND diet with cognitive function in the Japanese population: the Suita Cohort Study

Hinata Koyama[1], Fuka Takeda[1], Mie Awaya[1], Kiyoko Odani[1], Saya Nosaka[2], Misa Takegami[2], Aya Higashiyama[2], Yoshihiro Miyamoto[2], Yoshihiro Kokubo[2], Masahiro Tsuji[1]

1. Kyoto Womens University (Japan), 2. National Cerebral and Cardiovascular Center (Japan)

Background and Objectives: MIND (Mediterranean-DASH Intervention for Neurodegenerative Delay) diet is a healthy dietary pattern combining the Mediterranean diet and DASH (the Dietary Approaches to Stop Hypertension) diet and reportedly beneficial for delaying cognitive decline in older populations. However, its favorable effects are reported mainly in the US populations, and it effects for the Japanese population are unknown. The objective of the present study was to investigate associations of MIND diet with cognitive function in the Suita Cohort Study.

Methods: The Suita Cohort Study is following the urban-dwelling general Japanese population. A total of 1,503 participants correctly responded to questionnaire for MIND diet scoring. Among them, 103 participants (aged 75-90 years; 49% men) had recently been tested with Japanese version of Montreal Cognitive Assessment (MoCA-J) together with regular medical check-up.

Results: The average MIND scores (0-15; higher score is considered to be favorable to delay cognitive decline) were 8.93 for men and 9.69 for women. The average MoCA-J scores (the full score is 30) were 23.8 for men and 24.5 for women. Linear regression analysis demonstrated no association between MIND diet score with MoCA-J score (r = 0.139). Then, we analyzed associations between each score out of 15 dietary items of MIND diet with MoCA-J score. Five dietary items exhibited negative correlations, which were the opposite correlations observed in reported populations. For instance, frequent intake of red meat was favorable in this cohort, while less intake of red meat was favorable in previous reports. We modified MIND score using 10 dietary items, which exhibited positive correlations with MoCA-J score. Linear regression analysis demonstrated a modest but significant association between modified MIND diet score with MoCA-J score (r = 0.259, p = 0.008).

Conclusions: Favorable dietary patterns to delay cognitive decline may vary depending on the population and need to be modified accordingly.

Relative caloric price of food groups is associated with dietary intake of children 6-23 months of age at the subnational level. Evidence from UN WFP's Fill the Nutrient Gap assessments.

Janosch Klemm[1,2], Christopher Coffey[2], Mysbah Balagamwala[2], Zuzanna Turowska[2], Sabrina Kuri[2], Saskia de Pee[2,3]

1. University of Bonn (Germany), 2. UN World Food Programme (Italy), 3. Tufts University (USA)

Background and objectives: Understanding food environments and how they shape dietary and nutrition outcomes is key to transforming food systems for healthy, sustainable diets for the most vulnerable. Using subnational data from 28 LMIC countries, we explore how availability, relative and absolute food price relate to dietary intake of young children.

Methods: We utilize subnational price data from 28 FNG assessments, carried out between 2015 and 2021. We calculate minimum relative caloric price (RCP) of food groups, using the cheapest caloric price per food group and caloric price of local staples, identified by stakeholders at the subnational level. Accounting for datatype and country-level effects, we estimate the relationship between subnational food group information (relative price, absolute price, number of foods) and dietary intake indicators of children 6-23 months old (obtained from DHS or MICS surveys).

Results: Relative caloric price is negatively associated with dietary intake of children 6-23 months old on the subnational level, market assortment shows positive association to the same indicators. Specifically, the proportion of children that consumed a minimum diverse diet shows association with the RCP of eggs, fish, green leafy vegetables (GLV) and meat. Percentage of children that consumed iron-rich foods is associated with the RCP of eggs, fish and meat. Intake of Vitamin A is associated with RCP of GLV, meat, fish and fruit. No significant association was found for absolute price of the same food groups. The variation of subnational RCP within a country can be as high as the variation across countries.

Conclusion: We provide evidence that relative caloric price and market assortment are better predictors of dietary intake for children under two years of age than absolute price. This indicates that the food environment restricts individual choice because of market assortment. Furthermore, the association of child dietary diversity with relative prices suggests that relative price of foods affects the choices households (can) make. The heterogeneity of food environment indicators within countries is an urgent call to pay close attention to deprived areas within low and low-middle income countries, where compounding of risk factors leads to poor nutrition and health.

Chrononutrition behavior of young adults in Malaysia

Nur Islami Mohd Fahmi Fahmi Teng[1], Juliana Norsham[2], Khainunnisa Fazira Hairudin[1], Mazuin Kamarul Zaman[1], Wan Asma' Wan Abdul Fatah[1]

1. Universiti Teknologi MARA (Malaysia), 2. Universiti Sains Islam Malaysia (Malaysia)

Background and objectives: Chrononutrition is the interplay between nutrition and circadian rhythm. The emerging field of chrononutrition provides valuable information on how we manage food intake across the day. Additionally, the timing of meals and eating misalignment may impact an individual's adiposity. Therefore, this study aimed to investigate the potential association of chrononutrition behavior with Body Mass Index (BMI). Consistent with previous studies, we expected to find significant differences concerning chrononutrition patterns and body weight.

Methods: This is a cross-sectional study among 409 young adults, college students above 18 in Malaysia. The chrononutrition behaviour was assessed using the validated Chrononutrition Profile Questionnaire (CP-Q). Data were collected using an online platform. Participants self-reported their body weight and height. Data analyses were performed using SPSS.

Results: Our participants consisted of 89.5% female, and 10.5% of male (n=409). Participants' mean age is 21.5 ± 2.2 years old, with a mean BMI of 22.4 ± 5.13 kg/m2. The prevalence of underweight, normal, and overweight is 24.7%, 49.4%, and 25.9%, respectively. The chrononutrition behavior revealed that participants took breakfast about four times/week (mean 4.27 ± 2.43 days), and only 135 (33.0%) consumed breakfast daily. The largest meal taken is during lunch (75.8%). The prevalence of night eating is low, where most of the participants (70.9) did not wake up at night to eat. The mean of snacking after the last meal is 3.23 ± 2.01 days. We observed a significant association between BMI and eating window, evening latency, evening eating, and night eating. It was found that the underweight has a poor eating window (>14:00) (p = 0.001), poor evening latency (≦2:00) (p=0.001), poor evening eating (≧23:00) (p=0.002), and poor night eating (≧4 days/week) (p=0.042) as compared to those with normal and overweight BMI.

Conclusions: Underweight young adults are more likely to have poor chrononutrition behavior. This research suggests that nutrition intervention should also focus on the underweight as this population tend to develop poor eating habits.

Keyword: Chrononutrition, chronotype, college students, overweight, young adults

Health-related physical fitness and body weight status among children aged 6-12 years old in Malaysia: Findings from SEANUTS II

Kai Sze Chan[1], Farah Nor MF[1], Koh Denise[1], Jyh Eiin Wong[1], Job JM van Leeuwen[2], Bee Koon Poh[1], on behalf of the SEANUTS II Malaysia Study Group

1. Universiti Kebangsaan Malaysia (Malaysia), 2. FrieslandCampina (Netherlands)

Background and objectives: Childhood obesity is associated with reduced physical activity (PA) and health-related physical fitness (HRPF), all of which can increase the risk for non-communicable diseases in children. The present study aimed to assess HRPF according to body weight status among children aged 6-12 years old.

Methods: This was a nationwide, cross-sectional study conducted in Malaysia, part of the second South East Asian Nutrition Surveys (SEANUTS II). A total of 1504 primary school children (mean age: 9.6±1.7 years) participated in this study. Bodyweight and height were measured and classified using WHO 2007 BMI-for-age Z-score. HRPF was assessed with the following components: cardiorespiratory fitness (15-meter shuttle run), muscular strength (handgrip strength, standing long jump), muscular endurance (sit-ups), flexibility (V-sit and reach), and body composition (body fat percentage). The body fat percentage was assessed using InBody® body composition analyser.

Results: About 16% and 14% of the children were overweight (OW) and obese (OB), respectively, while 61% were normal weight (NW) and 9% were underweight (UW). NW children (VO_2 peak: 43.5 ml/kg/min) showed best cardiorespiratory fitness compared to OW (VO_2 peak: 41.4 ml/kg/min), OB (VO_2 peak: 40.2 ml/kg/min, p<0.001) and UW children (VO_2 peak: 42.7 ml/kg/min). In addition, NW children demonstrated the greatest lower-limb strength in the standing long jump (NW: 114.8cm vs. UW: 108.7 cm vs. OW: 107.5cm vs. OB: 96.5cm, p<0.001), and the highest muscular endurance (NW: 11 reps vs. UW: 10 reps vs. OW: 10 reps vs. OB: 8 reps, p<0.001) compared to OW, OB and UW counterparts. However, NW children showed lower handgrip strength (11.9kg) compared to children who were OW (14.5kg) and OB (14.7kg), while UW children demonstrated the lowest handgrip strength (10.1kg, p<0.001). No significant difference was found for flexibility among body weight groups. For body composition, UW children had the lowest body fat percentage (13.9%), followed by NW children (19.7%), OW (31.6%), and OB (40.7%, p<0.001).

Conclusions: Compared to normal-weight children, overweight and obese children demonstrated lower cardiorespiratory fitness, lower-limb strength, and muscular endurance. Interventions focusing on increasing PA and improving HRPF among school children are warranted to promote better weight control and overall health.

Ultra-processed food consumption, cancer risk and cancer mortality: a prospective study of the UK Biobank

Kiara Chu-Mei Chang[1], Christopher Millett[1], Fernanda Rauber[2], Renata B. Levy[2], Inge Huybrechts[3], Nathalie Kilemann[3], Marc J. Gunter[3], Eszter P. Vamos[1]

1. Imperial College London (UK), 2. University of São Paulo (Brazil), 3. International Agency for Research on Cancer (France)

Background and objectives: Dietary patterns worldwide are increasingly displaced by many cheap, highly palatable, and ready-to-eat ultra-processed foods (UPFs). Previous research has linked higher UPF consumption to increased risk for obesity, type 2 diabetes, and cardiovascular disease. However, prospective evidence is limited on cancer incidence and cancer mortality. This study aimed to examine the association between UPF consumption and risk for overall and site-specific cancer incidence and cancer mortality in a large and contemporary cohort of British adults.

Methods: The analytic sample included participants of the UK Biobank study who completed one or more web-based 24-hour dietary recalls between 2009-2012. Food items consumed were categorised according to their degree of processing using the NOVA food classification system. Individual UPF consumption were derived as a percentage of total food intake (g/d), averaged across multiple 24-hour recalls. Prospective association was assessed using multivariable Cox proportional hazards models adjusted for baseline socio-demographic characteristics, lifestyle factors, and total energy intake. Baseline menopausal status, use of oral contraceptives, hormone replacement therapy, and parity were additionally adjusted for female-specific cancers.

Results: A total of 197,426 UK Biobank participants (54.6% women) were included. Mean age at baseline was 58.0 (SD=8.0) years and mean UPF consumption was 22.9% (SD=13.3%). During a median follow-up time of 9.8 years, 15,921 individuals developed cancer and 4,009 cancer deaths encountered. Consumption of UPFs was associated with a higher incidence of overall cancer (hazard ratio [HR] per 10% increment in UPF consumption=1.01; 95% CI: 1.00-1.03), gastrointestinal cancer (HR=1.03; 95% CI: 1.00-1.07), lung cancer (HR=1.06; 95% CI: 1.00-1.13), and ovarian cancer in females (HR=1.15; 95% CI: 1.04-1.27). Furthermore, higher UPF consumption (per 10% increment) was associated with higher risk for overall cancer mortality (HR=1.07; 95% CI: 1.04-1.10), gastrointestinal cancer mortality (HR=1.05; 95% CI: 1.00-1.10), lung cancer mortality

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

(HR=1.07; 95% CI: 1.00-1.16), and ovarian cancer mortality in females (HR=1.31; 95% CI: 1.14-1.52).

Conclusions: This large UK cohort study presents evidence of positive associations between UPF consumption and risks for incidence and mortality of overall and many site-specific cancers. Consideration of the degree of food processing and lowering UPF consumption is crucially important for cancer prevention.

Availability and Accuracy of Nutritionally Relevant Interactive Information Management Tools (IIMTs) in UK Supermarket Websites

Sally Grace Moore[1], Katie Anna Louise Body[1]

1. University of Leeds (UK)

Background: Supermarket websites may provide nutrition information for individual products but also Interactive Information Management Tools (IIMT) which use this data to enable consumers to make nutritionally appropriate food choices by presenting a range of listed products. Given the lack of insight into the nutrition-related aspects of IIMTs within UK supermarket websites, this study aimed to outline the current consumer-facing practices in this area; to describe the availability and nature of nutritionally relevant IIMTs across all major UK retailers and explore their accuracy.

Methods: Products included in four categories (granola, pork sausage, children's yoghurt, and frozen chips) at seven UK supermarket websites were surveyed from May to September 2021. For each category, data was collected on the availability and nature of each website's nutrition-related IIMTs. In addition, the accuracy of IIMTs was evaluated by calculating the percentage of products which were ranked in the correct order when “sorted” by nutrient content (e.g. sugar, fibre, etc.) according to that expected from nutrition information as declared on the individual product's webpage.

Results: A total of 28 category product listing pages were surveyed across the seven supermarket websites. Only three websites provided IIMTs which utilised a variety of nutrition-related product attributes, including “filter” functions based around nutrition claims (e.g. "low sugar”, “high fibre”) (n=2) or “sorted” products according to the content of a specified nutrient (i.e. sugar, salt) (n=1). For the latter, the percentage accuracy of product listings varied across categories (29-58%) and by specified nutrient (20-100%).

Conclusion: This is the first known UK[1] study to describe the availability and nature of IIMTs which use product nutrition-related attributes, as well as indications of their accuracy. Findings can underpin future research evaluating the impact of these tools on consumers' online food choice behaviours and purchases[2].

Relationship between obesity and subjective eating speed in elementary school students

Nozomi Okamoto[1], Masako Kawanishi[2], Chiho Myojin[2], Toshiyuki Kohri[3]

1. Hyogo University of Teacher Education (Japan), 2. Kindai University (Japan), 3. Konan Wowen's University (Japan)

Background and objectives: According to the School Health Statistics Survey conducted in 2020, the proportion of obese children aged 10 years is 14.2% for boys and 9.5% for girls, and the proportion is increasing. The purpose of this study was to examine the relationship between obesity, lifestyle and nutritional intake.

Methods: From the 4th grade of elementary school (94 boys, 96 girls) in 2020 and 2021 at a private elementary school in Nara city, height, weight, body fat percentage, lifestyle questionnaire, brief-type self-administered diet history questionnaire (BDHQ) data was collected. The Rohrer index was calculated from height and weight. Body fat percentage was measured with a body composition analyzer “Inbody” (by bioelectrical impedance analysis method).

Results: The subjects were divided into three groups, less than 115 group (boys: n = 24, girls: n = 29), 115 or more and less than 145 group (n=48 and 52), and over 145 group (n=22 and 15), depending on the Rohrer's index. Among boys, the mean values of body fat percentage increased significantly to 13.1 (S.D. 3.6) %, 21.2 (5.1) %, and 33.0 (3.6) % as the Rohrer's index increased. A similar tendency was seen in girls. Compared to the other two groups, the percentages of students who answered that they were on a diet and who answered that they did not eat snacks were higher in the over 145 group of boys, while the percentages of students who answered that their subjective eating speed was fast and who answered that they did little exercise were higher. There was no association between nutritional intake and physique in both boys and girls.

Conclusions: It was suggested that subjective eating speed and low exercise frequency are involved in boys' obesity.

PAB(T6)-270

Increase in Micronutrient Adequacy in Resource-Poor Areas of Bangladesh through Making Market Works for Women (M2W2): A Quasi-Experimental Study in the Chittagong Hill Tracts

Chowdhury Abdullah Al Asif[1], Md. Mehedi Hasan[1], Aminuzzaman Talukder[1]

1. Helen Keller International (Bangladesh)

Background and Objectives: In 2013, Helen Keller Intl's Making Markets Work for Women (M^2W^2) project, funded by UKAID/SHIREE, aimed to reduce food insecurity, malnutrition, and poverty among 2,500 extremely poor households in six unions of Panchari and Dighiniala sub-districts in Khagrachhari District. This presentation outlines the impact M2W2 had on household economy, food security, and diets.

Methods: A quasi-experimental impact assessment among a panel of 470 propensity score matched extremely poor households was undertaken by survey in October 2013 and October 2015 (235 treatment and 235 control). Households were identified through a community wealth-ranking process in both treatment and control villages. Nutrition was measured through dietary diversity, food security was measured using the household hunger scale, household expenditure, and self-reported ownership of household assets.

Results: M2W2 significantly reduced the odds of a household experiencing hunger [OR 0.2, p< 0.002] and increased the quality (i.e., diversity) of food consumption month of adequate household food provisioning [4.75 months, p<0.000]. Women's diets in treatment households significantly improved over control [0.5, p<0.000] with only 0.35 odds of having an inadequate diet [p<0.000]. Treatment households owned significantly more assets at end line compared to control [1.2 items, p<0.003]. The number of total assets mediated 11% of the impact of the treatment effect on household experiencing hunger [p<0.007] and 25% of the impact of the household food consumption score [p<0.000]. M2W2 activities did not impact mean monthly expenditures per person [p<0.34]. However, when controlling the mean monthly expenditure per person, the number of total assets mediated 7% of the impact of the treatment effect on households experiencing hunger and 21% of the impact from the household food consumption score.

Conclusion: The M2W2 project improved women's dietary diversity, the quality of household food consumption, and control of assets while reducing household hunger of extremely poor households. However, expenditures were increased, even when periods of food insecurity were reduced and the asset base of household increased due to M2W2 interventions. Further research is needed to ascertain the long-term impacts of these improved coping abilities to identify the most critical indicators to target for food security, nutrition, and poverty.

Genetic predisposition to metabolically unfavourable adiposity and risk of prostate cancer: A Mendelian randomization analysis

Aurora Perez-Cornago[1], Karl Smith-Byrne[1], Susan Martin[2], Timothy Frayling[2], Sarah Lewis[3], Richard M Martin[3], Hanieh Yaghootkar[4,5], Ruth Travis[1], Tim Key[1]

1. University of Oxford (UK), 2. Royal Devon & Exeter Hospital (UK), 3. University of Bristol (UK), 4. Brunel University London (UK), 5. University of Westminster, London (UK)

Background and objectives: Previous prospective studies have shown that obesity is associated with a lower risk of non-aggressive prostate cancer but higher risk of aggressive forms of the disease. Recent genetic studies have identified genetic variation associated with adiposity coupled with unfavourable and favourable metabolic effect, which could offer insights into the association between adiposity and prostate cancer risk. We aimed to estimate the association of genetically predicted metabolically unfavourable adiposity (UFA) and metabolically favourable adiposity (FA), which are both associated with higher adiposity but have opposite associations with metabolic markers, with prostate cancer risk.

Methods: We used a two-sample Mendelian randomization (MR) approach; data for UFA and FA genetic instruments were from UK Biobank participants, and genetic outcome data were from the PRACTICAL consortium (up to 85,554 cases, 91,972 controls). For the statistical analyses we used the inverse-variance weighted (IVW) method, and also utilised a variety of robust methods and sensitivity analyses to assess the possibility of violation of MR assumptions.

Results: In IVW models, the two-sample MR analyses did not provide evidence that a genetically determined one standard deviation (1-SD) higher UFA or FA was associated with a difference in overall prostate cancer risk [OR: 0.81 (95% CI: 0.64-1.04) and 1.04 (0.80-1.35), respectively]. Methods robust to violations of the MR assumptions were largely consistent with the IVW estimates. Genetically determined UFA and FA were also not associated with advanced or early age onset prostate cancer. Similar estimates were found in the sensitivity analyses conducted to assess the influence of pleiotropy.

Conclusions: Our findings do not support a role of UFA or FA in the development of prostate cancer. Although the UFA and FA genetic instruments did not cover all aspects related to metabolic health, these findings may suggest that the positive association between adiposity and aggressive prostate cancer found in previous prospective studies may be due to differences in detection in men with obesity

Biophysical environment and food environment influence on food choices and food security in Breede valley municipality, South Africa

Mthokozisi Kwazi Zuma[1], Vhushavhelo Nedzingahe[1], Xikombiso Mbhenyane[1]

1. Stellenbosch University (South Africa)

Background and objective: Food environments are the interface through which people interact with the broader food system. In order to determine the effects of food environments on peoples' food choices, it is crucial to understand what people consume. A cross-sectional study was applied to investigate how bio-physical environment and food environment influence food choices and food security in Western Cape, South Africa.

Methods: A sample of 365 households were randomly selected from the Breede valley local municipality. The bio-physical environment, food environments, food choices and food security status of the participants were assessed, using a questionnaire.

Results: The findings indicated that just over half (51.0%) of the participants were aged 36-55 years. The total monthly household income of over a third ranged from 1 000 to 3 000 South African Rand with salary being stated as the main source of income by over half of the household informants (51.8%). In more than 50% of households, food often available included staple foods, vegetables and meat products. Cereals (92.8%), white tubers and roots (31.1%) were the most consumed starches. There was a lower consumption of vitamin A-rich foods (37.6%) compared to dark green leafy vegetables (45.3%). The findings revealed that the households did not struggle to access fruits and vegetables as a total of 68.3% of the households always had easy access to fruits and 74.9% to vegetables. Three quarters (75.1%) of the households were found to be food insecure with almost half (45.5%) being moderately food insecure. The findings showed that the most used coping strategy was relying on less preferred and less expensive foods by 76.1% of the households during times of food shortages.

Conclusions: The study revealed that households had different types of foods from all 17 food groups. The dietary diversity was low in most households, with more than half of the households being food insecure. Biophysical and food environments had influence on food choices and nutrition transition in the study area.

Differences in vegetable consumption between day workers and sift workers: analysis from the 2018 National Health and Nutrition Survey, Japan

Tomomi Yamazaki[1], Hidemi Takimoto[1]

1. National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition (Japan)

Background and objectives: Health problems can be caused by severe working conditions, such as shift work. There are indications of an association between shift work and a major risk factor for disease onset. We hypothesized that there may be differences in the eating behaviors between day and shift workers, and that these differences may induce disease. We therefore conducted a secondary analysis of the 2018 National Health and Nutrition Survey (NHNS) data.

Methods: Of the total participants in the 2018 NHNS, 6,739 participants were aged ≧ 20 years. For the present analysis, we excluded participants who were unemployed and those without dietary information. The final participants consisted of 3,213 Japanese adults (1,755 men and 1,458 women). A non-parametric test was used to determine potential relationships between the eating behaviors and employment type, day shift or not. Food group and nutrient intakes were adjusted for total dietary energy intake using the density method and the residual method, respectively.

Results: Among night and shift workers, men consumed more wheat and processed foods and fewer green and yellow vegetables, while women consumed fewer green and yellow vegetables, although there were fewer items with differences compared to men. Regarding the amount of nutrients, men who work irregular hours have a low intake of potassium, vitamins, and folic acid, possibly due to a low intake of green and yellow vegetables, while women have fewer items with differences compared to men, and like men, they have a low intake of protein.

Conclusions: There is a large body of research evidence suggesting that high vegetable intake may prevent a variety of health outcomes. Therefore, the fact that night and shift workers have a low intake of green and yellow vegetables may be associated with one of the health problems.

PAB(T6)-274

Children's exposure to sugars and non-sugar sweeteners (NSS) in non-alcoholic beverages (NAB) marketed on television in Sri Lanka

Samarakoon Mudiyanselage Dinithi Ravindrika Samarakoon[1], Agampodi Nethmi Yasodha Senevirathne[1], Hansamali Abeysinghe[1], Waruni Piyasena[1], V Pujitha Wickramasinghe[1], Piyanjali de Zoysa[1], Carukshi Arambepola[1], S Tharanga Thoradeniya[1]

1. Faculty of Medicine,University of Colombo,Sri lanka (Sri Lanka)

Background and Objective: Unhealthy non-alcoholic beverages (NABs) increase risk of diet-related overweight/obesity leading to non-communicable diseases (NCDs). Yet NABs are marketed to children in Sri Lanka despite the policies in place. This study intended to explore the total, added and hidden sugars and non-sugar sweeteners (NSS) in NABs marketed on television targeting 4-15 year-olds.

Methods: Advertisements (n=1518), aired in top three popular TV channels for 33 hours (three hours of children's peak viewing time (PVT) and eight hours of non-PVT in each channel), were analyzed based on the International Network for Food and Obesity/NCDs Research, Monitoring and Action Support (INFORMAS) protocol and the Sri Lankan nutrition profile model (SL-NPM). The data were analyzed using SPPS.

Results: Twenty three products were identified among 130 NAB advertisements; tea products (n=8), malted beverages (n=4), milk drinks (n=3), follow-up milk (n=4), juices (n=2), a carbonated drink, and an energy drink. More NAB advertisements were noted during the PVT than NPVT, with a ratio of total NAB advertisements per hour during PVT and NPVT of 3:2. According to SL-NPM, only 9/23 NABs were permitted; eight tea products and one malted beverage. Six products were not-permitted, while four had insufficient nutrition information to code. The manufacturer recommended total sugar intake per day (based on serving size and number per day) from these NABs was 1.5 to 4 teaspoons. Nearly 42% of the NAB advertisements were on products with added sugars (maltodextrin, lactose, sucrose, glucose). Over half (54.61%) of advertisements displayed claims related to sugars, some of which were misleading. For example 'No added sugar' was claimed in malted beverages where the sugars from malt extracts were hidden. NABs containing NSS (Steviol glycosides-INS 960) (n=2) restricted by the food act and follow-up milk (n=4) for children aged <36months, which is not recommended by the Sri Lanka breastfeeding code and were marketed. Worrisomely, these products were frequently aired, which accounted for nearly 1/4 of total NAB advertisements (32/130).

Conclusion: Marketing of unhealthy NABs, particularly with unacceptable sugar levels, hidden sugars, misleading claims and NSS for children is of great concern. It should be urgently restricted.

Climate friendly and nutritionally adequate? An explorative case study using mathematical optimization on the Danish diet

Matilda Nordman[1], Anders Stockmarr[1], Anne Dahl Lassen[1], Ellen Trolle[1]

1. Technical University of Denmark (Denmark)

Background and objectives: Optimizing our food consumption plays a key role in the necessary global climate change mitigation. The objective of this study was to investigate how much the greenhouse gas emissions (GHGE) of the Danish diet can be reduced theoretically by changing dietary composition, while ensuring that the diet is nutritionally adequate.

Methods: Linear programming was used to obtain the optimal quantities of foods aggregated into 57 food sub-groups to minimize diet-related GHGE emissions of a 10 MJ diet. We compared to the current average diet of the adult Danish population, based on dietary intake data from Danish National Survey of Diet and Physical activity 2011-2013. Nutritional adequacy was ensured by constraining the model for content of 24 micro- and macronutrients according to the Nordic Nutrition Recommendations. The amounts of water, spices and condiments were set to represent amounts in the current diet, due to their supporting role in the diet and uncertainties in GHGE estimates of these products. The GHGE of the optimized diet was compared to the GHGE of the current average diet of the adult Danish population.

Results: These preliminary results indicate that it is theoretically possible to compose a nutritionally adequate diet with a GHGE of 1.12 kg CO_2-eq /10 MJ, resulting in a 75% GHGE reduction compared to the current diet. In addition to water spices, and condiments the obtained diet contained approximately 410 g of oats, 50 g of dried beans, 240 g of low-climate impact fish, 2 g of nuts, 150 g of skimmed milk, 90 g of dark green vegetables, and 70 g of other vegetables.

Conclusions: This study shows how a substantial GHGE reduction of 75% can be obtained while achieving nutritional adequacy of the Danish diet, establishing the theoretical lower limit for the GHGE of the diet. However, the optimized diet is unrealistic and cultural acceptability severely compromised. Our future optimizations will include additional aspects of health, food safety and cultural acceptability, as well as analyses of the trade-offs between these aspects and GHGE, in order to facilitate the population's transition towards a sustainable healthy diet.

Self-reported dietary changes among adults with type 1 and type 2 diabetes during the first wave of the COVID-19 pandemic in the UK

James Bradfield[1,2], Dominic Crocombe[1,3], Marjorie Lima do Vale[1], Charlotte Summers[4], Sumantra Ray[1,5,6]

1. NNEdPro Global Centre for Nutrition and Health (UK), 2. Department of Nutrition & Dietetics, King's College Hospital NHS Foundation Trust, London (UK), 3. Royal Free London NHS Foundation Trust, London (UK), 4. DDM Health Ltd, Coventry (UK), 5. School of Biomedical Sciences, Ulster University, Coleraine (UK), 6. School of Humanities and Social Sciences, University of Cambridge, Cambridge (UK)

Background and objectives: The COVID-19 pandemic placed restrictions on movement, travel and access to shopping facilities (1) as well as enforcing behaviour and lifestyle changes for many. Our aim was to evaluate changes to the dietary behaviours of adults living with type 1 (T1DM) or type 2 (T2DM) diabetes in the UK during the first wave of the COVID-19 pandemic.

Methods: An online survey was sent to >11,000 people over 18 years old who had previously volunteered to take part in research. The survey was live between 6th July and 31st August 2020 and included questions on lifestyle factors, including diet.

Results: 4764 people completed the survey, of whom 26% had T1DM and 59.9% had T2DM. 72.4% of people with T1DM, and 86.6% with T2DM, reported at least one comorbidity. Only 2.4% of the total cohort reported being diagnosed with COVID-19 at any time up until completing the survey. Although 33.1% of all respondents reported eating more in general, there were no statistical difference in changes between individuals with T1DM, T2DM, or other/no health conditions. T1DM was associated with more reported weight gain whereas T2DM was associated with reported weight loss ($p < 0.001$). Compared to people with T1DM, those with T2DM reported significantly higher consumption rates of fresh foods ($p=0.002$), sugary foods ($p=0.011$) and alcohol ($p<0.001$). There was no difference across groups in reported rate of skipping meals, changes to meal timings, rates of home cooking, or binges on sweet foods.

Conclusions: This survey suggests that changes in eating behaviours during eating during the first wave of the COVID-19 pandemic in the UK were heterogenous and varied significantly between groups with T1DM, T2DM, and other or no health conditions. The differencial effects of global events like the COVID-19 pandemic on diet and nutrition must be taken into consideration when planning national and international policy responses.

Keyword: COVID-19, Diet, Lifestyle, Diabetes, Behaviour

Conflict of Interest Disclosure: CS is employed by DDM which owns and operates Diabetes.co.uk which is the platform we used to recruit participants to complete the survey.

Association of diet and risk of being overweight/obese among Nigerian adults: evidence from a nationally-representative survey

Chinwe Adaugo Uzokwe[1,2], Bassey Ebenso[1], Janet Cade[1]

1. University of Leeds (UK), 2. Michael Okpara University of Agriculture Umudike (Nigeria)

Background: Overweight is a global health problem linked to noncommunicable diseases (NCD). Prevalence in Nigeria, like other African countries, is high. In 2020, 25% of adults were overweight or obese and rates are increasing. Overweight/obesity is found with other nutrition problems such as undernutrition and micronutrient deficiency. This analysis aims to identify the association of diet and overweight risk among Nigerian using the most recent nationally-representative data. **Methods:** This study was a secondary data analysis of the 2018 Nigeria Demographic and Health Survey. This was a cross-sectional survey carried out to monitor the health of women (15-49y) and under-five year-old children in Nigeria. A total of 12904 women (aged 15-49y) with data on body mass index were included. A 12 point Nigerian healthy diet score was created, adapted from the African and Caribbean Eat-well guide. We ran logistic regression analysis, adjusting for confounders, to examine associations of the Nigerian healthy dietary score with overweight/obesity.

Results: The prevalence of overweight/obesity was 28%. Women in the oldest age group (45-49y) had lower rates of overweight/obesity (10%) compared to the youngest age group (15-19y) at 20%. Overweight/obesity was also higher with higher education and wealth indicators. Women living in urban areas, being married, TV watching, contraceptive use were all associated with higher rates of overweight/obesity. Muslim women had lower rates (19%) compared to Christian women (38%). In our fully adjusted model, each increase in the Nigerian healthy dietary score was found to be associated with a 5% increase (OR 1.05, 95%CI 1.01, 1.08) in the odds of overweight/obesity. **Conclusion:** Diet and some sociodemographic factors have significant associations with overweight in Nigeria. This knowledge highlights the importance of interventions targeted at these factors to reduce the risk of overweight/obesity in Nigeria and contribute towards meeting the United Nations Agenda 2030 NCD reduction target.

PAB(T6)-278

Comparing different sources of data to estimate per capita cereal grains consumption among total population in Kenya and Bangladesh

Manpreet Chadha[1], Meng Wang[2], Daniel Lopez de Romana[3], Mandana Arabi[4], Helena Pachon[5]

1. Nutrition International (Canada), 2. Emory University (USA), 3. Nutrition International (Canada), 4. Nutrition International (Canada), 5. Food Fortification Initiative and Emory University (USA)

Background and objective: Fortification of cereal grains, including wheat flour (WF), maize flour (MF) and rice (R), is a proven and cost-effective intervention to address micronutrient deficiencies. Estimating accurate cereal grains consumption ensures reliable food fortification program design, and reach, coverage, and impact assessment. The objective was to compare different sources of data that report cereal grains consumption among total population in Bangladesh and Kenya.

Methods: Data received from the following were analyzed and compared across three approaches: 1) Existing dietary/proxy surveys; 2) Milling associations on grains available for human consumption; 3) FAO's food balance sheet. For approach 1, Bangladesh Household Income and Expenditure survey 2010 (BHIES) and Kenya National Micronutrient Survey 2011 (KNMS) data were used. For approach 2, information provided by milling associations on the amount of cereal grains available annually for human consumption in both countries was used. For approach 3, FAO data on per capita amount of cereal grains available in Bangladesh and Kenya for human consumption was used.

Results: Among all population groups, average (mean) consumption of grains in Bangladesh was 34.7 (WF) and 423.8 (R) grams/capita/day (g/c/d) respectively, and in Kenya, was 56.9 (WF), 171 (MF) and 21.1 (R) g/c/d respectively (approach 1). Grains available in Bangladesh from mid-2018 to mid-2019 was 109 g/c/d (WF) and 599.8 g/c/d (R), and in Kenya in 2018 was 116.8 g/c/d (WF), 245.7 g/c/d (MF) and 58 g/c/d (R) (approach 2). Supply of wheat/wheat products, maize/maize products, and rice/rice products in Bangladesh from mid-2018 to mid-2019 was 51.2 g/c/d, 1.9 g/c/d and 711.5 g/c/d respectively, and in Kenya in 2018 was 110 g/c/d, 206.5 g/c/d and 60 g/c/d respectively (approach 3).

Conclusion: In both Bangladesh and Kenya, cereal grains consumption estimates from dietary/comparable surveys was lower than those received from milling associations and FAO food balance sheet. These findings show that fortification program design, and the potential coverage, reach, and impact of fortified grains can vary based on the source of grain intake data and should be reviewed using several sources of data available for the country of interest.

PAB(T6)-279

Maternal depression and child feeding practices: Determinants to malnutrition among young children in Malaysian rural area

Maizatul Azlina Chee Din[1,2], Nur Islami Mohd Fahmi Teng[1], Zahara Abdul Manaf[3]

1. UiTM Puncak Alam, Selangor (Malaysia), 2. Ministry of Health Malaysia (Malaysia), 3. Universiti Kebangsaan Malaysia (Malaysia)

Background and objective: Maternal depression may affect child feeding practices and growth. The objective of this study is to determine the relationship between child feeding practices and current maternal depression with malnutrition among young children in a rural community.

Methods: This is a case controlled study consisted of 52 Malay mothers of malnourished children (cases) and 50 Malay mothers of well-nourished children (controls) in Kuala Langat, Selangor, Malaysia. Structured questionnaires on child feeding practices and Beck Depression Inventory Second Edition (BDI-II) questionnaire were distributed to mothers.

Results: Depressed mothers stopped exclusive breastfeeding (2.8 ± 2.1 months) earlier than non-depressed mothers (3.7 ± 2.0 months) ($p = 0.045$). Binary logistic regression analysis showed current maternal depression was a primary contributor associated with risk of malnutrition in children (AOR 2.5, 95% CI 1.08 – 6.09), and followed by the number of children (AOR 1.3, 95% CI 1.02 – 1.77). Mothers who experienced depression were twice as likely to have malnourished children. Each additional child in the family will increase the risk of malnutrition by 1.3 times.

Conclusions: Maternal depression is associated with child feeding practices and a risk factor to malnutrition among young children in the studied population. Preliminary screening to identify depression symptoms should be conducted to all mothers as early as the first trimester to prevent the incidence of malnutrition in children.

Keyword: child feeding practices, malnutrition, maternal depression, underweight, young children

Conflict of Interest Disclosure: The authors have no conflict of interest to declare. This manuscript has not been published and is not under consideration for publication elsewhere.

Integrating Growth Monitoring and Promotion into the Expanded Programme on Immunization in Four Rural Districts in Bangladesh: A Government Initiative

Deborah Ash[2], Saydur Rahman Siddiquee[1], Zakaria Chowdhury[1], Gourob Kundu[1], Md Moinul Haque[1], Zeba Mahmud[1], Jessica Escobar DeMarco[2], Santhia Ireen[1]

1. FHI Solutions (Bangladesh), 2. FHI Solutions, USA (USA)

Background and objectives: The Government of Bangladesh started National Nutrition Services (NNS) in 2011 to mainstream nutrition through health system platforms. However, Growth Monitoring and Promotion (GMP) is still not operational as a preventive service. The 2020 mid-term review of the Health Sector Program prioritized integration of GMP into the Expanded Programme on Immunization (EPI). NNS requested technical assistance (TA) from Alive & Thrive (A&T) in December 2020 to operationalize integration and test feasibility for at-scale system uptake. Early implementation of this TA will end in August 2022.

We aim to describe the process for integrating GMP into the EPI platform, and A&T TA role in health system strengthening to operationalize this.

Methods: A&T identified areas of TA drawing on learnings from its previous system strengthening activities and formative research informing design of interventions to strengthen routine nutrition services. National and global evidence base informed the design of a feasible approach for services integration. Government and A&T reports and mixed monitoring data were used to describe the integration process.

Results: The integration process started in December 2020 following 6 steps: co-design workshops with government; development of technical resources; advocacy and sensitization; training of trainers; training of providers and supervisors; integrated service delivery. A COVID-19 surge slowed down the activities in 2021. Three co-design workshops informed the integration design. Technical resources include an operational guide; training materials; tools for monitoring, supportive supervision and use of data. The high-level sensitization meeting included 34 officials from relevant directorates in the Ministry of Health and Family Welfare (MoHFW) with responsibilities at national and sub-national levels. Training covered 316 providers. During February-March, 66% of EPI centers provided integrated service. Of the EPI target children, 97% were weighed; for 52% length was measured; and 98% of caregivers received age-appropriate nutrition counseling.

Conclusions: With strong coordination within the MoHFW and well-designed TA, it was feasible to integrate GMP into EPI service. The initial findings indicate that integration of this preventive nutrition service across the national EPI platform, one of the most accessible and effective community-based services, is feasible. A cross-sectional evaluation of the integration process is on track to inform national scale up.

Weight change is associated with stress, dietary habits, and sleep quality among Saudi adults under home confinement during COVID-19 outbreak

Abeer M. Aljaadi[1], Ruba H. Eid[1], Rinal J. Bogus[1], Ebtisam A. Alatfy[1], Nouf A. Alreheeli[1], Saja O. Alharbi[1], Essra A. Noorwali[1]

1. UQU University (Saudi Arabia)

Background and Objectives: The coronavirus disease 2019 (COVID-19) pandemic has forced Saudi Arabia to implement a range of measures including curfew, mandatory home confinement, banning the entry of many cities, and suspended religious activities. The Western region had more restrictions compared to other cities. This study aimed to assess the lifestyle changes and psychological impact of COVID-19 before and during home confinement and explore the associations between weight change, dietary habits, and stress.

Methods: A cross-sectional study was conducted on Saudi adults using an online survey administered in Arabic and English languages. Pregnant and lactating women and those living outside Saudi Arabia were excluded. Data on demographics, dietary habits, and physical measurements were collected. Sleep quality was assessed using the Pittsburgh Sleep Quality Index. Stress was assessed using a subscale in Calgary Symptoms of Stress Inventory.

Results: A total of n=271 participants were included in the analysis. Of these, 85% were females and 46% had BMI ≧25 kg/m^2. About 80% were under lockdown for >40 days and 72% were from the Western region. During home confinement, 31% reported decreased weight and 27% increased weight. A significant association was found between increased weight and confinement >40 days. Stress scores and screen-time significantly increased, whereas sleep quality and number of days spent in walking decreased during confinement than before confinement. In multiple linear regression, higher stress scores before confinement were negatively associated with age. Stress scores during confinement were positively associated with stress scores before confinement while negatively associated with age. In multiple logistic regression, the odds of gaining weight during confinement were higher with higher stress scores and consuming ≧4 meals than consuming 1-2 meals; however, the odds of gaining weight was lower with increased days spent in moderate activity. The odds of losing weight were higher with poorer sleep quality and increased days spent in moderate activity, but the odds of losing weight was lower with consuming >2 snacks and consuming 3 meals compared to 1-2 meals.

Conclusion: Home confinement negatively impacted stress, sleep quality, physical activity and weight status among Saudi adults. These factors could be addressed in future restrictions to improve individual's wellbeing.

Keyword: COVID-19, Saudi Arabia, sleep quality, weight, stress

Intakes of micronutrients and heavy metals in stunted and non-stunted under-two children in urban and rural East Nusa Tenggara, Indonesia: a study using duplicate portion sampling and nuclear analytical technique

Umi Fahmida[1], Arienta Rahmania Putri Sudibya[1], Diah Dwiana Lestiani[2], Syukria Kurniawati[2], Endah Damastuti[2], Woro Yatu Niken Syahfitri[2], Putu Amrytha Sanjiwani[3], Indriya Laras Pramesthi[1], Fitrah Ernawati[4], Muhayatun Santoso[2]

1. Southeast Asian Ministers of Education Organization Regional Center for Food and Nutrition (SEAMEO RECFON), Pusat Kajian Gizi Regional Universitas Indonesia, Jakarta (Indonesia), 2. Nuclear Energy Research Organization, National Research and Innovation Agency, Jakarta (Indonesia), 3. Health Polytechnic of Kupang, Kupang (Indonesia), 4. Health Research Organization, National Research and Innovation Agency, Jakarta (Indonesia)

Background and objectives: Many studies reported micronutrient intakes of stunted and non-stunted children, but little is known about their intakes of trace elements and heavy metals. Nuclear analytical technique (NAT) can assess micronutrients and heavy metals in food samples which are difficult to estimate using dietary assessment given the limitations in food composition tables. This study aims to compare intakes of micronutrients and heavy metals in stunted and non-stunted under-two children in urban and rural East Nusa Tenggara (NTT), Indonesia using NAT.

Methods: Stunted (length-for-age <-2.00) and non-stunted under-two children, matched for sex and age, were recruited in NTT: Kupang (urban, n=186) and Timor Tengah Selatan (TTS) (rural, n=214). Two-day 24-hour dietary recalls (24HRs) were done, and duplicate-portion samples were collected based on foods consumed on the 1st day of 24HRs. Two NATs were used, neutron activation analysis (NAA) to assess Se, Fe, Zn, Cr, Co, Hg and total X-ray Fluorescence (XRF) to assess Ca, Cu, Pb.

Results: Compared to their normal counterparts, stunted children had lower intakes of Ca (12-23mo, both sites, p=0.006) and Fe (6-11mo, TTS, p=0.045). There was no difference in Zn and Se intakes between stunted and normal children. Intakes of heavy metals were higher in Kupang than TTS for Pb (12-23mo, p=0.019) and Cr (6-11mo, p=0.011; 12-23mo, p=0.016). On the other hand, exposure to Hg was higher in TTS than Kupang (6-11mo, p<0.001; 12-23mo, p<0.001) at the level close to the provisional tolerable daily intake. There was no significant difference in exposures to Co and Cu between Kupang and TTS.

Conclusions: The study found that stunted children in both sites had lower Ca and Fe intakes. There was significant difference in exposures to Pb, Cr and Hg between sites. The findings suggest the importance of assessing not only nutrient intakes, but also exposures to heavy metals known to have negative consequence to health and nutritional status. Further study to identify potential food sources as contaminants of Hg particularly in TTS is recommended.

Frequency of milk consumption among the adult population of Aktobe city and a comparative evaluation of the results of laboratory studies of milk

Akmaral Baspakova[1], Aiym Tilektes

1. West Kazakhstan Marat Ospanov Medical University (Kazakhstan)

Background and objectives: Milk is one of the main products of the consumer basket, and has specific characteristics due to its chemical and microbiological composition. The aim of the research is assessment of the frequency of milk consumption among the adult population and a comparative assessment of the results of laboratory studies of milk sold in the consumer market of the city of Aktobe.

Methods: The research was approved by the Local Ethics Commission of the West Kazakhstan Marat Ospanov Medical University in Aktobe city, Republic of Kazakhstan. The research involved 461 adults. The experimental part of the work was carried out using the method of capillary electrophoresis, chromatographic, voltammetric, spectrophotometric, titrimetric methods.

Results: According to the frequency of milk consumption: 369 people consume daily, which accounted for 79%, and 6 people who do not consume milk at all-1%. For the most commonly used milks, using the Spearman power correlation coefficient, milk number 8 accounted for a maximum of 20% of all milks, and milk number 16 was the least consumed, which was 0.6%. Total for 2021-2022 57 samples of pasteurized drinking milk of various fat content were studied, of which 7 samples did not meet the requirements of regulatory documents for physical, chemical and organoleptic quality indicators. In 7 rejected samples, the mass fraction of protein was underestimated by 20-45%, the mass fraction of dry skimmed milk residue - by 7-12%, density - by 1-2%. For 2 years, the share of products that do not meet the requirements of regulatory documents in terms of quality indicators, identified during laboratory tests, amounted to 3.7%.

Conclusions: It was found that adult residents of Aktobe often consume milk, and women are 68% more likely than men. Based on the results of the control and surveillance activities carried out in 2021-2022, 7 milk samples were rejected.

Estimating the affordability of Indonesian dietary guideline

Dini Ririn Andrias[1]

1. Universitas Airlangga (Indonesia)

Background and Objectives: Dietary guideline is developed to guide a healthy diet. However, healthy diet not always affordable to certain groups. This analysis is aimed to estimate the cost of following the Indonesian dietary guideline, and analyze its affordability to Indonesian population. **Method:** Modified Cost of Recommended Diet (CoRD) method was applied to calculate the cost of following the Indonesian dietary guideline. A household of 4, consist of children aged 12-23 months, adolescent girl aged 15-16 years, moderately active lactating women aged 30-39 years, and moderately active men aged 30-59 years was set for the calculation. We review the guideline and extract information on quantifiable portion size suggestion for each age group and each food groups, i.e. staple foods, animal source protein, plant source protein, vegetables, fruits, sugar, oil, salts and water. For each food groups, local food items were listed, and the price were obtained from the most recent national consumer price data available from the national statistical agency. For each foods, the price was adjusted to raw-cooked conversion factor and percent of edible portion. To calculate the cost per day, in staple, animal source, plant source protein, and fruits groups, the average of 2 lowest cost food items were calculated. In vegetable group, the average price of three lowest cost food items (1 dark green leafy vegetable and 2 other vegetables) was taken. The cost per person per day for all food groups were summed to obtained the cost of Recommended Diet. **Results:** The cost of Recommended Diet for Indonesian is IDR 29,339.5/person/day (USD 2/person/day) or IDR 880,186/person/month, which is relatively comparable to those in low and lower middle income countries (Hirvonen et al, 2020). However, this cost is higher compared to the national average of household food expenditure, i.e. IDR 572,551/person/month, indicating that healthy diet may not be affordable for many Indonesians. The cost was also varied across provinces, with the 3 highest were South Kalimantan, West Papua, and Riau Islands. **Conclusion:** The Indonesian dietary guideline may not be affordable for many Indonesians, as the cost of following the guideline is higher compared to the average household food expenditure.

Mobilizing European youth to fight childhood obesity. How data from WHO/Europe COSI study and initiatives from CO-CREATE project are helping to drive policy progress.

Ana Isabel Rito[1,2]*, Sofia Mendes*[2]*, Samantha Nesrallah*[3]*, Knut-Inge Klepp*[4]*, Julianne Williams*[5]*, Ivo Ravokac*[5]*, Martin Webber*[5]*, Kremlin Wickramasinghe*[5]*, João Breda*[5]

1. National Institute of Health Doutor Ricardo Jorge, Portugal (Portugal), 2. Centre for Studies and Research on Social Dynamics and Health (Portugal), 3. EAT Foundation (Sweden), 4. Division of Mental and Physical Health, Norwegian Institute of Public Health (Norway), 5. WHO Regional Office for Europe (Denmark)

Background and objectives: Over the past two decades, efforts to combat the rising tide of childhood overweight and obesity has taken shape. Data from WHO's European Childhood Obesity Surveillance Initiative (COSI)[1], have improved our understanding of this public health challenge in the WHO European Region, and informed many of the national policy actions to combat obesity in the Region[2,3]</sup>. Additionally, the CO-CREATE[4] European project has engaged young people as active agents in formulating obesity prevention policies. This paper aims to examine national policies and measures against policy ideas formulated by adolescents in five European countries. **Methods:** We examined national policies and areas of action[5] from Portugal, the United Kingdom, the Netherlands, Poland and Norway. These policies were checked for consistency and alignment with several policy ideas developed between CO-CREATE adolescents and relevant stakeholders, across the same countries.

Results: Countries´ policy actions included in Portugal (sugar-sweetened beverage tax, integrated nutrition strategy), United Kingdom (soft drink levy, active commuting programs, urban design principles), Norway (industry and government partnerships to promote healthier foods, nutrition education curriculum for schools), Poland (investing in sports infrastructure), and the Netherlands (preconception and pregnancy care)[4]. Whereas in the CO-CREATE project, adolescents identified four demands that they see as crucial starting points towards ending childhood obesity, namely: 1) Stop all marketing of unhealthy foods to children under the age of 18; 2) Secure all children high-quality, practical based food and nutrition education in school and a healthy school cafeteria; 3) Implement a sugar-sweetened beverage tax to make unhealthy foods more expensive; 4) Offer all children and adolescents free, organized physical activities at least once every week[6].

Conclusions: Although the present work seems to show that the policy responses to COSI data and youth-led policy ideas are on similar path, no country is on track yet to meet the targets set out by international organizations[1]. Thus, further collaborative action, particularly involving young people in shaping the current and future policies is needed, as a key element to tackling this major public health challenge.

Feeding practices and nutritional status of urban population in Benin: Current situation in Cotonou, Southern Benin

Fifali Sam Ulrich Bodjrenou[1], Waliou Amoussa Hounkpatin[1], Faick Bello[1], Chimene Loko[1], Grace Allagbe[1], Kevin Wabi[1]

1. University of Abomey-Calavi (Benin)

Background and objectives: Urbanization often results in a change in eating habits that can affect the nutritional status of individuals. This study aimed at describing the current food habits and nutritional status of urban population living in Cotonou, the biggest town of Benin Republic.

Methods: Literature review and data collection among public primary schools food environment.

Results: Spatial organization of the city requires a large part of the active population to travel daily or weekly between their residence and their place of work. Populations are adopting diets that combine "domestic meals" with "out-of home meal". Consumption of a meal outside home counts for 20% of meals in Cotonou, 18% in other urban areas and only 14% in Benin rural areas. Various places are available to out-of-home catering : gargotes, maquis, restaurants, cafeterias, markets. However, gargotes are the most frequented places. Mobile structures have also recently appeared and offer dishes that are often popular with middle and upper classes. Food production of foreign origin is becoming important and tends to replace small food artisans. Out-of-home catering reaches all social strata including school children. Food vendors are regularly installed in every school. Professional occupations most concerned are: 'handicrafts and small services', 'civil servants and private workers' and 'processing and trade'. The most common meals offered in gargotes are rice, maize, yam, wheat, cassava and beans made. Inadequate sanitary quality of street foods/meals leads to several cases of foodborne illnesses notably diarrhea and gastroenteritis of presumed infectious origin. One hospital (Cotonou CHD) had recorded an average of 365 peoples suffering from these illnesses from 2012 to 2016. There are also non-infectious colitis, bacterial food poisoning, bacterial intestinal infections, intestinal parasitosis, typhoid and paratyphoid fevers. Official statistics in Benin also report an epidemiological situation of emergency of non-communicable diseases, particularly those related to urbanization, sedentary lifestyle and changes in diet. Hypertension affects 27.5% of Beninese and diabetes 4.6%. Overweight and obesity affect 23% and 24% of women of childbearing age respectively. Regarding schoolchildren, 34% are anemic, 13%wasted, 5% stunted and 5% overweighed or obese. A challenge of mult burden is also a concern.

Conclusions: Urbanization has led to hybrid, complex and dynamic food practices in Cotonou. Street food/meal affects all social strata and is at the root of the increase in non-communicable diseases and the Multi burden of malnutrition. Appropriate policies to manage this nutritional transition are needed.

Keyword: Multi burden of malnutrition, Urban areas, Out-of-home foods, Domestic meals, non-communicable diseases

Food environment issues that perpetuate food insecurity among university students

Louise van den Berg[1], Rebecca Nokuthula Mabena[1], Liska Robb[1], Mariette Nel[1]

1. University of the Free State (South Africa)

Background and objectives: Low food security (FS) has emerged as a global threat to student success, but few studies have been conducted in Africa. We report on the prevalence of FI in the context of food environment (FE) and academic achievement at a university in South Africa.

Methods*:* In an observational cross-sectional study, an online survey pertaining to pre-lockdown conditions was made available to all students registered at the UFS in early 2020. FS level was measured with the validated USDA 10-item HFSSM. Associations of food insecurity with biographical attributes, food environment, and academic success were determined with Chi-square and Wilcoxon rank sums tests ($p<.05$ = significant).

Results: Of the 1387 eligible respondents (who statistically represented the demographics of the 2020 student body well), 75% were food insecure (52% with very low FS, which is much higher than the general national and provincial levels). Lower levels of FS were significantly associated with gender (males>females), being single, being a first-generation student, and being on financial support. Lower FS level was significantly associated with lower average 2019 end-of-year academic scores. Food insecure students were significantly more likely than their peers to skip breakfast, eat all their meals alone, and not bring a lunchbox to class/work. Lack of time and access to procure ingredients and prepare their own meals, lack of storage and cooking facilities, lack of food procurement and preparation skills, lack of facilities to warm lunchbox food on campus/at workplace, and lack of time and money to buy and eat meals on campus/at workplace.

Conclusion: The institutional organization of its food environment is a driver of levels of food insecurity among students.

The association of sociodemographic and lifestyle changes with body weight status during COVID-19 pandemic among university students in Shah Alam, Selangor

Iffa Nadia Mokhtar[1], Sarina Sariman[1], Pauziyah Mohammad Salim[2]

1. Management and Science University (Malaysia), 2. Universiti Teknologi Mara (UiTM) Shah Alam (Malaysia)

Background and objectives: This cross-sectional study was conducted to determine sociodemographic factors and lifestyle changes with body weight status during COVID-19 among university students in Shah Alam, Selangor.

Methods: Respondents (n= 403) completed an online self-administered questionnaire comprising self-reported height and weight, sociodemographic characteristics, and Simple Lifestyle Indicator Questionnaire (SLIQ), which includes questions on diet, physical activity, alcohol intake, smoking and stress level before and during the COVID-19 pandemic.

Results: Most of the respondents were females (59.6%), of Chinese ethnicity (38.7%), with bachelor's degrees (72.2%) qualification. During this study period, most of the respondents were staying at home (77.2%), living with family (81.4%) with a household income of less than RM2500 (43.7%). There was no significant difference in body mass index (BMI) between male and female respondents in this study, either before or during the COVID-19 pandemic, with $p>0.05$. As for BMI differences, the majority (44.7%) had no changes in BMI. However, most respondents (53.8%) were weight gain in body weight changes. Varying total SLIQ scores can be observed across sociodemographic characteristics before and during the pandemic. However, the results were not statistically significant ($p>0.05$). In terms of body weight status and SLIQ scores were reported higher mean SLIQ scores among overweight respondents than in the other BMI categories ($p<0.05$) before the pandemic. A similar trend was observed during the pandemic. However, the result was not statistically significant. Different lifestyle changes can be observed across sociodemographic factors and body weight status, specifically before the pandemic.

Conclusions: Different lifestyle changes can be observed across sociodemographic factors and body weight status, specifically before the pandemic. Findings can be utilized to develop effective intervention strategies which is also crucial in the fight against COVID-19, obesity and other non-communicable diseases

Keyword: Eating habit, Body weight status, University students, Lifestyle , Sociodemographic

Effects of exclusive breastfeeding for six months compared to four months on growth and infection among Indian Children using the Healthy Birth, Growth & Development Knowledge Integration (HBGDKi) dataverse

Samarasimha Reddy N[1], Aravind Dharmaraj[2], Kulandaipalayam Natarajan Sindhu[2]

1. ICMR- National Institute of Nutrition (India), 2. Christian Medical College, Vellore (India)

Background and Objectives: World Health Organization recommends exclusive breastfeeding (EBF) for six months, but the proportion of children exclusively breastfed for six months from individual south Indian cohort datasets is between 1-11%. This analysis compared growth (underweight, stunting and wasting) and infections (respiratory and diarrheal) at 12, 18 and 24 months among Indian children exclusively breastfed for four and six months, respectively, using the HBGDKi dataverse.

Methods: Healthy Birth, Growth and Development Knowledge integration (HBGDKi) dataverse integrates 29 datasets of various cohort studies and randomized control trials from India between 1990-2014. Of the 29 studies, 8 with variables in line with the objectives of this analysis were harmonized. The proportion of infants exclusively breastfed for four and six months of age was computed. A one-one propensity score matching was performed for the baseline characteristics to ensure comparability of children between the four and six month exclusively breastfed groups. Linear mixed models were used for comparing the continuous outcomes between the two groups. Generalized linear mixed models were used for binary outcomes to account for multiple repeated measures over time.

Results: Of the 55,263 infants, 2606 (4.7%, 95% CI 4.6%-4.9%) and 1657 (3%, 2.9%-3.1%) infants were exclusively breastfed for four and six months, respectively. Following propensity score matching, 238 children were available for comparison in each of the four- and six-months groups. Children with six months of EBF had better growth at 18 months [LAZ score: -1.53 (1.04) versus -1.97 (1.08)] and 24 months [LAZ score: -1.67 (0.99) versus -2.08 (0.95)] compared to their counterparts with four months of EBF. Further, children exclusively breastfed for six months had a decreased risk of respiratory (RR 0.26 ,95% CI 0.15, 0.45) and diarrhoeal (RR 0.49, 95% CI 0.44, 0.45) infections during the first two years of life, compared to those exclusively breastfed for four months.

Conclusion: Indian children exclusively breastfed for six months had better growth and lower risk of infections compared to those exclusively breastfed for four months. This reiterates the importance of the six-month exclusive breastfeeding practice that needs to be strongly promoted in the Indian setting.

Keyword: Exclusive Breastfeeding, Indian Children, Growth, Infections

Healthy and sustainable diets in The Gambia: an assessment of deviations from EAT-Lancet recommendations

Zakari Ali[1], Pauline F.D Scheelbeek[2], Jyoti Felix[2], Bakary Jallow[3], Amanda Palazzo[4], Alcade C. Segnon[5], Andrew M. Prentice[1], Rosemary Green[2]

1. MRC Unit The Gambia at the London School of Hygiene and Tropical Medicine (Gambia), 2. London School of Hygiene and Tropical Medicine (UK), 3. National Nutrition Agency (NaNA) (Gambia), 4. International Institute for Applied Systems Analysis (IIASA) (Austria), 5. Alliance of Bioversity International and International Center for Tropical Agriculture (CIAT) (Senegal)

Background and objectives: Appropriate dietary change is pivotal for improving population health, increasing food system resilience, and minimizing adverse impacts on the environment. However, there is little research on the sustainability of diets in low-and middle-income settings. Our objective was to assess deviation of the Gambian diet from the EAT-Lancet guidelines for health and sustainability and identify potential areas to improve nutritional and planetary health.

Methods: We performed secondary analyses using the recent Integrated Household Survey dataset with food consumption data from 12,713 households. We assessed deviation from health and sustainability by comparing intake of different food groups against the EAT-Lancet dietary guidelines. We computed a context-specific "sustainable and healthy diet index (SHDI)" based on adherence of different food groups to the EAT-Lancet recommendations and modelled the socio-economic and geographic determinants of households that achieved higher scores on this index, using multivariable mixed effects regression.

Results: There was very low adherence to EAT-Lancet recommendations in The Gambia. The intake of refined grains and added sugars exceeded the recommendations while consumption of important food groups such as fruits, vegetables, dairy, poultry, and beef and lamb were much lower than the EAT-Lancet targets. Higher SHDI scores were associated with female headed households, small household sizes, high wealth index, and residing in an urban settlement. Furthermore, seasonality and crop production diversity played an important role in the diet, with healthier and more sustainable diets reported in the dry season as compared to the rainy season, and increased SHDI score in households with high crop production diversity.

Conclusions: We show that while the Gambian diet is less healthy, it is low in components known to impact most on the environment such as beef, dairy, and pork. Dietary policy to improve on health and sustainability should focus on the substitution of refined grains by wholegrains and reduction in added sugar consumption. Agricultural diversification and poverty reduction are also important factors for improving diet quality and sustainability in The Gambia.

Keyword: Dietary sustainability, EAT-Lancet diet, Diet composition, Environmental footprint

PAB(T6)-291

Dietary diversity does not equal nutritional adequacy in pregnant women in Northern Ghana

Shaibu Mohammed Osman[1], Paul Amuna[1], Francis Bruno Zotor[1], Fred Newton Binka[1], Gity Sotoudeh[2]

1. University of Health and Allied Sciences (UHAS) (Ghana), 2. Tehran University of Medical Sciences (TUMS) (Iran)

Background: Adequate dietary intake during pregnancy is necessary for optimum pregnancy weight gain and desirable outcomes. Dietary diversity during pregnancy has been promoted as a means of meeting the nutrient needs for foetal growth and development, mother's wellbeing and preparation for lactation.

Objective: We investigated the relationship between the diversity of the mother's diet in pregnancy and their nutrient adequacy among pregnant women in a low socio-economic environment in Northern Ghana.

Methods: In a prospective cohort study, we recruited and followed up 596 pregnant women from their first trimester (10-12 weeks) of pregnancy through to delivery. Three repeat 24-hour dietary recall measurements at recruitment, second trimester and late third trimester were used to ascertain dietary intake and diversity score (DDS). Nutrient adequacy was measured by computing the Nutrient Adequacy Ratio (NAR) and the Mean Adequacy Ratio (MAR). Chi-square test for proportions was used for DDS comparisons. Independent t-test and ANOVA were used for NAR and MAR with a significance level of $p<0.05$.

Results: Nearly 41% of the study participants (40.9%) were observed to consume highly diverse foods (consumption from 5 or more food groups). However, over 80% of total daily energy intake was carbohydrate. Overall, MAR was found to be low although relatively higher among those with higher DDS ($p<0.001$). Of 11 key nutrients in pregnancy studied, except for carbohydrate and ascorbic acid, nutrient adequacy was not met even among participants with higher dietary diversity scores.

Conclusion and recommendation: Among pregnant women in this low-income community, diversifying dietary intake alone may not be sufficient to improve nutrition and enhance pregnancy outcomes. There is a need for nutrition literacy emphasizing portion sizes and food combinations to maximize nutritional benefits.

Keyword: Nutrient adequacy, Dietary diversity, Pregnant women, Low income, Northern Ghana

Conflict of Interest Disclosur: There is no conflict of interest.

PAB(T6)-292
A comparative analysis of key attributes and performance ratings across prominent food industry assessment tools

Ella Robinson[1], Gary Sacks[1], Jasmine Chan[1], Meghan O'Hearn[2], Dariush Mozaffarian[2]

1. Deakin University (Australia), 2. Tufts University (USA)

Background and objectives: Large food companies hold substantial power within the global food system and can act as a significant barrier and opportunity to progress on addressing nutrition. In an effort to promote private sector accountability for population and planetary health, several food industry assessment tools have been developed to benchmark companies on their Environmental, Social, and Governance (ESG) performance, including in relation to nutrition. Investors are increasingly using ESG data to inform their decision-making and corporate engagement activities. Given the growing burden of diet-related disease and increasing recognition of business risks and opportunities for addressing nutrition, it is critical to understand the scope of nutrition performance data currently available to investors. This study aimed to compare prominent tools used to assess food companies on their nutrition performance, in order to generate consensus on appropriate metrics for investors.

Methods: A comparative analysis of the type, number and weightings of relevant metrics across five civil society-led food industry assessment tools and a commercially-available ESG dataset was conducted (2021). Data on the nutrition-specific and overall ESG performance ratings of 25 major global food and beverage manufacturers were extracted and compared across three of these initiatives, with companies assigned a performance rating of 'low' (score = 0-25% or D), 'moderately low' (25-50% or C), 'moderately high' (50-75% or B) and 'high' (75-100% or A).

Results: Methodologies across the six tools were not standardised, with substantial variation in the number of indicators and the weightings assigned to assessment criteria. However, tools were largely found to assess similar nutrition-relevant topics, including 'product healthfulness', 'product marketing and labelling', 'product distribution and equity' and 'corporate governance'. Despite methodological differences, when three initiatives were applied in practice to assess 25 major global food and beverage manufacturers, companies were found to perform relatively poorly on nutrition-specific and overall ESG metrics across all initiatives (median score = 'moderately low'). No companies across any of the tools received a performance rating of 'high'.

Conclusions: Harmonization and prioritization of metrics across existing food industry assessment tools is necessary to drive uniform and consistent use of nutrition-related ESG data in financial markets.

PAB(T6)-293
Consumption of legumes in two seasons of the year during the COVID-19 pandemic in Chile

Samuel Duran-Aguero[1], Leslie Landaeta[2], Yadira Morejón[3], Maria Jose Mardones[1], Claudia Barrientos[1]

1. Universidad San Sebastian (Chile), 2. Universidad de las Américas (Chile), 3. Universidade Federal de Bahia (Brazil)

Background and objectives: In Latin America, the number of studies that have investigated the consumption of legumes during the pandemic is limited. The objective of the present study is to describe the intake of legumes in 2 different seasonal periods, during the COVID-19 Pandemic in Chile.

Methods: Serial cross-sectional study surveys were distributed during the summer and winter seasons using different digital platforms and social networks. We investigated the frequency of consumption, access to purchase any type of preparations. **Results:** A total of 3,280 adults in summer and 3,339 in winter, mean age 33 years. 97.7 and 97.5% of the population indicate consuming legumes in both periods, with consumption increasing in the group of 3 times a week in winter. In both periods, the main preference for consumption is that they are rich and nutritious, followed by the fact that they replace meat and that they are profitable, the main barrier for their non-consumption in both periods is that they are expensive (29% in summer and 27.8% in winter) and are difficult to prepare (12.1% in summer and 11.6% in winter). The main form of preparation is in traditional stews and salads. Although the supermarket is the preferred place, the purchase changes according to the season, sales increase during the winter in supermarkets, online purchases, but decrease in free fairs and neighborhood stores. 35% indicate that they know the recommendations of the food guides on legumes and the most recognized property "they are rich in protein and provide fiber".

Conclusions: During the pandemic there is a good consumption of legumes, seasonal differences in consumption are observed, since there is a greater frequency of consumption in winter, considering greater than or equal 3 time a day, we also found differences in purchases according to seasonality, but not in the form of preparation, on the other hand among the factors that favor consumption is that they are rich and nutritious, change among the factors that hinder consumption is that they are expensive and difficult to prepare.

Nutrient Intakes Among 0.5 – 11.9-year-old Children in Vietnam in 2020

Ha Thu Nguyen[1], Son Duy Nguyen[1], Ilse Khouw[2], Nga Thuy Tran[1]

1. Vietnam National Institute of Nutrition (Viet Nam), 2. FrieslandCampina (Netherlands)

Background and Objectives: Vietnam, as a new developing country, has undergone a period of rapid change over a few decades. As a result, the country's population has experienced remarkable transition of diet from relatively poor rations toward foods richer in animal proteins, lipids, and processed products. The Vietnamese South East Asian Nutrition Survey II (SEANUTS II Vietnam) was conducted in 2020 in alignment with SEANUTS I from 2010/2011 to assess the nutritional status together with dietary pattern of children aged 0.5-11.9 years. The up-to-date information obtained can serve as inputs for country policy and development of nutrition programs.

Methods: SEANUTS II Vietnam is a cross-sectional study conducted in six representative regions of the country. Dietary intake was assessed using one-day 24 hours dietary recall and food diary. The data was converted into nutrient intakes with the Nutrisoft program developed by the National Institute of Nutrition, using the Vietnamese food composition table, and compared to Vietnamese Estimated Average Requirement (EARs) and Recommended Nutrient Intakes (RDAs).

Results: In total, 3904 children between 0.5-11.9 years old were included in the analysis. In general, boys and urban children consumed higher amounts of macro- and micronutrients than girls and rural children respectively. The differences were more prominent in the older children.

Overall, 75% of the children did not meet the estimated energy requirements and this percentage was higher in the older children (84%) compared to the younger children (59%). For calcium, ~60% of the younger children did not meet the RDA while it was 93% in the oldest children. For Vit D, >84% of the children did not meet RDA irrespective of age.

Conclusions: The data suggest that further efforts must be undertaken to ensure that children in Vietnam receive adequate nutrients for a healthy growth and development.

Keyword: nutrient intake, SEANUTS, children survey

PAB(T6)-295
Establishing online dietary assessment models to facilitate strategies for reducing sugar intake

Chien Yin Chen[1], Po Hsiu Kuo[2], Shwu Huey Yang[1]

1. Taipei Medical University (Taiwan), 2. National Taiwan University (Taiwan)

Obesity is a major challenge to global public health. According to "Taiwan Nutrition and Health Status Change Survey 2013-2016" showed that the prevalence of adult overweight and obesity reached 45.4%. Poor dietary quality could lead to lots of metabolic diseases. Excessive intake of sugary foods leads to an increased risk of obesity and its derived chronic diseases. However, an increase in the intake of sugary foods will result in an increase in total calories consumed and a decrease in the intake of other essential nutrients. The World Health Organization published the "Guidelines on Sugar Intake for Adults and Children" in 2015. It is recommended that the intake of free sugars in the diet should be kept below 10% of the total daily caloric intake, which can reduce the incidence of overweight, obesity and tooth decay. Therefore, the trend of sugar reduction has been attached great importance. More and more commercial products use sugar substitute, due to their low cost and sweeter taste. First, we conduct the systematic review and network meta-analysis to evaluate the effect of low-calorie sweeteners (LCS) on weight management. Second, establish an online dietary database, combined Taiwan, United States, Japan and Vietnam database. To collect different group of their dietary records used to analyze the daily sugar consumption. Third, design an interventional experiment, using design thinking model to create an active sugar reduction plan. The experimental design has a total of four weeks of experience. The online social network platform is equipped with AI chatbot interactive technology. It interacts with participants daily to set tasks challenge, reflect on the body's feelings and daily health hazards of taking too much refined sugar, and then increase the motivation to reduce sugar. Integrate online sugar reduction education to effectively establish healthy literacy concepts, improve physical health, achieve a healthy lifestyle of sugar reduction program!

Agricultural production diversity, dietary intake, and child nutritional status: Evidence from clustered longitudinal study in rural Ethiopia

Girmay Ayana Mersha[1,2], Masresha Tessema Anegago[2], Befikadu Tariku Gutema[1,3], Kazienga Adama[1], Stefaan De Henauw[1], Souheila Abbeddou[1]

1. Ghent University (Belgium), 2. Ethiopian Public Health Institute (Ethiopia), 3. Arba Minch University (Ethiopia)

Background: Infants and young children have low access to a diversified diet in low- and middle-income countries. Diversified diet predicts the adequacy in macro-and micro-nutrients to cover the child increasing nutrient requirements for their growth and development. Integrating agriculture into the framework of interventions targeting undernutrition reduction has been promoted. Evidence on the contribution of nutrition-sensitive interventions to dietary diversity at the household and the individual levels, and children's nutrition status is limited.

Objective: To assess the association between agricultural production diversity, household dietary diversity, and the nutritional status of 0-59 months aged children in Ethiopia.

Method: Using a cluster trial design, rural communities in four agricultural regions in Ethiopia were assigned to receive the Sustainable Undernutrition Reduction in Ethiopia (SURE) program intervention or to non-intervention between 2016 and 2021. The program intervention package includes promoting diversified agriculture, infant and young child feeding and water, sanitation, and hygiene practices. At baseline, children who were 0-23 months of age were assessed for their weight, height, and hemoglobin concentrations. Dietary and agriculture production data were collected using a structured questionnaire. The same assessments were carried out after four years of intervention, on the same children who were 48-59 months of age. Length/Height-for-age, weight-for-age, and weight-for-length/height Z-scores were calculated based on 2006 World Health Organization standards. Food production diversity was regrouped to fall in line with the recommended seven food groups used in defining dietary diversity scores in children. Bivariate and multivariate regression models were used to determine the association of production diversity and children's nutritional status.

Result: Totally 1289 participants included. At baseline, 44.1 %, 18.6%, and 2.5 % of infants and children were stunted, underweight, or wasted, respectively. The mean adjusted hemoglobin concentrations (mean ± SD) in children were respectively 10.2 ±1.48 g/dl and 11.9 ± 1.3 g/dl at baseline and endline. Prevalence of anemia decreased from 69.3% to 22.1% (P=0.01). Household dietary diversity score has a significant association with child dietary diversity score, stunting and hemoglobin concentration (P<0.001).

Conclusions: Producing a variety of foods at the household level was positively associated with child dietary diversity score and hemoglobin status.

Plant-based meat alternatives can help to lower the dietary animal to plant protein ratio

Mark Messina[1]

1. Soy Nutrition Institute Global (USA)

Background and objectives: For personal and planetary health reasons, recommendations are to consume more plant protein. Developed countries consume ~2-fold protein from animals than plants. The optimal animal to plant protein ratio has not been determined; however, the 2:1 ratio in developed countries is generally recognized as being too high. The Eat Lancet Commission recommends obtaining most protein from plants whereas the Dutch Dietary Guidelines recommend a 1:1 animal to plant protein ratio. Even meeting the Dutch recommendation will be challenging because of the culinary and cultural role meat plays in many societies.

Methods: One approach to lowering the animal to plant ratio is to rely more on legumes. These protein- and fiber-rich foods are underutilized in most areas of the world. Globally, only 6% of protein is derived from pulses (a type of legume). However, despite their many accolades and public health efforts to promote their consumption, there is little evidence to suggest legume intake will substantially increase in the near future.

Results: An alternative to consuming legumes is to consume plant-based meat alternatives (PBMAs) made from concentrated sources of legume protein such as soy and pea. Research indicates that for PBMAs to be embraced by consumers, they need to mimic the taste, texture, visual appearance, and cooking method of meat. The new generation of PBMAs meets those criteria. Not only is their environmental footprint lower, but research shows that when compared to their animal product counterparts, PBMAs favorably affect several chronic disease risk factors, help reduce body weight and favorably affect the gut microbiome. A potential obstacle to greater PBMA intake is their classification by NOVA as ultra-processed foods (UPFs). However, recent research shows that none of the common criticisms attributed to UPFs apply to soy-based meat alternatives more than they do to beef, which is classified by NOVA as unprocessed or minimally processed. Additionally, many PBMAs are rated highly by other nutrient profiling models.

Conclusions: NOVA does a disservice to consumers by classifying PBMAs as UPFs as they represent a convenient, nutritious, and environmentally friendly option for lowering the animal to plant protein ratio in developed countries.

Intervention of whole grain education program improves knowledge, attitude, and behaviors toward whole grains intake among community-dwelling elderly

Su-E Susan Kuo[1,2], Hui-Fang Huang[1,3], Pei-Fang Siao[1,4], Hsiu- Wen Chen[1,5], Po-Yu Chiu[1,6], Yi-Ting Zhang[1], Jing-Yi Wang[1], Huei-Min Chin[1,7,8]

1. Taiwan Dietitian Association (Taiwan), 2. National Cheng Kung University Hospital (Taiwan), 3. Kaohsiung City Community Nutrition Promotion Center (Taiwan), 4. Tainan City Community Nutrition Promotion Center (Taiwan), 5. Chiayi City Community Nutrition Promotion Center (Taiwan), 6. Yilan County Community Nutrition Promotion Center (Taiwan), 7. National Yang Ming Chiao Tung University (Taiwan), 8. Fu Jen Catholic University (Taiwan)

Background and objectives: According to Health Promotion Administration, Ministry of Health and Welfare's recommendation, at least 1/3 of daily grains intake should be whole grains (WG). This study aimed to evaluate the influence of the WG education program for community-dwelling elderly on knowledge, attitude, and behavioral changes.

Methods: This program included three sessions: (1) to identify the difference between WG and refined grains, and understand the benefits of WG and how to prepare good-tasting WG; (2) to know where to buy and how to choose WG; and (3) to know how to preserve WG. Knowledge changes were evaluated before and after the course at each session with four questions. All participants completed the questionnaire at pre- and post-program intervals to evaluate attitude change about eating WG, while behavioral change was evaluated as the frequency and quantity of WG intake.

Results: Ninety-six participants were included with average age of 74.7±7.2 years with 50% being over 75 years; average BMI was 23.9±3.1 kg/m^2; and 25.0% lived alone. At commencement, the average score of differentiating WG and refined grains was 9.6±4.1, and this had increased to 14.7±2.4 (p<0.001) after the course. The scores of "to point out the benefits of WG" were 5.6±2.0 and 6.8±0.7 pre- and post-program separately (p<0.001). Knowledge changes concerning WG were significantly increased after each session (1.8±1.2/3.7±0.6, 3.2±0.8/4.0±0.1 and 3.1±0.9/3.8±0.5 for pre-/post-session at sessions 1, 2 and 3 separately, p<0.001). "The willingness toward eating WG at least 1/3 of daily grain intake" was 7.1±3.0 pre-program increasing to 7.9±2.7 post-program (p<0.01). "The confidence toward eating WG at least 1/3 of daily grain intake" was 5.6±3.4 and 7.7±2.8 pre- and post-program separately (p<0.001). Frequencies of WG intake at breakfast, lunch and dinner all increased significantly post-program (p<0.001); besides, the quantity of initial daily intake of WG averaged 2.0±2.8 Ex increasing to 4.7±3.9 Ex after program administration (p<0.001).

Conclusions: A series of a WG education program could improve the knowledge of WG choosing, purchasing, and storage; strengthen the confidence and attitude toward eating more WG; and finally transfer to the daily practice of eating more WG.

The role of fish in biodiverse patterns of household food expenditure and its socioeconomic determinants in Ghana

Zachary Park Gersten[1], Ana Baylin[1], Daniel Bruce Sarpong[2], Andrew David Jones[1]

1. University of Michigan (USA), 2. University of Ghana (Ghana)

Background and objectives Fish is an important component of African diets; however, there are socioeconomic differences in its contribution to health and nutrition. In lower socioeconomic settings, fish is a nutrient-dense animal source food that supports maternal and child nutrition. In higher socioeconomic settings, fish consumption with whole grains, fruits, and vegetables is protective against overnutrition outcomes. Furthermore, fish is a loosely defined food group that can include many types of biodiverse marine and freshwater fish or shellfish with variable prices or nutrient composition. The objectives of this study were to assess patterns of food expenditure among Ghanaian households, their socioeconomic determinants, and whether they were sensitive to disaggregating fish into biodiverse food groups.

Methods The analysis used nationally representative cross-sectional data collected from 13,944 households as part of the seventh round of the Ghana Living Standards Survey. We used a principal component analysis (PCA) to identify patterns in food expenditure, then stepwise multivariate regression analysis to assess relationships between each pattern and a range of socioeconomic variables. In a sensitivity analysis, we disaggregated fish into food groups that reflect its ecosystem origin (marine or freshwater) or genera/species (mackerel, herring, or tilapia) and repeated the PCA and stepwise regression.

Results: We found three dominant patterns of food expenditure that align with the nutrition transition: a 'Plants and fish' pattern of starchy staples, fruits, vegetables, and fish; 'Processed foods' included refined grains, processed meats, dairy, and sweets; and 'Food away from home' (FAFH) included meals prepared in restaurants. In general, the 'Plants and fish' pattern was tied to low socioeconomic status and the 'Processed foods' and 'FAFH' patterns to high socioeconomic status. Disaggregating fish did not change the composition of the three patterns nor their relationships with socioeconomic determinants, though it revealed that two types of freshwater fishes were correlated in the 'Plants and fish' pattern and two types of marine fishes in 'Processed foods'.

Conclusions Incorporating biodiversity principles into food and nutrition research may reveal important nuances in fisheries-food systems where many types of fishes are produced and consumed as part of a nutrition transition.

Predictors for weight retention and barriers for weight management in postpartum women: A cross-sectional study.

Divjyot Kaur[1], Piyush Ranjan[2], Archana Kumari[2], Anita Malhotra[1], Gaurishankar Kaloiya[2], Ashish Datt Upadhyay[2]

1. University of Delhi (India), 2. All India Institute of Medical Sciences, New Delhi (India)

Background and objectives: To study the association of postpartum weight retention with socio-demographic, obstetrics and lifestyle-related factors. To investigate barriers/myths associated with postpartum weight management.

Methods: A hospital-based telephonic cross-sectional survey was carried out using a pre-developed and validated questionnaire to assess the predictors of weight retention and barriers associated with weight management. Convenience sampling technique was employed to recruit women from different phases of the postpartum period i.e. women in the first three months post-delivery, four to six months post-delivery and beyond six months post-delivery. Chi-square test and regression analysis were applied to assess the association of various factors with weight retention/weight gain in different postpartum phases.

Results: The final sample comprised 505 postpartum women with a mean age of 29±4 years. Among socio-demographic variables, socio-economic status was associated with weight retention during the first three months post-delivery ($p<0.05$) whereas type of family and education qualification were associated with weight retention during four to six months post-delivery ($p<0.05$). Among obstetrics correlates, gestational weight gain was associated with weight retention in all three phases of the postpartum period ($p<0.05$). Among lifestyle-related factors, 50.7% of women did not consume regular meals and around 70% women had lower consumption of fruits and vegetables with a higher intake of HFSS foods. Only 5% indulged in low to moderate intensity physical activity whereas 95% had more than 4-hour exposure to screen time and sedentariness. Barriers such as lack of knowledge about diet and physical activity, lack of time, boundation to abide by family's advice and myths such as eating for two, consumption of high-calorie diet and energy-dense galactagogues restricted participants from adopting healthy lifestyle practices.

Conclusions: The study findings will assist in formulating and implementing weight management strategies for postpartum women. Future longitudinal studies must be carried out for further understanding of predictors of postpartum weight retention.

Current situation of nutritional pattern and body weight of mining workers

Purevjav Mejeenov[1], Enkhtaivan Gombosuren[1], Gurbazar Lhamsuren[1]

1. Mongolian University Science and Technology (Mongolia)

Background: The objectives of this research work were to determine the current dietary condition and reality of implementing a program aimed at improving the nutritional status of mining workers in accordance with improving health indicators such as decreasing obesity rate. The level of obesity in Mongolia has been increasing dramatically over the years, and that it is likely to be higher than the national average among mine workers.

Method A total of 300 mining workers, aged 20-63 were collected. Dietary study was used FFQ and 24 recall method and total diet energy intake was calculated by the using food composition data. Obesity rates were measured using Inbody370.

Results The average energy intake was 2530±251 kcal and the consumption of dietary protein was high and the consumption of carbohydrates was less than the RDA. Comparing to recommended dietary allowance, energy and fat intake were adequate, protein intake was 1.4-2.2 times higher than the recommended amount. The average body mass index of the miners was 29.2±2.8 kg/m^2, there was no difference between men and women. According to the results of the survey, the percentage of people with a normal weight is 27%, and the percentage of overweight and obesity is 73%. In our country, the prevalence of overweight and obesity is common among the population aged 15-49 and has increased from the level of the 2010 IV nutrition survey. Mining workers overweight and obesity level is higher than the national level. It is necessary to pay attention to the fact that the prevalence of severe obesity is 7.6%.

Conclusion The daily calorie intake is not high, but the level of obesity has become too high, it is necessary to continue to carefully study and improve the nutritional knowledge related to balanced diet of the mining workers in further.

Current status of self-efficacy and food environment regarding fruit intake among working generations

Kimi Sawada[1], Chizuko Hotta[2]

1. Tokiwa University (Japan), 2. Suzuka University of Medical Science (Japan)

Background and objectives: The recommended average daily fruit intake for the Japanese is 200 g (two servings; SV), but the actual intake of working generations does not meet 100g (one SV) per day. Therefore, to promote fruit intake, we conducted a questionnaire survey targeting working generations with low fruit consumption. In this study, we analysed the participants' recognition of fruit intake and the current state of the food environment.

Methods: In 2020, we conducted a questionnaire survey targeting approximately 400 employees of a certain company in Mie Prefecture. We distributed 357 questionnaires and obtained 346 responses (response rate of 96.9%). The analysis items included fruit intake recognition (self-efficacy/outcome expectancy), food environment (food access/family consumption behaviour), purchasers, and purchase locations. All statistical analyses were performed with IBM SPSS Statistics Version 26.

Results: Of the participants, 92.8% were men, and individuals in their 50s (36.7%) and 20s (23.7%) constituted the highest percentage of respondents, followed by individuals in their 30s (19.7%), 40s (10.5%), and > 60s (7.2%). While 43.4% of the respondents acknowledged that fruit intake prevents lifestyle-related diseases, only 6.4% answered that they were “extremely confident” about consuming fruits every day. Additionally, majority of the purchasers were “family members” (73.0%), of whom only 16.8% ate fruits “almost every day”.

Conclusions: Self-efficacy for daily fruit intake was low despite high expectations for fruit intake results; therefore, devices or supports to increase self-confidence in fruit intake are needed. Moreover, we confirmed that the fruit intake frequency of family members, who are the main purchasers, is extremely low. It is crucial to strengthen dietary education involving not only working generations with low fruit intake but also their family members.

Nutrition International's efforts in strengthening capacity of medium- and small-scale salt processors to achieve universal salt iodization in Asia: Experiences from Bangladesh, India, Indonesia, and Pakistan

Preeti Kamboj[1], Suvabrata Dey[1]

1. Nutrition International (India)

Background and objectives: Salt is fortified with an ‘essential' mineral iodine, which is crucial for healthy brain development; and prevention of goitre, reduced intellectual and motor performance, cretinism, brain damage, stillbirth, and miscarriage. Universal Salt Iodization (USI) is described as iodization of all salt for human and livestock consumption; and helps in improving iodine intake levels of the population and preventing iodine deficiency disorders (IDD). Around 126 countries globally and 35 Asian countries have mandated fortification of salt. In Asia, Nutrition International (NI) is supporting USI in four countries namely, Bangladesh, India, Indonesia, and Pakistan.

Methods: NI works on the following aspects in the salt sector: creation of an enabling environment by supporting improvement of policy and programmes at national and sub-national level to address IDD; and provision of support to salt processors and government officials to ensure improved quality and production of adequately iodized salt. Majority of salt in the listed countries is produced by small and medium-scale salt processors (SMSPs). Use of non-mechanized and rudimentary iodization techniques by SMSPs and lack of effective enforcement of edible salt standards results in production of considerable proportion of inadequately iodized salt. NI provides critical technical and financial assistance to the SMSPs to enable production and sale of adequately iodized salt.

Results: Under NI's “cost sharing model/ pull finance model”, partial cost (25%) of the centrifuge/ dewatering device provided to medium-scale salt processors (SPs) is reimbursed as per the terms in the cost sharing agreement. This helps in mainstreaming edible salt value chain and ensuring better compliance of the edible salt standard. NI supports small-scale SPs by consolidating them and turning them into suppliers of raw salt for medium and large-scale SPs; and/ or packagers of iodized salt produced by large-scale SPs. Additionally, NI undertakes supportive supervision and rigorous monitoring of the SMSPs.

Conclusions: NI's continued efforts in supporting the salt industry have helped in supporting 1,589 SPs, producing 942,300 MTs of adequately iodized salt and reaching an additional 337 million people in Bangladesh, India, Indonesia, and Pakistan in 2022.

Twenty-year trends in consumption of main meals and snacks from ultra-processed foods among Korean adults from 1998 to 2018

Sohyun Park[1,2], Sukyoung Jung[3], Jee Young Kim[4]

1. Hallym University (Korea), 2. The Korean Institute of Nutrition (Korea), 3. The George Washington University (USA), 4. National Food Safety Information Service (Korea)

Background and objectives: Unfavorable changes in eating patterns over time may contribute to upward trends in chronic diseases such as obesity. We examined 20-year trends in the percentage of energy from main meals and snacks, and the food sources of snacks among Korean adults.

Methods: This study used nationally representative data from the 1st, 4th, and 7th Korea National Health and Nutrition Examination Survey (1998, 2007-2009, and 2016-2018) among adults aged 20–69 years (n=29,389). Each eating occasion (breakfast, lunch, dinner, and snacks) was defined as respondents specified during a 24-hour dietary recall interview. To identify major sources of snacks, we used NOVA system. The percentage of energy from each eating occasion and that from ultra-processed foods(UPFs) in snaking across survey cycle were estimated and tests for linear trends were conducted using orthogonal polynomial contrasts in linear regression models. All analyses accounted for the complex survey design.

Results: Between 1998 and 2018, after adjusting for age and sex, the percentage of energy from breakfast decreased from 25.0% to 16.7% (difference, -8.2%, (95% CI, -8.9% to -7.6%)), whereas percentages of energy from dinner and snacks increased from 31.1% to 33.8% (difference, 2.7%, (95% CI, 2.0% to 3.4%)) and from 14.0% to 19.0% (difference, 5.0%, (95% CI, 4.1% to 5.9%)), respectively (all P < .001 for trend). When stratified by age, 30-39 years old had the largest change in percentages of energy from three main meals. Although we observed the largest increase among older adults (≧50 years), the youngest (20-29 years) consumed the largest energy from snacks. For snaking, from 1998 to 2018, the overall percentage of energy from UPFs increased from 22.9% to 58.4% (difference, 35.5%, (95% CI, 33.7% to 37.4%)) and a greater increase was observed among younger adults than older adults.

Conclusions: The eating patterns of Korean adults have changed from 1998 to 2018, with the greatest decrease in breakfast consumption and the greatest increase in snacking. UPFs have become a major source of energy from snaking, especially among younger adults.

Association between Diet Quality and Stunting among Primary School Children in Mbita District, Western Kenya; A Cross-Sectional Study

Azumi Hida[1], Madoka Kishino[1], Shinjiro Hamano[2], Sachiyo Nagi[3]

1. Tokyo University of Agriculture (Japan), 2. Nagasaki University (Japan), 3. Tokyo Women's Medical University (Japan)

Background and objectives: A healthy diets is critical for better health and growth. Diet quality included variety and adequate intake had been rarely investigated in the developing regions of Africa. This study aimed to examine the relationship between diet quality and stunting among school-aged children in western Kenya.

Methods: This study included 237 fourth-grade school children (9-17 years old) in Mbita district, western Kenya. Anthropometric measurements and parasitic infection (malaria and schistosoma monsoni) test were conducted to assess their nutritional status. Child's age, sex and household socioeconomic status (SES) were surveyed. Food intake data were estimated using a food frequency questionnaire developed specifically for this population and evaluated based on the adherence to the recommendation of Kenyan food pyramid dietary guideline (FP). The FP score consists of the five food groups (staple foods, protein-rich foods, dairy products, vegetables, and fruits). If the number of servings consumed is within the recommended serving range, 10 points are added. If outside the recommended range, a lesser number of points will be assigned. The FP score was examined for trend associations with characteristics of participants, nutritional status and energy and food intakes. Logistic regression analysis was performed to examine the risk factors for stunting, with the outcome being stunting and explanatory variables being age, sex, SES, parasitic infection and FP score. Statistical analyses were performed using the IBM SPSS Statistics ver. 28.

Results: Of the school children studied, 13.9% were stunted. FP score ranged widely between 10 and 43 out of 50 points. Higher FP score indicated higher energy and dairy products, pulses and fruits, and were negatively associated with the stunting (adjusted odds ratio = 0.93 [95% confidence interval: 0.88-0.99]). Male and older age children tended to be associated with stunting, although not statistically significant.

Conclusion: Male, older age child and poor diets tended to be associated with stunting. Support for more vulnerable children and encouragement of adequate energy and balanced diets are required.

Association between personality questionnaire and eating pattern revealed by a food-log App data.

Lyie Nitta[1], Yu Tahara[2,1], Takae Shinto[1], Saneyuki Makino[1], Mai Kuwahara[1], Ayako Tada[3], Mikiko Michie[3], Shigenobu Shibata[1]

1. Waseda University (Japan), 2. Hiroshima University (Japan), 3. asken Inc. (Japan)

Background and Purpose: Advances in technology have made it easy to precisely record an individual's varied nutritional intake status. Using this technique, we investigated the relationship using 27 different nutritional intake data for each meal (breakfast, lunch, and dinner) and personality.

Method: In collaboration with the dietary management application "Asken," a questionnaire survey of approximately 50 items including “Big5” was conducted on 4,174 members residing in Japan. Asken users answered several questionnaires including age, weight, sleep duration, exercise intensity and frequency, and personality score (TIPI-J), and collected nutrition intake records for approximately one month through the app function. Based on those data, we performed correlation and multiple regression analysis.

Result: Those who were more conscientiousness had lower BMI and body fat percentage, exercised more often, ate breakfast earlier, and tended to sleep and wake up earlier. Both men and women with more conscientiousness had higher iron and zinc intake at breakfast and lower carbohydrate intake at dinner. Women also consumed more dietary fiber and minerals such as magnesium and folic acid at breakfast. Their qualities of sleep were better and had a higher sense of health and happiness Open-minded individuals also had higher total daily physical activity (METs), but there were no significant differences in BMI or body fat percentage, and in women, sleep time were shorter.

Conclusion: High conscientiousness individuals have higher exercise habits, sleep quality, and subjective wellness. Highly open-minded individuals have higher levels of well-being, but there are no significant differences in BMI or health. Those results suggest that the personality is somehow correlated to the daily eating pattern, and the personalized nutritional intervention should be considered in the understanding individual personality in the future. PAB(T6)-307
The role of diet on seasonal variations in growth in children under 5 years in rural India

Tinku Thomas[1], Rekha Ravindran[2], Sumathi Swaminathan[2]

1. St. John's Medical College (India), 2. St. John's Research Institute (India)

Background & Objective India has a high burden of undernutrition and the national surveys have demonstrated that there are seasonal variations in the prevalence of undernutrition in children under 5 years, particularly in the prevalence of wasting. The impact of morbidity and labour demands on this seasonal effect is documented. It is expected that variations in dietary intake would also impact the seasonality. This longitudinal study examines the role of consumption of different foods on weight standardized for age and height of children aged 12-60m in Bihar state of India. **Methods** Anthropometry and 24-hr diet recall data were collected from rural children residing in 1732 households in two major cropping seasons, monsoon and winter. Additional data on socio-demographic characteristics was also collected. Age and sex specific standardized weight and height (HAZ, WAZ and WHZ) of children were computed. The dietary intake of cereals, legumes, fats & oils, added sugar, fruits and milk in gms per day was computed. The consumption of food groups was regressed on age of the child in round 1 and the estimated equation was used to predict the consumption of each child in round 2 based on its age. The difference from the expected consumption was consumption of the food groups was considered as a dependent variable in multiple linear regression of standardized weight and height scores in round 2. **Results** There mean WHZ improved from -1.11(1.52) to -0.42(1.07) from monsoon to winter seasons reflecting in a 16% point reduction in wasting (WHZ<-2). There was an improvement in WAZ but not in HAZ. Milk consumption in children improved from round 1 to 2in the lower quintiles of consumption. Increase in milk intake improved all anthropometric measures (WHZ (Beta= 0.001, 95% CI: [0.0002, 0.001]), WAZ (Beta= 0.001, 95% CI: [0.001, 0.003]) and HAZ (Beta= 0.0014, 95% CI: [0.001, 0.002])) and that of fruits improved WAZ (Beta= 0.002, 95% CI: [0.0001, 0.003]). **Conclusion** Increased consumption of milk and fruits in the winter season compared to monsoon can improve WAZ of children aged 12-60m.

Plant-based diets and metabolic status in children: vegan and vegetarian diets may predispose to anemia and protect from high cholesterol

Topi Hovinen[1], Elina Kettunen[1], Riitta Freese[1], Maijaliisa Erkkola[1], Anu Suomalainen[1,2], Liisa Korkalo[1]

1. University of Helsinki (Finland), 2. Helsinki University Hospital (Finland)

Background and objectives: The diets of children in the Western world are shifting towards more plant-based, yet barely any studies have been conducted on the metabolic effects of fully or almost fully vegan diets in children. In the MIRA Helsinki (2017) and MIRA2 (2022) cross-sectional studies, we aimed to fill this gap in knowledge by investigating the nutritional and metabolic effects of vegan and vegetarian diets in children.

Methods: We collected 3- to 4-day food records and blood and urine samples from 54, 26, and 33 children who followed an omnivore, vegetarian and vegan diet, respectively. The children were recruited from day care centers in Helsinki and were of 1-7 years of age. A targeted set of clinical laboratory tests from the biological samples were conducted to assess the nutritional status of the participants. Serum amino acids were analyzed only for the latter (28 omnivore, 16 vegetarian and 27 vegan diet), and erythrocyte folate for the former study (26 omnivore, 10 vegetarian and 6 vegan diet).

Results: Supplementation guidelines for vitamin D (> 7.5 µg/day) were met by 82%, 85% and 100% of children on omnivore, vegetarian and vegan diet, respectively. Vitamin B12, iodine and EPA+DHA supplements were used by 31 (94%), 31 (94%) and 4 (12%) vegans, respectively. The vegan diet group had significantly lower serum/plasma concentrations of LDL cholesterol and essential/non-essential amino acid ratio, and significantly higher erythrocyte folate and plasma triglyceride concentration than omnivore group. The vegetarian diet group showed average concentrations between the omnivore and vegan diet groups. One (2%), three (12%), and four (12%) children on an omnivore, vegetarian, and vegan diet had mild normocytic anemia (Hb < 112 g/L). Two non-anemic children on vegan diet had potential vitamin B12 deficiency (Transcobalamin-bound B12 < 70 pmol/L). 12 (22%) omnivores, no vegetarians and 2 (6%) vegans had hypercholesterolemia (LDL > 3 mmol/L).

Conclusions: Planning an adequate vegan diet for children is complex and requires thorough understanding based on sufficient research with child participants. Special attention may be required to ensure adequate erythropoiesis and use of diverse sources of proteins to provide all essential amino acids.

Keyword: vegan, children, cholesterol, amino acids, anemia

Food insecurity and changes in food consumption during the Covid19 pandemic in Brunei Darussalam: a cross sectional study

Lubna Abdul Razak[1], Norhayati Kassim[1], Najihah Othman[1], Si Yee Chan[2], Sattha Engpornsin[2], Sharleen Othman[2], Wei Yuan[3], Hong Shen Lim[3], Sophie Goudet[4]

1. Ministry of Health (Brunei), 2. EVYD Technology Ptd Ltd (Brunei), 3. EVYD Technology Research Pte Ltd (Singapore), 4. UNICEF (Fiji)

Background and objectives: The COVID-19 pandemic has affected the economy, social, emotional wellbeing and dietary behaviours. Due to movement restrictions and anxiety of the Covid-19 infection; takeaway foods, more frequent snacking and less physical activity became normalised. It was deemed critical to investigate the changes in dietary practices and child food security. Remote method of data collection support adherence to the low contact guidance.

Methods: Contact numbers were retrieved randomly from the health information systems database. Eligible respondents (caregivers of children between 2 to 14 years and adolescents aged 15 to 19 years) were invited to answer a 10 minute online survey adapted from standardized indicators to collect nutrition data. Food Insecurity Experience Scale (FIES) calculations was conducted through the Food Agriculture Organisation's Voices of the Hungry (VoH) website. Targeting through notifications on the Bruhealth, the mobile health application, the cross sectional survey was carried out from June to August 2022.

Results: 459 caregivers (98% female) and 60 adolescents (70% female) responded. It was found 25.7% (n=118) of children aged 2-18 years with reported decreased consumption of one or more healthy food groups (out of 13) due to Covid-19. A mean of 5.1 (standard deviation 3.6) food groups (out of 13) with reported decreased consumption by child aged 2-18 years. Of note, 27.2% (n= 125) of caregivers reported Meats food group with reported decreased consumption. 16.1% of caregivers of children aged 2-18 years report moderate and 12.8% severe household food insecurity according to the Food Insecurity Experience Scale (FIES). According to the Child Food Insecurity Experience Scale, 40% of adolescents aged 15-18 years reported many food insecurity experiences (n=24).

Conclusions: This study quantified the food insecurity experience and the changes of food consumption among children aged 2-18 years. The use of innovative method to collect information on caregiver and adolescent experiences during a period when household surveys were not recommended, may provide guidance for wider use. Further analysis is required to assess whether government initiatives lessen the impact of Covid-19 on households.

How much does the food industry spend on advertising food and beverage products heavily advertised on youth-appealing television stations in Canada?

Elise Pauzé[1], Monique Potvin Kent[1], Mariangela Bagnato[1], Julia Soares Guimarães[1], Lauren Remedios[1], Mary R. L'Abbé[2], Christine Mulligan[2], Laura Vergeer[2], Madyson Weippert[2]

1. University of Ottawa (Canada), 2. University of Toronto (Canada)

Background and Objectives: Exposure to unhealthy food marketing is likely promoting poor eating habits and obesity among Canadian adolescents. The purpose of this study was to quantify advertising expenditures on food and beverage products frequently advertised to adolescents in Canada and assess how much is spent advertising less healthy products.

Methods: Advertising expenditure estimates for 57 select food categories for January to December 2019 were licenced from Numerator. This company estimates advertising expenditures for five media (television, out-of-home, radio, print and digital) using advertising, audience measurement and/or billing data that it collects itself or that is provided by other companies (e.g., broadcasters). Sixty-one food and beverage products or brands identified as frequently advertised on two youth-appealing television channels using television advertising data were included in the study. The nutritional information of these products was collected, and their healthfulness was assessed based on their content in sodium, sugar, and saturated fat using a nutrient profiling model (NPM) proposed by Health Canada. This NPM classifies products as "would be" or "would not be subject to food advertising restrictions". The distribution of advertising expenditures by media, food category and NPM classification were tabulated.

Results: In 2019, about $111 million was spent advertising the 61 food and beverage products or brands heavily advertised on youth-appealing television stations. Television accounted for 77% of this spending, followed by out-of-home media (7.6%), radio (7.5%) and digital media (7.4%). The top three food categories accounting for the largest share of these expenditures were fast food (51%), soft drinks (12%), and milk and dairy alternatives (9.7%). More than two-thirds (77%) of this spending were allocated to products classified as "would be subject to restrictions".

Conclusion: The food industry is spending millions to promote unhealthy food and beverages heavily advertised on youth-appealing television stations in Canada. While this study cannot assert that all this spending was used to target adolescents specifically, findings nevertheless suggest that Canadian youth are likely exposed to unhealthy food advertising across media channels.

PAB(T6)-311
A comprehensive review on the double burden of childhood malnutrition and micronutrient deficiencies in four Southeast Asian countries: prevalence, determinants, current gaps and potential solutions

Pui Yee Tan[1], Chong Ling Chan[1], Louise Dye[1], Yun Yun Gong[1]

1. University of Leeds (UK)

Background and objectives: Several countries in Southeast Asia (SEA) face the rising challenge of the double burden of malnutrition (DBM) alongside micronutrient deficiencies (MND). This review examines the prevalence and determinants of DBM and MND, and identifies current gaps and potential strategies to address childhood DBM and MND in Indonesia, Malaysia, Thailand and Vietnam.

Methods: A comprehensive literature search was conducted in four databases to identify studies reporting the prevalence, determinants and approaches to tackling malnutrition and micronutrient deficiencies (iron, anaemia, vitamins A and D) in children under 19 years in the four SEA countries.

Results: 197 studies were identified. According to recent national surveys (2014-2020), prevalence of stunting in children under 5 (girls and boys) in Indonesia, Malaysia, Thailand, and Vietnam were 30.8% (29.7%, 31.7%), 21.8% (23.5, 20.2%), 13.4% (11.4%, 15.2%) and 19.6% (20.6%, 18.6%), respectively, especially higher in rural regions, 13.1-34.9% (*vs.* urban=12.4-27.3%). Overweight and obesity were more prevalent in older children (~5-19 years old) (Indonesia: 20.0%, Malaysia: 29.8%, Thailand: 12.4% and Vietnam: 19.0%), particularly higher in boys, 6.9-33.2% (*vs.* girls: 6.4-26.2%), and in urban regions, 15.5-33.7% (*vs.* rural: 11.2-26.9%). Low birth weight, low socio-economic status, low maternal height and education, suboptimal feeding practices and food insecurity were the factors commonly associated with undernutrition. Sedentary lifestyles, increased screen time and high-energy dense foods were associated with weight gain. Vitamin A deficiency (0.3-14.2%) was of less concern. Anaemia and iron deficiency varied from 4.0-55.6% and 5.2-44.9%, respectively, and were higher in girls and in rural regions, potentially caused by dietary practices, intestinal infection, thalassemia and hemoglobinopathies that merit further investigation. Vitamin D deficiency varied from 7-83%, and was higher in girls and in urban regions, possibly related to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

dietary practices (e.g., lower milk consumption), sun-avoidant lifestyles and religious practices. Intervention trials demonstrated the effectiveness of supplementation, fortification and obesity-related lifestyle programmes in improving child malnutrition, with limited data for nutrition-sensitive programmes to inform policy strategies.

Conclusion: DBM and MND remain significant public health concern in SEA, and the magnitude varied across the countries. More research is warranted to identify effective double-duty actions to end all forms of malnutrition.

PAB(T6)-312
Unintended consequences of policy actions to reduce added sugar: The global rise of non-nutritive sweeteners

Cherie Russell[1], Phillip Baker[1], Carley Grimes[1], Rebecca Lindberg[1], Mark Lawrence[1]

1. Deakin University (Australia)

Background and objectives: Humans have a biological preference for sweetness. Subsequently, the food industry has increasingly produced and promoted highly desirable and potentially addictive products sweetened with added sugars. Current added sugar intakes exceed recommendations, constituting a dietary risk for poor health. Policy actions to reduce consumption have been implemented internationally and may promote reformulation to reduce the added sugar content of packaged foods, often with the addition of non-nutritive sweeteners (NNS): non-caloric substances which impart sweetness. NNS health impacts and their effect on dietary patterns are contested. We aimed to assess whether there was an association between longitudinal trends in worldwide sales of added sugars and NNS and policy actions to reduce added sugar consumption.

Methods: We adopted a mixed methods approach, including a longitudinal trend-analysis of the apparent consumption of added sugars and NNS using per-capita market sales data from 2007-2019 from the Euromonitor Passport Database, and policy mapping of global policy actions to reduce added sugar consumption from The NOURISHING Database.

Results: NNS sales supplied by beverages increased globally (2g/capita, 36%). This was significantly ($p < 0.05$) correlated with the overall number of policy actions to reduce added sugar consumption and increased advertising regulations, food standards in public institutions and increased availability of healthy foods. Added sugar sales supplied by beverages, and the ratio of added sugar and NNS use, decreased in high-income countries (8kg/capita, 22%) but increased in upper- and lower-middle income countries (1kg/capita, 40% and 0.5kg/capita 13% respectively). Added sugar sales increased globally for packaged food (0.5kg/capita, 9%).

Conclusions: The use of NNS, and the sweetness of the packaged food supply, is increasing. These trends are associated with implemented policy actions to reduce added sugar consumption. Additionally, we suggest that NNS use is driven by industry responses to proposed policy; consumer demand for low energy/sugar products; favourable regulatory environments; and technological advances. Sweetener growth in middle-income countries is associated with an increased supply of ultra-processed foods associated with the 'nutrition transition'. The health and dietary impacts of our increasingly sweet food supply, and increased NNS intakes, will require ongoing monitoring to determine public health outcomes.

Reaching Zero-Dose Children: Delivering Vitamin A Supplementation (VAS) to Children 6-59 months in Hard-to-Reach Settings of Nigeria

Banda Ndiaye[3], Ayodele Gbemileke[1], Deborah Benneth[1], Titilola Abolade[1], Adeyemi Oladeji[2], Jacob Korir[3], Jacqueline Kung'u[3], Audree Montpetit[3], Caitlin Gomez[4], Alison Greig[4]

1. Nutrition International, Nigeria (Nigeria), 2. Association for Reproductive and Family Health (Nigeria), 3. Nutrition International, Kenya (Kenya), 4. Nutrition International, Canada (Canada)

Background and Objective: Two-dose VAS coverage in Nigeria remains very low (41%). The inequity is more glaring in hard-to-reach settings (HTRS), worsened by the impact of COVID-19 pandemic. Nutrition International supported the government in Rivers, Cross Rivers and Sokoto states through its Covid-19 Emergency Response project to deliver two rounds of VAS in HTRS between September 2021 to June 2022. The objective is to reach eligible children in HTRS with VAS through extended outreach of the bi-annual maternal newborn and child health weeks (MNCHW).

Methods: Advocacy with state-level policy and decision makers was undertaken to increase commitment to extend VAS to the vulnerable children in HTRS. Mapping and categorization of hard-to-reach communities with security challenges, inaccessible/difficult road networks were conducted with the state MNCH teams using a participatory bottom-up micro-planning. The state consolidated micro plans were updated with this information ensuring HTRS were included and used to prioritize and deploy adequate human resources, commodities, data tracking tools and transport logistics to these areas. About 2,545 front-line health workers (FHW) and community resource persons drawn from the HTRS were trained and deployed to over 1,000 outreach sites across the three States. Town announcers and guides were mobilized to generate demand and facilitate

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

safe entrance into these communities. 40 independent monitors were also trained and deployed to give real-time reports, including daily data reviews using WhatsApp platform.

Results: A total of 1,312,089 (90%) children 6-59 months received two -doses of VAS in HTRS across the three states. Of these, 787,769 children are additional due to the project.

Conclusion: This approach resulted in reaching children who are frequently missed with the MNCHWs in each of the states and in some cases had never been reached with VAS.

PAB(T7)-1
Nutritional value and properties of plain bread made from powdered wood

Noriko Sato[1], Tetsuya Ohashi[1]

1. Koshien University (Japan)

Background and objectives: Dietary reference intake for Japanese (2020) indicates that the quantity of aim of the daily dietary fiber intake of Japanese people is more than 21 g for male from 18 years old to 49 years old. It indicates that the quantity of aim of the daily dietary fiber intake of Japanese people is more than 18 g for female from 18 years old to 49 years old. But the national health and nutrition survey Japan (2018) indicates that average of the daily dietary fiber intake of Japanese people is 14.4g. It indicates that average of the daily dietary fiber intake of Japanese people from 18 years old to 49 years old is 12.4g. Therefore, it should be recommended that we take dietary fiber positively. In addition, the most of thinning are discarded in the forest. We should consider that we use these resources effectively. We do not usually make it edible. But we suggest that we eat powdered wood in everyday life. We will do the suggestion of eating habits to take in dietary fiber positively.

Methods: Commercial edible powdered wood, strong flour, sugar, butter, powdered skim milk, salt, dry yeast were used for plain bread. We purchased powdered wood from Taruwakien (Shizuoka). Powdered wood of 0% or 3% or 5% or 10% of strong flour was included in plain bread. The bread was baked using a bake machine. Plain breads were cut the middle of the bread in a square. Using a rheometer, hardness of plain bread was measured. In addition, nutritive values were calculated.

Results: As ratios of powdered wood in plain bread increased, the hardness of plain bread increased. As ratios of powdered wood in plain bread increased, the quantity of dietary fiber in plain bread increased.

Conclusions: The plain bread containing the powdered wood is hard, but some people may enjoy a texture with the resistance to teeth of the bread. We will think that it is necessary to consider by sensory evaluation in future. It suggests that eating habits to take bread containing the powdered wood helps increase dietary fiber intake.

PAB(T7)-2
Maternal Perspectives on Probiotics and Probiotic Food Consumption of Children in Urban Communities in Laguna, Philippines

Cherry Ann Durante[1,2,3], Ernani Bullecer[2]

1. Emilio Aguinaldo College - Manila (Philippines), 2. University of the Philippines - Manila (Philippines), 3. University of Perpetual Help - Dr. Jose G. Tamayo Medical University (Philippines)

Background and objectives: Probiotic consumption has been on the rise in the Philippine market. However, research has yet to be done on the level of knowledge and attitudes of mothers regarding these commercially-available probiotics. This study described the consumption of probiotics among children and its relationship with the maternal perspectives on probiotic food.

Method: This study is a cross-sectional, analytic study on 680 mothers and 680 children recruited in selected urban communities in Laguna, Philippines.

Results: Most mothers (92%, n=625) had highly positive attitude to probiotics. Composite scores were computed for questions on maternal attitude to probiotics, perceived behavioral control, and intention of giving probiotics to children. Path analysis was run to check for association and the resulting path showed significant association between attitude and intention, attitude and intake, behavioral control and intake, behavioral control and intention, and intention and intake of probiotic food. Female children (42.43%) have higher intake than males (30.61%). High intake was also noted among children of mothers with educational attainment of Vocational (45.45%) and College and higher (41.09%); among low- (38.92%) and middle-income families (44.06%). As for the frequency of consumption of probiotic food, 3 out of 10 of the respondents reported daily intake of at least one bottle of the probiotic foods enumerated.

Conclusion: Mother's attitude, perceived control and intention are positively associated with higher total intake among children. The intake of probiotics among children in the sample population was high. One out of three children consumed a probiotic drink daily.

Citrus tamurana Hort. Ex Tanaka (Hyuganatsu Orange) derived arabinogalactan suppresses bone turnover in postmenopausal women. A double blind, placebo-controlled study (DB-SAHBo Study)

Masatoshi Yamaguchi[1], Toshiko Yoshiyama[2], Ruriko Maruyama[1], Masanao Ohashi[3], Shoko Nishizono[4], Taichi Kobayashi[5], Munetoshi Miyatake[5], Yoichiro Sakatani[6], Hiroshi Sameshima[5]

1. University of Miyazaki, Faculty of Medcine (Japan), 2. Kitahara Clinic (Japan), 3. Miyazaki Medical Association Hospital (Japan), 4. Sojo University (Japan), 5. University of Miyazaki (Japan), 6. Miyazakiken Nokyokaju Co. Ltd. (Japan)

Background and objectives; We previously reported that water soluble substance of this orange suppresses osteoclast formation in ovariectomized rat and 3T3E1 cell. This substance was determined as arabinogalactan. We also showed that Hyuganatsu arabinogalactan stimulates fibroblast migration in vitro. From these basic findings, we then investigated a pilot clinical study to compare Hyuganatsu juice intake group and no treatment control group. Rates of changes between pre- and post-consumption were significantly increased in TRACP5b and P1NP concentration in the Hyuganatsu group. Therefore, in this study, we performed a double blind, randomized study on the effect of arabinogalactan rich Hyuganatsu juice on the bone metabolism.

Methods; 63 women were assigned to Hyuganatsu and placebo groups with stratification randomization. Hyuganatsu group took a paper pack containing 125ml of Hyuganatsu juice with arabinogalactan (31.3mg) every day for 90 days. Placebo group took a different juice in a same paper pack, which had similar flavor and color to Hyuganatsu juice and did not contain arabinogalactan.

Results; TRACP5b concentrations were not different between the 2 groups at the pre-intervention period, which were significantly different at 90-day treatment, and then became insignificant at 30-day recovery. Repeated measures linear mixed model analysis revealed a significant accumulation effect in TRACP5b. The temporal changes in P1NP were significantly different ($p<0.05$) and a significant accumulation effect was observed after 90-day treatment. There was no significant difference in other parameters.

Conclusions; Our results suggested that Hyuganatsu arabinogalactan serves as a useful functional food, which has some clinical efficacy for osteoporosis caused by ovarian hormone deficiency.

Comparison of the therapeutic potentials on functional properties of regulating lipid metabolism and intestinal/fecal lipid absorption between chitosan and chitosan oligosaccharide in high-fat diet-induced obese rats

Shing-Hwa Liu[1], Rui-Yi Chen[2], Meng-Tsan Chiang[2]

1. National Taiwan University (Taiwan), 2. National Taiwan Ocean University (Taiwan)

Background and Objectives: Chitosan and its derivative, chitosan oligosaccharide (CO), possess hypolipidemic and anti-obesity effects. A previous study found that the effects and mechanisms on improving lipid metabolism were different between 5% CO and 5% high-molecular-weight (MW) chitosan (HC)/5% low-MW chitosan (LC) in high-fat (HF) diet-fed rats for 8 weeks. However, it is still unclear if the mechanisms are different or similar between chitosan and CO. This study was designed to investigate and compare the effects of CO and HC on liver lipogenesis and lipid peroxidation, adipose lipolysis, and intestinal/fecal lipid absorption in HF diet-fed rats for 12 weeks.

Methods: Rats were randomly divided into four groups after a 1-week acclimation: normal control diet (chow diet) (NC), HF diet (chow diet+10% lard) (HF), HF diet+5% HC, HF diet+5% CO. The experiment period was 12 weeks.

Results: Both HC and CO supplementation could reduce liver lipid biosynthesis, but HC had a better effect than CO on improving liver lipid accumulation in HF group. Both HC and CO supplementation effectively reduced the increases in plasma and hepatic lipids, activated the AMPK activation, decreased the PPARγ protein expression, and decreased the lipogenesis-related enzyme (ACC, FAS, and HMGCR) activities in the livers. The increased triglyceride level and lipoprotein lipase activity and the decreased lipolysis rate in perirenal adipose tissues of HF group could be significantly reversed by both HC and CO supplementation. HC, but not CO, supplementation promoted liver antioxidant enzymes glutathione peroxidase and superoxide dismutase activities and reduced liver lipid peroxidation. HC supplementation significantly increased the fecal TC and TG levels, while CO supplementation slightly increased the fecal lipids levels. HC, but not CO, supplementation could significantly increase the amount of bile acid excretion into feces. HC mainly used its physical properties to increase lipid excretion and inhibit lipid absorption, while CO reduced lipid absorption by reducing the expression of *fabp2* and *fatp4* mRNA in the intestines.

Conclusions: These results suggest that HC and CO have different mechanisms for improving lipid metabolism in HF diet-fed rats. A long-term study may be needed to clarify the positive actions of CO in HF diet-induced obesity.

Long-term supplementation with omega-3 fatty acids-enriched fish oil improves inflammation and protein synthesis/degradation signals and prevents skeletal muscle atrophy in an obese rat model

Meng-Tsan Chiang[1], Yu-Ching Chen[1], Shing-Hwa Liu[2]

1. National Taiwan Ocean University (Taiwan), 2. National Taiwan University (Taiwan)

Background and Objectives: Fish oil with an abundance of omega-3 fatty acids eicosapentaenoic acid and docosahexaenoic acid is a beneficial dietary supplement for improvement of metabolic disorders. Here, we investigated the beneficial effects and mechanisms of long-term supplementation with fish oil on obesity-related changes of muscle metabolism and muscle atrophy in rats.

Methods: High-fat (HF) diets were applied to induce obesity in male Sprague-Dawley rats with or without omega-3 fatty acids-enriched fish oil (FO; 5%) supplementation for 16 weeks. Control mice were fed with normal diet.

Results: Diets supplemented 5% FO showed a significant decrease in the final body weight and body weight gain compared to HF diet-fed rats (n=8, $p<0.05$). Diet supplementation of FO decreased blood total cholesterol and triglyceride and tumor necrosis factor-α levels in HF diet-fed rats (n=8, $p<0.05$). The muscle fiber atrophy (decreased cross-sectional area) of gastrocnemius, soleus, tibialis anterior, and extensor digitorum longus muscles in HF diet-fed rats could be improved by FO supplementation (n=8, $p<0.05$). FO supplementation increased phosphorylated FOXO3A and decreased Atrogen-1 and MuRF1 (muscle atrophy-related proteins) protein expression in soleus muscles of HF diet-fed rats (n=4-6, $p<0.05$). The activation of adenosine monophosphate (AMP)-activated protein kinase (AMPK) in muscle is known to enhance glucose uptake, fatty acid oxidation, and mitochondrial biogenesis. The peroxisome-proliferator-activated receptor-γ coactivator 1α (PGC-1α) is a downstream signaling of AMPK. FO supplementation could significantly activate AMPK phosphorylation and PGC-1α protein expression in soleus muscles of HF diet-fed rats (n=4, $p<0.05$). FO supplementation could also increase the phosphorylation of Akt/mTOR/p70s6k (protein synthesis pathway) in soleus muscles of HF diet-fed rats (n=4-6, $p<0.05$).

Conclusion: These results suggest that diet supplementation of FO exerts a beneficial improvement in imbalance of muscle metabolism in obesity. The increases in signaling pathways of AMPK/PGC-1α and Akt/mTOR/p70s6k and the decrease in signaling pathway of FOXO3/muscle atrophy-related proteins are involved in the FO-prevented obesity-induced muscle atrophy.

Keyword: Fish Oil, Skeletal Muscle, Obesity, Muscle Atrophy-Related Proteins

PAB(T7)-6

Bioavailability of prenylated isoflavones, glyceollins, in Sprague-Dawley rats

Chizumi Abe[1], Ye Zhang[1], Kazuhiro Takao[1], Koji Ochiai[2], Toshiro Matsui[1]

1. Kyushu University (Japan), 2. DAIZ Inc. (Japan)

Background and objectives: It has been evidenced that prenylation of isoflavones displayed apparent physiological effects rather than their mother isoflavones (*e.g.* daidzein and genistein), while their bioavailability remains unclear. This study, thus, aims to obtain insight on the bioavailability of prenylated isoflavones, glyceollins, in Sprague-Dawley (SD) rats, in terms of intestinal absorption and subsequent tissue distribution.

Methods: Glyceollins (glyceollin I and III) obtained from germinating soybeans and daidzein (as control) were orally administered to the rats (1.0 mg/kg) and blood samples from tail veins collected at 0.5, 1, 4, and 8 h were subjected to an LC-TOF/MS analysis. Deconjugation treatments with β-glucuronidase Type B-I and sulfatase Type H-I were performed to evaluate the amounts of conjugates. Ex vivo transport experiments using rat jejunum membrane were also performed to examine pharmacokinetics of glyceollins. Furthermore, accumulation of absorbed glyceollins in organs was assayed using organs (the liver, kidneys, heart, lung, soleus muscle, and abdominal aorta) taken at 0.5, 1, 3, 6, and 24 h after a single administration.

Results: LC-MS analysis revealed that glyceollins I and III, as well as daidzein, were absorbed in conjugated forms, but not intact forms into rat circulating bloodstream. Absorption of conjugated forms of glyceollin I was > 8-times higher than that of daidzein ($AUC_{0-8\ h}$: glyceollin I, 8.5 ± 0.7 nmol·h/mL-plasm; glyceollin III, 1.0 ± 0.2 nmol·h/mL-plasma; daidzein, 0.6 ± 0.1 nmol·h/mL-plasma), depending on their hydrophobicity or log *P*. MS analyses of blood sample also demonstrated that conjugated forms of glyceollins were sulfated, glucuronidated, and methylated ones. After intestinal absorption, glyceollins were found to be distributed into the circulatory organs rapidly (T_{max} of 0.5 h), in the order of the liver > kidney > heart > lung > soleus muscle and abdominal aorta. In contrast, daidzein and hydroxy equol were accumulated only in the liver and kidneys at lower concentrations (1/100-times), compared to glyceollins.

Conclusions: This study demonstrates that prenylation of isoflavones caused high bioavailability into blood and organs rather than their mother isoflavones in their conjugated forms.

Keyword: glyceollins, isoflavone, prenylation, bioavailability

Neutraceutical and medicinal insights on the antidiabetic and anti-pancreatic cancer activity of *Morus rubra* Linn: disruption of crosstalk between G protein-coupled receptor and insulin receptor signaling systems

Glenn Oyong[1], Jasmine Ting[1], Maria Carmen Tan[1]

1. De La Salle University (Philippines)

Background and objectives: Pancreatic cancer cells exhibit crosstalk between G-protein coupled receptor (GPCR) and insulin receptor (IR) signaling pathways. Disruption of the crosstalk by metformin was previously elucidated with anti-diabetic activity and AMP kinase (AMPK) activation leading to mTOR antagonism. This study probed whether a semi-purified ethyl acetate fraction of *Morus rubra* (red mulberry) bark (M1) can also impede the signaling crosstalk in pancreatic cancer cells.

Methods: The cytotoxic activity of M1 in BxPC-3 cultured with insulin (10 ng/mL) and GPCR agonist angiotensin II (Ang II) (5 nmol/L) was assessed via PrestoBlue® assay. Half maximal inhibitory concentration (IC_{50}) after 72 hours was extrapolated using GraphPad Prism. BxPC-3 was challenged with M1 IC_{50} to quantify intracellular Ca^{2+} induction ($[Ca^{2+}i]$) and AMPK phosphorylation fluorescence by Ang II followed by DNA synthesis activity via absolute telomere length (aTL) through qPCR. M1 phytochemical constituents were profiled by GC-MS and the identified compounds were subjected to molecular docking with AMPK via AutoDock Vina.

Results: Viability assessment of BxPC-3 afforded an IC_{50} of 5.503 µg/mL after M1 treatment suggesting high antiproliferative activity. Subsequently, treatment of BxPC-3 with insulin and Ang II for 5 minutes displayed significant increase in $[Ca^{2+}i]$. However, pretreatment with M1 IC_{50} completely abrogated insulin-induced $[Ca^{2+}i]$ potentiation which was not observed with the effect of Ang II alone. M1 also negated DNA synthesis revealed by significant decrease in aTL. Additionally, anchorage-dependent growth induced by insulin and Ang II were also inhibited after 24-hour incubation. M1 promoted sustained increase in AMPK phosphorylation but addition of dosomorphin (5 µmol/L), a selective AMPK inhibitor, reversed the effects of M1 on $[Ca^{2+}i]$ and aTL inferring that AMPK activation is the underlying M1-driven mechanism. GC-MS analysis afforded lupeol and γ-sitosterol as main potential bioactive compounds inferred from molecular docking to the three AMPK binding sites (BS). Lupeol showed high affinity to BS1 (-9.5 kcal/mol) while γ-sitosterol exhibited -8.6 and -7.9 kcal/mol to BS2 and BS3, respectively, demonstrating higher affinities than metformin (-4.7 kcal/mol).

Conclusions: These results raise the prospect that *Morus rubra* could be a source of novel phytochemical leads for the treatment of diabetes and human pancreatic cancer.

Action mechanism of low molecular weight peptides, Trp-Val (WV) and Ala-Trp (AW) by oral glucose tolerance test animals

Eiji Seki[1]

1. Yamaki, Ltd. (Japan)

Objective: We found dipeptidylpeptidase (DPP) IV activity inhibition in protease-enzymatic decomposition products of bonito stock lees [Methods and Results] A 10 % ethanol-eluting fraction (N5-2 fraction) (IC_{50}=73.71 µg/ml) was obtained from N5 using a Sep-Pak C18 column. Trp-Val (0.14%; Trp-Val content 15.24 mg/100 g N5-2 fractions, DPP IV inhibition IC 50 values; 11.21 µ g/ml) was identified The addition of 400 mg/ml of the N5-2 fraction to Caco-2 cell membranes significantly ($p<0.05$) inhibited DPP IV activity, suggesting that the N5-2 fraction inhibits DPP IV activity on cell membranes in human small intestinal epithelial cells. N5-2 fractionwas administered before glucose administration (100 mg/kg) , followed by 1 g/kg BW glucose, and the blood glucose level was measured in the blood collected from the tail vein . The increase in blood glucose level was significantly ($p<0.05$) suppressed at 30 min compared with the control group mice. It was identified using UPLC and LC-MS. For Trp-Val (WV) and Ala-Trp (AW), 100 mg concentrations were used in the oral OGTT test and were significantly (5%) inhibited by placebo and at each time [Conclusion] Trp-Val (WV) and Ala-Trp (AW) are suggested to be the major dipeptides in the protease enzymatic degradation products of dried bonito lees.

Development of skin permeable L-theanine gel for premenstrual syndrome

Kaana Ando[1], Ikumi Sugiyama[1], Yasuyuki Sadzuka[1]

1. Iwate Medical University (Japan)

Background and objectives: Premenstrual syndrome (PMS) with anxiety and tension of the breast is developed about 80 percent of women in Japan. L-theanine is specific amino acid in green tea and it has especially affected relaxation in PMS. However, the efficacy of L-theanine is not defined well because its blood half-life is short. Thus, we think that the gelation of L-theanine would improve skin permeability and have a long half-life in blood. In this study, we examined preparation method, characterization, and skin permeability of the L-theanine contained gel.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: L-theanine gels were prepared by different combination ratios of stearic acid, stearyl alcohol, and propylene glycol, and some preparation methods. Permeability of L-theanine in gel formulation was evaluated using franzcell with Strat-M membrane. Spreadability of these gels were evaluated by spread meter. *In vivo* experiment, mice were applied the L-theanine gel on their back for 7 days, and the L-theanine level in the blood were determined.

Results: L-theanine in solution did not permeate the Strat-M membrane at all. In contrast, L-theanine in the gel was permeated time dependently. When L-theanine content in gel formulation was changed from 5 to 40%, the permeable amount of L-theanine was increased at 20%. The L-theanine gel was prepared by heating and melting the mixture at 83℃ of stearic acid, stearyl alcohol, and propylene glycol in the ratio of 1:2.4:18(w/w) and 20% L-theanine had the best permeability and spreadability. *In vivo* experiment, serum level of L-theanine in gel treated group was higher than that of solution group.

Conclusion: The L-theanine gel, which was consisted of stearic acid, stearyl alcohol, and propylene glycol in the ratio of 1:2.4:18(w/w) and 20% L-theanine, had the best permeability, spreadability and L-theanine level in mice serum. These results suggested that L-theanine gel is useful for symptom relaxation of the PMS.

PAB(T7)-10
Development of green tea with reduced caffeine and its properties

Kieko Saito[1], Noriyuki Nakamura[1]

1. University of Shizuoka (Japan)

Background and objectives: Green tea (*Camellia sinensis*) is a traditional beverage that provides physiological health benefits; however, caffeine is one of the main components of green tea and has side effects such as sleeplessness. Senior citizens, children, and pregnant women should avoid tea despite its known beneficial effects. In this study, we developed green tea with reduced caffeine content (low-caffeine tea) as a palatable tea that can be offered to everyone. Further, the physiological function of the tea was assessed.

Methods: Fresh tea leaves (Camellia sinensis) were plucked and automatically sprayed with hot water (95°C, 180 seconds) to reduce the caffeine content of tea leaves. After centrifugal dehydration at 3000 rpm for 1 min, the green tea was prepared through a standard manufacturing process. The tea leaf infusions were applied to a reversed-phase high-performance liquid chromatography to determine the caffeine, catechin, and theanine contents. In addition, the anti-oxidative activity was investigated using a stable free radical and the anti-lipase activity using an artificial substrate to assess the physiological function of the tea.

Results: We successfully produced a low-caffeine tea infusion with 30% caffeine content. In the low caffeine tea infusion, the concentrations of other main components, such as catechins and theanine, did not differ from green tea as a control. In addition, there were no significant differences between the infusions of low caffeine tea and green tea in anti-oxidative and anti-lipase activities.

Conclusions: The results showed that our developed low caffeine tea could be an attractive, high-quality tea with health benefits for everyone.

Anti-inflammatory mechanism of EGCG by suppressing expression of Elf-1

Mai Yamashita[1], Motofumi Kumazoe[1], Haruka Kobarai[1], Yuki Nakamura[1], Yoshinori Fujimura[1], Hirofumi Tachibana[1]

1. Kyushu University (Japan)

Background and objectives: Toll-like-receptor 4 (TLR4) is an important membrane protein for innate immunity and induces the secretion of inflammatory cytokines by recognizing Lipopolysaccharide (LPS) which are constituents of the outer membrane of gram-negative bacteria. Abnormal inflammation through TLR4 signaling leads to the induction of sepsis and insulin resistance. In previous reports, we revealed that green tea catechin (−)-epigallocatechin-3-O-gallate (EGCG) increased the expression of Toll-interacting protein (Tollip), one of the negative regulators for TLR4 signaling pathway, and suppressed the expression of inflammatory cytokines in macrophages. In this study, we examined the molecular mechanism of EGCG induced Tollip expression in macrophages.

Methods: The macrophage cell line RAW264.7 cells were treated with EGCG. The nuclear expression of E74-Like Factor 1 (Elf-1), which is a transcriptional repressor of Tollip, Protein phosphatase 2A (PP2A) activity, and phosphorylation level of endothelial nitric oxide synthase (eNOS) were measured. Female C57BL6J mice were treated with LPS (0.05 mg/kg i.t.) and administrated with EGCG (15mg/kg p.o.).

Results: EGCG reduced Elf1 expression level in nuclei. Activity of PP2A and phosphorylation levels of eNOS were upregulated by EGCG. Also, PP2A inhibitor suppressed EGCG-elicited Tollip expression. Akt inhibitor and NOS inhibitor treatment suppressed the increase of Tollip expression by EGCG. In addition, the cGMP synthase inhibitor also inhibited the increasing the expression of Tollip by EGCG. The cGMP synthase activator induced activation of PP2A, decreased expression of Elf-1 in the nucleus, and increased expression of Tollip. EGCG suppressed lung inflammation status in acute lung injury model.

Conclusions: We found that EGCG increases Tollip expression by reducing Elf-1 nuclear expression through the Akt / eNOS / sGC / cGMP/ PP2A pathway.

Keyword: EGCG, Tollip, inflammation, Elf-1, cGMP

Polyunsaturated fatty acids-rich dietary lipid prevents high fat diet-induced obesity in mice

Yuri Haneishi[1,2], Yuma Furuya[1], Yuri Tanioka[2], Junki Miyamoto[1]

1. Tokyo University of Agriculture and Technology (Japan), 2. Tokyo University of Agriculture (Japan)

Background and objectives: Diet is the most important factor affecting host nutrition and metabolism; however, excess food intake, especially high-calorie diets, such as high-fat and high-sugar diets, has led to an increased risk of obesity. And, obesity results in changes in the composition of gut microbiota, as well as reductions in microbial diversity, and changes in specific bacterial taxa. Although dietary lipids can alter the composition of gut microbiota in obese mice, it is unclear how the compositions of polyunsaturated fatty acid in dietary lipids regulate the gut microbiota and affect the host energy homeostasis. Here, we demonstrated that the difference of polyunsaturated fatty acids composing dietary lipid improves metabolic conditions in high fat diet-induced obesity.

Methods: C57BL/6J male mice were fed normal chow (NC), high-fat diet (soybean oil), or modified high fat diet (linseed oil, fish oil, or olive oil) for 8 weeks. After feeding, body weight changes, tissue weights, biochemical analysis, glucose tolerance test, and gut microbiota were analyzed.

Results: The intake of the different polyunsaturated fatty acids-rich dietary lipid improved metabolic conditions in high fat diet-induced obesity by regulating glucose tolerance and insulin resistance. Gut microbial compositions were different among high-fat diet and each modified high fat diet fed mice.

Conclusions: In conclusion, these results suggested that a new mechanism underlying the function of the difference of polyunsaturated fatty acids composing dietary lipid in assistant regulating host energy homeostasis in obesity.

Keyword: dietary lipids, polyunsaturated fatty acids, obesity, gut microbiota

Zeolite improves high-fat diet-induced hyperglycemia, hyperlipidemia and obesity in mice

Kazuhiro Kubo[1], Yasuyuki Kawai[2]

1. Gifu University (Japan), 2. Bikensangyo Co., Ltd (Japan)

Background and objectives: Zeolite, an abundant mineral in the Earth's crust, is utilized in a wide range of fields because of its well-known adsorption properties. Its application as a functional food ingredient resembling dietary fiber is expected, but it has not yet been investigated in the context of prevention of lifestyle-related diseases. The present study was designed to evaluate the availability and safety of a natural zeolite preparation for this purpose.

Methods and Results: Acute oral toxicity testing showed that the lowest lethal dose (LDLo) of zeolite was more than 2,000 mg/kg body weight for both male and female mice. In a prolonged feeding test for 18 weeks using model mice with high-fat-induced obesity and type 2 diabetes mellitus, intake of a 10% zeolite-containing diet suppressed body weight gain, as well as liver and visceral fat weights, without any changes in food and energy intake. Moreover, plasma lipid (triacylglycerol, total cholesterol and high-density-lipoprotein cholesterol) levels and fasting blood glucose levels decreased in parallel with zeolite intake. No changes in the glycated hemoglobin level were found. However, in an oral glucose tolerance test at week 12, increased postprandial blood glucose levels were suppressed in accordance with zeolite intake, and then insulin secretion was also decreased. On the other hand, a decrease of plasma amylase activity and increases in total bilirubin and urea nitrogen suggested the need for further investigation of safety.

Conclusions: The present study has determined the LDLo of this new natural zeolite preparation and shown that when taken as a dietary component it is able to improve hyperglycemia, insulin sensitivity and chronic lipid metabolism disorders in model mice with high-fat diet-induced obesity and type 2 diabetes mellitus.

Keyword: zeolite, lowest lethal dose, hyperlipidemia, type 2 diabetes mellitus, obesity

Similar distribution of eicosapentaenoic acid and mesenchymal stem cells in the abdominal aortic aneurysm wall

Mayo Higashihara[1], Hirona Kugo[1], Hirofumi Enomoto[1], Tatsuya Moriyama[1], Nobuhiro Zaima[1]

1. Kindai University (Japan), 2. Teikyo University (Japan)

Background and objectives: Abdominal aortic aneurysm (AAA) is a vascular disease with progressive dilatation of the abdominal aorta, eventually resulting in rupture. At this time, no preventive methods for AAA have been established. It is reported that AAA development is closely associated with aortic inflammation. Previous studies suggested that eicosapentaenoic acid (EPA) has suppressive effect on AAA development via anti-

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

inflammatory activities in various animal AAA model. However, relationships between anti-inflammatory activities of EPA and cells in AAA wall are poorly understood. To investigate the cells in AAA wall which can be associated with anti-inflammatory effects of EPA, we visualized the distribution of EPA-containing phosphatidylcholine (EPA-PC) in animal AAA wall by matrix-assisted laser desorption ionization-mass spectrometry imaging (MALDI-MSI), which can visualize the distribution of molecules of interest in tissue sections.

Methods: The animal experiments were approved by the Institutional Animal Care and Use Committee and conducted according to the Kindai University Animal Experimentation Regulations (approval number KAAG-31-006). In this study, 6-week-old male SD rats were used to induce AAA by abdominal aortic ligation procedure after 1 week of preliminary rearing. MALDI-MSI revealed characteristic distribution of EPA-PC in animal AAA wall, suggesting the existence of cells which preferentially incorporate EPA into their cell membranes. To identify the cells, the regions in the AAA wall were divided into two groups: EPA-PC-low and EPA-PC-high. Immunohistochemical analysis was performed to screen cells of which distribution are similar to EPA-PC.

Results: As the result, we found the distribution of CD44, a mesenchymal stem cells (MSCs) marker, was similar to the distribution of EPA-PC. Previous studies have reported that MSCs are associated with aortic inflammation and abnormal adipogenesis in aortic wall, which result in AAA development or rupture.

Conclusions: These data suggest EPA can be preferentially incorporated into MSCs and attenuate the dysfunction of MSCs in AAA wall.

Keyword: AAA, EPA, MSCs, MALDI-MSI

PAB(T7)-15
Effects of *Undaria pinnatifida* (wakame) on postprandial glycemia: in vitro and in vivo studies

Rieko Mitamura[1], Keiko Yoshinaga[2]

1. Fuji Women University (Japan), 2. Riken Vitamin Co., Ltd (Japan)

Background and objectives: Brown seaweeds like *Undaria pinnatifida* (wakame) contain sodium alginate which could affect postprandial blood glucose levels. We previously reported the effects of wakame on postprandial glycemia in humans; however, the underlying mechanism is unclear. The purpose of this study was to investigate the mechanism of ingested wakame's influence on postprandial blood glucose levels.

Methods: We conducted in vitro studies to determine the inhibitory activity of wakame on glucose release rate and α-glucosidase activity and in vivo studies to determine the acute effects of wakame on postprandial blood glucose levels in young Japanese women. The in vitro study assessed wakame powder, fat-free wakame powder, soluble and insoluble fractions obtained from dried wakame, and commercially available sodium alginate. Glucose release rate was measured using the in vitro digestion model, and α-glucosidase activity was measured using the maltase reaction. The in vivo study was conducted using a crossover method where healthy young adult participants were given 150 g of rice with or without wakame soup (2 g dried wakame) or wakame salad (4 g dried wakame). Blood glucose levels were measured at 0, 15, 30, 45, 60, 90, and 120 min after meal consumption.

Results: The glucose release rates of all wakame products and sodium alginate were significantly lower than those of control. The soluble fraction significantly inhibited glucose release. No significant difference was found in α-glucosidase activity. In the in vivo study, blood glucose levels 15 min after ingestion were significantly lower after consuming rice with wakame soup than when consuming rice alone. Moreover, ingestion of wakame salad also resulted in significantly lower blood glucose levels at 15, 30, and 45 min after meal consumption.

Conclusions: These results suggest that the highly viscous soluble fraction of wakame, which contains sodium alginate, increases the viscosity of gastrointestinal contents and delays glucose absorption.

Keyword: Undaria pinnatifida, wakame, glucose releasing rate, postprandial blood glucose

PAB(T7)-16
Effect of maternal quercetin intake during lactation on renal inflammation in high fructose-fed female rat offspring exposed to maternal undernutrition

Shin Sato[1], Toshio Norikura[1], Yuuka Mukai[2]

1. Aomori University of Health and Welfare (Japan), 2. Kanagawa University of Human Services (Japan)

Background and objectives: Maternal undernutrition during pregnancy and lactation is known to induce renal disease in later life. High fructose intake causes metabolic syndrome, which results in an increased risk of chronic kidney disease development. Quercetin is one of the flavonoids and possesses various physiological functions. For instance, it has been reported to attenuate high-fructose-feeding-induced atherosclerosis by suppressing inflammation. Moreover, quercetin is involved in the activation of autophagy. We investigated the effects of quercetin intake during lactation on inflammation in the kidneys of high fructose-diet-fed adult female offspring exposed to maternal normal-protein or low-protein diets.

Methods: Pregnant Wistar rats received diets containing 20% (NP) or 8% (LP) casein, and 0 or 0.2% quercetin containing NP diets (NP/NP or NP/NPQ) in experiment (Expt.) 1 and 0 or 0.2% quercetin containing LP diets (LP/LP or LP/LPQ) in Expt. 2 during lactation. At weaning (week 3), pups that received a diet

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of distilled water (Wa) or 10% fructose solution (Fr) were divided into six groups: NP/NP/Wa, NP/NP/Fr, and NP/NPQ/Fr in Expt. 1, and LP/LP/Wa, LP/LP/Fr, and LP/ LPQ/Fr in Expt. 2. At week 12 after treatments, macrophage infiltration, mRNA levels of TNF-α and IL-6, and markers of autophagy flux in the kidneys of female offspring were examined.

Results: The number of macrophages in the tubulointerstitium of the kidneys of the NP/NPQ/Fr group was significantly lower than that in the NP/NP/Fr group. In the LP/LPQ/Fr group, the macrophage number was significantly lower, compared with the LP/LP/Fr group. The TNF-α and IL-6 mRNA levels increased in the kidneys of the NP/NP/Fr or LP/LP/Fr, respectively. Conversely, the IL-6 mRNA levels in the NP/NPQ/Fr or LP/LPQ/Fr decreased. LC3B-II levels were downregulated in the NP/NP/Fr or LP/LP/Fr. In contrast, LC3B-II levels were upregulated, while p62 protein levels were downregulated in the NP/NPQ/Fr and LP/LPQ/Fr.

Conclusions: Our results suggested that quercetin intake during lactation may cause long-term alterations in inflammation and autophagy flux in the kidneys of high fructose-diet-fed adult female offspring.

Keyword: quercetin, maternal undernutrition, inflammation, fructose, rat

PAB(T7)-18
The promotion of Japan's system of Foods with Function Claims and development of "balanced and healthy meals" to improve dietary habits

Tomomi Hattori[1,2], Yoichi Nagamura[1]

1. Graduate School of Health Science ,Suzuka University of Medical Science (Japan), 2. Tsu City College (Japan)

Background and objectives: In Japan, there is a system of Foods with Function Claims (FFC) that contributes to health based on scientific evidence. The FFC exist in the form of processed and fresh foods as well as pills. Foods included in the system of FFC has been enforced to help people choose the right foods for maintaining and improving their health. The dietary recommendations are based on the premise a diet of well-balanced meals should be supplemented staple foods, main dishes, and side dishes. Therefore, we developed a nutritionally balanced menu using foods in the system of FFC, with "balanced and healthy meals." We aim to make this system more accessible to the public and motivate individuals to improve their dietary habits.

Methods: A menu was prepared by setting the nutritional value of each food in the system of FFC based on its expectation to improve blood pressure, blood glucose, blood lipids, etc., while considering the recommended daily intake amount and referring to national standards. And we disseminated it.

Results: We developed about 80 "balanced and healthy meals" and disseminated them to the public through conference presentations, newspaper articles, and lectures. The responses of the participants after the lectures on FFC use, including "balanced and healthy meals," revealed that more than 90% of the participants achieved an increased health and dietary habit awareness, to varying degrees.

Conclusions: Our results suggest that the dissemination of FFC from Japan's unique system of FFC by registered dietitians as "balanced and healthy meals" for the maintenance and promotion of public health could, under correct use, provide a useful health education method to improve health and dietary habits.

Keyword: Foods with Function Claims (FFC), balanced and healthy meals, registered dietitians

Effect of Sea Buckthorn Berry Extract on Allergy and Inflammation

Shiman Qiu[1], Ryuuya Kobayashi[1], Yuka Yamaya[1], Anuu Zorig[1], Enkhtsetseg Sukhbold[1], Mikako Takasugi[2], Toshitsugu Sato[1], Hirofumi Arai[1]

1. Kitami Institute of Technology (Japan), 2. Kyushu Sangyo University (Japan)

Background and Objectives: While the immune system is an important biological defense mechanism against the infection of pathogens, an excessive immunological response can cause physiological injuries. In type-I allergy, the specific binding of antigens to immunoglobulin E antibodies on the membrane of mast cells and basophils induces the cell stimulation, causing various symptoms by releasing chemical mediators such as histamine and leukotrienes (LTs). In inflammation, viral or bacterial infections and the allergic reaction stimulate macrophages, which release nitric oxide (NO) and the cytokines involved in inflammatory signs. Sea buckthorn (*Hippophae rhamnoides* L.) is a deciduous shrub belonging to the family Elaeagnaceae. Sea buckthorn berries are used for many healthy foods, although the physiological functions are not clear. In this study, the anti-allergic and anti-inflammatory effects of sea buckthorn berry extracts were investigated *in vitro*.

Methods: Freezed sea buckthorn berries were homogenized with methanol, and the supernatant after the centrifugation was evaporated. The extract was subjected to reversed-phase column chromatography and fractionated by the gradient elution with 0-100% methanol. After the evaporation, the total polyphenol content of each fraction was determined. The rat basophilic leukemia cell line (RBL-2H3) was stimulated by antigen-antibody reaction, and the released histamine and intracellular signal transduction were analyzed. The mouse bone marrow-derived mast cell line (PB-3c) was stimulated with calcium ionophore, and the generated LTB4 was measured. The mouse macrophage-like cell line (RAW 264.7) was stimulated with lipopolysaccharide and the released nitric oxide (NO) was quantified, and the inflammatory cytokines were measured.

Results: Total polyphenol content was highest in the 80% methanol-eluted fraction. This fraction significantly suppressed histamine release and LTB4 production from the cells, as well as

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

tyrosine phosphorylation. The 80% methanol-eluted fraction significantly inhibited NO release from the cells, as well as the release of IL-1β, IL-6, and TNF-α, which are associated with the initial inflammatory response.

Conclusions: The results suggest that sea buckthorn berries may alleviate type-I allergy by inhibiting the release of chemical mediators and inflammation by inhibiting the release of NO and cytokines from macrophage, in which the polyphenols in the fraction may contribute to the inhibitory activities.

Keyword: Sea buckthorn, Allergy, Inflammation, Polyphenols

Contents and functions of catechins and free amino acids in microorganism-fermented teas

Akiko Watanabe[1], Sayaka Yokoyama[1], Yuri Kusano[1], Hana Kozai[1], Xiaohua Lyu[2], Rui Lu[1], Mamoru Tanaka[1]

1. Chubu University (Japan), 2. Sichuan University (China)

Background and objectives: Microorganism-fermented tea is a rare type of tea that is fermented by microorganisms, such as lactic acid bacteria. We have previously shown that Sichuan dark tea, a microorganism-fermented tea, had a suppressive effect on lipid metabolism and the development of atherosclerosis in a rat model of diet-induced atherosclerosis, compared with green tea. The purpose of the present study was to determine the biochemical properties of Japanese and Chinese microorganism-fermented teas *in vitro*.

Methods: Six types of microorganism-fermented tea were investigated, and green tea was used as a control. The antioxidant capacity (The 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity), enzyme inhibitory activity (against a-glucosidase, lipase, and hyaluronidase), and anti-allergic activity of the teas were evaluated in *in vitro* tests. The anti-allergic activity was assessed via degranulation inhibition tests conducted using the rat basophil-like cell line RBL-2H3 as an indicator of b-hexosaminidase release activity. The catechin and free amino acid contents were determined by HPLC.

Results: The antioxidant activity was more than 50% at 1 mg/mL in Awa-bancha, green tea, Go-ishi tea, and Ishizuchi dark tea. a-Glucosidase inhibitory activity was generally low, but Awa-bancha, Goishi tea, and green tea showed 30%–40% activity. In lipase inhibitory activity, all the microorganism-fermented teas, except Bataba tea, showed more than 50% activity at 1 mg/mL, and green tea and Awa-bancha showed more than 90% activity, followed by Sichuan dark tea and Goishi tea. The hyaluronidase inhibitory activity was different from the results for the other enzyme inhibitory activities, with Bataba tea and green tea showing more than 50% activity at 1 mg/mL, followed by Puer tea. b-Hexosaminidase release activity showed a decrease in the order green tea, Sichuan dark tea, Awa-bancha, and Ishizuchi dark tea at 100 μg/mL.

Conclusions: We determined the functionality of six types of Japanese and Chinesemicroorganism-fermented teas *in vitro*. In the future, we plan to investigate the relationship between the functional properties and the catechin and free amino acid content of the teas.

Keyword: microorganism-fermented tea , food functionality, catechins, free amino acid, in vitro tests

Effect of *Nigella sativa* L. on degranulation in mast cells and immunoglobulin production in mouse spleen lymphocytes

Sayaka Yokoyama[1], Kaho Miyake[1], Mayumi Nagashima[1], Akiko Watanabe[1], Takeaki Okamoto[2], Mamoru Tanaka[1]

1. Chubu University (Japan), 2. Ehime University (Japan)

Background and objectives: *Nigella sativa* L. (black cumin) has been reported to contain active ingredients, including thymoquinone, which has anti-inflammatory properties, but the anti-allergic effects of *Nigella sativa* L. have not been fully elucidated. In this study, we investigated the anti-allergic effect of black cumin seeds and the inhibitory mechanism.

Methods: Black cumin seeds (BCS) were crushed and sequentially extracted using *n*-hexane, ethyl acetate, 100% methanol, 50% methanol, and water, and then dissolved in DMSO. The evaluation of degranulation inhibition was performed using the rat basophilic leukemia cell line RBL-2H3 as an indicator of β-hexosaminidase, and the intracellular Ca^{2+} concentration was measured for evaluation of the degranulation inhibition mechanism. For the evaluation of antibody production capacity, the spleens of type I allergy model mice were collected and lymphocytes were isolated. Lymphocytes were cultured for 72 h under co-stimulation with egg white albumin (OVA) alone or samples to measure OVA-specific IgE, IgG1, and IgG2a.

Results: The recovery rates for the extracts were 21.9% with *n*-hexane, 2.4% with ethyl acetate, 3.8% with 100% methanol, 8.7% with 50% methanol, and 1.9% with water. In the degranulation inhibition test, a decrease in β-hexosaminidase-releasing activity was observed for all extracts, except the hexane extract at a concentration of 100 µg/mL. In particular, a strong decrease was observed for the 100% methanol, 50% methanol, and water extracts, with IC_{50} values of 1.2, 0.8, and 2.5 µg/mL, respectively. In addition, significant inhibition of the increase in intracellular Ca^{2+} levels was observed for the 100 % and 50 % methanol, water extracts.

Conclusions: An anti-allergic effect of BCS was observed, suggesting that there are active components in the 100% methanol, 50% methanol, and water extracts that inhibit degranulation, and the inhibitory mechanism appeared to be related to inhibition of the increase in intracellular Ca^{2+} concentration. The antibody production capacity will be evaluated and the results will be reported in this presentation.

Cholesterol-lowering pentapeptide IIAEK (lactostatin) specifically interacts with intestinal alkaline phosphatase to improve cholesterol metabolism

Asahi Takeuchi[1], Kentaro Hisamatsu[1], Natsuki Okumura[1], Keigo Takada[1], Maihemuti Mijiti[1], Yuyang Ye[1], Arata Banno[1], Emiko Yanase[1], Yoshihito Ueno[1], Satoshi Nagaoka[1]

1. Gifu University (Japan)

Background and objectives: IIAEK (Ile-Ile-Ala-Glu-Lys, lactostatin) is a novel cholesterol-lowering pentapeptide derived from bovine milk β-lactoglobulin. However, the molecular mechanism underlying the IIAEK-induced intestinal cholesterol absorption remains unclear. In this study, we identified the target protein interacting with IIAEK and evaluated whether IIAEK specifically interacted with the target protein to improve cholesterol metabolism.

Methods: We tested the effect of IIAEK on intestinal cholesterol metabolism using Caco-2 cells as a human intestinal model (1). We chemically synthesized a novel molecular probe, IIXEK, which can visualize a complex of target proteins interacting with photoaffinity-labeled IIAEK by fluorescent substances for photoaffinity labeling (1). We used photoaffinity labeling and nano LC-MS/MS analyses using IIXEK to capture and identify the target protein that interacted with IIAEK (1). We evaluated the direct interaction between IIAEK and the target protein using surface plasmon resonance (SPR). We studied whether IIAEK targets IAP to improve cholesterol metabolism using the introduction of IAP siRNA into Caco-2 cells.

Results: We found that IIAEK significantly reduced the expression of intestinal cholesterol metabolism-associated genes, particularly that of the ATP-binding cassette transporter A1 (ABCA1). Through photoaffinity labeling and MS analysis with IIXEK for intestinal lipid raft fractions of Caco-2 cells and rat intestinal mucosal proteins, we identified intestinal alkaline phosphatase (IAP) as a specific molecule interacting with IIAEK and discovered the common IIAEK-binding amino acid sequence, GFYLFVEGGR (1). Surprisingly, studies using SPR showed the specific interaction of IIAEK with human IAP was 2.63 times stronger than that of *in vivo* substrate of IAP (vitamin B_6). Also, the alanine scanning of IIAEK (e.g. IAAEK) disappeared the IIAEK-IAP interaction. Interestingly, the introduction of IAP siRNA counteracted the IIAEK-induced decrease in ABCA1 mRNA levels in Caco-2 cells.

Conclusions: We found that IIAEK specifically interacted with intestinal alkaline phosphatase (IAP) in the amino acid sequence-dependent manner to improve cholesterol metabolism with specific activation of IAP and downregulation of ABCA1 (1).

Novel antidepressant-like peptide in collagen hydrolysate

Naoki Ohama[1], Takafumi Mizushige[1], Yuki Taga[2], Masashi Kusubata[2], Dai Nogimura[1], Yukihito Kabuyama[1]

1. Utsunomiya University (Japan), 2. Nippi Research Institute of Biomatrix (Japan)

Background and objectives: Our previous results demonstrated that food-derived peptides exhibited antidepressant-like activity by oral administration. Collagen is the most abundant protein in vertebrates. In this study, we tested whether collagen hydrolysate or its constituting peptides show antidepressant-like activity by oral administration. Then, we investigated the hippocampal mechanism underlying the antidepressant-like effects of collagen peptides.

Methods: We tested depression-like behavior by forced swim test in normal mice and in corticosterone-administered mice. This test was carried out for 6 min and the immobility time was measured. Collagen hydrolysate or its constituting peptides, which was dissolved in saline was administered orally 3 hours before the test. Antagonists of neurotransmitters associated with depression-like behavior were administered intraperitoneally 30 min before the ingestion of collagen hydrolysate, peptides, or amino acids. The amount of neurotransmitter in hippocampus were measured by HPLC-ECD system. The number of hippocampal neural progenitor cells was measured *in vivo* and *in vitro* by counting specific marker-positive cells. Also, we measured expression of hippocampal growth and neurotrophic factors by real time RT-PCR.

Results: Collagen hydrolysate exhibited antidepressant-like activity after oral administration in normal and corticosterone-administered mice. The antidepressant-like activity of collagen hydrolysate was inhibited by SCH23390, an antagonist of dopamine D_1 receptors. Amount of dopamine in hippocampus was significantly increased after oral administration of collagen hydrolysate. Prolyl hydroxyproline (Pro-Hyp), which was circulated stably after digestion and absorption of collagen hydrolysate, also exhibited antidepressant-like activity. The constituent amino acids had no effect on depression-like behavior. Pro-Hyp increased several gene expressions of growth and neurotrophic factors in hippocampus and promoted proliferation of hippocampal neural progenitor cells *in vivo* and *in vitro*. Together, these results suggest that collagen hydrolysate exhibits antidepressant-like activity and promotes proliferation of hippocampal progenitor cells via dopamine pathway. Also, Pro-Hyp was found as an active peptide of antidepressant-like activity.

Conclusions: We found that Pro-Hyp exhibits antidepressant-like activity after oral administration, probably

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

through activation of dopamine pathway, neurotrophic factor, and neurogenesis in mice.

Combination effects of quercetin and various prebiotics on the flavonoid metabolism and intestinal flora in rats.

Noriko Matsukawa[1], Ohki Higuchi[2], Takaya Momiyama[3], Yoko Suzuki[3], Yukiya Gondoh[3], Hiroshi Hara[4]

1. Sapporo University of Health Sciences (Japan), 2. Biodynamic Plant Institute Co., Ltd. (Japan), 3. New Drug Research Center Inc. (Japan), 4. Fuji Women's University (Japan)

Background and objectives: Quercetin is known to exhibit various physiological actions including antioxidantion. Quercetin has a low absorption rate. We previously showed that most of ingested quercetin flows into the large intestine are decomposed by the intestinal flora. The flavonoid metabolites produced by intestinal microbes also exert physiological effects. The purpose of this study is to investigate changes in the intestinal flora when quercetin and three types of nondigestible oligosaccharides [fructooligosaccharides (FOS), lactosucrose and raffinose] are ingested by rats for two weeks, and to investigate the amount of residual quercetin aglycon in the large intestine as part of quercetin metabolism.

Methods: Male Sprague-Dawley rats were given AIN-93G based test diets containing 1% quercetin with or without 3% FOS, lactosucrose, or raffinose for 2 weeks. On the last day, the cecum with their contents were collected after killing under an anesthesia. Quercetin derivatives in samples were measured by LC/MS analyses. Microbiome profiles in the cecum contents were examined by 16SrRNA sequencing.

Results: The amount of remaining quercetin aglycone in the cecum were much higher in the three prebiotic groups, especially in raffinose group, which agrees with our previous results and indicates the oligosaccharides suppress quercetin decomposition by intestinal flora. Microbiome analyses in the cecal contents showed changes in the populations of Firmicutes, Verrucomicrobia, and Actinobacteria phylum in the all oligosaccharide groups. The Firmicutes phylum was increased in the FOS and lactosucrose group compared to the control and raffinose groups, whereas the Verrucomicrobia was decreased in the FOS and lactosucrose group compared to the control group. Actinobacteria phylum increased most in the raffinose group, followed by in the FOS group, but not in the lactosucrose group. These changes in intestinal flora may affect decomposition of quercetin aglycone.

Conclusion: Combination intakes of oligosaccharides and quercetin are expected to alter the microbiome profiles and beneficial effects of quercetin with changes in its metabolism, and the effects may depend on type of prebiotics.

Keyword: Quercetin, Nondigestible oligosaccharides, Intestinal flora

Potential skin protective effects against photoaging of sea cucumber derived indigestible peptide

Shuyu Liu[1], Yi Lu[2], Masahiro Kurono[2], Yoshiharu Matahira[2], Shinsuke Mohri[1], Yuki Manabe[1], Kenji Sato[1], Tatsuya Sugawara[1]

1. Kyoto University (Japan), 2. Sunsho Pharmaceutical Co. (Japan)

Background and objectives: Sea cucumber (*Stichopus japonicus*) (SC) has been used as food ingredient and folk medicine for centuries in Asian countries. In the present study, we examined the potential effects of SC and its enzymatic hydrolysate (SCH) on photoaging *in vivo*. Photoaging is characterized by skin dysfunctions and wrinkle formation primarily caused by chronic exposure to ultraviolet (UV) irradiation. Moreover, *in vitro* studies were conducted to explore the potential photoprotective activity of a peptide remained after *in vitro* digestion of SCH to understand potential mechanisms.

Methods: Hairless Hos:HR-1 mice in experimental groups were exposed to UVA at a dose of 20 J/cm^2 five times weekly for 10 weeks, fed with a diet of AIN-93G containing 5% sea cucumber powder or its hydrolysate. Every four weeks, the transepidermal water loss (TEWL) was measured and dorsal skin was replicated using silicone for analysis of wrinkle formation. After 10 weeks, the mice were sacrificed, and dorsal skin specimens were collected for morphological analysis as well as mRNA expression analysis. Furthermore, *in vitro* protease digestion using endo- and exo-proteases was conducted to SC and SCH, followed by evaluating the anti-photoaging capacity of the indigestible peptide using normal human dermal fibroblast (NHDF).

Results: UVA significantly induced transepidermal water loss and wrinkle formation in hairless mice, which were significantly mitigated upon oral administration of SC and SCH. Additionally, SC and SCH mitigated the UVA-induced downregulation of epidermal natural moisturizing factors. Through *in vitro* digestion, Gly-Pro was found to be a main peptide in the endo- and exo-proteases digest of SCH. Further study showed that Gly-Pro inhibited the UVA-driven generation of reactive oxygen species (ROS) in NHDF in a culture system, and attenuated UVA-induced changes in mRNA expression and the activation of proteins in MAPK-NF-κB signaling pathway.

Conclusions: Dietary SC and SCH exert anti-photoaging effects *in vivo*, probably by modulating filaggrin synthesis and desquamation in the epidermis. Moreover, Gly-Pro found in the protease digest of SCH has potential applications as an anti-photoaging reagent.

Keyword: sea cucumber, anti-photoaging, collagen hydrolysate, bioactive peptide, NF-κB

Effects of synbiotics on muscle protein metabolism in chronic alcohol-fed rats

Yi-Hsiu Chen[1], Wan-Chun Chiu[1], Qian Xiao[1], Ya-Ling Chen[1], Jiun-Rong Chen[1], Hitoshi Shirakawa[2], Suh-Ching Yang[1]

1. Taipei Medical University (Taiwan), 2. Tohoku University (Japan)

Background: Chronic alcohol consumption might lead to intestinal microbiota dysbiosis and endotoxemia. Endotoxemia could cause the increase of muscle loss including autophagy through gut-muscle axis. The purpose of this study is to investigate whether synbiotics supplementation can ameliorate the muscle loss by improving intestinal health in rats with chronic alcohol feeding.

Materials and methods: Thirty 8 weeks old male Wistar rats were divided into control group (n=12) and synbiotics group (n=18), which were given 2 weeks of control liquid diet and provided with distilled water (control group) or synbiotics solution (synbiotics group, 1.5g/kg BW/day). At the 3rd week of the experiment, control group was divided into 2 groups, one was given control liquid diet (C group) and the other one was given ethanol liquid diet (E group). The synbiotics group was divided into 3 groups such as control diet with synbiotics solution (SC group), ethanol liquid diet with synbiotics solution (ASE group), and ethanol liquid diet with distilled water (PSE group). During the experimental period, all groups were isoenergetic pair-feeding based on E group and sacrificed at the 8th week.

Results: E group showed liver damage including higher AST and ALT activities, hepatic fatty changes, inflammation and higher CYP2E1 protein expression. Intestinal occludin and claudin-1 mRNA expressions were significantly decreased and the plasma endotoxin level was significantly higher in E group. In muscles, E group had a significantly higher beclin-1 protein expression and a trend of higher TLR-4 protein expression. Compared to E group, PSE and ASE groups had lower plasma ALT activities, hepatic fatty changes, CYP2E1 protein expressions. PSE and ASE groups had significantly higher occludin and claudin-1 mRNA expression and lower muscle beclin-1 and TLR-4 protein expression when compared to E group.

Conclusion: In conclusion, synbiotics supplementation might inhibit muscle protein degradation by lowering muscle beclin-1 expression which might be linked to the improvement of intestinal health in chronic alcohol fed rats.

Hesperidin promotes NO production and Mas receptor expression in human umbilical vein endothelial cells by binding to a transient receptor vanilloid 1

Saya Nakamura[1], Guanzhen Gao[1], Sumire Asaba[1], Kenta Sakai[1], Yuji Miyata[2], Hisayuki Nakayama[2], Toshiro Matsui[1]

1. Kyushu University (Japan), 2. Industrial Technology Center of Nagasaki (Japan)

Background and objectives: In the previous study, we revealed that hesperidin exerted an anti-hypertensive effect via upregulation of aortic MasR expression in spontaneously hypertensive rats[1]. The aim of this study was to clarify the underlying mechanisms of hesperidin-stimulated aortic MasR expression in human umbilical vein endothelial cells (HUVECs).

Methods: HUVECs were cultured with hesperidin (1 µM, 2 h) in the presence or absence of vasomotor-related signal inhibitors, following the measurement of nitric oxide (NO) production in cell culture medium and vasomotor-related protein expression in cells.

Results and Discussion: Hesperidin (1 µM, 2 h) exhibited a significant NO promotion ($p < 0.01$). Among the receptors relating to NO production (AT_1R, AT_2R and MasR), only MasR expression was significantly increased ($p < 0.01$), whereas a MasR antagonist had no effect on the level of the hesperidin-induced NO production. In contrast, a transient receptor potential vanilloid 1 (TRPV1) antagonist significantly abolished the hesperidin-induced NO production ($p < 0.01$). By knockdown of TRPV1 or inhibition of Ca^{2+}/calmodulin-dependent kinase II (CaMKII) and p38 mitogen-activated protein kinase (p38 MAPK), the increased MasR expression was disappeared. Inhibitions of CaMKII and eNOS also caused the abolishment of hesperidin-induced NO production. These results indicated that hesperidin binding to TRPV1 may activate two axes: TRPV1/CaMKII/p38 MAPK/MasR axis and TRPV1/CaMKII/eNOS/NO axis.

Conclusion: This study provides the first finding that hesperidin preferably binds to TRPV1 in HUVECs, leading to the activation of two signaling axes of CaMKII/p38 MAPK/MasR and CaMKII/eNOS/NO.

The influence of dietary composition on anti-obesity effects of D-allulose in rats

Chihiro Yokoyama[1], Takako Yamada[2], Tetsuo Iida[2], Masaru Ochiai[3], Tatsuhiro Matsuo[1]

1. Faclty of Agriculture, Kagawa University (Japan), 2. Research and Development, Matsutani Chemical Industry Co., Ltd. (Japan), 3. School of Veterinary Medicine, Kitasato University (Japan)

Background and Purpose: D-allulose (D-psicose) is a rare sugar with zero calories and 70% sweetness compared to sucrose. Recently, many studies have shown the anti-obesity effect of D-allulose by suppressing lipogenesis and increasing energy expenditure. However, these studies have been conducted under low-fat (high-carbohydrate) dietary conditions because D-allulose primarily affects carbohydrate metabolism. Conversely, under extremely low-carb conditions, D-allulose may not exert its anti-obesity effect, and there may be specific thresholds for dietary nutrient composition for D-allulose to function. .. In this study, rats were fed a diet supplemented with 5% D-allulose under conditions of gradually varying proportions of dietary fat (10% to 20% (Experiment 1), 25% to 35% (Experiment 2)). Gave to The effect of dietary nutrient composition on the anti-obesity effect of D-allulose was investigated.

Methods: 84 male Wistar rats (3 weeks old) were randomized into 12 groups of 7 rats. The respective groups were the 10F, 15F, and 20F groups fed a diet containing 10%, 15%, and 20% fat, and 10FP, 15FP, and 10FP fed a diet containing 5% D-allulose. It was a 20FP group (Experiment 1). Similarly, the 25F, 30F, 35F, 25FP, 30FP, and 35FP groups were classified (Experiment 2). In each experiment, rats were given a free experimental diet for 8 weeks and then sacrificed.

Results: Two experiments confirmed the significant effect of D-allulose on reducing body fat accumulation. Conversely, the effect of dietary fat percentage on body fat accumulation was confirmed only in Experiment 2, which is a high-fat diet condition. In Experiment 1, it was found that the total fat mass was significantly lower in the 15FP group than in the 15F group. On the other hand, in Experiment 2, it was found that the 25FP and 30FP groups had significantly less total fat mass than the 25F and 30F groups, but no significant difference was observed between the other F-FP groups. ..

Conclusion: These results suggest that the anti-obesity effect of D-allulose is exerted even under high-fat diet conditions, but the exact threshold cannot be determined.

Effect of ketone bodies on lipid metabolism: focusing on skeletal muscle

Takumi Sugimoto[1], Chihiro Sakamaki[1], Mamoru Oyabu[1], Yasutomi Kamei[1]

1. Kyoto Prefectural University (Japan)

Background and objectives: Ketogenic diet, consisting of high-fat and low-carbohydrate diet promotes ketone body production. Ketone bodies are made from free fatty acids in the liver when carbohydrates cannot be used as energy source, and are released into the blood to be used by the brain and skeletal muscles. Generally, concentration of ketone bodies in the blood is 0.2 mM, which increases to 1.0 mM after prolonged exercise or 24 h of fasting, and can be as high as 20 mM under diabetic ketoacidosis. Recently, beta-hydroxybutyrate (βHB) has been reported to act not only as energy source but also as signaling molecule. However, the function of βHB in skeletal muscle has not yet been completely explained. In this study, we investigated the effects of βHB on skeletal muscle, focusing on lipid metabolism.

Methods: Gene expression analysis of βHB treated C2C12 myotubes was performed using qRT-PCR. The GAL4 reporter assay was used to evaluate the transcriptional activity of PGC1 and FOXO. In addition, the effects of FOXO1 overexpression on the lipoprotein lipase (LPL) promoter activities were examined by transfection of HEK293T cells with reporter plasmids. Mitochondrial activity was also evaluated using MitoTracker.

Results: Gene expression of LPL, which is important for lipid metabolism, increased in a βHB concentration-dependent manner. Also, the expression of genes known to increase LPL expression was increased (FOXO, PGC1, PPAR). Interestingly, the expression of LPL, which is increased by 24 h fasting (fasting-induced increased FOXO expression), was suppressed in skeletal muscle-specific FOXO-deficient mice. The transcriptional activity of FOXO1 and FOXO3a increased in a βHB concentration-dependent manner. Furthermore, FOXO1 expression increased LPL promoter activity, but the effect of βHB addition could not be observed. Mitochondrial activity was not affected by βHB.

Conclusions: In this study, we observed that LPL expression and transcriptional activity of FOXO was increased by βHB. Furthermore, gene expression of LPL was increased by fasting but decreased by FOXO-deficient mice. These results suggest that FOXO is involved in the increase of LPL expression by βHB.

Delphinidin suppresses disuse muscle atrophy and upregulates microRNA-23a-3p expression in extracellular vesicles derived from intestinal cells

Yuki Marugame[1], Motoki Murata[1,2], Megumi Goto[1], Yoshinori Fujimura[1], Hirofumi Tachibana[1]
1. Kyushu University (Japan), 2. Ehime University (Japan)

Background and objectives: Delphinidin, a major anthocyanidin, exhibits beneficial properties including anti-oxidative, anti-cancer and anti-inflammatory effects. In addition, delphinidin prevents disuse muscle atrophy[1]. MicroRNA (miRNA) is one class of small noncoding RNAs that regulates target gene expression. We revealed that delphinidin increased miR-23a-3p[1] that suppresses muscle atrophy[2]. However, the mechanism has been poorly understood. This study aimed to elucidate the mechanism of miR-23a-3p expression induced by delphinidin in skeletal muscle.

Methods: 20 mg/kg body weight delphinidin was orally administered to C57BL/6J mice for 7 days and measured the miR-23a-3p expression in small intestine, skeletal muscle and plasma by qRT-PCR. Differentiated human intestinal epithelial-like Caco-2 cells were incubated with delphinidin, and miR-23a-3p level was evaluated by qRT-PCR. C2C12 myotubes with or without dexamethasone, an inducer of muscle atrophy, were treated with extracellular vesicles (EVs) derived from Caco-2 cells incubated with delphinidin. The expressions of miR-23a-3p and MuRF1, one of the muscle atrophy-related genes, were measured by qRT-PCR.

Results: Delphinidin intake increased miR-23a-3p expression in plasma and quadriceps. Delphinidin upregulated miR-23a-3p expression level in basolateral EVs secreted from Caco-2 cells. Additionally, the basolateral EVs derived from delphinidin-treated Caco-2 cells upregulated miR-23a-3p expression and downregulated MuRF1 expression in C2C12 cells.

Conclusions: Delphinidin upregulated miR-23a-3p expression in basolateral EVs from intestinal cells. The uptake of its EVs into skeletal muscle cells increased miR-23a-3p level and decreased MuRF1 expression in skeletal muscle, indicating that it may prevent muscle atrophy.

A study on the association between anti-obesity effects of lactoferrin and genetic variations

Kanae Nakamura[1], Ayumi Matsuno[1], Shun Nogawa[2], Daisuke Nishiura[1], Tomoji Ono[1], Yoshiyuki Obayashi[1], Kenji Saito[2,3], Hisanori Kato[3]

1. Lion Corporation (Japan), 2. Genequest Inc. (Japan), 3. The University of Tokyo (Japan)

Background and objectives: For advancements in functional food science, clarification of the relationship between the health effects of food intake and genetic variations is a critical issue, but it has barely been addressed. Therefore, a genome-wide association study (GWAS) was carried out to investigate an association between the anti-obesity effects of lactoferrin (LF), a milk-derived protein, and genetic variations.

Methods: A 12-week, placebo-controlled, randomized, double-blind, parallel-group comparative study was conducted in healthy Japanese men and women. The subjects were administered enteric-coated LF or placebo tablets. Before and after the administration of tablets, obesity-related parameters, such as visceral fat area and body mass index (BMI), were evaluated. The data were obtained from approximately 700,000 single nucleotide polymorphisms (SNPs) and a lifestyle questionnaire, such as daily food intake and exercise. The association between the rate of change in the parameters and the SNPs was analyzed using linear regression analysis adjusted by subject attributes, such as age and sex.

Results: The GWAS analysis revealed that several SNPs were potentially associated with the anti-obesity effects of LF, such as visceral fat area and BMI reduction. These SNPs were selected based on the p-value of the association in the LF group and the interaction between the LF and the placebo group. Furthermore, the annotation data showed that missense mutations are contained in these SNPs. Additionally, prediction models of the anti-obesity effects of LF were created using subject attributes, SNPs, and lifestyle data using a step-wise regression method. The coefficients of determination of all the prediction models on the effects of LF, such as visceral fat area and BMI reduction, were >0.8.

Conclusions: The GWAS indicated that genetic variants could be involved in the anti-obesity effects of LF. This observation could help utilize functional foods based on an individual's constitution and lifestyle.

Effect of black tea residue on glucose and lipid metabolism in mice

Naoko Takamizawa[1], Akiko Harauma[2], Yukino Hoshi[2], Toru Moriguchi[2], Kazunaga Yazawa[1]

1. Waseda University (Japan), 2. Azabu University (Japan).

Background and objectives: Many people are suffering from food shortages. On the other hand, a lot of foods are wasted every day. Food loss and food waste also includes waste during the food manufacturing process. The purpose of this study is to find out the effectiveness of black tea residue generated in the process of manufacturing black tea beverages. In this study, we investigated the effect of black tea fiber intake on glucose and lipid metabolism in mice.

Methods: Black tea residues were provided by the beverage factory and were freeze-dried and powdered for use. 5-week-old male ICR mice were preliminarily reared for 2 weeks and divided into two groups. The control group fed a standard diet (AIN-93M), and the experimental group fed identical diet supplemented with 3% black tea residue for 6 weeks. During the feeding period, body weight was measured once a week. The HbA1c level was measured on the last week of the feeding period. On the last day of the feeding period, blood was collected and measured for blood glucose, triglyceride, and total cholesterol. In addition, the weight of three adipose tissues (perirenal, epididymal and mesenteric) were measured.

Results: From fourth week of feeding period, the body weight of the black tea residue group tended to be lower than the control group. The weight of perirenal, epididymal and mesenteric adipose tissues of black tea residue group tended to be lower than the control group. The HbA1c ($p < 0.05$), blood triglyceride ($p < 0.01$), and total cholesterol ($p < 0.05$) value were significantly lower in the black tea residue group than in the control group.

Conclusions: These results suggest that long-term intake of black tea residue may suppress body fat accumulation. In addition, long-term intake of black tea residue showed an effect of suppressing the HbA1c, blood triglyceride, and total cholesterol elevation. Hence, this study suggests that black tea residue is useful for controlling glucose metabolism and lipid metabolism.

Epidermal hydrating and anti-melanogenic effects of rice-derived glucosylceramides and elasticamide on cell basis evaluation

Hiroshi Shimoda[1], Shogo Takeda[1], Yoshiaki Manse[2], Kenchi Miyasaka[1], Akari Yoneda[1], Toshio Morikawa[2]

1. Oryza Oil & Fat Chemical Co. Ltd. (Japan), 2. Pharmaceutical Research and Technology Institute, Kindai University (Japan)

Background and objectives: Skin ceramides (Cer) are lipids mainly existing in stratum corneum and play pivotal rolls on epidermal hydrating and barrier function. In terms of plant-derived major Cer, glucosylceramides (GlcCer) dominantly exist in wide variety of botanical resources. Among them, GlcCer are well studied about clinical effects on skin barrier function. As other biological effects of GlcCer on skin, maize cerebroside mixture has been reported to suppress melanogenesis in B16 melanoma cells. Beside GlcCer fraction, there are free Cer as minor constituents including elasticamide (ceramide[AP]). However, no study results have been reported regarding epidermal hydrating and anti-melanogenic effects of these single molecules of GlcCer and elasticamide. In this study we have evaluated epidermal moisturizing activity and anti-melanogenic effects of rice GlcCer and elasticamide.

Methods: Epidermal hydrating effects on the reconstructed human epidermal keratinization (RHEK) model were evaluated by measuring transepidermal water loss (TEWL) chronologically after adding samples (10 μM) to the membrane side of RHEK. For evaluation of elasticamide in RHEK, we determined Cer contents by TLC and measured mRNA and protein expressions of Cer synthesizing enzymes. On the other hand, anti-melanogenic effect in B16 melanoma cells was performed inducing melanogenesis by theophylline. For elasticamide and GlcCer[d18:2 (4*E*, 8*Z*)/20:0], we also evaluated anti-melanogenic effects in a human 3D cultured epidermal melanocytes and mRNA expressions of melanin synthesizing enzymes and ATP concentration in normal melanocytes.

Results: As a result of evaluation of TEWL, 10 μM of 4*E* ,8*Z* type GlcCer including GlcCer[d18:2(4*E*, 8*Z*)/18:0], GlcCer[d18:2(4*E* /8*Z*)/20:0], GlcCer[d18:2(4*E*/8*Z*)/22:0], GlcCer[d18:2(4*E* /8*Z*)/24:0], GlcCer[d18:2(4*E* /8*Z*)/26:0] and elasticamide decreased TEWL. Among GlcCer, TEWL was improved depending on the length of fatty acids and GlcCer[d18:2(4*E*/8*Z*)/26:0] exhibited most potent hydrating effect. The hydrating effect of elasticamide was stronger than GlcCer[d18:2(4*E*/8*Z*)/26:0]. Moreover, elasticamide (14.3 μM) significantly increased total Cer and Cer[NS/NDS] with enhancing expression of GlcCer synthase. On melanogenesis in B16 melanoma cells, GlcCer[d18:2(4E, 8Z)/18:0], GlcCer[d18:2(4*E*, 8*Z*)/20:0], and elasticamide suppressed melanin production with IC50 values: 6.6, 5.2, and 3.9 μM. Elasticamide but not GlcCer[d18:2 (4*E*, 8*Z*)/20:0] suppressed melanogenesis in a human 3D cultured epidermal melanocytes and tyrosinase related protein-1 (TYRP-1) expression in melanocytes.

Conclusions: Rice-derived GlcCer were found to exhibit fatty acid length-dependent epidermal hydrating effects. Elasticamide showed strongest hydrating effect with enriching Cer[NS/NDS] by enhancing GlcCer synthase expression. On the other hand,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

GlcCer [d18:2(4*E*, 8*Z*)/18:0] and GlcCer [d18:2(4*E*, 8*Z*)/20:0] suppressed melanogenesis in B16 melanoma cells. However, the structure-activity relationship of GlcCer was not clarified except the fact that longer fatty acid length potentiated cytotoxicity. Elasticamide suppressed melanogenesis without cytotoxicity in both melanoma cells and normal melanocytes. Suppression of TYRP-1 was involved in the suppressive mechanism of elasticamide. Our result showed that elasticamide is one of the promising skin whitening compound in rice Cer with strong barrier function.

Roasted chicken breast extracts interfere with muscle protein synthesis

Hiroaki Kanouchi[1], Saya Shida[1], De-Xing Hou[2], Shigeo Takenaka[1]

1. Osaka Metropolitan University (Japan), 2. Kagoshima University (Japan)

Background and objectives: Prevention of muscle atrophy is essential to support healthy aging. It is well known that adequate protein intake is necessary to prevent muscle atrophy. Still, there are few research reports on what meats are suitable for the prevention of muscle atrophy. We compared the effect of beef, pork, or chicken breast feeding on immobilization-induced muscle atrophy.

Methods: Experimental diets based on AIN-93M were prepared by replacing casein with meat flake of roast duck, roast chicken breast, roast pork fillet, or roast beef thigh. The protein, lipid, and carbohydrate contents in diets were adjusted to be identical. Male mice (9 wk old, C57BL) were fed one of the experimental diets. The ankle of the right limb was immobilized using a cast tube at 10–12 wk old, after which the cast was removed and sacrificed at 13.5 wk old. The tibialis muscle was collected at 12 and 13.5 wk. Muscle atrogin-1 mRNA and S6K protein levels were evaluated. Hydrophobic and hydrophilic extracts were prepared from the roasted chicken breast using liquid-liquid extraction method. C2C12 cells were cultured in the chicken extract-added medium. Cell proliferation rate and protein synthesis capacity were measured.

Results: Immobilization decreased the tibialis muscle weight by 21%. Meat type did not have a significant effect on muscle loss. Following release from the cast tube, muscle weight increased by 12% in the control food group but was not increased in the chicken breast food group and duck meat food group. Atrogin-1 mRNA expression was not significantly different among the groups. Phospho-S6K in the chicken breast food group was significantly lower than in the control group. In vitro study, C2C12 cell proliferation was suppressed in the medium added 10 mg/mL hydrophobic extracts from the chicken breast but not hydrophilic extracts. The protein synthesis level of C2C12 cells was attenuated when cells were cultured in 10 mg/mL hydrophobic extracts for 24 hours.

Conclusion: Consumption of large amounts of the roasted chicken breast may inhibit recovery from muscle atrophy. We found that this inhibitory effect may involve hydrophobic molecules with antiproliferative and protein synthesis properties in roasted chicken breast.

Nutrient profiling of different land races of Bamboo rice (*Bambusa arundinacea* Willd) collected from the southern Western Ghats of India

Julia Sebastian[1], Ananthan Rajendran[1], Subhash Kalpuri[1], Thingnganing Longvah[1]

1. National Institute of Nutrition, India (India)

Background and objective: Bamboo rice refers to seeds of edible wild bamboo grass (*Bambusa arundinacea* Willd). It forms a major part of diet of the tribal people of Western Ghats of South India. They are highly dependent on bamboo rice during its flowering season and generally use it as a rice substitute. The study was intended to address the lacunae in available literature on bamboo rice. The objectives of the study were to determine the proximate composition, vitamins, minerals including trace elements, fatty acid composition, individual and total polyphenolic content and the antioxidant activity exhibited by different land races of bamboo rice.

Methods: Bamboo rice samples were collected from six different regions of the Southern Western Ghats of India for analysis and compared with commonly consumed rice varieties. The proximate composition was analysed using AOAC procedures. The vitamins and individual polyphenols were analysed using the HPLC techniques. Macro minerals were analysed using AAS and the trace elements were quantified using ICP-MS. The fatty acid composition was estimated using GC-FID. The total polyphenolic content was determined using the Folin Ciocalteu method. Antioxidant activity was evaluated on the basis of scavenging capacity of 2,2-diphenyl-1-picrylhydrazyl (DPPH) radicals, 2,2′-azino-di-[3-ethylbenzthiazoline sulphonate] (ABTS) radical cations and by ferric reducing antioxidant power.

Results: Bamboo rice had a higher content of the proximate components protein and total dietary fiber and had a lesser fat content when compared to the commonly consumed rice varieties. They were significantly rich in the minerals zinc, iron, copper and calcium and had a higher content of polyphenols namely gallic acid, protocatechuic acid, protocatechuic acid, sinapic acid, 4-coumaric acid and luteolin 7-O-glucoside. Bamboo rice exhibited a higher antioxidant activity against ABTS radical cations. The total polyunsaturated fatty acid content was higher in Bamboo rice.

Conclusions: Bamboo rice was found to have a good nutrient profile when compared to few commonly consumed rice varieties in India. Owing to its significant contribution to the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

environment, extensive research needs to be carried out to reduce the long vegetative growth phase of bamboo and hence improve its cultivation and thereby increase the availability of bamboo rice.

Keyword: Bamboo rice, Nutrient composition, Bambusa arundinacea

The volatile compounds and aroma profile of various rice bran after solid-state fermentation

Ardy Ardiansyah[1], Wahyudi David[1], Retno Dwi Astuti[2], Dwi Larasatie Nur Fibri[2], Dody Dwi Handoko[3], Slamet Budijanto[4], Hitoshi Shirakawa[5]

1. Universitas Bakrie (Indonesia), 2. Universitas Gadjah Mada (Indonesia), 3. Indonesian Center for Rice Research, Ministry of Agriculture (Indonesia), 4. IPB University (Indonesia), 5. Tohoku University (Japan)

Background and objectives: Rice bran is one of the by-products produced from the rice milling process with beneficial nutrients and bioactive compounds. Solid-state fermentation (SSF) is well known to improve the bioactivity and aroma profile of rice bran. These studies were undertaken to analyze volatile compounds and aroma profiles of various varieties of rice bran without (non-fermented rice bran, NFRB) and after SSF with *Rhizopus oligosporus* (fermented rice bran, FRB).

Methods: Four varieties of rice (Ciherang, Inpari30, IR64, and Inpari42) bran were used in these studies. The volatile compounds were analyzed by headspace-solid phase microextraction coupled with GC/MS and the aroma profile was characterized by qualitative descriptive analysis (QDA).

Results: There were seventy-two and sixty-eight compounds identified in FRB and NFRB, respectively. They are aldehydes, ketones, alcohols, acids, esters, fatty acids, phenol, benzenes, furan, thiazole, pyrazines, pyridine, lactones, terpenes, and hydrocarbons. The QDA with ten trained panelists described nine aromas such as rancid, smoky, musty, grassy, green, earthy, cereal, and sweet in FRB and NFRB. The SSF enhances fermented aroma in FRB. Furthermore, there was a relationship between volatile compounds and aroma descriptions of various rice bran varieties.

Conclusion: These studies proved that fermentation can increase the variety of volatile compounds as well as improve the sensory profile of rice bran.

Preventive Role of Gnetin C against Nonalcoholic Fatty Liver Disease (NAFLD) in Mice Model

Tohfa Kabir[1], Haruki Yoshiba[1], Afifah Zahra Agista[1], Halima Sultana[1], Yusuke Ohsaki[1], Chiu-Li Yeh[1 2] , Hitoshi Shirakawa[1]

1. Tohoku University (Japan), 2. Taipei Medical University (Taiwan)

Background and objectives: Non-alcoholic fatty liver disease (NAFLD) is the most common form of chronic liver disease, the global prevalence of which is approximately 25%. NAFLD can progress to hepatic steatosis, liver inflammation, and advancing fibrosis with an increased risk of cirrhosis. Resveratrol, a natural polyphenol, having anti-cancer, antioxidant, and anti-inflammatory properties, is found to be beneficial for prevention and cure of multiple metabolic diseases. Gnetin C which is a resveratrol derivative and is thought to have similar health promoting properties. Our current research intended to investigate the role of these food ingredients as a preventive measure for NAFLD in mice model as well as comparison between the protective effects of gnetin C and resveratrol.

Methods: NAFLD model mice were established by feeding C57BL/6J male mice with choline and methionine deficient high fat diet (HFD). The experiment was continued for 12 weeks with four groups- control (Research diet Inc. A06071314M), NAFLD (HFD; Research diet Inc. A06071318M), gnetin C (HFD + gnetin C) and resveratrol (HFD + resveratrol).

Results: Diet supplementation with gnetin C could successfully reduce the body weight gain, liver weight and improved blood glucose level as well as insulin sensitivity. Hepatic steatosis was found to be reduced by both gnetin C and resveratrol supplemented diet indicated by decreased fat droplets in H & E-stained liver sections, which was also confirmed by the liver lipid content. Hepatic fibrosis induced by high fat diet was successfully ameliorated by gnetin C and resveratrol supplementation. Results from mRNA expressions and western blot analyses showed that gnetin C and to some extent resveratrol downregulated fibrosis markers and improved anti-fibrotic genes in the TGF-β signaling pathway indicating possible safeguarding mechanism of both polyphenols against NAFLD.

Conclusion: The results suggest that dietary supplementation with gnetin C may have protective effects against fat deposition as well as hepatic fibrosis.

PAB(T7-38)
Examination of methods for inhibition of rat small intestinal disaccharidase activity by resistant maltodextrin

Yugo Nakamura[1], Kayo Yamamoto[2], Yuko Uehara[2], Kunihiro Kishida[1]

1. Kindai University (Japan), 2. Matsutani Chemical Industry Co., Ltd. (Japan)

Background and objectives: Resistant maltodextrin (RMD) is a water-soluble dietary fiber made from starch and is widely used as an ingredient in functional foods. The mechanism by which RMD inhibits postprandial blood glucose elevation is generally thought to be due to inhibition of absorption of monosaccharides generated by hydrolysis of sugars, rather than inhibition of digestion. However, the inhibitory effects of RMD on intestinal maltase and sucrase activities also have been reported. In this study, we compared the inhibitory effects of RMD by measuring the amount of glucose (Glu-method) and fructose (Fru-method) released by rat intestinal sucrase and isomaltase. We also evaluated the inhibitory effects of RMD using *p* nitrophenyl-α-glucopyranoside *p* NPG).

Methods: Rat small intestinal disaccharidases were prepared by Kessler's method[1]). Sucrase and isomaltase activities were determined by Dahlqvist's assay with a slight modification[2]).

Results: Inhibition of RMD on sucrase activity was dose-dependent by the Glu-method while the Fru-method showed lower and no dose-dependent inhibition. As for inhibition on isomaltase activity, the Fru-method also showed a lower inhibition rate than the Glu-method. The reason for the different inhibition rates obtained by the Glu- and Fru- methods may be attributed to the blank sample which includes glucose released from RMD by digestion. In the Glu-method, the inhibition rate is calculated by subtracting the release of glucose from RMD. The blank sample reaction, in which RMD and the digestive enzyme react with each other under the condition that the substrate is not included, may result in greater hydrolysis of RMD than under the condition that the substrate is included. Therefore, we considered that glucose amount from the blank sample was overestimated in the Glu method, and as a result, the inhibition rate was apparently increased. Another evaluation of the inhibition of RMD on α-glucosidase activity using *p* NPG showed a similar inhibition rate to the Fru-method, which supports the fact that the inhibition rate obtained by Glu-method is overestimated.

Conclusions: We confirmed that RMD had certain inhibitory effects on rat intestinal sucrase, isomaltase, and α-glucosidase activities.

Identification of G protein-coupled receptors GPR55 and GPR97 as molecular targets of curcumin and involvement of GPR55 in the antidiabetic function of curcumin

Naoki Harada[1,2], Mai Okuyama[2], Yoshiaki Teraoka[2], Yumi Arahori[2], Tomoya Kitakaze[1,2], Takashi Inui[1,2], Naoki Goshima[3], Claus Schneider[4], Hiroshi Inui[1,2,5], Ryoichi Yamaji[1,2]

1. Osaka Metropolitan University (Japan), 2. Osaka Prefecture University (Japan), 3. Musashino University (Japan), 4. Vanderbilt University (USA), 5. Otemae University (Japan)

Background and objectives: The identification of molecular targets of bioactive food components is important to understand the mechanistic aspect of their physiological functions. Curcumin is the predominant bioactive curcuminoid in turmeric (*Curcuma longa*), which is widely used as a spice for preparing curry. Activities of curcumin, such as anti-diabetic properties, have been widely investigated. However, the molecular mechanisms by which curcumin exerts its biological effects have not yet been fully elucidated. Recently, G protein-coupled receptors have been identified as molecular targets of food factors.

Methods: We have developed an expression screening system using a luciferase reporter assay that enables to determine the activation of G protein-coupled receptors (GPCRs) by food components. HEK293FT cells were transfected with GPCR expression vectors and a p4xCRE-3xSRE-TATALuc2P reporter vector followed by stimulation with curcumin. Using a number of natural and synthetic curcumin analogs we examined the structure-activity relationship between curcumin and the identified receptors. The regulation of glucagon-like peptide-1 (GLP-1) secretion by curcumin via one of the identified receptors was investigated using GLUTag enteroendocrine L-cells.

Results: After screening 258 human GPCRs, we identified GPR55 and GPR97 as targets of curcumin. Structure-activity relationship analysis shows that both the methoxy group and the heptadienone moiety of curcumin were required for activation of both GPR55 and GPR97. Docking simulation and luciferase reporter analysis using GPR55 mutants showed that the F190 residue of GPR55 was important for the interaction with curcumin. The curcumin-induced secretion of glucagon-like peptide-1, an incretin hormone that promotes insulin secretion, and intracellular calcium levels in GLUTag cells were inhibited by a GPR55 antagonist.

Conclusions: Expression screening was a useful system to identify GPCRs as targets of food components. We have identified GPR55 and GPR97 as targets of curcumin. Activation of GPR55 may be involved in the antidiabetic activity of curcumin by promoting GLP-1 secretion.

Lactate positively modulates skeletal muscle mass in mice regardless of loading condition

Yoshitaka Ohno[1,2], Masashi Nakatani[1], Yohei Suda[2], Koki Ando[2], Yuki Matsui[2], Takafumi Ito[2], Kazuya Ohashi[2], Shingo Yokoyama[2], Katsumasa Goto[2]

1. Seijoh University (Japan), 2. Toyohashi Sozo University (Japan)

Background and objectives: Lactate, one of molecules released from skeletal muscle cells, is suggested to contribute to muscle mass gain. It is shown that extracellular lactate increases C2C12 myotube diameter. Recently, it was reported that oral lactate administration stimulates muscle hypertrophy and injured muscle regeneration in mice. However, the effects of lactate on unloading-related atrophy and reloading-related regrowth of skeletal muscle remain unclear. In the present study, the effects of lactate on mechanical loading-related changes of skeletal muscle mass in mice were investigated.

Methods: All animal studies were carried out in accordance with the Guide for the Care and Use of Laboratory Animals by the National Institutes of Health and were approved by the Animal Use Committee of Toyohashi SOZO University. Male C57BL/6J mice, aged 8 weeks old were divided into (1) control, (2) lactate-administered, (3) unloaded, (4) unloaded with lactate-administered, (5) reloaded, and (6) reloaded with lactate-administered groups. Mice in the unloaded and reloaded groups were subjected to hindlimb suspension (HS) for 2 weeks and 2-week ambulation recovery after HS, respectively. Mice of the lactate-administered groups were orally administered sodium lactate (1,000 mg/kg body weight) 5 days per week. At the end of the experimental period, both plantaris and soleus muscles were dissected from both hindlimbs of mice. Isolated muscle tissues were weighed and stored until the later analyses. Phosphorylation level of AMPK in each muscle sample was evaluated.

Results: Oral administration of lactate increased the weight of mouse plantaris and soleus muscles. Unloading-associated atrophy of plantaris and soleus muscles was partially attenuated by lactate administration. Further, lactate administration stimulated the regrowth of atrophied plantaris muscle induced by unloading. Decrease in the phosphorylation level of AMPK in plantaris muscle was observed by lactate administration in spite of the loading condition.

Conclusions: Findings from the present study indicate that lactate stimulates skeletal muscle growth and suppresses unloading-associated skeletal muscle atrophy. Stimulating effects of lactate on muscle mass may be dependent on fiber type. This work was partially supported by JSPS KAKENHI (18K10796 and 21K11276).

Keyword: Lactate, skeletal muscle, hypertrophy, atrophy, regrowth

Biological effects of oleanolic acid on lipolysis, antioxidative and mitochondrial activities in 3T3-L1 adipocytes

Yoshiaki Ito[1], Kouki Morishita[1], Takashi Nagasawa[1]

1. Iwate University (Japan)

Background and objectives: Oleanolic acid (OA), a natural triterpenoid found in various edible plants having anti-obesity and antioxidative activities, could be useful against obesity, a serious global public health problem. In the present study, to clarify these properties of OA and understand the underlying mechanisms, we examined its effects on lipolysis, antioxidative and mitochondrial activities in 3T3-L1 adipocytes.

Methods: Mouse 3T3-L1 preadipocytes were differentiated to matured adipocytes by culturing in DMEM + 10 % FBS, 10 µg/mL insulin, 250 nM dexamethasone, and 0.5 mM 3-isobutyl-1-methylxanthine for 3–4 days, and then in DMEM + 10 % FBS and 5 µg/mL insulin for the next 6 days. Lipolysis activity was evaluated by measuring the level of released glycerol in the medium from matured adipocytes treated with 50 µM OA. Antioxidative activity was assessed by measuring the oxidation of 2,7-dichlorofluorescein diacetate in matured 3T3-L1 cells pretreated for 48 h with 50 µM OA in the absence or presence of 10 µM zinc protoporphyrin-9, an inhibitor of heme oxygenase-1 (HO-1). The protein expressions and phosphorylation induced by OA were analyzed by Western blotting with cell lysates from matured adipocytes incubated for various times and with various concentrations of OA.

Results: OA induced lipolysis and phosphorylation of hormone-sensitive lipase (HSL) in 3T3-L1 adipocytes, which was blunted by a PKA inhibitor H-89. Furthermore, OA increased the expression of HO-1 and reduced intracellular oxidative stress. Treatment with HO-1 inhibitor suppressed the antioxidative effect of OA but did not affect its lipolytic activity. In addition, OA increased citrate synthase, a mitochondrial enzyme.

Conclusions: These results indicate that OA exerts lipolytic activity through the PKA pathway and possesses antioxidative properties. In addition, OA has a possible effect to modulate mitochondrial activity. These results suggest OA has a potential of a useful candidate for the treatment of obesity and its related oxidative stress.

Dietary D-allulose reduces body fat accumulation in rats fed medium-chain triglyceride diets

Tatsuhiro Matsuo[1], Takako Yamada[2], Tetsuo Iida[2]

1. Kagawa University (Japan), 2. Matsutani Chemical Industry (Japan)

Background and objectives: D-Allulose (D-psicose) is a rare sugar, which contains zero calories and has 70% sweetness relative to sucrose. Recently, many studies have shown the anti-obesity effect of D-allulose by suppressing lipogenesis and increasing energy expenditure. Conversely, medium-chain triglycerides (MCT) are lipids formed by three medium-chain fatty acids with 6–12 carbon atoms attached to the glycerol. MCT has been studied for years in an attempt to reduce body fat accumulation in rats and humans. The anti-obesity effect of MCT was not confirmed depending on the nutritional conditions because MCT might promote lipogenesis. This study has investigated the effects of simultaneous intake of d-allulose and MCT on body fat accumulation in rats.

Methods: Exp. 1] Forty male Wistar rats (3 weeks old) were randomly divided into five groups. One group of rats was given a commercial diet, which is the control (C1) group. The remaining four groups were the LM, HM, LMA, and HMA groups, respectively. L, H, M, and A are abbreviations for low, high, MCT, and D-allulose, respectively [Exp. 2] Thirty-two male Wistar rats (3-week-old) were divided into four groups, the C2 (control), M, A, and MA groups, respectively. The LM, LMA, M, and MA diets contained 5% MCT, the HM and HMA diets contained 13% MCT, and the LMA, HMA, A, and MA diets contained 5% D-allulose. In each experiment, rats were fed with experimental diets *ad libitum* for 8 weeks, and then the rats were sacrificed.

Results: [Exp. 1] Intra-abdominal adipose tissue weights were significantly greater in the HM group than that in the C1 group. D-Allulose significantly decreased the weights of intra-abdominal adipose tissue, carcass fat, and total body fat, while these increased as the amount of MCT added increased. [Exp. 2] D-Allulose significantly decreased the weights of intra-abdominal adipose tissue, carcass fat, and total body fat, on the other hand, these were not influenced by the presence or absence of MCT addition.

Conclusion: The anti-obesity effect of D-allulose was observed with or without dietary MCT, but no synergistic effect between D-allulose and MCT has been observed.

Keyword: D-allulose, medium-chain triglycerides, body fat, rat

PAB(T7-43)
Postprandial blood glucose response of sponge cake intake containing resistant starch in healthy female university students

Aya Kamei[1], Hikaru Shimoji[1]

1. Miyagi University of Education (Japan)

Background and objectives: Resistant starch escapes digestion until reaching colon and acts like dietary fiber. Many studies have shown that consuming meals with high RS contents were lower postprandial blood glucose concentration compared with consuming ordinary meals. Western confectionary of sponge cakes are very popular, and are preferred to women than men in Japan. Sponge cakes contain a lot of sugar and fat, therefore, too much consumption of these could lead to overweight, obesity and non-communicable diseases. Amylofiber®SH (AF-SH) is derived from high amylose corn starch and contains 68% of RS which was measured by AOAC method 2002.02. In this study, we baked sponge cakes using AF-SH, kindly provided from J-OIL MILLS, INC., and evaluated the postprandial blood glucose of healthy female university students when they consumed AF-SH sponge cake.

Methods: This study was a single-arm design. The difference of ingredient between standard sponge cake and AF-SH sponge cake was using wheat flour or 100% AF-SH. Nine volunteers of female students, aged 20-23 years, were participated in this study. During study period, subjects could consumed foods and drinks freely. The day before the experiment, they fasted after dinner until the experiment began. Subjects were given standard sponge cake first, then were given the AF-SH sponge cake a week later. Using self-monitoring blood glucose equipment (NIPRO TRUEpico®), subjects measured by themselves of peripheral blood glucose levels at 0, 15, 30, 60, 90, 120 minutes after standard sponge cake intake or AF-SH sponge cake intake.

Results: The consumption of AF-SH sponge cake resulted in a significant reduction in postprandial blood glucose incremental area under curve from 0 to 120 minutes compared with that of standard sponge cake ($p<0.05$).

Conclusions: This study demonstrated that sponge cake made from high amylose corn starch contained of 68% RS reduced postprandial blood glucose compared to standard sponge cake, therefore, it might be helpful for glycemic control for healthy people.

PAB(T7-44)
Development of Glucagon-Like Peptide-1 Sandwich ELISAs and Their Application for the Effects of Black Tea Polyphenols in STC-1 Cells.

Kevin Odongo[1], Ken-yu Hironao[1], Yoko Yamashita[1], Ashida Hitoshi[1]

1. Kobe University (Japan)

Background and objectives: Glucagon-like peptide-1 (GLP-1) is one of the incretin hormones and plays an important role in the metabolic response. GLP-1 is secreted in its active form but is rapidly degraded by the dipeptidyl peptidase-4, converting >90% to the inactive metabolite before reaching the target organs via circulation. Therefore, promoting endogenous GLP-1 secretion is a good strategy for diabetes treatment. It has been reported that various nutrients stimulate GLP-1 secretion. However, whether non-nutrients, including black tea polyphenols, possess properties for the secretion of GLP-1 is not yet fully understood. The ability to identify the effective plant bioactive compound is severely limited by the high cost of commercial assays. Thus, we aimed to 1) develop a cost-effective sandwich ELISAs (s-ELISAs) for detecting the 'active' and 'total' GLP-1 and 2) apply the s-ELISAs to investigate the effects of black tea polyphenols in STC-1 cells, and elucidate their secretory mechanisms.

Methods: To develop the s-ELISAs, all antibodies used recognized different GLP-1 epitopes and were optimized by the checkerboard titration method. GLP-1 secretion studies were conducted in STC-1 cells. The molecular mechanism of the bioactive compounds was examined by Western blot and immunofluorescence microscopy analysis.

Results and Conclusion: Three s-ELISAs were developed; total, sensitive active, and wide-range active GLP-1 ELISAs. The s-ELISAs exhibited high sensitivity; dynamic ranges between 1.62 ~ 240, 1.40 ~ 62.5, and 8.3 ~ 4480 pmol/L, respectively. High precision was observed; i.e., CVs within 5% and 20% for intra- and inter-assay variations, respectively, and excellent recoveries, with the same performance as the commercial kits. Cinnamtannin A2-induced GLP-1 secretion was confirmed by the developed s-ELISAs as consistent with our previous findings, indicating that the developed s-ELISAs were applicable for the measurement of GLP-1. Using these s-ELISAs, we found that theaflavins (TFs) in black tea polyphenol extract, in particular TF1 and TF2B, significantly increased both active and total GLP-1 levels. As for the secretory mechanism, TFs induced GLP-1 secretion via the Ca^{2+}/CaMKII pathway through MEK-ERK1/2 signaling. Therefore, we successfully developed the new GLP-1 s-ELISAs and demonstrated the novel function of TFs in regards to GLP-1 secretion.

The influences of biofilm formation on Myoga (Zingiber myoga) extraction.

Kouki Asai[1], Daishi Kawai[1], Rino Ito[1], Mikoto Matsuo[1], Asumi Ohta[1], Asuka Sueyoshi[1], Kaho Ohmori[1], Kaori Kitakoshi[1]

1. Shigakkan University (Japan)

Objectives: Dental caries have become a major global health problem. Patients may experience difficulties chewing when dental caries becomes severe; thus, oral care is important to maintain a high quality of life. *Streptococcus mutans* and *S. sobrinus* are etiologic agents of human dental caries, as they form biofilm that progresses the formation of cavities, and controlling biofilm production prevents dental caries. It has been reported that Zingiberaceae plants, such as myoga, cinnamon, and ginger, contain a stable antibacterial substance. In this study, we extracted components from myoga using hexane, ethyl acetate, and methanol, and examined their effects on biofilm formation.

Methods: Hexane was added to freeze-dried myoga, and the mixture was left for 24 hours and filtered. Ethyl acetate was added to the filtration residue, and the mixture was filtered, and finally, methanol was added to the filtration residue. The solvents were removed from each extract. *S.mutans* or *S.sobrinus* was added to a liquid medium containing sucrose. Thereafter, the hexane, ethyl acetate, and methanol extracts from myoga were added at different concentrations. After culturing for 24 hours, biofilm formation was examined using a crystal violet assay.

Result and consideration: Biofilm formation by *S. mutans* and *S. sobrinus* was suppressed at lower concentrations with methanol extract. Ethyl acetate extract suppressed biofilm formation by *S. mutans* and *S. sobrinus*, as the concentration decreased. However, hexane extract suppressed biofilm formation by *S. mutans* at lower concentrations, and biofilm formation by *S. sobrinus* at higher concentrations. Therefore, methanol and ethyl acetate extracts with low concentration were effective for suppressing biofilm formation by both *S. mutans* and *S. sobrinus*.

Analysis of antioxidative polyphenols from Virgin moringa leaves

Shoko Nishizono[1], Kae Satake[1], Toru Yomoda[2], Nobuhiro Fukuda[3], Tsuyoshi Ikeda[1], Toshiro Matsui[4]

1. Sojo University (Japan), 2. Amakusa Moringa Farm (Japan), 3. Miyazaki International College (Japan), 4. Kyushu University (Japan)

Background and objectives: *Moringa oleifera* is harvested in many tropical countries. The plant leaves, seeds, bark, roots, sap, and flowers are widely used to treat many ailments, including inflammation-related and infectious diseases, and cardiovascular, gastrointestinal, hematological, and hepatorenal disorders. We cultivated moringa in Amakusa, Japan, and successfully developed a functional food product, namely "Virgin moringa leaf" (VML). In this study, we tried to find which part of moringa contains the most abundant antioxidants. Furthermore, we focused on the identification and characterization of individual antioxidative polyphenols.

Methods: Moringa leaves harvested in Japan, India, and Brazil and VML were air-dried, ground to powder, and extracted by mixing with hot water. Various parts of moringa in Japan, such as leaves, flowers, roots, stems, and seeds were also extracted with hot water. Antioxidative activity was estimated from the DPPH radical-scavenging activity. Online HPLC-DPPH screening method, a real-time HPLC coupled to the DPPH assay, was performed for evaluation of radical scavenging polyphenols in VML. Liquid chromatography-time-of-flight/mass spectrometry (LC-TOF/MS) was used for the identification and characterization of antioxidative compounds.

Results: In comparison with leaves from Japan, India, and Brazil, VML yielded the highest antioxidative activities and polyphenol contents. Leaves and flowers exhibited the highest antioxidative activities and polyphenol contents among the various parts of moringa. Four compounds matching with high antioxidant activities were detected in VML on the chart of online HPLC-DPPH screening method. Two of the compounds from the respective MS peak in negative ion mode and retention time were identified 3-*O*-caffeoylquinic acid (3-CQA, *m/z* 353.0901) and 5-*O*-caffeoylquinic acid (chlorogenic acid, 5-CQA, *m/z* 353.0845), respectively, and were the most potent quenchers of DPPH radical. While there was no difference between the amounts of 3-CQA and 5-CQA in VML, trolox equivalent antioxidant capacity (TEAC) of 3-CQA was 1.3 hold higher than that of 5-CQA. Contribution rate of 3-CQA to the antioxidative activity of VML was also 1.3 hold higher than that of 5-CQA. The other two compounds (*m/z* 463.0863 and *m/z* 549.0849) were estimated as quercetin glycosides.

Conclusions: 3-CQA and 5-CQA in VML have pronounced antioxidant activities. VML is a promising functional food product.

Keyword: moringa leaf, antioxidants, chlorogenic acid, polyphenols, online HPLC-DPPH screening method

Ameliorating Effect of Cinnamon Extracts Dietary Supplementation on Serum and Hepatic Lipid Profiles in High-Fat-Diet induced Obese Mice Model

Joohee Oh[1], Hyun-Sook Kim[1]

1. Sookmyung Women's University (Korea)

Background and Objectives: The previous research has identified that the Cinnamon extracts has an excellent anti-obese effects among traditional medicine. Also, Cinnamon has been known for modulating several metabolic disorders by regulating insulin sensitivity. This study aimed to investigate the ameliorating effects of cinnamon extracts on serum and hepatic lipid profiles in high-fat-diet induced obese mice model.

Methods: After 1 week of acclimation, the 6-week-old male C57BL/6J mice were randomly divided into 4 groups of 10 mice each (n=10 for each group): normal diet group (ND), normal diet with 1% cinnamon extracts (NC), high-fat-diet group (HF), and high-fat diet with 1% cinnamon extracts (HC). All groups were treated with respective diet for 14 weeks.

Results: Serum TG (Triglyceride) levels and TC (Total cholesterol) levels were higher in HF group than other 3 groups (P=0.000); HC group presented significantly decreased levels compared to that of HF group (P=0.000). Hepatic TG and TC levels were higher in HF group than other 3 groups (P<0.05); HC group showed significantly decreased levels compared to that of HF group(P=0.008).

Conclusions: The present data showed Cinnamon Extracts may have the ameliorating function in vivo by reducing the elevated lipids (TG and TC) levels, especially in high-fat-diet induced model. The further analysis of protein expression of related enzymes and tissue factors are in progress.

Keyword: Cinnamon Extracts, Anti-Obese, Lipid profiles, Triglyceride(TG), Total cholesterol(TC)

Daily maslinic acid intake combined with physical exercise improves muscle strength and muscle mass in healthy adults: a randomized, double-blind, two-dose placebo-controlled trial

Yuki Yamauchi[1,2], Tetsu Kinoshita[3,4], Satoshi Fukumitsu[1,2], Kazuhiko Aida[1], Koutatsu Maruyama[3], Isao Saito[5], Naofumi Yamamoto[3]

1. NIPPN CORPORATION (Japan), 2. University of Tsukuba (Japan), 3. Ehime University (Japan), 4. Institute of Community Life Sciences Co., Ltd. (Japan), 5. Oita University (Japan)

Background and objectives: Age-related changes in physical function are closely related to the impairment of daily activities among the elderly. Although continuous maslinic acid (MA) intake may improve skeletal muscle mass, the concentration-dependent benefits of MA for food functionality are yet to be clarified. We hypothesized that differences in MA absorption in the blood resulting from variations in MA intake improve muscle mass and strength. Herein, we evaluated the difference in blood MA absorption at different MA intake levels and examined the effect of MA intake on skeletal muscle and quality of life in healthy adults.

Methods: In experiment 1, five healthy adult men were administered test diets containing 30, 60, or 120 mg of MA in a single-blind crossover trial, and the plasma MA content was analyzed before and 0.5, 1, 2, 3, 4, 8, 12, and 24 h after test diet ingestion. In experiment 2, 69 healthy adults were administered a placebo or 30 or 60 mg MA continuously for 12 weeks with physical exercise in a randomized, double-blind, two-dose placebo-controlled trial. Before and after the intervention, we assessed body composition, grip strength, leg strength, walking speed, and QOL score.

Results: In experiment 1, the MA concentration peaked at approximately 3 h after administration. A concentration-dependent increase in the blood MA level was observed ($p < 0.01$). In experiment 2, the trunk muscle mass ($p < 0.05$) and vitality score according to the Short Form-8 ($p < 0.05$) were significantly higher in the 60 mg MA group than in the placebo group. In addition, the grip strength significantly increased in the 30 mg ($p < 0.05$) and 60 mg ($p < 0.05$) groups than in the placebo group.

Conclusions: These results could suggest that the combination of MA intake and physical exercise improved muscle strength, and the muscle mass and quality of life improved in a MA-intake-dependent manner.

Oleuropein Aglycone Enhances UCP1 Expression in Brown Adipose Tissue in High-Fat-Diet-Induced Obese Rats by Activating β-Adrenergic Signalling

Yuriko Oi-Kano[1], Yusaku Iwasaki[2], Toshiyuki Nakamura[3], Tatsuo Watanabe[3], Tsuyoshi Goto[4], Teruo Kawada[4], Kazuo Iwai[1]

1. Kobe Women's University (Japan), 2. Kyoto Prefectural University (Japan), 3. University of Shizuoka (Japan), 4. Kyoto University (Japan)

Oleuropein is the pungent principle of raw olives. Oleuropein aglycone (OA) is a major phenolic compound in extra virgin olive oil and the absorbed form of oleuropein. We aimed to determine the mechanism underlying the nutritional effects of oleuropein and OA on interscapular brown adipose tissue (IBAT) in rats with high-fat (HF) diet-induced obesity by examining the agonistic activity of oleuropein and OA toward the transient receptor potential ankyrin 1 (TRPA1) and vanilloid 1 (TRPV1). Four-week-old-male Sprague-Dawley rats were fed a HF (palm oil 30% wt:wt) diet alone or with oleuropein (HF-O, 1 g/kg diet) for 28 d. In rats fed HF-O compared to HF, urinary noradrenaline, adrenaline and UCP1 levels in IBAT were significantly higher, whereas plasma leptin levels and the total weight of the abdominal cavity adipose tissue were significantly lower. In anesthetized 7-wk-old -male Sprague-Dawley rats, the OA (3.8 mg of intravenous injection)-induced increase in plasma noradrenaline secretion was suppressed byTRPA1 or TRPV1 antagonist and by a β2- or β3-adrenoceptor antagonist. Furthermore, OA activated rat and human TRPV1s expressed on HEK293 cells at the same level as zingerone (pungent component in ginger). OA also activated humanTRPA1 and its potency was approximately 10-fold stronger than that for TRPV1. These findings suggest that OA is the agonist of both TRPA1 and TRPV1 and that OA enhances UCP1 expression in IBAT with a concomitant decrease in the visceral fat mass of HF diet-induced obese rats through enhanced noradrenaline secretion via β-adrenergic action following TRPA1 and TRPV1 activation.

Keyword: Brown adipose tissue, Noradrenaline, Oleuropein aglycone, TRPA1, TRPV1

Conflict of Interest Disclosure: No conflict of interest.

The milk casein hydrolysate-derived peptide enhances glucose uptake through AMP-activated protein kinase signaling pathway in C2C12 skeletal muscle cells

Masayo Iwasa[1,2,3], Hidetoshi Miyazaki[4], Wataru Aoi[2]

1. National Hospital Organization, Kyoto Medical Center (Japan), 2. Kyoto Prefectural University (Japan), 3. Beppu Clinic (Japan), 4. Asahi Quality & Innovations, Ltd (Japan)

Background and objectives: Improvement of glucose metabolism in skeletal muscle has a key role in physical performance and prevention of metabolic diseases. Previously, we have shown that intake of milk casein hydrolysate improves glucose metabolism in humans, but the mechanism of action is unclear. In this study, we aimed to investigate the mechanism of action of milk casein hydrolysate and its derived peptides (valine-proline-proline and isoleucine-proline-proline) on glucose metabolism by focusing on the insulin-dependent and insulin-independent signaling pathways in cultured skeletal muscle cells.

Methods: C2C12 myoblasts were differentiated for 96 h after growth until the cells achieved confluence, and the confluent cells were used in each experiment. Experiments using milk casein hydrolysate, valine-proline-proline, and isoleucine-proline-proline were carried out after 4-hour incubations in unsupplemented medium. Subsequently, the rate of 2-deoxy-glucose uptake and phosphorylation levels of insulin-dependent and -independent signaling factors were examined.

Results: The rate of 2-deoxy-glucose uptake in both milk casein hydrolysate and isoleucine-proline-proline-treated cells was higher than that in the control cells ($P < 0.01$). Immunoblotting assays showed that the phosphorylation levels of AMP-activated protein kinase, a rate-limiting factor in insulin-independent signaling, and that of liver kinase B1, an upstream factor of AMP-activated protein kinase, in both milk casein hydrolysate and isoleucine-proline-proline-treated cells were higher than those in the control cells ($P < 0.05$). Such significant effects were not observed after treatment with valine-proline-proline. The insulin-dependent signaling was not significantly affected by either milk casein hydrolysate or the peptides.

Conclusions: The findings of our study suggest that milk casein hydrolysate enhances glucose uptake by activating insulin-independent AMP-activated protein kinase signaling in skeletal muscle cells, which might be mediated by a milk casein hydrolysate-derived peptide, isoleucine-proline-proline. These observations suggest potential for mechanism of metabolic improvement induced by milk casein hydrolysate in humans.

Involvement of circadian rhythm on luteolin-induced antioxidant enzymes through Nrf2 activation in hepatocytes

Hitoshi Ashida[1], Tomoya Kitakaze[1,2]

1. Kobe University (Japan), 2. Osaka Metropolitan University (Japan)

Background and objectives: Luteolin has various health-promoting activities. It has been reported that high dose of luteolin activates the Nrf2/ARE pathway in the liver. However, an intake amount of luteolin and its glycosides from a dietary meal is limited. In this study, we investigated the effect of the low dose range of luteolin on the induction of antioxidant enzymes and its molecular mechanism in HepG2 cells. We also investigated whether an administration timing affects the induction of antioxidant enzymes in ICR mice.

Methods: HepG2 cells were treated with luteolin at 0.01 nM-1 μM for 24 h. Activation of Nrf2/ARE pathway was examined by an electrophoretic mobility shift assay. Nuclear accumulation of Nrf2 and the expression of antioxidant enzymes were determined by western blot. U0126 and PD98059 were used as MEK inhibitors. Mice were orally administered luteolin at 0.01-10 mg/kg body weight/day for 7 consecutive days at the beginning of inactive phase and that of active one. Plasma concentration of luteolin was determined by HPLC.

Results: Luteolin at 1 nM significantly induced antioxidant enzymes, namely NQO1, HO-1 and AKR1B10, in HepG2 cells accompanied by phosphorylation and nuclear accumulation of Nrf2 and binding of Nrf2 to ARE. MEK inhibitors cancelled both phosphorylation and transcriptional activity of Nrf2. Oral administration of luteolin at 0.1-10 mg/kg body weight increased expression of NQO1 and HO-1, and nuclear accumulation of Nrf2 in the liver at the beginning of active phase, but not that of inactive one. The plasma concentration of luteolin aglycon was higher in the beginning of active phase than in that of inactive one.

Conclusion: These results indicated that low dose of luteolin increased antioxidant enzymes through the ERK1/2-mediated Nrf2/ARE pathway. There existed a suitable administration timing to reveal this beneficial function of luteolin depending on difference of the level of aglycon form of luteolin in plasma. In conclusion, a dietary level of luteolin-induced antioxidant enzymes and this function may contribute to prevent many diseases through suppression of oxidative stress in the liver. This work was supported by JSPS KAKENHI 17H0818.

Clitoria ternatea flower extract suppresses postprandial lipemia and improves antioxidant status induced by a high-fat meal in overweigh/obese subjects

Thavaree Thilavech[1], Sirichai Adisakwattana[2], Charoonsri Chusak[2]

1. Faculty of Pharmacy, Mahidol University (Thailand), 2. Faculty of Allied Health Sciences, Chulalongkorn University (Thailand)

Background and Objective: High-fat (HF) meal-induced postprandial lipemia, oxidative stress and low-grade inflammation, contributing to an increased risk of metabolic disorders. *Clitoria ternatea* L. or butterfly pea is a natural food source of phytochemical compounds, especially anthocyanins. The pharmacological properties of *C. ternatea* has been revealed as antioxidant, anti-hyperlipidemic, and anti-inflammatory effects. The aim of this study was to investigate the effect of *C. ternatea* L. flower extract (CTE) on postprandial lipemia, antioxidant status, and inflammatory response following high-fat meal consumption in overweight/obese men.

Methods: In randomized, crossover, control trial study, sixteen overweight/obese men (body mass index, 25.7 ± 0.7 kg/m^2) were assigned to three groups that consumed HF meal or HF with 1 or 2 g CTE in the beverage. Blood samples were collected at fasting state and then at 30, 60, 90, 120, 180, 240, 300 and 360 min after the meal consumption.

Results: Phenolic and anthocyanins content of CTE were 50.19 ± 0.86 mg gallic acid equivalent and 0.87 ± 0.13 mg delphinidin-3-glucoside equivalents/g dried extract, respectively. DPPH radical scavenging activity and the ferric reducing antioxidant power of CTE were 18.64 ± 3.07 µg ascorbic acid equivalent and 0.32 ± 0.01 mM $FeSO_4$ equivalent/mg extract, respectively. The ingestion of CTE (2 g) significant decreased the incremental area under the curve (iAUC) of postprandial serum triglyceride and the level of serum free fatty acid (FFA) at 360 min following HF-meal consumption. Postprandial plasma antioxidant capacity presented by ferric reducing ability of plasma and protein thiol was significantly increased after consumption of HF meal plus CTE, corresponding to the improvement of glutathione peroxidase activity. In consistence, CTE consumption also decreased the elevated plasma lipid peroxidation product, malondialdehyde, after administration HF meal. However, no significant difference was observed for the level of serum inflammatory cytokines (interleulin-6, interleulin-1β and tumor necrosis factor-α) and the expression of interleulin-6 and interleulin-1β genes in peripheral blood mononuclear cells response to HF consumption among three groups.

Conclusion: These findings suggest that acute ingestion of CTE may improve postprandial lipemia and antioxidant status when consumed with HF meal in overweight/obese subjects.

Effects of heat killed *Bifidobacterium* on anti-obesity

Hitomi Maruta[1], Baojun Sun[1], Yusuke Fujii[2], Naoki Toyokawa[2], Syoji Nakamura[2], Hiromi Yamashita[1]

1. Okayama prefectural university (Japan), 2. Ohayo Dairy Products Co., Ltd. (Japan)

Backgraound and objectives: Obesity is a serious health problem worldwide. It is reported that gut microflora is a contributing factor for the leading or protection of obesity. *Bifidobacteria* are colonize the human gastrointestinal tract and *Bifidobacterium* species are known to have beneficial health effects on human physiology and pathology, such as immunomodulation. These effects have led to use of *Bifidobacteria* as components of probiotics products. *Bifidobacterium* species produce acetic acid as a final metabolite, but the level of production is different among the species and/or depending on living or dead cells. It has been indicated that supplementation of acetic acid has an effect on improving obesity, lipid accumulation in the liver, or glucose tolerance. In addition, in our recent study, long-term supplementation of one of *Bifidobacterium* species had the effect on improving obesity. In this study, we investigated the efffect of heat killed *Bifidobacterium* cells on energy metabolism and prevention of obesity.

Methods: *Bifidobacterium* isolated from infant feces were heat killed and suspended into 12% (w/w) skimmed milk. Each suspension was administered to Otsuka Long-Evans Tokushima Fatty (OLETF) rats, which are type 2 diabetes model animals that develop obesity and diabetes due to overeating, at 5 mL / kg of body weight for 5 days per week from 7 to 15 weeks of age. Food consumption and body weight of each rat were recorded every day. At 16 weeks of age, the rats were anesthetized, dissected, isolated muscles, liver, and white adipose tissues, and those tissues were used for subsequent experiments.

Results: The weight gain and food efficiency were suppressed significantly in the rats administered heat killed *Bifidobacteria* as compared with rats administered water, and lipid accumulation in the liver was also inhibited in heat killed *Bifidobacteria* group as compared with water group. Furthermore, the gene expression of mitochondria-related in soleus were significantly higher in the rats administered heat killed *Bifidobacteria* than rats administered water.

Conclusions: It is suggested that heat killed *Bifidobacterium* cells may have similar effect to living cells.

Keyword: Bifidobacterium, obesity, acetic acid

Oligosaccharides from agar extends lifespan through the activations of unfolded protein response and IIS pathway in *Caenorhabditis elegans*

Natsumi Desaka[1], Hitomi Nishikawa[1], Katsura Mizushima[2], Tomohisa Takagi[2], Yuji Naito[2], Yasuki Higashimura[1,2]

1. Ishikawa Prefectural University (Japan), 2. Kyoto Prefectural University of Medicine (Japan)

Background and objectives: Agarose, the main component of polysaccharides in agar, comprises of D-galactose and 3,6-anhydro-L-galactose. The α1-3 bond is easily hydrolyzed to produce agaro-oligosaccharides (AGO) with repeating agarobiose units composed of D-galactose at the non-reducing end and 3,6-anhydro-L-galactose at the reducing end. AGO exhibits various physiological activities including antioxidative and antiinflammation activities. Because the cumulative oxidative stress and chronic inflammation are involved in the physiological ageing process, we speculated that AGO is effective in preventing ageing. The aim of this study is to evaluate the effect of AGO on lifespan extension and to elucidate the mechanism of AGO-mediated longevity in *Caenorhabditis elegans* (*C. elegans*).

Methods: Young adult worms were placed on nematode growth medium plates containing AGO, fructooligosaccharides (FOS), isomalto-oligosaccharides (IMO), or polydextrose (PDX). The mean lifespan, body size, brood size, locomotory activity, lipofuscin accumulation, and heat stress resistance of worms were examined. To elucidate mechanisms of AGO-mediated longevity, we conducted comprehensive expression analysis using microarrays. We used quantitative real-time PCR (qRT-PCR) to verify the genes showing differential expression levels. Furthermore, we measured the lifespan of mutant worms to determine the genes related to AGO-mediated longevity.

Results: The lifespans of the worms fed AGO, but not FOS, IMO, or PDX, were significantly longer than control group. The growth curves of worms and brood sizes were similar to control group. The worms fed AGO displayed higher locomotion and lower lipofuscin accumulation. The microarray analysis revealed that the endoplasmic reticulum-unfolded protein response (ER-UPR) and insulin/insulin-like growth factor-1-mediated signaling (IIS) pathway were activated in worms fed AGO. Results of the qRT-PCR analyses, AGO treatment suppressed *sir-2.1* expression, which is a negative regulator of the ER-UPR, and increased *abu/pqn* families of genes downstream of *sir-2.1.* In the heat condition, the mean survival time of the worms fed AGO was significantly longer than control group. AGO-induced longevity and heat stress resistance were decreased or cancelled completely in the *sir-2.1* mutant. Furthermore, the AGO-mediated longevity was decreased in mutants of *daf-2* and *daf-16*, which are IIS pathway-related genes.

Conclusions: AGO extended the lifespan of *C. elegans* through the activations of ER-UPR and the IIS pathway.

The effects of prebiotics intervention on gut microbiota and short chain fatty acid in healthy adults: a systematic review and meta-analysis

Jo Hsuan Wang[1], Shyh Hsiang Lin[1]

1. Taipei Medical University (Taiwan)

Background and objectives: Gut microbiota can be affected by genetic, western diet, poor lifestyle, stress and aging, and cause the dysbiosis. Dysbiosis have already been implicated in multiple diseases such as metabolic syndrome, obesity, and diabetes, while recent search suggests a potential role of the microbiota-gut-brain axis in neuropsychiatric disorders, such as cognitive deficit disorders and depression. Diet is one of the major factor to modify the gut microbiota composition, and prebiotics supplementation may increase specific bacterial numbers and metabolites, including short-chain fatty acid (SCFA). In this study, a systematic review and meta-analysis were undertaken to assess the effect of prebiotics intervention on gut microbiota and SCFA in healthy adults.

Methods: A systematic search was conducted including Cochrane library, EMBASE, and Pubmed for these inclusive criteria: (1) randomized controlled trials; (2) healthy adults aged 18-65 yr; (3) prebiotics intervention compare to placebo or no supplement; (4) using culture and/or molecular microbiological techniques and mass spectrometric techniques; (5) major outcome were gut microbiota composition and/or metabolites SCFA. Meta-analyses via a random-effects model were performed on specified bacterial abundances including *Bifidobacterium, Lactobacillus, Clostridium, Bacteroides* and fecal SCFA concentrations comparing prebiotics interventions with placebo comparators.

Results: Twenty two independent studies involving 810 healthy adults were included in the present meta-analysis. Prebiotics intervention resulted in higher abundance of *Bifidobacterium* (standardized mean difference (SMD): 0.72; 95% CI: 0.32, 1.10) compared with placebo/ no supplement comparators. No differences in effect were found between prebiotics intervention and comparators for abundances of other bacteria, or all SCFA concentrations.

Conclusions: The present meta-analysis shows that prebiotics interventions, involving xylo-oligosaccharide (XOS) , inulin, fructans, and partially hydrolyzed guar gum, lead to a higher abundance of *Bifidobacterium*, but other bacteria and fecal SCFA show no trend.

Tryptophan microbial metabolites play a key role in fermented rice bran function in preventing DSS-induced colitis

Afifah Zahra Agista[1], Jahidul Islam[1], Takuya Koseki[2], Yusuke Ohsaki[1], Michio Komai[1], Chiu-Li Yeh[3], Suh-Ching Yang[3], Ardy Ardiansyah[4], Slamet Budijanto[5], Hitoshi Shirakawa[1]

1. Tohoku University (Japan), 2. Yamagata University (Japan), 3. Taipei Medical University (Taiwan), 4. Bakrie University (Indonesia), 5. IPB University (Indonesia)

Background and objectives: Supplementation of rice bran (RB) which has been fermented with *Aspergillus kawachii* and a mixture of lactic acid bacteria (FRB) has been shown to induce some health benefits, such as improving the blood pressure, lipid profile, and glucose metabolism in stroke-prone hypertensive rats. It was also able to prevent muscle waste in streptozotocin-induced diabetic rats. In this study, we evaluated the effect of FRB supplementation in mitigating dextran sodium sulfate (DSS)-induced colitis. An investigation over which fermented rice bran bioactive compounds play a key role in this colitis-preventing effect was also conducted.

Methods: Male C57BL/6N mice were divided into three groups. One group was provided with a control diet, another was fed with a 10% RB supplemented diet, and the remaining group was given a 10% FRB supplemented diet. The diet treatment was started 4 days before colitis was induced. Colitis was induced by dextran sodium sulfate (DSS) treatment for 12 consecutive days. Moreover, FRB was separated into several different fractions and its anti-inflammatory activity was evaluated with lipopolysaccharide (LPS)-stimulated RAW 264.7 cells. FRB fractions, along with mice serum and fecal contents, were analyzed for their bioactive compounds.

Results: DSS treatment caused severe body weight loss and mucosal inflammation in the control and RB group, but not in the FRB group. FRB also markedly decreased mRNA levels of pro-inflammatory cytokines in mice colons. On the other hand, FRB fractions which were rich in tryptophan and tryptamine were able to reduce the inflammatory markers in LPS-stimulated RAW 264.7 cells. The presence of tryptophan and tryptophan metabolites in mice feces and serum were also increased in mice fed FRB and might serve as a confirmation that tryptophan metabolites in FRB played a key role in FRB's colitis preventive effect.

Conclusions: Tryptophan metabolites, especially tryptamine, might have played a key role in FRB's protective effect against DSS-induced inflammation in mice. This effect might have been achieved due to tryptophan metabolites' ability to act as a ligand to aryl hydrocarbon receptor.

Keyword: dextran sodium sulfate, fermented rice bran, inflammation, tryptamine, tryptophan

Background and Objectives: Thermophile-fermented compost is an agricultural material produced by the fermentation of unutilized marine resources under high temperature and aerobic conditions. Previous studies have shown that the administration of the compost has beneficial effects such as lowering the disease incidence and promoting the growth of piglets. It has also been reported that *Bacillus hisashii* N-11^T strain identified from the cecal feces of gnotobiotic mice fed with thermophile-fermented compost reduces the accumulation of visceral fat in mice and pigs. In addition, a bacterium that is closely relative to *Clostridium. isatidis* have also been isolated from the cecal feces, but their biological function has not been evaluated. In this study, we investigated the effect of *C. isatidis*. on high-fat diet-induced obese mice.

Methods: Five-week-old male C57BL/6J mice were fed with a normal-fat diet (NFD) or a 60% kcal high-fat diet (HFD). Mice of each diet group were received one of the following doses of *C. isatidis*. in drinking water; 0 (control), 5.0×10^2 (low), or 1.0×10^8 (high) cfu/mouse/day. After performing oral glucose tolerance test (OGTT), mice were sacrificed at the 17th week.

Results: Body weight gain was significantly decreased under NFD and tended to be decreased under HFD by *C. isatidis*. Plasma glucose level during OGTT performed to evaluate glucose metabolism tended to be reduced by *C. isatidis*. under both diets. In addition, plasma insulin level during OGTT was significantly decreased by a high amount of *C. isatidis*. under HFD. Furthermore, the exposure significantly decreased triglyceride level in the liver under HFD.

Conclusion: These results suggested that *C. isatidis*. could improve abnormal glucose and lipid metabolism induced by a high-fat diet.

Simultaneous detection of food compounds by a graphite carbon black-aided laser desorption ionization-mass spectrometry

Haruna Ide[1], Keishiro Arima[1], Toshiro Matsui[1], Mitsuru Tanaka[1]

1. Kyushu University (Japan)

Background and objectives: Conventional analytical methods for the assay of functional and nutritional compounds, such as polyphenols, vitamins, amino acids, etc., require tedious sample preparation prior to analysis. For example, hydrophobic vitamins are extracted with organic solvent, while hydrophilic ones are extracted with polar aqueous solvent, when vitamins are analyzed liquid chromatography< LC>. In contrast, a laser desorption ionization-mass spectrometry is a powerful analytical technique for simultaneous detection of compounds without sample extraction and purification. Thus, the aim of the present study was to establish a simple analytical method for simultaneous detection of food compounds by an advanced LDI−MS using a graphite carbon black , since it possesses non−targeted adsorption property for diverse analytical targets and high thermal conductivity for UV laser irradiation.

Methods: Target compounds were dissolved in MS−grade water at each 10 mM concentration. GCB was suspended <2.5 mg/mL> in 50% 2−propanol, dropped onto an ITO-coated glass slide <2 µL/spot>, and air-dried. An aliquot <2 µL> of sample solution was dropped onto the GCB-spotted ITO glass slide and subjected to an LDI−MS analysis.

Results: GCB−aided LDI−MS measurement achieved the detection of all targets at negligible noise signals at 100−400 *m/z* in positive and negative ion modes for a few seconds. For the detection of amino acids by the LDI−MS, 11 amino acids except for Cys were detected in positive ionization mode without any interference with noise signals. In contrast, the measurement in negative ionization mode allowed the detection of all the target amino acids. This indicates that the present GCB−LDI−MS analysis can be assayed for a variety of amino acids in terms of *m/z* value. The GCB−aided LDI−MS was also applicable for simultaneous detection of nutrients in commercially available sports drink, containing hydrophobic vitamin A, hydrophilic vitamins B1, B2, B6, niacin, cystine, Val, Leu, and Gln.

Conclusions: This study demonstrated that the established GCB−aided LDI−MS is a novel food analytical method to measure a variety of food compounds, by its rapid, comprehensive, and convenient advantages.

Effects of Matcha Green Tea Consumption on Dynamic Visions (a Randomized Double-Blind Human Trial)

Emiko Oda[1], Miho Nakayama[1], Wakana Harada[1], Yukimi Mogi[1], Yukino Nakamura[1], Yoichi Fukushima[2,3], Kazuhiro Uenishi[1]

1. Kagawa Nutrition University, Laboratory of Physiological Nutrition (Japan), 2. Nestlé Japan Ltd, Tokyo (Japan), 3. Daito Bunka University, Saitama (Japan)

Background and objectives: Lutein is an abundant pigment in the macula, and its dietary intake is suggested to improve sight contrast and may have protective effects against pigmentary degeneration of retina. Matcha green tea is rich in lutein, however, the information on efficacy of matcha on visual properties is limited. This study was aimed to clarify the effects of matcha green tea consumption on dynamic vision in healthy humans.

Methods: A randomized double-blind controlled trial was conducted on 31 female university students aged 20–22 years (16 in the matcha group as a test group; 15 in the barley tea group as a control group). The subjects consumed either test drink containing 3 g/day of matcha green tea powder, or the same amount of control drink containing 3 g/day of barley tea powder for 3 months. Dynamic visual acuity and eye movement were measured using ArrowZeye (Japan Sports Science Inc.), a PC software, before and after the intervention. The score was calculated at rank number, 1 to 10, plus correct response ratio (0.0 to 0.9) at their highest speed rank. A rank had 15 sets of measurements, and the speed increased when subjects earned at least 90% correct responses at the rank. Lutein intake was calculated using the Japanese database on carotenoid contents (Fukushima et al., 2021).

Results: In the test group, eye movement score significantly increased from 1.73 [1.60–1.80] to 1.80 [1.73-2.68] after intervention ($p<0.05$). In the control group, there was no changes. There were no differences between two groups in the eye movement before and after intervention. There were no significant changes for both groups in the dynamic visual acuity. Basal daily intake of lutein was 0.98[0.72–2.25] mg from the test group and 0.84[0.69–1.99] mg from the control group, where matcha consumption increase lutein intake at 2 mg/day during intervention in the test group.

Conclusions: The results suggest that consuming 3 g/day of matcha green tea for 3 months, provided about 3 times higher daily intake of lutein, effects eye movement in healthy humans.

The suppressive effect of rice-albumin hydrolysates on postprandial hyperglycemia on glucose loading.

Rio Ogawa[1], Shigenobu Ina[1], Yusuke Yamaguchi[1], Hitoshi Kumagai[2] Hitomi Kumagai[1]

1. Nihon University (Japan), 2. Kyoritsu Women's University (Japan)

Background and objectives: Diabetes mellitus is one of the most severe diseases because it may lead to various complications. For the prevention of diabetes mellitus, it is effective to suppress or retard the increase in postprandial blood glucose level. We reported that oral administration of rice albumin (RA) suppressed blood glucose elevation not only on starch loading but also on glucose loading. Although RA did not inhibit the activity of mammalian α-amylase, the intraperitoneal glucose tolerance test (IPGTT) suggested that RA and its hydrolysates would act in the gastrointestinal tract. In addition, both indigestible high-molecular-weight peptides (HMP) and low-molecular-weight peptides (LMP) produced from RA by digestive enzymes suppressed the elevation of blood glucose level. However, the mechanism of the suppressive effect of HMP and LMP has not been clarified yet. As RA was shown to adsorb glucose similar to dietary fiber in our previous study, HMP may be responsible for the adsorption and promote glucose excretion. On the other hand, as LMP is too small to adsorb glucose, the possible mechanism would be the inhibition of glucose-transporter expression. Therefore, in this study, we examined if indigestible HMP would adsorb glucose to the same level as RA and LMP would inhibit the expression of sodium-dependent glucose transporter 1 (SGLT1).

Methods: The glucose-adsorption capacity of HMP was evaluated by measuring the glucose diffusion rate from the mixture of HMP and glucose through the dialysis membrane and compared the results with that of carboxymethyl cellulose (CMC). The effect of LMP on SGLT1 expression was investigated by using the intestinal secretin tumor cell line (STC-1) derived from mouse small intestinal epithelium. The SGLT1 expression level was evaluated with and without the addition of LMP to STC-1 by Western blotting.

Results: The suppressive effect of HMP on glucose diffusion was slightly lower than that of RA, and comparable to that of CMC. LMP suppressed the expression of SGLT1 in STC-1 cells.

Conclusions: The suppressive effect of RA on blood-glucose level would be attributed both to the glucose-adsorption capacity of HMP and to the inhibitory activity of LMP against SGLT1 expression.

Effects of matcha on lipid metabolism, oxidative stress and inflammation in Cafeteria diet-induced NAFLD rat model

Ya-Ling Chen[1], Shu Ting Tang[1], Yu Chieh Tseng[1], Suh Ching Yang[1], Yasuo Watanabe[1], Shizuo Yamada[2], Ohashi Kazuteru[3], Ho Ching Chong[1]

1. Taipei Medical University (Taiwan), 2. University of Shizuoka (Japan), 3. KAWANE MATCHA CO., LTD. (Japan)

Background and objectives: Non-alcoholic fatty liver disease (NAFLD) becomes the most common disease in the world, and unhealthy eating habits maybe one of the key pathogenic factors. Cafeteria diet, providing human junk food with basal rat diet can successfully induce metabolic syndrome and NAFLD. Matcha, contains much more active compounds such as total phenolic, caffeine and catechin than green tea, however, the protective effects of matcha on NAFLD were still controversial. This study aims to investigate the protective effects of matcha on lipid metabolism and inflammation damage in Cafeteria diet-induced rat model.

Method: Forty-eight of 7-week-old male Wistar rats were divided into 6 groups (n=8), including control group (C) (normal diet, Labdiet 5001, Richmond, USA), C+0.2% Matcha group (C+0.2%), C+1% Matcha group (C+1%), Cafeteria group (Caf) (Cafeteria diet), Caf+0.2% Matcha group (Caf+0.2%) and Caf+1% Matcha group (Caf+1%). The Cafeteria diet contain cheese sandwich crackers, potato chips, milk puffs, sausages and blend with normal diet. Rats were sacrificed after 12 weeks.

Results: Body weight of Caf, Caf+0.2% and Caf+1% group were significantly increased when compared with C group. Blood sugar, serum insulin, HOMA-IR significantly increased at 12th week and improved in both matcha intervention groups. Cafeteria diet increased plasma leptin, adipose tissue weight and both matcha intervention groups showed reversed results in the above items. Plasma TG were increased by cafeteria diet and 1% matcha could improve the situation of it. The raise of liver TC and TG in Caf group were decreased after the intervention of 0.2% matcha. Hepatic tumor necrosis factor (TNF)-α, Interleukin (IL)-1β, IL-6 and IL-10 of Caf group were significantly increased than those of C group, 1L-1β were reduced in both matcha intervention groups when compared to Caf group while only 1% matcha improved the situation in TNFα and IL-6. Liver pathological section showed steatosis and inflammation results in Caf group and it reversed in both matcha intervention groups. NAFLD score was significantly increased in Caf group and matcha improved the steatosis score significantly.

Conclusion: These results suggested that combined treatment of matcha can alleviate insulin resistance, lipid accumulation and inflammation in Cafeteria diet-induced rat model.

Effects of azuki bean polyphenols on glucose and lipid metabolism in mice fed a high-fat diet and the role of intestinal bacteria

Yuuka Mukai[1]

1. Kanagawa University of Human Services (Japan)

Background and objectives: Plant polyphenols (PPs), which have beneficial effect on obesity and diabetes, are partially absorbed in the intestinal tract, and most of them pass through the intestinal tract. We speculated that these unabsorbed PPs may regulate the metabolism by acting on intestinal bacteria. The purpose of this study was to investigate the role of intestinal bacteria in the modulatory effects of azuki bean PPs (APP) on metabolism.

Methods: Five-week-old male ICR mice were divided and fed *ad libitum* for 4 weeks: a control (C) diet and normal tap (N) water for CN and CNP groups, a high-fat (F) diet and N-water for FN and FNP groups, and the F-diet and antibiotic-containing (A) water for FA and FAP groups. The CNP, FNP, and FAP groups were also orally administered APP (40 mg/kgBW; daily) that was extracted from azuki beans. The intestinal flora, short-chain fatty acid (SCFA) contents of cecum, and blood chemistry were analyzed. The expression of insulin signaling factors in the liver was measured by western blotting.

Results: The antibiotic-treated groups (FA and FAP) showed cecum hypertrophy and liquefaction of its contents, decreased species diversity of the intestinal flora, and decreased SCFA contents. The FN group had significantly higher body and adipose tissue weights; these weights decreased in the FNP group, while the FAP group showed opposite trend. Plasma TG and HOMA-IR levels in the FNP group were significantly lower than those in the FN group, while there were no significant differences between FAP and FA groups. The CNP and FNP groups showed lower liver mTOR and Akt, and higher phosphorylated FoxO1 levels than respective control groups, while the FAP group showed opposite trend.

Conclusions: Administration of APP increased the diversity of the intestinal flora, inhibited fat accumulation caused by high-fat diet, lowered blood lipids, and improved insulin resistance via mTOR, Akt, and FoxO1. However, these effects were lost or reduced under the dysbiosis by antibiotics. Thus, this study indicate that intestinal bacteria may be involved, at least in part, in the physiological regulatory functions of APP.

PAB(T7-63)
Synergetic effect of dietary allitol and d-allulose on body fat accumulation in rats.

Reiko Inai[1]*, Atsuhiro Toyota*[2]*, Shunsuke Higaki*[3]*, Tatsuhiro Matsuo*[2]

1. University of Kochi (Japan), 2. Kagawa University (Japan), 3. Hokkaido Bunkyo University (Japan)

Background and objectives: Allitol is rare sugar alcohol obtained by reducing d-allulose (d-psicose) and can be found in *Itea*, a deciduous shrub of the family Saxifragaceae, with d-allulose. Our previous study reported that the long-term feeding of rats with a dietary supplement of dried *Itea* powder suppresses body fat accumulation. The effect may be due to d-allulose and allitol contained in *Itea*. This finding suggested that allitol might have low available energy and an anti-obesity effect. However, information on the effects of long-term dietary allitol intake is limited. This study aimed to investigate the synergetic effect of allitol and d-allulose supplementation on body fat accumulation under restricted feeding in rats.

Methods: Thirty-two male Wistar rats (3 weeks old) were randomized into four groups of eight rats. The rats were fed with 10g of high sucrose diet (C), the C diet added 0.5g of d-allulose (P), 0.5g of allitol (A), or 0.5g of d-allulose and 0.5g of allitol (PA) for 12 weeks. After the experimental period, all rats were sacrificed by beheading. Blood was collected to obtain serum. The heart, liver, kidneys, spleen, cecum, and abdominal adipose tissues were quickly removed and stored at −80°C, and the carcass samples were stored at −20°C until analysis.

Results: Final body weight was significantly lower in the P and PA groups than that in the C group. The intra-abdominal adipose tissue weight and carcass fat mass were lower in the P and PA groups than that in the C group, whereas no significant difference has been observed between the C and A groups. A synergistic effect of allitol and d-allulose supplementation was found in the reduced intra-abdominal adipose tissue weight. The serum and cecal acetic acid were found to be significantly higher in the A and PA groups than those in the C and P groups.

Conclusion: In this study, the synergetic effect of allitol and d-allulose on intra-abdominal fat accumulation in rats has been clarified. Our results suggested that d-allulose inhibits lipogenesis from short-chain fatty acids produced by the cecal fermentation of allitol. Further research is needed to investigate its detailed mechanisms.

Effects of Neuropeptide GALP on Peripheral Glucose Metabolism via Hepatokinesis

Satoshi Hirako[1], Nobuhiro Wada[2], Haruaki Kageyama[3], Yuzuru Iizuka[4], Fumiko Takenoya[5], Seiji Shioda[6]

1. University of Human Arts and Sciences (Japan), 2. National Institute of Health and Nutrition, National Institutes of Biomedical Innovation, Health and Nutrition (NIBIOHN) (Japan), 3. Kiryu University (Japan), 4. Tokyo Women's Medical University School of Medicine (Japan), 5. Hoshi University School of Pharmacy and Pharmaceutical Science (Japan), 6. Shonan University of Medical Sciences (Japan)

Background and objectives: GALP is a neuropeptide isolated and identified from the porcine hypothalamus. Previous studies have reported the anti-obesity effect of GALP. We found that intraventricular administration of GALP resulted in a gradual increase in respiratory quotient after 12 hours of administration. We thought that GALP also affects glucose metabolism, but the detailed mechanism has not been elucidated. In this study, we investigated the regulatory effects of GALP on glucose and lipid metabolism in the liver and skeletal muscle.

Methods: Eleven-week-old male C57BL / 6J mice were used as experimental animals, and saline or GALP was administered intraventricularly and dissected 16 hours later. Blood glucose levels and plasma lipid levels were measured, and mRNA expression levels of glucose metabolism-related genes in liver and skeletal muscle were measured.

Results: There was no significant difference in body weight between the two groups, but food intake decreased in the GALP group. There was no significant difference in blood glucose levels. G6Pase gene expression associated with hepatic gluconeogenesis was reduced in the GALP group. In addition, the gene expression of selenoprotein P (SeP), LECT2 and Fetuin-A, which are hepatkines and known to induce insulin resistance in the liver and skeletal muscle, was all decreased in the GALP group, and SeP and Fetuin-A were significantly decreased. On the other hand, GK, which is a glycolytic enzyme, gene expression tended to increase in the GALP group. There were no significant differences in gene expression associated with lipid metabolism.

Conclusions: In this study, glycolysis and suppressed gluconeogenesis in the liver enhanced by GALP. In addition, decreased expression of the SeP, LECT2 and Fetuin-A genes it is suggested that GALP regulates glucose metabolism via hepatkine.

Keyword: GALP , anti-obesity effect, glucose metabolism, Fetuin-A

PAB(T7-65)
Effects of dietary allitol on body fat accumulation in rats

Shunsuke Higaki[1], Reiko Inai[2], Tatsuhiro Matsuo[3]

1. Hokkaido Bunkyo University (Japan), 2. University of Kochi (Japan), 3. Kagawa University (Japan)

Background and objectives: Allitol is a rare sugar alcohol that can be obtained by reducing D-allulose (D-psicose) and can be found in Itea, a deciduous shrub of the family Saxifragaceae, with D-allulose. Our previous study has reported that the long-term feeding of rats with a dietary supplement of dried Itea powder suppresses body fat accumulation. The effect may be due to D-allulose and allitol contained in Itea. This finding suggested that allitol might have low available energy and an anti-obesity effect. However, information on the effects of long-term dietary allitol intake is limited. This study aimed to investigate the effect of allitol supplementation, as a sugar substitute, on body fat accumulation in rats compared with that of sucrose, rare sugar D-allulose, or erythritol.

Methods: Thirty-two male Wistar rats (3 weeks old) were fed experimental diets including 5% sucrose, allitol, erythritol, or D-allulose for 8 weeks ad libitum. Bodyweight and food intake were recorded daily. After the experimental period, all rats were sacrificed by beheading. Blood was collected to obtain serum. The heart, liver, kidneys, spleen, and abdominal adipose tissues were quickly removed and stored at −80°C until analysis. Carcass samples were obtained by removing the head, the remains of the intra-abdominal and intra-thorax tissues. They were stored at −20°C until analysis of carcass fat.

Results: No significant difference has been observed in weight gain, food intake, and food efficiency among the groups. The total body fat mass and percentage, and intra-abdominal adipose tissue weights were found to be significantly lower in rats fed with the allitol diet than in those fed with the sucrose diet. These body fat indicators tended to be lower in rats fed with the erythritol and D-allulose diets than in those fed with the sucrose diet, but no significant difference has been observed.

Conclusion: In this study, the anti-obesity effect of allitol in rats has been clarified. Furthermore, the anti-obesity effect of allitol may be equal to or greater than that of D-allulose. Further research is needed to investigate the allitol's anti-obesity effect and metabolic pathway.

Keyword: allitol, D-allulose, body fat

Ann Nutr Metab 2023;79(suppl 1):14–1172

PAB(T7-66)
Effect of dynamic high-pressure treated chicken meat on skeletal muscle of sarcopenia model mice

Sarasa Kogure[1], Hikaru Nagano[2], Yuri Tanioka[1], Jun Yamauchi[1], Tadasu Furusho[1]

1. Tokyo University of Agriculture (Japan), 2. Osaka Prefecture University (Japan)

Background and objectives: The water pressure in running water is called dynamic high-pressure (DHP), and it is characterized by the physical forces of shear, impact, and cavitation that act with the pressure. DHP treatment of protein is expected to modify the structure of protein and improve absorption. Exercise and high-quality protein intake are necessary to prevent sarcopenia, which has become a nutritional problem in an aging society in recent years. However, most of the protein supplements on the market are powders obtained by enzymatically treating milk and soybeans. In this study, chickens were DHP-treated with a high-pressure homogenizer and tested in vitro for improved absorption of denatured protein. Furthermore, the effects of Ezm+DHP intake the increase in skeletal muscle mass was investigated in sarcopenia model animals.

Methods: Chicken breast strips were treated with DHP (150MPa, 15passes: DHP), enzymatic (protease, 30min: Ezm), and combination of them (Ezm+DHP). Then they were freeze-dried and pulverized. Protein denaturation was evaluated by the protein solubility test and quantification of amino groups by OPA method. Improvement digestibility of these samples were evaluated by artificial digestive test. SAMP8, which develops sarcopenia due to accelerated aging, were given Control diet containing CTL(n=10) or a test diet containing Ezm+DHP(n=10), and treadmill training was performed for 5 months.

Results: The results of the protein solubility test, DHP and Ezm+DHP decreased hydrogen bonds and increased hydrophobic interactions. The quantitative of amino groups increased significantly in the order of DHP, Ezm, and Ezm+DHP relative to CTL. This result suggests that the lowest molecular weight is achieved in the combined treatment of Ezm+DHP, rather than in the treatment of Ezm or DHP alone. Ezm+DHP diet group was shown to have significantly increased the extensor digitorum longus muscle (EDL) compared to that of the CTL diet group.

Conclusions: These results indicate that intake of meat reduced in molecular weignht by Ezm+DHP treatment improved protein absorption, and amino acid or prptides retained in the body were used for skeletal muscle synthesis through endurance exercise. Ezm+DHP-treated meat could become a new protein material in the future.

Influence of a long-term diet including Tsuyama-grown apios on gastrointestinal function

Rie Watanabe[1], Shota Gima[1], Yui Morioka[1], Shiori Yamamoto[1], Kaori Hayashi[1], Yusuke Matsunaga[2]

1. Mimasaka University (Japan), 2. Tsuyama Kogyo Genryo Co., Ltd. (Japan)

Background and objectives: Apios americana Medikus is a member of the legume family Apios fortune, containing isoflavones and DDMP saponins, and also showing a weak alpha-glucosidase inhibitory effect as its functional activities. The activities of these functional components have been reported to indicate biological defense, anti-cancer, anti-inflammatory and anti-hyperglycemic effects. However, detailed mechanistic understanding and evidence for efficacy and safety of Apios components are limited. In this study, wild mice were fed Apios powder-containing diets in order to evaluate the effects and safety of Apios.

Methods/Results: Apios and potato (as a control) were freeze-dried, powdered and admixed with a standard powdered feed at a final concentration of 20% (w/w). Wild mice (C57BL/6, 8 weeks old) were fed 20% Apios or potato powder-containing diets ad libitum for 62 weeks. Compared to the potato group, the Apios group tended to increase food intake, while its body weight significantly decreased. In the Apios group, AST and ALT values decreased, and HDL value significantly increased compared to the potato group. The Apios diet reduced sizes of lipid droplets in liver, suggesting Apios decreases fat accumulation in the livers of 70-week-old aged mice. The number of goblet cells in intestinal villus and the thickness of the circular and longitudinal muscle layers in the small intestine increased in the Apios group, suggesting increases in mucin secretion and peristaltic movements in the small intestine of the Apios group.

Conclusions: Apios-containing diet might be associated with anti-aging effects.

Protease treated royal jelly enhance muscle regeneration though the regulation of muscle stem cell proliferation

Sachiko Yamashita Takeuchi[1], Tomohiko Shirakawa[1], Hideto Okamoto[2], Nobuaki Okumura[2], Takuma Matsubara[1], Tatsuo Kawamoto[1], Shoichiro Kokabu[1]

1. Kyushu Dental University (Japan), 2. Institute for Bee Products and Health Science, Yamada Bee Company, Inc. (Japan)

Background and objectives: Royal jelly (RJ) is involved in longevity and fertility in the queen honeybee. RJ is generally

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

considered beneficial to skeletal muscle health. We recently reported that protease-treated RJ (pRJ), which we had developed to reduce anaphylactic reactions, prevents the skeletal muscle atrophy following denervation. However, in contrast to atrophy, the exact effect and mechanism of pRJ on muscle regeneration remains unknown.

Methods: Lyophilized protease-treated RJ was prepared by Yamada Bee Company. Experimental diets were prepared by mixing pRJ with commercially available powder diet at a concentration of 1%. Four-week-old female C57BL/6 mice were fed control diet or pRJ diet for 3 weeks pre and for 7 days post-operation. Muscle regeneration was induced by injecting 50 µl of 10 µM cardiotoxin into tibial anterior muscle. Single fibers of the muscle were extracted from the extensor digitorum longus muscles and treated with or without 0.5 mg/ml pRJ solution. C2C12 cells were treated with or without 1.0 mg/ml pRJ solution for 2 days after which total RNA was isolated. Gene expression levels were determined by RNA-seq analysis. Target genes of microRNAs were predicted using TargetScan bioinformatics software.

Results and Discussion: The fiber size of regeneration muscle was increased in pRJ fed group. pRJ treatment stimulated the increment of the number of satellite cells, skeletal muscle stem cells. Treatment of C2C12 cells with pRJ downregulated 155 genes and upregulated 124 genes. Two microRNAs, miR-29a and miR3058 were amongst the 155 significantly downregulated genes. 51 of the 155 downregulated genes (33%) were predicted to be targets of either miR-29a or miR3058. These data suggest that pRJ induces skeletal muscle regeneration though the regulation of stem cell proliferation. It is also indicated that miR-29a and miR3058 play an important role in the regulation of gene expression downstream of pRJ treatment.

Conclusions: pRJ induces regeneration of skeletal muscle via activation of satellite cell proliferation. Therefore, pRJ is a natural product which contributes to keep the health of skeletal muscle.

Effects of milk basic protein supplementation on bone density and bone metabolism markers in female college long-distance runners: A double-blind randomized controlled trial

Noa Itou[1], Kazuhiro Uenishi[2]

1. Kagawa Nutrition University(Currently KYORIN Pharmaceutical Co.,Ltd.) (Japan), 2. Kagawa Nutrition University (Japan)

Objective: It has been reported that long-distance runners have a high incidence of stress fractures. Milk basic protein has been shown to help build healthy bones in people of all ages. However, little is known about how milk basic protein function in athletes. Therefore, we clarified the effect of milk basic protein ingestion on bone mineral density and bone metabolism markers and decided to use it to reduce the incidence of stress fractures in athletes and improve bone strength.

Methods: This was a double-blind, randomized controlled trial. The ingestion group was instructed to consume a soft drink containing 40 mg of milk basic protein, and the non-ingestion group was instructed to consume a 50-mL bottle of placebo soft drink daily for 6 months. Thirteen of the 14 participants, excluding one who declined to participate in the study, were stratified and randomized based on their baseline height, weight, and lumbar bone mineral density measurements; the ingestion group included six women, and the non-ingestion group included seven women. The survey included physical measurements, bone mass/density measurements, blood/urine biochemical tests, food ingestion frequency surveys, and menstrual and mileage surveys. The survey period was from May to December 2019.

Results: There were no significant differences in the changes in bone formation, bone resorption, or bone quality markers between the two groups. However, when the bone formation rate (= bone formation marker/bone resorption marker) was calculated, a higher bone formation rate was observed in the ingestion group, although the difference was not significant. Regarding changes in bone mineral density, the radial cancellous bone mineral density tended to be higher in the ingestion group than in the non-ingestion group, and the lumbar spine bone mineral density was higher in the ingestion group.

Conclusion: An increase in radial cancellous bone mineral density and lumbar spine bone mineral density were observed after ingestion of milk basic protein for 6 months. This indicates that the bone mineral density of athletes may increase.

Keyword: milk basic protein, BMD, bone metabolism markers, long-distance runners

PAB(T7-70)
Effect of Kiwifruit Intake on Antioxidant Activity and Mood among College Male Middle- and Long-Distance Runners

Hiroko Motohashi[1], Nami Imai[2], Kazuhiro Uenishi[1]

1. Kagawa Nutrition University, Laboratory of Physiological Nutrition (Japan), 2. Nihon Pharmaceutical University, Department of Pharmaceutical and Medical Business Sciences (Japan)

Background and Objectives: Long-distance runners exercise for many hours on a daily basis, which may increase oxidative stress and expose them to psychological stress. Kiwifruit is rich in vitamins C and E and can be expected to enhance antioxidant activity and suppress the increase in oxidative stress. Furthermore, Kiwifruit is thought to have the effect of reducing psychological stress. The objective of the study is to clarify the effects of kiwifruit intake on antioxidant activity and mood of college male middle-and long-distance runners.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: Study (1): Thirty middle-and long-distance runners belonging to the Track and Field Club of A college were investigated from May to July 2017. They were divided into two groups: intake group (15 subjects) who consumed kiwifruit for a month, and non-intake group (control: 15 subjects) who did not consume kiwifruit. The changes in d-ROMs (oxidative stress), BAP (antioxidant activity), and BAP/d-ROMs ratio (potential antioxidant capacity) were compared between the two groups. Study (2): Thirty-six middle-and long-distance runners belonging to the Track and Field Club of A college, similar to Study (1), were investigated from August to October 2020. They were divided into two groups: intake group (16 subjects) who consumed kiwifruit for two months and non-intake group (control: 20 subjects) who did not consume kiwifruit. The changes in each scale (AH: anger, CB: confusion, DD: depression, FI: fatigue, TA: tension, VA: vigor, and TMD: total mood disturbance) were compared between the two groups.

Results: Study (1): In the intake group, d-ROMs significantly decreased while the BAP/d-ROMs ratio significantly increased after the intervention compared to pre-intervention. However, in the control group, no significant difference was observed in all items. Study (2): In the intake group, AH significantly increased after the intervention, with no increase observed in other scales compared to pre-intervention. However, in the control group, AH, CB, DD, and several other negative mood scales significantly increased.

Conclusions: Both studies suggest that intake of kiwifruit, with its high antioxidant activity, may improve potential antioxidant ability by decreasing d-ROMs and maintaining BAP. Furthermore, it was suggested that intake of kiwifruit may possibly affect psychological factors.

Conflict of Interest Disclosure: The authors (Kazuhiro Uenishi) have financial conflicts of interest disclose concerning the study from Zespri International (Japan) K.K. We receive kiwifruit offerings from the company.

Keyword: Runners, Kiwifruit, Antioxidant activity, d-ROMs, BAP

Cirsium setidens water extracts containing linarin inhibit estrogen deficiency-induced osteoporosis in mice

Moon-Sik Oh[1], Soo-Il Kim[1], Sin-Hye Park[1], Young-Hee Kang[1]

1. Hallym University (Korea)

Background and objectives: Osteoporosis typically manifest in postmenopausal women is an osteolytic disease characterized by bone loss that further increases the susceptibility to bone fractures and frailty. The use of complementary therapies to alleviate postmenopausal osteoporosis is fairly wide-spread among women. Edible Cirsium setidens contains various polyphenols of linarin, pectolinarin, and apigenin with antioxidant and hepatoprotective effects. This study aimed to determine whether linarin present in Cirsium setidens water extracts (CSE) and its aglycone acacetin inhibited ovariectomy (OVX)-induced bone loss.

Methods: This study employed OVX C57BL/6 female mice as a model for postmenopausal osteoporosis. CSE, acacetin or linarin was orally administrated to the OVX mice at a dose of 20 mg/kg for 8 weeks.

Results: Surgical estrogen loss of mice for 8 weeks reduced bone mineral density (BMD) of mouse femurs and serum 17β-estradiol level, and enhanced serum receptor activator of NF-κB ligand (RANKL)/osteoprotegerin ratio with uterine atrophy. CSE and linarin ameliorated uterine atrophy with an increase in serum 17β-estradiol level and enhanced femoral BMD in OVX mice. Oral administration of CSE and linarin attenuated TRAP activity and expression of αβ integrins and carbonic anhydrase II elevated in femoral bone tissues of OVX mice. In addition, CSE and linarin curtailed bone levels of cathepsin K and matrix metalloproteinase-9 responsible for osteoclastic bone resorption. These findings showed that CSE and linarin inhibited lacunar acidification and bone matrix degradation in the osteoclast-bone interface. Further, supplementing CSE, acacetin or linarin to OVX mice elevated formation of collagen fibers in OVX trabecular bones, evidenced by Masson's trichrome staining. Accordingly, the presence of CSE and linarin inhibited bone resorption accelerated by surgical estrogen deficiency along with increased bone matrix formation.

Conclusions: CSE rich in linarin effective in retarding osteoclast function and active bone resorption and promoting bone formation and matrix mineralization may be a natural compound targeting against postmenopausal osteoporosis and pathological osteo-resorptive disorders.

Keyword: Acacetin, Cirsium setidens, linarin, ovariectomy, postmenopausal osteoporosis

Dietary ferulic acid suppresses body fat accumulation via induction of beige adipocyte formation and cyclodextrin inclusion ferulic acid improves bioavailability in mice.

Jumpei Tanaka[1], Sana Yamashita[1], Takanori Tsuda[1]

1. Chubu University (Japan)

Background and objective: It has been reported that dietary ferulic acid (FA) significantly suppressed body fat accumulation, despite its poorly soluble in water and low oral bioavailability [1]. However, molecular mechanism of this effect remains unclear. We hypothesized that anti-obesity by dietary FA is due to

induction of beige adipocyte formation. In addition, highly water soluble and bioavailable FA formulation would be able to obtain FA-mediated various biological function even at low doses. Several reports indicated that cyclodextrin (CD) inclusion complex can enhance its oral bioavailability [2]. Therefore, CD inclusion FA (CD-FA) can be expected to induce beige adipocyte formation even at low doses. According to these backgrounds, the aim of this study is to demonstrate induction of beige adipocyte formation by dietary FA, evaluation of bioavailability of CD-FA, and dietary CD-FA-mediated beige adipocyte formation at low doses.

Methods: 1) Five-week-old male C57BL/6J mice were assigned to four different groups: control diet group, control diet supplemented with 0.2, 0.5, or 1.0 % FA groups (0.2FA, 0.5FA and 1.0FA) for 4 weeks. After 4 weeks, blood and adipose tissue samples were collected. 2) Mice received single oral doses of native FA or CD-FA by intragastric intubation. Blood and inguinal white adipose tissue (iWAT) samples were collected at 15, 30, 60, 120 and 240 min after loading. FA concentration in plasma and iWAT were determined.

Results: Overall weight gain as well as WAT weight significantly decreased in the 1.0FA group relative to the control. Dietary FA (0.5 and 1.0FA groups) significantly induced beige adipocyte formation in iWAT in mice. Both total (free and conjugated form) and free form of FA in plasma concentration were significantly elevated after CD-FA compared with these of native FA. **Conclusions:** Dietary FA significantly induces beige adipocyte formation in iWAT and contributes suppression of body fat accumulation. CD-FA significantly improves low bioavailability of native FA. We are continuing to examine whether CD-FA induces beige adipocyte formation even at low doses.

Is lactate an exercise-replacement food-derived factor? Investigation from stimulation of TGFβ2 secretion and induction of beige adipocyte formation

Nana Esaki[1], Misaki Inaba[1], You Miyazaki[1], Takanori Tsuda[1]

1. Chubu University (Japan)

Background and objective: Lactate has long been considered a waste product of anaerobic metabolism. However, recent studies indicate that lactate is an important signaling molecule that regulates various metabolic processes in the body. Furthermore, the exercise-induced production of lactate is reported to stimulate the secretion of transforming growth factor-beta 2 (TGFβ2) from white adipose tissue (WAT), leading to the suppression of body fat accumulation [1]. In addition, we recently demonstrated that the intake of an amino acid mixture combined with exercise synergistically induced beige adipocyte formation in inguinal WAT (iWAT), which was associated with a significant elevation of plasma lactate levels [2]. According to these findings, we hypothesized that the oral intake of lactate would provide various exercise-related benefits in the absence of exercise. Therefore, the aim of this study was to examine whether lactate intake stimulates TGFβ2 secretion and beige adipocyte formation.

Methods: Five-week-old male C57BL/6J mice were allowed to ingest sterilized water or 100 mM sodium L-lactate solution ad libitum. After 4 weeks, plasma and WAT were collected. C3H10T1/2 cells were differentiated into beige adipocytes and then treated with lactate and/or *N*-acetylcycteine (NAC). After treatment, reactive oxygen species (ROS) production and uncoupling protein 1 (UCP1) mRNA levels were determined.

Results: Lactate intake did not significantly increase plasma TGFβ2 levels, despite the increase in plasma lactate levels. However, lactate significantly induced beige adipocyte formation in iWAT. Lactate significantly induced the expression of the lactate transporter MCT1 and lactate dehydrogenase B (LDHB). These data suggest that lactate incorporated via MCT1 is metabolized into pyruvate by LDHB, which would increase the $NADH:H^+/NAD^+$ ratio and ROS production. Lactate treatment significantly induced ROS production and UCP1 expression in differentiated C3H10T1/2 cells, which were significantly suppressed by treatment with NAC.

Conclusions: Lactate intake induces beige adipocyte formation. ROS function as a second messenger of lactate and are involved in the induction of beige adipocyte formation. Lactate may be used as an exercise-replacement food-derived factor.

Keyword: lactate, TGFβ2, beige adipocyte

Combination of exercise and intake of β-conglycinin synergistically induces beige adipocyte formation in mice

Teruto Kato[1], Taisei Kitamura[1], Takanori Tsuda[1]

1. Chubu University (Japan)

Background and objectives: Soy protein contains about 20 % of β-conglycinin (β-Con). It has been reported that a significant suppression of body fat accumulation was observed when the protein source was only β-Con [1]. Several published reports have shown that exercise (EX) induces the development of beige adipocytes in white adipose tissue (WAT) [2]. Based on these findings, it is likely that a combination of food-derived factors and EX may effectively induce beige adipocyte formation in WAT, thus contributing to body weight control or providing other EX-mediated health benefits. In addition, it may be difficult to ingest only soy protein as the entire protein source for nutrition for

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

many people. Accordingly, we hypothesized that the combination of EX and intake of soy protein synergistically induces beige adipocyte formation. Therefore, the aim of this study is to examine whether intake of protein partially replaced by β-Con combined with EX significantly induces beige adipocyte formation, as well as to clarify possible mechanisms by which β-Con combined with EX induce beige adipocyte formation.

Methods: Five-week-old male C57BL/6J mice were assigned to one of four groups: sedentary control (AIN-93G based diet), sedentary control + 50β-Con diet (Half of the protein sources in the diet were β-Con), EX (AIN-93G based diet), and EX + 50β-Con diet (Half of the protein sources in the diet were β-Con). After 4 weeks, adipose tissue and liver were collected.

Results: 50β-Con diet combined with EX for 4 weeks synergistically induced beige adipocyte formation compared with 50β-Con or EX alone in mice. Plasma FGF21 concentration and the mRNA level was significantly increased in EX + 50β-Con group. Furthermore, activating transcription factor 4 (ATF4), which is one of the triggers of upregulation of FGF21 expression was also significantly increased in EX + 50β-Con group.

Conclusions: 50β-Con combined with EX synergistically induced beige adipocyte formation in association with ATF4-FGF21 signaling in the liver. Our findings suggest that it is not necessary to ingest all protein source from only soy protein in order to expect induction of beige adipocyte formation.

Anti-aging effects of constituents in *Moringa oleifera* Leaves

Miki Matsue[1], Katsuya Maruoka[2], Yoshitaka Fujita[3], Akiyoshi Sawabe[1,2]

1. Graduate School of Agriculture, Kindai University (Japan), 2. Faculty of Agriculture, Kindai University (Japan), 3. Oji Foods Inc., Ltd. (Japan)

Background and objects: The people have an interest for health, and cosmetics market and the health food market accomplish sudden growth. Also, the use of the natural system material in behalf of the synthetic pathway material by the naturalism point is demanded. The search of these new materials becomes the important research theme. Therefore we search for an ingredient derived from nature for the purpose of the anti-aging. In this study, we examined the anti-aging effects (AGEs inhibitory activity) in the leaves of *Moringa oleifera*.

Methods: As a means to evaluate anti-glycation, we conducted the AGE inhibition test. Remarkable inhibitory active substance in the leaves of Moringa oleifera was separated by gel filtration and silica gel column chromatography.

Results: Six compounds were isolated from the leaves of *Moringa oleifera*, and their structures were established on basis of MS and NMR spectroscopy. They were 1-(4'hydroxyl-3'-methoxyphenyl)-2-{2-menthoxy-4-[1-propen-3-*O*-glucopyranosyl]-phenoxy}-propan-1,3-diol 1, 4'-Acetyl-niazirin 2, niazirin 3, kaempferol 3-*O*-glucopyranoside 4, quercetin 3-*O*-glucopyranoside [5] and 4-rhamnopyranosiloxy phenyl carbamate [6] . As a result, compounds 1 -5 showed high AGEs inhibitory activity.

Conclusions: As for compounds and extracts, it might be used in general as supplement and food additives to take every day.

Keyword: Moringa oleifera, AGE inhibitory activity, anti-glycation, food additives, supplement

PAB(T7-76)
A Change Point Regression Model for Treatment Effects Estimation of Functional Foods in a Pre-Post Design

Kohsuke Hayamizu[1], Shiori Kobuna[1]

1. Yokohama University of Pharmacy (Japan)

Background and Objective: In an intervention study for functional foods, the study population is often a mixed group of healthy individuals and/or those who are not so healthy but are not definitely disease. This is one of the major differences between using pharmaceuticals and functional foods. However, statistical analysis of human trials involving healthy and disease-bordering individuals requires stratified analysis, which is problematic in terms of increased sample size and higher study costs. For such heterogeneous populations, we propose an alternative approach for evaluating the efficacy of dietary supplements and functional foods based on a change point regression model (CPRM).

Methods: CPRM: Consider the following CPRM for between-group comparisons of RCT,

$$y_i=\alpha+b_1x_i+b_2I(x_i x_{cp})(x_i<x_{cp})g_i+e_i \ (\ i = 1,2,3,\ldots,n\ )$$

where n is the number of participants, y_i is the observation at the study's end of participant i or the change from baseline after treatment, x_i is the observation at baseline of participant i, x_{cp} is a constant, g_i is the group indicator (control = 0; treatment = 1), and $I(\cdot)$ is an indicator function defined as $I(x_i<x_{cp}) = 1$, if $x_i \geqq x_{cp}$ and as 0 otherwise. The proposed method was applied to skeletal muscle ratio study data, and the merit of the proposed method was demonstrated by comparing it with the conventional method.

Results: Applied to the skeletal muscle ratio study data, the results showed that the CPRM was indicated more fitting to data and power of statistical analysis was stronger than the conventional method. And, the CPRM also provides useful information, change-point as efficacy appearance point.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusion: We have proposed a new approach for the efficacy evaluation of dietary supplements or functional foods based on a CPRM. By using AIC-based profile likelihood methods, inferences can easily be made with standard statistical software. The proposed method was applied to the s skeletal muscle ratio study data, and the merit of the method was demonstrated by comparing it with the conventional method.

Impact of fish oils and/or probiotics on serum CathepsinD in pregnancy

Kirsi Laitinen[1,2], Kati Mokkala[1], Johanna Gustafsson[1], Tero Vahlberg[1], Anita CE Vreugdenhil[3], Lingling Ding[3], Ronit Shiri-Sverdlov[3], Jogchum Plat[3]

1. University of Turku (Finland), 2. Turku University Hospital (Finland), 3. Maastricht University (Netherlands)

Background and objectives : Serum CathepsinD (CatD) has been proposed as a new marker for liver inflammation. Overweight and obese pregnant women as well as those with gestational diabetes mellitus (GDM) have a higher risk for developing metabolic inflammation and nonalcoholic fatty liver disease. The objective was to investigate whether supplementation with probiotics and fish oil separately or in combination, would exert any effect on CatD concentrations during pregnancy, and whether the effect is GDM dependent.

Methods: Overweight/obese pregnant women (n=438) were randomized into fish oil+placebo, probiotics+placebo, fish oil+probiotics or placebo+placebo groups. Fish oil contained 1.9 g docosahexaenoic acid and 0.22 g eicosapentaenoic acid and probiotics were *Lacticaseibacillus rhamnosus* HN001 (formerly *Lactobacillus rhamnosus* HN001) and *Bifidobacterium animalis ssp. lactis* 420, 10^0 colony-forming units each. Serum CatD levels were analysed by ELISA at early and late pregnancy. GDM was diagnosed by OGTT.

Results: CatD concentrations did not differ among the intervention groups or by GDM status. The CatD concentrations decreased from early to late pregnancy in the fish oil group (-37.8±121.5 ng/ml; p=0.004) and in the probiotic group (-41.5±105.6 ng/ml; p<0.001), but not in the combined intervention group (-13.4±161.9 ng/ml; P=0.434) or in the placebo group (-1.4±125.9 ng/ml; p=0.901).

Conclusion: The serum CatD concentration of pregnant women was not modified by this dietary intervention. A decrease in CatD concentrations due to the consumption of either probiotics or fish oil supplements, but not the combination, was seen, an observation that deserves further investigation.

Antihyperglycemic effect of cardamom through promotion of glucose uptake in skeletal muscle cells

LiYuan Fang[1], Ken-yu Hironao[1], Yoko Yamashita[1], Hitoshi Ashida[1]

1. Kobe University (Japan)

Objectives: Diabetes is a metabolic disease with high incidence in the world. Many studies have shown that spices have multiple biological regulatory functions, including preventing hyperglycemia. In our previous report, we prepared the hot-water washed ethanol extract from 24 kinds of spices and measured the glucose uptake activity in L6 myoblasts and found that nutmeg, turmeric, cardamom and pepper showed significant increase in the glucose uptake activity. In this study, we focused on cardamom and tried to isolate and identify the effective compound that can promote the glucose uptake activity in L6 myotubes. We also carried out an oral glucose tolerance test in mice to verify the anti-hyperglycemic effect of the extract.

Methods: Isolation of the effective fraction was performed by solvent partition and HPLC. Identification of the effective compound and its chemical structure was investigated by instrumental analyses. Cardamom extract, its fractions and isolated compound were subjected to measurement of the glucose uptake activity by enzymatic 2DG uptake assay.

Results: When the ethanol extract of cardamom was step-wisely separated by solvent partition using hexane, ethyl acetate, chloroform, butanol, and water, the ethyl acetate and chloroform fractions significantly promoted glucose uptake. The ethyl acetate fraction was orally given to mice and performed oral glucose tolerance test to confirm its effect on preventing hyperglycemia. Then, the ethyl acetate fraction was applied to HPLC and separated four sub-fractions. It was found that Fr. 3 promoted glucose uptake. This fraction was further separated ten fractions by HPLC. Of these, it was found that Fr. A-g, Fr. A-h and Fr. A-i promoted glucose uptake in L6 myotube cells. From UV-scanning data, these sub-fractions may contain terpenoids and flavonoids. Further isolation and identification of the effective compounds are in progress.

Conclusion: The ethyl acetate fraction from the ethanol extract of cardamom prevented postprandial hyperglycemia. This fraction may contain several effective compounds including terpenoids and flavonoids and these effective compounds may contribute to prevention of hyperglycemia.

Bioavailability of maltobionic acid, newly developed nondigestible oligosaccharide, in humans

Kenichi Tanabe[1], Asuka Okuda[2], Sadako Nakamura[2], Tsuneyuki Oku[2]

1. Nakamura Gakuen University (Japan), 2. Jumonji University (Japan)

Background and objectives: Maltobionic acid (MA), formed by a gluconic acid and glucose linked by α-1,4 bond, may have the property of a nondigestible oligosaccharide. The objective of this study is to elucidate the bioavailability of MA in humans by observing digestion and absorption of MA, excretion rate to urine, and the fermentation of MA by gut microbiota.

Methods: Experiment1: Observation of digestibility of MA; A within-subject repeated measures design was used for experiments with 10 healthy females. After participants ingested the equivalent of 10 g of MA dissolved in 200 ml of safely distilled water, blood was collected by puncturing a fingertip: before ingestion and 30, 60, 90, 120, 150, and 180 min after ingestion of the test material. Urine was collected by asking participants to pass urine before ingestion and at 4 and 8 h after ingestion. Plasma glucose concentration was measured using the glucose oxidase method. Insulin concentration was measured using the ELISA method. MA in urine was measured using HPLC. Experiment 2: Observation of fermentability of MA; A within-subject repeated measures design was used for experiments with 11 healthy females. For the test, participants ingested the equivalent of 5 g of MA or 5 g of fructooligosaccharide dissolved in 150 ml of safely distilled water. After ingestion of the test material, end-expiratory gas was collected at 1-h intervals for 8 h and at 2-h intervals until 14 h to measure breath hydrogen. The breath hydrogen concentration was measured using gas chromatography, and the area under the curves (AUCs) was calculated 0–14 h after ingestion.

Results: Ingestion of 10 g of MA did not elevate postprandial plasma glucose and insulin levels. The urinary excretion of MA was very small amounts. These results demonstrate that MA is negligibly digested and absorbed in the small intestine. Compared with the AUCs of breath hydrogen excretion for 14 h related to the ingested fructooligosaccharide, MA was 23.1%.

Conclusions: MA is highly resistant to digestion and fermentation. It expresses the characteristics of a nondigestible oligosaccharide, including being low energy.

Intact and glucuronidated flavonoid metabolites can promote NO production in HUVECs

Tint Ni Ni Tun[1], Guanzhen Gao[1], Ayano Soma[1], Toshiro Matsui[1], Yosuke Nishitani[2], Hiroyuki Kayaki[2], Hideaki Kawakami[2]

1. Kyushu University (Japan), 2. Maruzen Pharmaceuticals Co., Ltd. (Japan)

Background and objectives: A target compound, 3-(4-hydroxy-3-methoxyphenyl) propionic acid (HMPA), is a metabolite that is produced from flavonoids in the gut by microbiota. In this study, to clarify the physiological roles of HMPA and its possible metabolic forms in blood, we investigated their ability to produce nitric oxide (NO), a vasorelaxant trigger for preventive hypertension, in human umbilical vein endothelial cells (HUVECs).

Methods: HUVECs were cultured in EBM-2 medium using a bullet-kit containing growth factors and incubated at 37°C in a 5 % CO_2 incubator. Cells at the fourth passage were seeded in 24-well plates at a density of 5×10^4 cells. The NO assay was performed in the presence or absence of inhibitors regarding incorporation routes such as monocarboxylic acid transporter (MCTs) and organic anion transporting polypeptides (OATPs), by fluorometric NO assay kit (E_x/E_m: 360 nm/460 nm).

Results: Among the three targeted HMPAs, i.e., HMPA, glucuronidated HMPA (HMPA-GlcA), and sulfated HMPA (HMPA-S), HMPA and HMPA-GlcA showed a significant increase of NO level in HUVECs production at 1 μM concentration for 24 h-incubation: HMPA, 210 ± 18%; HMPA-GlcA, 194 ± 13% *vs. control,* $p < 0.05$). In contrast, HMPA-S conjugate form had no power to increase NO production, indicating that not only HMPA skeleton, but also glucuronic acid moiety may stimulate NO signaling cascades. The evidence that MCT and OATP inhibitors significantly ameliorated the NO promotion by HMPA and HMPA-GlcA strongly suggested that both HMPA and HMPA-GlcA was incorporated into cells to exert NO production.

Conclusions: The present results demonstrates that a flavonoid metabolite HMPA and its metabolic conjugate HMPA-GlcA are a novel NO promotor by incorporating into HUVECs.

Metabolic behavior of soybean protein glycinin in rat bloodstream by a coumarin-tagged MALDI-MS analysis

Risa Katagihara[1], Xiaojing Sheng[1], Satoshi Nagaoka[2], Mitsuru Tanaka[1], Toshiro Matsui[1]

1. Kyushu University (Japan), 2. Gifu University (Japan)

Background and objectives: Metabolic behavior of dietary proteins in the body system remains unascertained. In this study, soybean glycinin was orally administered to Sprague-Dawley (SD) rats to clarify the metabolic fragments in the bloodstream. To achieve the overall identification, we tried to establish a highly sensitive and selective detection method by a matrix-assisted laser desorption/ionization-mass spectrometry (MALDI-MS), in combination with several amine derivatization techniques.

Methods: For the optimization of MALDI-MS measurement, synthetic oligopeptides containing sarcosine (*N*-methyl-Gly, S) [GSS, GSSS, and GSSSS ($[M + H]^+$ = 218.1, 289.1, and 360.2 *m/z*, respectively)] were used in this study. Identification of metabolic fragments in glycinin-administered (100 mg/kg) SD rat plasma was conducted with the proposed MALDI-MS in a positive ionization mode.

Results: Synthetic oligopeptides were subjected to amine derivatizations, using either 3-aminopyridyl-*N*-hydroxysuccinimidyl carbamate (APDS), 2,4,6-trinitrobenzenesulfonic acid (TNBS), or 7-*O*-methyl-3-coumarin (Cou). Among the amine derivatizations, Cou-derivatization (30 mmol/L, 30 min, 25 ℃, pH 8.5) caused successful MALDI-MS detection of peptides by Cou-tagged mass increment of +202.0 *m/z*, while no detections of APDS- and TNBS-tagged oligopeptides were observed. Sensitive detection of oligopeptides (> 5 pmol/spot) was confirmed when DHB (10 mg/mL) was used as a matrix agent. With the aid of the proposed Cou-tagged MALDI-MS method, 15 characteristic MS signals corresponding to di- to tetrapeptides in glycinin sequence were observed in glycinin-administered plasma collected at 0.5 to 8 h (e.g., AI, LIV, YSPY).

Conclusions: By applying the proposed highly selective and sensitive Cou-tagged MALDI-MS method, it was demonstrated that the oral intake of soybean glycinin resulted in a production of a variety of oligopeptides in rat bloodstream.

Carotenoid transporter CD36 expression depends on HIF-1α under normal physiological conditions in soleus muscles of mice

Tomoya Kitakaze[1,2], Takashi Sugihira[2], Hiromichi Kameyama[2], Asami Maruchi[2], Naoki Harada[1,2], Ryoichi Yamaji[1,2]

1. Osaka Metropolitan University (Japan), 2. Osaka Prefecture University (Japan)

Background and objectives: Skeletal muscles play critical roles in physical activities, such as postural maintenance and locomotion, as well as regulating energy metabolism throughout the body. Dietary β-carotene induces muscular hypertrophy and prevents atrophy in red slow-twitch soleus muscles, but not in white fast-twitch extensor digitorum longus (EDL) and gastrocnemius muscles.[1,2] However, it remains unclear why these beneficial effects of β-carotene are elicited in the soleus muscles. In this study, we focused on the expression levels of carotenoid transporters in red and white muscles to elucidate the mechanism underlying the beneficial effects of β-carotene on soleus muscles.

Methods: C57BL/6J mice were orally administered micellar β-carotene, and small interfering RNA (siRNA) targeting *Cd 36* was transfected into their hind limb muscles. To evaluate hypoxic levels in the muscles, the hypoxia marker pimonidazole was injected into the tail veins of mice. CD36 expression in murine C2C12 myotubes was evaluated.

Results: *Cd 36* mRNA levels were higher in the red muscle than in the white muscle of mice. The *Scarb1* and *Npc1l1* mRNA levels were not significantly different between the soleus and EDL muscles. siRNA-mediated knockdown of CD36 decreased β-carotene uptake in C2C12 myotubes. In soleus muscles, CD36 knockdown inhibited the β-carotene-induced increase in soleus muscle mass. Intravenous injection of pimonidazole produced more pimonidazole-bound proteins in soleus muscles than in EDL muscles. Hypoxia-inducible factor-1α (HIF-1α) protein levels were higher in soleus muscles than in EDL muscles. In C2C12 myotubes, hypoxia increased the CD36 expression at both the mRNA and protein levels. Consequently, HIF-1α knockdown reduced *Cd36* mRNA levels in C2C12 myotubes as well as soleus muscles.

Conclusions: CD36 is predominantly involved in the β-carotene-induced increase in soleus muscle mass in mice. CD36 expression depends on HIF-1α in the soleus muscles of mice even under normal physiological conditions.

Degranulation of RBL-2H3 cells is synergistically inhibited by the combination of nobiletin and lactoferrin

Takeaki Okamoto[1], Kaho Miyake[2], Mamoru Tanaka[2]

1. Ehime University (Japan), 2. Chubu University (Japan)

Background and objectives: We have previously shown that a methanol extract of Shikuwasha (*Citrus depressa* Hayata) leaves and peel had a strong inhibitory effect on the allergic response. However, the suppressive effect of Shikuwasha may be modulated by food consumed at the same time. Thus, knowledge of the effects of a combination of Shikuwasha and other food ingredients is needed. The aim of this study was to elucidate the anti-allergic effect of polymethoxyflavonoids (PMFs), which are abundant in Shikuwasha leaves and peel, in combination with milk proteins, and the inhibitory mechanism.

Methods: The rat basophilic leukemia cell line RBL-2H3 was exposed to the PMFs nobiletin (NOB), tangeretin (TNG), and sinensetin (SNT) and the milk proteins lactoferrin (LF) and β-lactoglobulin (β-LG), and β-hexosaminidase was used as an indicator of degranulation inhibition. Then, we examined the effect of co-stimulation of the two factors that showed the strongest degranulation inhibition effect in the PMF and milk protein groups, and investigated the mechanism of action by measuring the intracellular Ca^{2+} concentration, and western blot analysis.

Results: The strongest degranulation inhibitors were NOB in the PMF group and LF in the milk protein group. Co-stimulation with NOB and LF showed stronger degranulation inhibition than with NOB or LF alone. Western blot analysis showed that co-stimulation with NOB and LF significantly downregulated the induction of Akt phosphorylation (p<0.05).

Conclusions: The degranulation response in RBL-2H3 cells was synergistically suppressed by co-stimulation with NOB and LF acting on both Ca^{2+}-dependent and Ca^{2+} independent pathways.

Impact of *Nopalea cochenillifera* on the intestinal environment and immune function in mice

Mamoru Tanaka[1], Hana Kozai[1], Ayaka Koida[1], Takanori Horibe[1]

1. Chubu University (Japan)

Background and objectives: Kasugai City, Aichi Prefecture, is Japan's largest producer of seedling cacti, and cacti have been used to revitalize the city. In recent years, the Chubu University Cactus Science Society has been established to conduct research on cacti from various perspectives. The Uchiwa cactus (*Nopalea cochenillifera*) is rich in cellulose, hemicellulose, and water-soluble viscous polysaccharides, and has been reported to have various effects on lipid metabolism and have antioxidant activity. The aim of this study was to determine the effects of *N. cochenillifera* on the intestinal environment and immune function. Methods: Five-week-old female BALB/c mice were divided into three groups (n = 8): the C group received AIN-93G as a control diet and the 5% and 10% groups received AIN-93G supplemented with 5% or 10% *N. cochenillifera* respectively. The mice were fed for 28 days. Blood and feces were collected from each group of mice every 7 days. On day 28, in addition to blood and feces, the small intestine, cecum, and large intestine were collected. The cecum content weight, cecum content pH, and fecal mucin were examined to evaluate the intestinal environment. The serum total IgM and total IgG, and fecal total IgA were measured to evaluate the immune function. Results: The dry fecal weight increased with the addition of *N. cochenillifera* beginning on day 7 and increased 1.3-fold in the 5% group, and 1.5-fold in the 10% group, over the entire experimental period. The cecum content pH was significantly decreased in the 5% and 10% groups compared with group C (p > 0.05). Serum antibody levels (total IgM) were significantly decreased on days 14 and 21 in the 10% group, compared with the C and 5% groups (p > 0.05). In contrast, the total IgG levels were increased significantly in the 5% and 10% groups, compared with the C group, at all time points (p > 0.05). The fecal mucin content and total IgA are currently under investigation.

Conclusions: The results suggested that *N. cochenillifera* ingestion regulates the intestinal environment and improves systemic immune function, mainly by increasing IgG levels, in mice.

PAB(T7-85)
Mogrol derived from *Siraitia grosvenorii* activates the bile acid receptor TGR5 and suppresses hyperglycemia in high-fat diet-fed KKAy mice

Chisato Tanaka[1], Hiroki Urushizaki[1], Yoshiaki Teraoka[1], Tomoya Kitakaze[1,2], Yuta Ito[3], Yuji Murata[3], Takashi Inui[1,2], Hiroshi Inui[1,2,4], Naoki Harada[1,2], Ryoichi Yamaji[1,2]

1. Osaka Prefecture University (Japan), 2. Osaka Metropolitan University (Japan), 3. Saraya Co., Ltd. (Japan), 4. Otemae University (Japan)

Background and objectives: Mogrosides, a group of cucurbitane-type triterpene glycosides, from *Siraitia grosvenorii* are natural sweetener and have various physiological functions such as antidiabetic effect. Mogrol is an aglycone of mogrosides and is the major form absorbed by the body following ingestion of mogrosides. However, the effect of mogrol on the prevention

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of type 2 diabetes has not been elucidated. TGR5 is a G protein-coupled receptor responsive to bile acids. TGR5 is widely expressed the body including pancreatic β-cells and plays a key role in glucose metabolism. Here, we focused on the structural similarity between mogrol and bile acids and examined whether mogrol activated TGR5. We further investigated the antidiabetic effects of mogrol using mice of diabetes mellitus.

Methods: HEK293FT cells were transiently transfected with human TGR5 expression vector and p4xCRE-Luc2P reporter vector, and stimulated with mogrol (50 μM) for 4 h. Five-week-old male C57BL/6J mice or KKAy mice were fed with a standard chow or a high-fat diet (HFD) for 5 weeks. Mice were divided into 4 groups: (i) C57BL/6J were fed a standard chow, (ii) KKAy were fed an HFD, (iii) KKAy were fed an HFD containing 0.01% mogrol, and (iv) KKAy were fed an HFD containing 0.05% mogrol.

Results: We found that mogrol, but not mogrosides, activated TGR5 in HEK293FT cells. We predicted the key amino acid residues of TGR5 that interact with mogrol using *in silico* docking simulation. We then evaluated a series of individual alanine mutants of TGR5 and found that W75 and R80 residues were important for interaction with mogrol, but not deoxycholate. We investigated the antidiabetic effects of mogrol. Mogrol had no effects on body weight or the relative weights of liver, subcutaneous and mesenteric white adipose tissue, or gastrocnemius and quadriceps muscles. Mogrol prevented hyperglycemia and ameliorated glucose tolerance both oral glucose and intraperitoneal glucose tolerance tests in a dose-dependent manner, whereas it did not affect insulin tolerance. Mogrol increased plasma insulin levels in a dose-dependent manner, suggesting that mogrol suppressed pancreatic β-cells dysfunction.

Conclusions: Our results show that mogrol activated TGR5 and suppressed hyperglycemia in HFD-fed KKAy mice.

Keyword: Mogrosides, G protein-coupled receptor, diabetes, sweetener, bile acids

The ability of phospholipids extracted from egg yolk and soybean: lipid regulation and intestinal protection

Mingyu Yin[1], Ryosuke Matsuoka[1], Yinci Xi[1], Xichang Wang[1]

1. Shanghai Ocean University (China)

Background and objectives: High-fat-and-sugar diets, which are responsible for abnormal lipid metabolism and disruption of the structure of the intestinal ecosystem, have become a common dietary habit. Phospholipids are used to treat chronic diseases such as cardiovascular and cerebrovascular diseases. Phospholipids derived from egg yolks and soybean have significant antioxidant and hypolipidemic abilities.

Methods: This study was to investigate the role and mechanism of egg yolk phospholipids and soybean phospholipids in improving HFD-induced obesity, intestinal short-chain fatty acids and intestinal bacterial structure in rats.

Results: The results showed that PLs reduced liver weight, liver TG and MDA levels, as well as serum ALT, AST, TBA and CRP levels. PLs also showed hypolipidemic and anti-inflammatory effects. Histological examination showed that ingestion of PLs improved liver tissue damage. EPLs increased the decrease in HFD-induced SCFAs and increased acetic acid, propionic acid, isobutyric acid and total SCFAs, thus effectively regulating the environment of intestinal microbial metabolism. In addition, EPLs decreased the ratio of *Firmicutes Bacteria* and the relative abundance of *Streptomyces*, *Arthrobacter* and *Desulfovibrio*, and increased the relative abundance of *Mucor* and *Cellulose bacteria*.

Conclusions: These results suggest that PLs have a good regulatory role in HFD-induced intestinal disease, and the therapeutic benefits of EPLs tended to be more effective than that of SPLs.

Keyword: Phospholipids, Obesity, Gut microbiota, Short-chain fatty acid

Pyrroloquinoline quinone attenuates fat accumulation in obese mice fed with a high-fat diet, *Daphnia magna* supplied with a high amount of food, and 3T3-L1 adipocytes

Nur Syafiqah Mohamad Ishak[2], Kazuhito Ikemoto[2], Midori Kikuchi[2], Mariko Ogawa[3], Kazeno Akutagawa[3], Mitsugu Akagawa[1]

1. Tokushima University (Japan), 2. Mitsubishi Gas Chemical Company Inc. (Japan), 3. Osaka Prefecture University (Japan)

Background and objectives: Obesity is a global health concern resulting from an increase in the consumption of high-energy diets that causes abnormal or excessive fat accumulation in the body. Obesity is often associated with various diseases, such as cardiovascular disease, type 2 diabetes, inflammation, and cancer. Without efficient treatment, an estimated one quarter of the global adult population will be overweight by 2030. However, currently available fat-loss drugs elicit multiple toxic side effects. Pyrroloquinoline quinone (PQQ), a redox-active o-quinone found in various foods and mammalian tissues, has received an increasing amount of attention because of a number of health benefits that can be attributed to its ability to enhance mitochondrial biogenesis. Supplementation with PQQ may help prevent obesity by suppressing body fat accumulation. In the current study, we examined the effect of dietary PQQ on the inhibition of fat accumulation in obese mice, *Daphnia magna*, and adipocyte cells.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods and results: Our results revealed that oral PQQ supplementation significantly reduced the accumulation of body fat, particularly that of the visceral fat in the abdominal region in high-fat diet-fed male mice. In *Daphnia*, body fat and body length increased with higher amounts of food; however, PQQ reduced body fat without affecting body growth. PQQ attenuated body fat accumulation under both high-fat and high-calorie consumption conditions. In differentiated 3T3-L1 adipocytes, PQQ increased phosphorylation of AMP-activated protein kinase (AMPK), which is a critical regulator of cellular lipid metabolism and functions as a important regulator of mitochondrial biogenesis, subsequently suppressing lipogenesis. PQQ also promoted mitochondrial biogenesis by inducing the nuclear translocation of peroxisome proliferator-activated receptor-γ-coactivator 1α (PGC1α), which is a master transcription regulator that stimulates mitochondrial biogenesis, in fat cells.

Conclusions: Dietary PQQ could prevent obesity by reducing body fat accumulation via suppressing lipogenesis and promoting mitochondrial biogenesis.

PAB(T7-88)
Polyphenol-rich extract from black soybean seed coat ameliorates high-fat diet induced obesity and abnormal feeding rhythm

Ken-yu Hironao[1], Hitoshi Ashida[1], Yoko Yamashita[1]

1. Kobe University (Japan)

Background and objectives: Healthy mice are nocturnal and mainly feed during the dark period, but high-fat diet (HFD) disrupts the daily feeding rhythm and leads to obese. The abnormal feeding rhythm causes obesity through hypothalamic inflammation. We have previously found that polyphenol-rich extract from black soybean seed coat (BE), which contains mainly flavan 3-ols and anthocyanins, suppresses obesity in HFD fed mice. However, the effect of BE on feeding rhythm is not fully understood. The objective of this study is to clarify whether the anti-obesity effect of BE is due to amelioration of the HFD-caused abnormal feeding rhythm.

Methods: C57BL/6J male mice were kept in 12 h-light/dark cycle, and fed a standard diet (SD), HFD, and HFD supplemented with BE at 2% (w/w) for 4 weeks. Body weight and food intake during the light and dark periods were measured throughout the experiment. Expression of inflammation related-factors in the hypothalamus and adipose tissue were evaluated in the mice at the end of the experiment. To find the active compound, BE was separated to three fractions (monomeric flavan 3-ols, procyanidins, and cyanidin 3-O-glucoside) and supplemented them to HFD with 0.5% (w/w) each for 4 weeks. Then, food intake and hypothalamic inflammation were measured.

Results: The SD group mainly fed the diet during the dark period and less during the light period. On the other hand, the HFD group disrupted the diurnal feeding rhythm with the light period hyperphasia, and increased body weight and fat accumulation. BE ameliorated the intake pattern in HFD group close to the SD group. In the HFD group, inflammation in the hypothalamus and adipose tissue was occurred in both acute and chronic stages, while the intake of BE prevented it. Among polyphenols in BE, cyanidin 3-O-glucoside was effectively ameliorated the abnormal feeding rhythm, obesity, and hypothalamic inflammation in HFD-fed mice.

Conclusions: Results from this study provided a novel mechanism in the anti-obesity effect of BE: that the intake of BE prevented HFD-caused hypothalamic inflammation and abnormal feeding behavior, especially inhibiting hyperphasia in the light period. Cyanidin 3-O-glucoside in BE was suggested to be the most effective compound.

Comparative investigation of the effects of beef-tallow and cottonseed oil diets on colonic luminal environment including the ALP activity in rats fed fructo-oligosaccharides

Yuki Nakaya[1], Tetsuyuki Katayama[2], Yukako Okazaki[1]

1. Fuji Women's University (Japan), 2. Institution of Life Sciences and Nutrition (Japan)

Background and objectives: We recently reported that fermentable non-digestible carbohydrates including fructo-oligosaccharides (FOS) commonly elevate colonic alkaline phosphatase (ALP) activity and the gene expression of *Alpi-1*, coding for rat intestinal ALP isozyme 1 (IAP-I), in rats fed a high-fat (HF) diet, with concomitantly elevated gut mucins and modulated gut microbiota. We also demonstrated that the elevating effect of FOS on colonic ALP activity was prominent in the lard diet groups compared with the soybean oil and corn oil diet groups. This study aims to investigate whether beef tallow or cottonseed oil diets influences the effect of oligosaccharides on colonic ALP and the luminal environment in rats.

Methods: Male Sprague-Dawley rats were fed a diet containing 30% beef tallow or cottonseed oil with or without 4% FOS for 2 weeks. Colon ALP activity, gene expression, and gut luminal variables including mucins and microbiota were measured.

Results: In the beef tallow diet groups, dietary FOS significantly elevated colonic ALP activity and the expression of *Alpi-1.* However, the cottonseed oil diet groups did not exhibit the elevating effect of FOS on colon ALP. Fecal ALP and mucins were significantly elevated by dietary FOS regardless of dietary fat types, and the effect of FOS was prominent in the beef tallow

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

diet groups. The fecal ratio of *Lactobacillus spp*. observed in fecal matter was significantly increased by dietary FOS in the beef tallow diet groups, but not in the cottonseed oil diets groups.

Conclusion: The results suggest that the elevating effect of FOS on colonic ALP activity and the gene expression, and colonic luminal variables including mucins was prominent in the beef tallow diet group compared with the cottonseed oil diet groups.

Anti-inflammatory effect and associated mechanism of djulis in HT-29 human colorectal cancer cells.

Wen-Ling Wu[1], Nien-Hsuan Lin[1], Tsai-Hsuan Ho[1], Chun-Kuang Shih[1]

1. Taipei Medical University (Taiwan)

Background and objectives: Inflammatory bowel disease (IBD) is a chronic and repetitive inflammatory disease of the gastrointestinal tract that has two major entities: Crohn's disease and ulcerative colitis. The incidence of IBD in Taiwan is increasing over the past few years. Diet plays an important role in the onset and progression of IBD. Western eating habits are closely associated with the high incidence of IBD. Djulis (*Chenopodium formosanum*) is a cereal crop native to Taiwan. Studies have confirmed that the bioactive compounds in djulis, such as betalains, rutin, chlorogenic acid and kaempferol, are directly related to its anti-inflammatory effect. The hull of djulis is usually recognized as an agricultural waste. However, recent studies have indicated that the hull of djulis contains a large amount of active compounds, which are important sources of functional components for the food and biotechnology industry.

Methods: This study investigated the anti-inflammatory effect and associated mechanism of djulis on IBD in a cell model. Whole djulis was extracted with 70% ethanol and intervened at different concentrations (0, 20, 40, 60, 80, 100 μg/mL) and time (24, 48 and 72 h) in inflammatory HT-29 human colorectal cancer cells induced by lipopolysaccharides (LPS) and tumor necrosis factor (TNF)-α. Inflammation-related proteins and cytokines were analyzed to elucidate the mechanism of djulis extracts.

Results: Low-dose (20 and 40 μg/mL) djulis extracts tended to promote cell proliferation, while high-dose (80 and 100 μg/mL) djulis extracts significantly inhibited cell proliferation. LPS- and TNF-α-induced HT-29 cells showed high expression of pro-inflammatory proteins. High-dose (100 μg/mL) djulis extract significantly decreased the expression of cyclooxygenase-2 (COX-2) and nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) compared to control group. There was no difference in COX-2 expression between high-dose and blank groups. The levels of TNF-α, interleukin (IL)-6 and IL-8 were significantly lower in high-dose (80 and 100 μg/mL) groups compared to control group.

Conclusions: These results suggest that djulis may have the potential to inhibit the development of IBD via modulating NF-κB signaling pathway.

Macro and Micro Characterization of Antioxidant Protein Hydrolysates from Hemp (*Cannabis sativa* L) seeds.

Maria del Carmen Millan-Linares[1], Alvaro Villanueva-Lazo[2], Elena Grao-Cruces[1], Maria Esther Martin-Rubio[1], Rocio Toscano Sanchez[1], Sergio Montserrat-de la Paz[1]

1. University of Seville (Spain), 2. Spanish National Research Council (CSIC) (Spain)

Background and objectives: Green industries, such as industrial agricultural hemp (*Cannabis sativa* L.), represents a new source of sustainable plant protein and bioactive peptides that can exert biological functions and promote health. The objective of this study was to obtain bioactive peptides from hemp protein hydrolysates (HPHs), to analyse their macro- and micronutrient composition and to evaluate antioxidant activity of these functional protein by-products of agri-food industry.

Methods: A hemp protein isolate (HPI), obtained from hemp defatted flour (HDF), was hydrolyzed by Alcalase and Flavourzyme enzymes, both food-grade endoproteases, under specific conditions. The resulting HPHs were chemically characterized in macro and micro-nutrients and their antioxidant capacity were evaluated by *in vitro* cell-free experiments owing to their measure of capacity to sequester DPPH free radical, β-carotene, and reducing power.

Results: Characterization and comparison of nutritional composition (macro and/or micronutrients) between all protein products showed than the chemical composition of HPHs was like HPI. Results showed that amino acid composition of the hemp protein products broadly complies with the adult requirements established by the Food and Agriculture Organization/World Health Organization/United Nations University (FAO/WHO/UNU) for indispensable dietary amino acid. Moreover, *in vitro* cell-free experiments led to the identification of two bioactive HPHs, HPH20A and HPH60A+15AF, which showed an IC50 value like positive control (BHT), in order to evaluate the hemp peptides with antioxidant activities.

Conclusions: Plant protein-based products supplemented in functional food and nutraceuticals are expected to grow considerably in the next years. Plant proteins, usually, present insufficient levels of at least one or even more essential amino acids thus limiting their biological value. However, antioxidant

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

peptides in HPHs presented a balanced amino acid profile and a digestibility higher than intact proteins, hence, these results show that HPHs could be considered as an effective option within the functional food generation and would support their use in future clinical food trials.

Effect of Fish Oil Supplementation in Preventing Paternal Obesity and Improving Offspring Metabolic Health

Akriti Shresta[1], Mariana Lugo Perez[1], Latha Ramalingam[1]

1. Department of Nutrition and Food Studies, Syracuse University, Syracuse, New York (USA)

Background: Currently in the United States, about 2 in 3 males of reproductive age are either overweight or suffer from obesity. This is critical since both animal and human studies provide strong evidence that children of obese fathers have an increased risk of obesity, regardless of mother's weight. Fish oil (FO) derived from fatty fish contains omega-3 polyunsaturated fatty acids and is beneficial in regulating body weight and lowering inflammation. FO reduces adverse effects of maternal obesity. Still unknown, however, is the role of FO consumption in paternal metabolic health and the subsequent impact on offspring. Hence, our objective is to identify mechanisms of FO that reduce paternal obesity and thereby improve metabolic health of offspring.

Methods: Male mice were fed high fat (HF) diets either with or without FO along with low fat (LF) diet for 10-weeks (preconception phase). They were then mated with a healthy female mouse to prevent effects of maternal obesity. All male and female offspring (n=12 per group) were on chow diets and followed for 16 weeks. Body weight was measured on day 1,7 and then weekly. Glucose and insulin tolerance tests were performed during the 12th week of offspring age.

Results: Body weight (BW) of fathers were comparable after 10 weeks on the respective diets. Male and female offspring born to HF fathers had higher BW on day 1 and 7 compared to offspring of LF fathers. Further, offspring of FO fathers had significantly reduced BW at these timepoints than offspring of HF fathers. Offspring BW were similar between weeks 3 - 8. Interestingly, offspring of FO fathers had reduced body weight between weeks 8-16. Offspring of HF fathers had significantly higher glucose intolerance than offspring of LF fathers, but the offspring of FO father had lower glucose intolerance than offspring of HF fathers. Lastly, offspring of FO fathers had better insulin sensitivity. Currently underway are genomic analyses of adipose tissue to better understand mechanisms.

Conclusion: These results are expected to provide strong scientific evidence for fish or FO consumption in fathers to improve their metabolic health and ultimately reduce rates of childhood obesity.

Anti-hyperglycemic effect of theaflavins in spontaneously diabetic Torii rats

Sumire Asaba[1], Chou Chihsuan[1], Lei Fu[1], Toshiro Matsui[1]

1. Kyushu University (Japan)

Background and objectives: Type Ⅱ diabetes mellitus, characterized by hyperglycemia and inadequate insulin secretion, causes mortality and morbidity. Improvement of hyperglycemia at pre−diabetic stagesis one of appropriate strategies for preventing the development of diabetes. In this regard an alternative medicinal food is acceptable to overcome these issues. According to previous finding that theaflavins, a non−absorbable condensed catechins, suppressed intestinal glucose transporters in Caco−2 cells, we tried to investigate whether theaflavins showed *in vivo* anti−hyperglycemic effect in spontaneously diabetic Torii rats. This study also investigated the underlying mechanism of the effect, using human colorectal adenocarcinoma cells.

Methods: A long−term administration of a mixture of theaflavins <25 mg/kg/day> for 20 weeks was performed to 8−week−old SDT rats. Measurements of oral glucose tolerance test and blood glucose level were performed in every 2 weeks. At the end of this protocol, glucose transporters as well as GLP−1 secretion and dipeptidyl peptidase−IV activity were examined by ELISA assays. NCI−H716 cell experiments were performed to clarify the mechanism of theaflavin−induced incretion secretion.

Results: During the 20−week protocol of theaflavin administration to SDT rats, an impaired OGTT in control group was significantly ameliorated in the theaflavin group, along with the increased insulin level and reduced BGL <0−120 min : control group, 598 ± 6 mg·h/dL; theaflavin group, 455 ± 18 mg·h/dL, $p < 0.01$>. At 28−week−old, an increased GLP−1 secretion in the jejunum membrane was observed in the theaflavin group, while no changes in glucose transporter expression and DPP−4 activity were obtained. This strongly suggested that theaflavins have anti−hyperglycemic potential *in vivo* through the incretin secretion in small intestine. The incretion secretion stimulated by theaflavins were involved in the incorporation process of theaflavins into membrane cells, leading to an AMPK activation toward GLP−1 secretion.

Conclusions: The present study demonstrated that non−absorbable theaflavins have anti-hyperglycemic potential through the AMPK−mediated GLP−1 secretion.

Cognitive benefit of breakfast combined with caffeinated coffee and malt drink (a randomized placebo-controlled double-blind crossover human study)

Mayumi Arai[1], Daisuke Harada[1], Noriko Yokoyama[1], Takahiro Ono[2], Kazuhiro Uenishi[3], Yoichi Fukushima[4]

1. Nestle Japan Ltd. (Japan), 2. Ueno Asagao Clinic (Japan), 3. Kagawa Nutrition University (Japan), 4. Daito Bunka University (Japan)

Background and objectives: Attention and memory are important cognitive functions and caffeine and glucose have been reported to improve these functions, respectively. However, information is limited when these components were consumed in regular diet. In the present study, we evaluated the effects of coffee and malt beverage, as sources of caffeine and glucose, on cognitive functions, when these consumed in breakfast.

Methods: A randomized, placebo-controlled, double-blind, crossover study was conducted in 19 healthy adult subjects (11 males and 8 females) in their 30s-40s. Test meal (259 kcal) was composed of bread rolls and salad with coffee containing 74 mg of caffeine (NESCAFÉ Excella) and a malt beverage (Nestlé MILO) containing 9.87 g of carbohydrate dissolved in 150 ml of cow's milk, or isocaloric control meal adjusted with butter and replacing from test drink to cocoa drink containing 0.75 g of carbohydrates dissolved in 150 ml of cow's milk was served as breakfast. Cognitive function test battery using Cognitrax, Uchida-Kraepelin test for simple calculation, and VAS questionnaire for sleepiness, alertness and mood were administered before and after each meal. The washout period was set for one week.

Results: The mean correct response time of part-2 of 4-part continuous performance test (FPCPT) after test meal was 26.9 ms shorter than the one after control meal ($p<0.05$). Although significant improvements were found in executive function, working memory, sustained attention, and number / time of correct responses of shifting attention test (SAT) after test meal ($p<0.05$), no increase were found after isocaloric control meal. Sleepiness, alertness and mood were also improved just after test meal ($p<0.05$).

Conclusions: A breakfast with caffeinated coffee and a malt beverage may be beneficial to improve not only sleepiness and mode but also cognitive functions, such as executive function, working memory, and sustained attention, even if doses of caffeine and glucose sources are moderate. The trial was registered with UMIN Clinical Trails Registry, number 000046600.

Diets modulate the age-dependent decline of associative learning in *Caenorhabditis elegans*

Masaru Tanaka[1,2], Sachio Tsukada[1,2], Mizuho Mohri[2], Satoshi Higurashi[1,2,3], Ikue Mori[2], Kentaro Noma[2]

1. Megmilk Snow Brand Co. Ltd. (Japan), 2. Nagoya University (Japan), 3. Bean Stalk Snow Co., Ltd. (Japan)

Background and objectives: Dietary intervention is a practical, non-invasive approach to ameliorate age-dependent decline of brain functions. We aimed to reveal the causality and molecular mechanisms of how diets affect the age-dependent decline of associative learning.

Methods: To investigate age-dependent phenotypes, we used *C. elegans*, whose lifespan is only a few weeks. *C. elegans* exhibits an associative learning behavior of temperature and food called thermotaxis. Thermotaxis ability declined within five days of adulthood. To investigate the dietary effects on thermotaxis decline, we screened 51 different lactic acid bacterial strains mixed with the regular bacterial diet, *E. coli*. We further evaluated the effect of select lactic acid bacteria on growth and lifespan.

Results: The screen of lactic acid bacteria identified species that ameliorated age-dependent thermotaxis decline. Furthermore, we found that some of those bacteria did not affect the growth or lifespan of *C. elegans*, compared to the regular diet, *E. coli*.

Conclusions: Our results demonstrate that select lactic acid bacteria can regulate neuronal functions independently of the organismal lifespan. We propose that the combination of *C. elegans* and its bacterial diet is ideal for studying dietary modulation of age-dependent phenotypes. Further mechanistic studies may shed light on the gut-brain axis in humans.

Keyword: Aging, Lactic acid bacteria, Caenorhabditis elegans, Learning and Memory, Diet

Long-term intake of *perilla* seed oil improves bone mineral density in healthy adults

Kentaro Matsuzaki[1], Shahdat Hossain[2], Harumi Wakatsuki[1], Yoko Tanabe[1], Miho Ohno[3], Setsushi Kato[3], Osamu Shido[1], Michio Hashimoto[1]

1. Shimane University (Japan), 2. Jahangirnagar University (Bangladesh), 3. Kato Hospital (Japan)

Background and objectives: This study investigated the effects of long-term intake of *perilla* seed oil (PO), a rich source of a-linoleic acid (LNA), on bone mineral density (BMD) and serum bone metabolism markers in healthy Japanese adults.

Methods: Fifty-two participants (mean age 54.2±6.4) were randomly divided into placebo (n=25) and PO (n=27) groups. PO group received daily 7.0 mL of PO, while placebo group received olive oil daily for 12 months. At baseline and after 3, 6, and 12 months, the BMD of the right calcaneus, serum levels of tartrate-resistant acid phosphatase 5b (TRACP-5b), and bone alkaline phosphatase (BALP) were measured. Additionally, LNA levels in the erythrocyte plasma membrane (RBC-PM), serum levels of biological antioxidant potential (BAP), and diacron reactive oxygen metabolites (d-ROM) were evaluated.

Results: Compared with placebo group, the BMD levels at 6- and 12-months increased in PO group. Serum TRACP-5b levels decreased significantly in PO group compared to that in placebo group, while serum BALP levels remained unchanged. Moreover, RBC-PM LNA levels and BAP/d-ROM ratios increased significantly in PO compared with placebo group. At 12-months, BMD levels were significantly correlated with RBC-PM LNA levels.

Conclusions: Long-term PO intake may improve age-related BMD decline in Japanese adults by suppressing bone resorption and increasing LNA levels.

PAB(T7-97)
Plasticity in taste preference to bitterness and astringency requires DAF-16/FOXO in the AIY interneurons in *Caenorhabditis elegans*

Seiryu Ishikawa[1], Yuka Takezawa[1], Chiharu Iida[1], Yuko Yamada[1], Mohammad Shaokat Ali[2], Simo Sun[1], Eriko Kage-Nakadai[1]

1. Osaka City University (Japan), 2. Chattogram Veterinary and Animal Sciences University (Bangladesh)

Background and Objectives: Bitterness is a gustatory feeling identified by taste receptors, whereas astringency is a mouth sensation including dryness or convergence. The inclination for bitterness or astringency in people might shift based on previous eating experiences. However, the cellular and molecular mechanisms underlying plasticity in taste preference remain largely unexplored. We investigated preference plasticity to bitter and astringent tastes using *Caenorhabditis elegans* as a model animal in this study.

Methods: Young adult animals of wild-type (N2) or mutant *C. elegans* strains were subjected to behavioural assays. Drop assay was used to examine avoidance behavior, in which a drop of each test compound's solution was dropped on the medium near the head of a moving worm. Synchronized larvae were raised with or without epigallocatechin gallate (EGCG) until they reached adulthood to test behavioral adaptability against it.

Results: *C. elegans* showed avoidance behavior against several bitter and astringent compounds. Depending on pre-exposure to EGCG throughout larval stages, worms exhibited decreasing avoidance of EGCG, which triggered astringency and bitterness. Anti-EGCG behavioral plasticity was disrupted in mutants with defective AIY interneurons. Furthermore, *daf-16*/FOXO mutants with aberrant AIY neurons were likewise plasticity deficient. The phenotype of the *daf-16* mutant was rescued by the *daf-16* transgene driven by AIY-specific promoter.

Conclusions: Genetic analyses revealed that experience-dependent plasticity in preference to EGCG requires a transcription factor DAF-16/FOXO in the AIY interneurons in *C. elegans.*

Keyword: bitterness, astringency, taste preference, EGCG, C. elegans

PAB(T7-98)
Anti-obesity effect of sesaminol and its mechanism

Miki Nakata[1], Toshio Norikura[2], Isao Matsui-Yuasa[1], Ayano Omura[3], Kunio Kiyomoto[3], Akiko Kojima-Yuasa[1]

1. Graduate School of Human Life Science, Osaka City University (Japan), 2. Aomori University of Health and Welfare (Japan), 3. Kiyomoto Co., Ltd. (Japan)

Background and objectives: Sesaminol (3,4-methylenedioxy phenol) is a one of sesame lignan found in sesame seeds, and it has a strong antioxidant activity and anti-cancer effect. Recently, we have already shown that sesaminol has a preventive effect on Parkinson's disease. Therefore, in this study to clarify the new physiological effects of sesaminol, we investigated the anti-obesity effect and its mechanism in an *in vitro* experimental system using 3T3-L1 preadipocytes.

Methods: 3T3-L1 preadipocytes were incubated in Dulbecco's modified Eagle's medium (DMEM) containing 10% fetal bovine serum (FBS). At 2 days after reaching confluence (day 0), adipocyte differentiation was induced with 0.25 µM dexamethasone, 0.5 mM 3-isobutyl-1-methylxanthine, and 0.2 µM insulin in DMEM supplemented with 10% FBS for 2 days. Then, the cells were treated with 0.2 µM insulin in DMEM

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

supplemented with 10% FBS for another 2 days and cultured for an additional 4 days in DMEM with 10% FBS. The intracellular triglyceride (TG) accumulation amount and the activity of glycerol-3-phosphate dehydrogenase (GPDH), a rate limiting enzyme of as the TG synthesis were measured. Furthermore, the expression of transcriptional regulators (PPARγ, C/EBPα, C/EBPβ) involved in adipose differentiation were examined using Western blotting and real-time quantitative PCR.

Results: Sesaminol significantly suppressed intracellular TG accumulation and GPDH activity. In addition, to clarify at which stage of differentiation that sesaminol is acting, an experiment was conducted by changing the sample addition period during the induction of differentiation. When sesaminol was added on Day 0, intracellular TG accumulation decreased significantly. However, the addition of sesaminol after Day 2 had no effect on the intracellular TG level. On the other hand, regarding the expression of transcriptional regulators involved in adipose differentiation, the addition of sesaminol significantly reduced both protein and gene levels at PPARγ and C/EBPα, but C/EBPβ did not change at the gene level and decreased at the protein level.

Conclusion: It was suggested that sesaminol suppressed the differentiation of adipocytes through the posttranscriptional regulation of C/EBPβ.

Keyword: Sesaminol, Anti-obesity, 3T3-L1 preadipocyte, Posttranscriptional regulation of C/EBPβ

Intestinal metabolism of DHA-bound phosphatidylcholine with different binding positions in rats

Kaeko Murota[1], Rinko Yamaura[1], Yukine Moda[1], Takeshi Ohkubo[2], Yomi Watanabe[3]

1. Shimane University (Japan), 2. Sendai Shirayuri Women's College (Japan), 3. Osaka Research Institute of Industrial Science and Technology Morinomiya Center (Japan)

Background and Objectives: Docosahexaenoic acid (DHA) is one of the n-3 essential fatty acids, especially important for the development of the brain and the central nerve function. Major dietary source of DHA is fish oil, which contains DHA in the form of triacylglycerol. Recently, marine phospholipids such as krill oil, marine microalgae and fish roe have attracted attention as another DHA source. Previously, we reported that phospholipids were better dietary source of DHA than triacylglycerols to increase the post-prandial level of systemic DHA-bound phospholipids, which may enhance the DHA uptake in the brain[1]. In this study, the influence of the binding position of DHA in phospholipids on the digestion and metabolism in the small intestine was investigated.

Methods: Phosphatidylcholine (PC) containing DHA either at sn-1 or sn-2 position (1-DHA-PC and 2-DHA-PC) was administered via duodenal tubing to conscious thoracic lymph-cannulated rats. Absorbed lipids in the lymph were fractionated using thin-layer chromatography and DHA and other fatty acids were determined with gas chromatography. Furthermore, DHA-bound phospholipids were digested with phospholipases *in vitro* to determine the chemical form of DHA as digestion products.

Results: DHA was mainly found as triacylglycerol esters in the lymph after administration, similarly to our previous report. The lymphatic phospholipid fraction appeared after 2-DHA-PC administration contained significantly higher level of DHA than that after 1-DHA-PC administration. *In vitro* digestion of 1-DHA-PC yielded mainly lyso-DHA-PC, while 2-DHA-PC liberated most of DHA as free fatty acid. Interestingly, digestion with pancreatin showed the suppression of hydrolysis of DHA at sn-2 position compared with the digestion with authentic pancreatic phospholipase A2.

Conclusion: Our result indicated that 2-DHA-PC was preferentially used to synthesize DHA-bound PC in the enterocyte compared with 1-DHA-PC. Digestion of DHA containing PC by the enzyme other than phospholipase A2 may be responsible for such differences.

Keyword: phosphatidylcholine, DHA, phospholipase, lymph, intestinal metabolism

Effects of feeding diets supplemented with low-calorie sweeteners on energy metabolism in rats.

Noriyuki Mori[1], Saori Sunagawa[1]

1. Doshisha Womens College of Liberal Arts (Japan)

Background and objectives: Low-calorie sweeteners are expected to reduce energy intake and decrease body weight. Erythritol, for example, is considered an almost zero calorie sweetener due to its absorption and metabolism mechanisms. However, there are reports that intake of artificial sweeteners (aspartame, acesulfame K, etc.) affects energy metabolism via incretin secretion, and further detailed studies on the effects on energy metabolism are considered necessary. In this study, we examined the effects on energy metabolism in rats fed diets with two different energy compositions of erythritol or erythritol with aspartame and acesulfame K.

Methods: Male rats (SD, 4weeks) were assigned into six groups: normal diet group (N), normal diet group with erythritol (NE), normal diet group with erythritol plus aspartame and acesulfame K (NP), high fat diet group (F), high fat diet group with erythritol (FE), and high fat diet group with erythritol plus aspartame and acesulfame K (FP). These groups were given each experimental diet for 28 days. The rats were then sacrificed and the plasma and various tissues were collected.

Results: Total energy intake did not differ between the N, NE, and NP groups and F, FE, and FP groups. Total fecal lipid weight was significantly higher in NE group compared to N group, and tended to be higher in FE group compared to F group. Plasma

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

triglycerides (TG), liver TG, and total visceral fat tended to be lower in NE group compared to N group, and in FE group compared to F group. These results suggest that erythritol intake may suppress lipid absorption from the intestinal tract and lower lipid content in the liver. On the other hand, total cholesterols in the liver was significantly higher in FP group compared to F and FE groups.

Conclusions: Low-calorie sweeteners may affect energy metabolism even when they are not a source of energy. In addition, even the same low-calorie sweetener may have different effects on energy metabolism with different feed compositions, suggesting that the effects of low-calorie sweeteners on energy metabolism may need to be studied in detail for each feed.

Keyword: erythritol, low calorie sweeteners, energy metabolisms, fat, rats

Bioactive iminosugar 1-deoxynojirimycin reverses neuronal insulin resistance and alleviates tau hyperphosphorylation: an in vitro study using insulin-resistant neuroblastoma

Isabella Supardi Parida[1], Soo Takasu[2], Junya Ito[1], Takahiro Eitsuka[1], Kiyotaka Nakagawa[1]

1. Tohoku University (Japan), 2. Gifu Pharmaceutical University (Japan)

Background and Objectives: Insulin signaling has been shown to be impaired in the brain of patients with Alzheimer's disease (AD). This prompted a growing search for bioactive compounds to maintain healthy neuronal insulin sensitivity. 1-Deoxynojirimycin (DNJ), a mulberry leaf-derived iminosugar with anti-diabetes properties, was shown to reverse obesity-induced dysregulation in adipose insulin signaling and present at a substantial level in brain following oral intake[1]. Hence, this study was aimed to investigate the ameliorative effect of DNJ against insulin resistance and AD-like tauopathy in the cell culture model of neuronal insulin resistance.

Methods: To induce an insulin-resistant state (INS-R), SK-N-SH cells (human neuroblastoma) were grown in the medium containing high insulin concentration (250 nM, 24 h). INS-R cells were then treated with DNJ (2.5, 5, or 10 µM) for another 24 hours. Meanwhile, cells in the Control group were grown without insulin or DNJ. Finally, all cells were stimulated with insulin (100 nM, 30 min) before being collected for RT-qPCR and western blotting analysis.

Results: INS-R cells showed lower expression of genes related to the insulin signaling cascade, glucose transport, and β-amyloid clearance. They also had a more blunt response to insulin, as shown by lower phosphorylation of insulin receptor (IR), protein kinase B (AKT), and glycogen synthase kinase 3 beta (GSK3B) at Tyr1146, Ser473, and Ser9 site, respectively, upon insulin stimulation. This occurs alongside an increase in tau phosphorylation at Ser202, which is one of the hallmark features of AD. DNJ treatment at 5 and 10 µM was able to reverse insulin-resistant-induced dysregulation in gene expression while also promoting the phosphorylation of IR and activation of AKT/GSK3B pathway. More importantly, DNJ lowered tau phosphorylation, presumably by inhibiting GSK3B activity via its phosphorylation at Ser9.

Conclusion: Our data suggests how DNJ exerts a neuroprotective effect by regulating neuronal insulin signaling, thus providing basis for its use as a multi-target therapy for diabetes and AD. Currently, we are analyzing the expression of other proteins related to neuronal insulin signaling and AD pathogenesis to gain a more comprehensive insight into DNJ's neuroprotective potential.

Keyword: 1-deoxynojirimycin, iminosugar, mulberry leaf, neuronal insulin resistance, tau hyperphosphorylation

Cancer chemopreventive potential of protein hydrolysates from black soldier fly (*Hermetia illucens*) larvae residue

Kwanchanok Praseatsook[1], Arpamas Chariyakornkul[1], Aroonrat Pharapirom[1], Rawiwan Wongpoomchai[1]

1. Chiang Mai University (Thailand)

Background and objectives: Cancer chemoprevention involves the use of natural compounds to either delay or stop cancer formation. These compounds can prevent DNA mutation, enhance the antioxidant system and reduce inflammation resulting in the suppression of each stage of carcinogenesis. Nowadays, insect consumption has become a popular trend because edible insects are rich in various essential nutrients, are environmentally sustainable and quite palatable. Black soldier fly larvae (BSFL) have been incorporated into numerous commercially-produced food products for their high protein content. Our previous study reported that glutelin was the most effective protein among BSFL proteins. Several recent studies have reported that protein hydrolysates obtained from diverse sources, including insects, exhibit various biological and pharmacological activities. The present study aims to investigate the cancer chemopreventive capacity of glutelin hydrolysates from BSFL residue and assess their potential antioxidant, anti-inflammatory, antimutagenic and anticarcinogenic activities.

Methods: Glutelin was prepared from defatted BSFL powder via alkali extraction and then digested by 3%(w/w) alcalase at pH 8, 50°C for 4 hrs. Glutelin hydrolysate (GH) was further fractionated by ultrafiltration (MWCO 3, 10 and 30 KDas) to obtain GHH30, GH10-30, GH3-10 and GHL3. Cancer chemopreventive capacity was determined by assessing antioxidant (FRAP, DPPH and ABTS assays), anti-inflammatory

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

(%nitric oxide production in RAW 264.7 cell line), antimutagenic (Ames test) and anticancer (liver (HepG2), lung (A549) and colon (SW480) cancer cell lines) activities.

Results: GHH30 containing more than 30 KDa peptides exhibited the greatest antioxidant value using FRAP, DPPH and ABTS assays when compared with GH and other fractions. Furthermore, GHH30 inhibited mutagenicity induced by aflatoxin B1 in *Salmonella typhimurium* strain TA98. GHL3 containing fewer than 3 KDa peptides could effectively reduce nitric oxide production induced by lipopolysaccharide in RAW 264.7 cell lines and inhibit the growth of HepG2, A549 and SW480 cells.

Conclusion: Large peptides isolated from GH of BSFL exhibited antioxidant and antimutagenic activities, while small peptides exhibited anti-inflammatory and anti-cancer activities. Black soldier fly larvae protein hydrolysate may be considered an alternative source of cancer chemoprevention. Importantly, the chemopreventive peptides from BSFL are presently under going further investigation.

PAB(T7-103)
The estimation of the energy value of allitol using growing rats

Kanon Ono[1]

1. Kagawa University (Japan)

Background and objectives: Allitol is rare sugar alcohol obtained by reducing d-allulose (d-psicose) and can be found in *Itea*, a deciduous shrub of the family Saxifragaceae, with d-allulose. Our previous study reported that dietary allitol has the same anti-obesity effect as d-allulose or erythritol. Because the energy values of d-allulose and erythritol were both 0 kcal/g, the energy value of allitol is also expected to be 0 kcal/g. This study has investigated the available energy of allitol for rat growth. Moreover, the degree of intestinal fermentability of allitol from the cecal morphology of rats has been examined.

Methods: Sixty-six male Wistar rats (3 weeks old) were randomized into eleven groups of six rats. One group of rats was sacrificed at the beginning (day 0 control). Each remaining group of rats received 7 g of high protein diet (basal diet) daily, to which a fixed amount of sucrose, maltitol, or allitol (0.4–1.2 g) was added for 20 days. On the final day, the rats were sacrificed and residual food in the digestive tracts was discarded. Body energy was determined by quantifying the fat (9.4 kcal/g) and protein (4.0 kcal/g) content of the carcass. To calculate the change in body energy content of each animal over 20 days, the difference between the average energy content of rats and the average value of the day 0 control was determined.

Results: Body energy gain increased with the increase in test carbohydrates and was higher in the rats fed with a sucrose added diet than those in the other rats. The cecal content and surface area were higher in the order of rats fed with allitol, maltitol, and sucrose. From increases in body energy, regression lines have been calculated. One gram of sucrose, maltitol, and allitol produced a net gain of 1.85, 1.02, and 0.94 kcal, respectively. The energy values of maltitol and allitol were estimated at 2.17 and 2.05 kcal/g, respectively.

Conclusion: This study has demonstrated that allitol is a sugar alcohol that provides about 2 kcal/g similar to maltitol. Furthermore, allitol was found to have stronger cecal fermentability than maltitol.

Keyword: Allitol, Rare sugar, Anti-obesity effect

PAB(T7-104)
Establishment of a fatty liver model system using the Hepa 1-6 strain and the effects of extracts from plants with high polyphenol content on fat accumulation

Kazuhito Takemoto[1], Hao Luo[1], Masaki Iji[1], Akari Koresawa[1], Ganlin Tian[1], Takahiro Narukwa[1], Tomohisa Koyama[1], Hiroyuki Watanabe[1]

1. University of Kochi (Japan)

Background and objectives: NAFLD is caused by daily dietary habits, and it is important to prevent and treat it because it can lead to cirrhosis and liver damage in cases of severe disease. In this study, we established an experimental screening system using mouse liver cancer cells, and investigated the effect of a plant-derived extract with high polyphenol content on the accumulation of triacylglycerol (TAG) in hepatocytes.

Methods: Mouse liver cancer cells, Hepa 1-6, were used in the experiments. DMEM containing 10% FBS was used and incubated (37°C, 5% CO_2). The cells were incubated in medium containing oleic acid for 48 hours; fixed in formalin; and then incubated in Oil Red solution. Absorbance was measured at 530 nm. Simultaneously, TAG was extracted from the cells and quantified. Itadori (*Fallopia japonica*) was used as the plant with high polyphenol content. The effect of the plant's extract on TAG accumulation was examined by measuring absorbance by using the Oil Red staining method after 48 hours of incubation in medium supplemented with oleic acid and Itadori leaf extract. In addition, the expression levels of the genes of *CD36, FAS, DGAT1, DGAT2, MCAD,* and *ACOX1* were determined by RT-PCR to analyze the expression of lipid metabolism-related factors.

Results: The addition of fatty acids to the medium resulted in Oil Red staining in an incubation oleic acid concentration-dependent manner, and increased absorbance at 530 nm. Intracellular TAG measurements showed a positive correlation between absorbance and TAG concentration (R=0.999). The expression levels of the *CD36, FAS, DGAT1, DGAT2,* and *ACOX1* genes increased with increasing oleic acid concentrations. On the other hand, TAG accumulation, significantly reduced in a concentration-dependent manner upon the addition of Itadori leaf extract at all oleic acid concentrations. Both *DGAT1* and *DGAT2* gene expression levels decreased, and the expression of the *FAS* gene significantly increased, while those of the *MCAD* and *ACOX1* genes significantly upregulated upon the addition of Itadori leaf extract.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: The addition of oleic acid to the Hepa 1-6 cells affected TAG synthesis. In contrast, the addition of Itadori leaf extract was thought to inhibit intracellular TAG accumulation.

Keyword: fatty liver, Hepa 1-6, Itadori (Fallopia japonica), triacylglycerol

PAB(T7-105)
Diosgenin, a natural steroidal saponin, suppresses COX-2 and mPGES-1 via the glucocorticoid receptor and improves LPS-induced liver injury in mice

Izumi Tsukayama[1], Nana Hojo[1], Takuto Mega[1], Keisuke Toda[1], Yuki Kawakami[1], Yoshitaka Takahashi[1], Toshiko Suzuki-Yamamoto[1]

1. Okayama Prefectural University (Japan)

Background and objectives: Prostaglandin (PG) E_2, one of the pro-inflammatory lipid mediators, induces acute and chronic inflammation. In some pathophysiological conditions, cyclooxygenase (COX)-2 and microsomal PGE synthase (mPGES)-1 are transiently induced, leading to PGE_2 overproduction. We previously found novel anti-inflammatory and anti-carcinogenic effects via the downregulation of COX-2 and mPGES-1 in a wild yam, *Dioscorea japonica*. Additionally, diosgenin, a steroidal saponin, was one of the potential substances in wild yam. In this study, we examined whether diosgenin suppressed COX-2 through the glucocorticoid receptor (GR), and ameliorated the inflammation in the lipopolysaccharide (LPS)-induced mouse acute liver injury.

Methods: Human non–small-cell lung carcinoma A549 cells were incubated with diosgenin (100 or 1000 nM), and with/without RU486 (0-100 nM) as GR antagonist. Mouse models of acute liver injury induced by LPS (10 mg/kg/day i.p.) were administered diosgenin (100 μmol/kg/day i.p.). Protein and mRNA expression levels were analyzed by western blotting and quantitative RT-PCR, respectively. Immunocytochemistry and immunohistchemistry were carried out by multiple immunofluorescence microscopy using specific antibodies against COX-2, mPGES-1, nuclear factor-kappa B (NF-κB; a potent transcription factor of COX-2) and F4/80 (a macrophage marker).

Results: We demonstrated that diosgenin suppressed COX-2 in A549 cells via NF-κB translocation and the effects were reversed by RU486. In LPS-induced mouse liver injury, COX-2 and mPGES-1 were induced and localized in sinusoidal macrophages and endothelial cells; however, diosgenin administration significantly suppressed *Ptgs2* (COX-2) and *Ptges* (mPGES-1) *expression* and decreased COX-2 and mPGES-1 immunopositive cells in the sinusoids. Multiple immunohistochemical analyses showed that diosgenin had an effect on COX-2 and mPGES-1, particularly in the macrophages.

Conclusions: These findings suggested that diosgenin downregulated COX-2 and mPGES-1 via the GR and suppressed COX-2 and mPGES-1 in the macrophages of LPS-induced acute mouse liver injury. Diosgenin may be an effective alternative therapy as a food-derived bioactive compound; it acts in a cell-specific manner without any adverse effects, such as thrombosis.

Amaranth-pearl millet-chickpea composite flour based nutritious gluten-free cookies with potential antioxidant activity and bioactive compounds

Para Dholakia[1], Anupa Siddhu[2], Ranjana Singh[1]

1. Shaheed Rajguru College of Applied Sciences for Women,University of Delhi (India), 2. Lady Irwin College, University of Delhi (India)

Background and Objective: Development of fortified bakery and pasta products from composite flours is the latest trend in bakery industry to overcome the nutritional disadvantages of refined wheat flour. Amaranth, a pseudocereal, and a front-runner in gluten-free bakery, has high nutrient, phenolic and flavonoid content with antioxidant activity. The objective of the present study was to develop gluten-free multi grain chocolate chip from composite flour of raw and popped amaranth, pearl millet and chick pea flour.

Methods: Phase I involved characterization of the individual flours followed by standardization of composite flour (CF) and cookies by mixture experiment and multi-factorial experiment design, respectively. In phase II, CF and cookies were analyzed for proximate and nutrient composition, total phenolic content (TPC), flavonoid content (TFC) and antioxidant activity by DPPH and FRAP. Shelf life studies were conducted. Consumer survey was done in phase III.

Results: CF and cookies showed following values-Protein 14%, 7.6%; dietary fibre 7.4%, 5.6%; iron 9.3 mg/100g, 6.2 mg/100g; calcium 89 mg/100g, 65 mg/100g; lysine 0.99g/100g, 0.53g/100g; TPC 277 mgGAE/100g, 315.56 mgGAE/100g and TFC 312.5 mgQE/100g, 250 mgQE/100g respectively. EC_{50} by DPPH was 22.78 mg/ml and 12.99 mg/ml and FRAP value was 151 mg GAE/ 100g and 204mg GAE/100 for CF and cookies respectively. Gluten content was found to be well below the threshold of 20 ppm in both CF and cookies. Shelf life of cookies was 5 months in a laminate of BOPP-metPET-BOPP. Consumer survey showed high acceptability of the product with 94.7% of the subjects liking it.

Conclusions: The study made a successful attempt in developing gluten-free cookies with good nutritional value and high overall acceptability. The cookies had high macro and micronutrient content, good total phenolic and flavonoid content and high antioxidant activity, thus providing possible health benefits. Consumer survey data showed that the cookies were accepted by all age groups. Thus the product can be used as a healthy alternative of refined wheat flour cookies by the public. Being gluten free it can even be used in the dietary

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

management of celiac disease. It is also a step towards processing and utilization of an indigenous pseudocereal.

Molecular basis of host resistance to pathogens conferred by feeding *Bacillus subtilis* var. natto in *C. elegans* as a surrogate model

Shun Yamaguchi[1], Rina Katayama[1], Yuumi Matsumoto[1], Simo Sun[1], Yoshikazu Nishikawa[1], Eriko Kage-Nakadai[1]

1. Osaka City University (Japan)

Background and Objectives: Methodologies and measures for prevention and alleviation of infectious diseases via familiar and inexpensive food products are desired, in addition to pharmaceuticals. We previously reported that *Bacillus subtilis* var. natto increases host resistance to Gram-positive bacteria using *C. elegans* as a human surrogate model. This study was conducted to elucidate the molecular mechanisms by which *B. subtilis* (natto) confers resistance to bacterial infection using *C. elegans*.

Methods: Wild-type *C. elegans* (N2) and mutants for genes related representative defense response pathways such as TGF-β, p38 MAPK and Insulin/IGF-1 signaling (IIS) pathways were used. Synchronized larvae were grown on agar medium coated with a standard diet of nonpathogenic *Escherichia coli* strain (OP50) or *B. subtilis* (natto) until they reached to the adult stage, and then transferred to medium coated with *Staphylococcus aureus* for survival analysis. Survival rates were calculated by the Kaplan-Meier method, and differences in survival rates were compared by the log-rank test.

Results: In the wild-type and *dbl-1*/TGF-β mutant animals, *B. subtilis* (natto)-fed group showed significantly shorter survival time in comparison with the OP50 (control)-fed group. In contrast, there was no significant difference in the survival times between control-fed and *B. subtilis* (natto)-fed *skn-1*/Nrf mutant worms upon *S. aureus* infection. These results suggest that SKN-1 is required for the *B. subtilis* (natto)-induced host resistance to *S. aureus*.

Conclusions: *B. subtilis* (natto) could increase host resistance to *S. aureus* infection through SKN-1-related pathway(s). The p38 MAPK and/or IIS pathway might be involved in the phenomenon, because *skn-1*/Nrf is a transcription factor regulated by those pathways. We are currently conducting mutant analyses to verify their involvement in the *B. subtilis* (natto)-induced host resistance.

Cholesterol lowering and anti-obesity effects by the combination of heat-treated lactobacillus KDP and guar gum in mice fed a high-fat diet

Ikuho Takao[1], Saika Ota[1], Hatsune Komaya[1], Naoki Igari[2], Xia Zhu[2], Shizuka Hirai[1], Yukari Egashira[1]

1. Chiba University (Japan), 2. Daiwa Pharmaceutical Co. Ltd (Japan)

Objectives: KDP, heat-treated *Lactobacillus sakei* is expected to function as paraprobiotics. Guar gum, a soluble fiber obtained from guar bean, has prebiotic properties. We found that the combination of paraprobiotics and prebiotics synergistically alleviated obesity and cholesterol levels, but the mechanism is unknown. Therefore, we conducted experiments to elucidate the mechanism by which the ingestion of heat-treated KDP alone and the combined ingestion of KDP and guar gum lowers cholesterol in high-fat diet-induced obese mice.

Methods: Six-week-old male C57BL/6J mice were divided into 5 groups: standard diet (ST), high-fat diet (HF), 5% guar gum + high-fat diet (Guar), 0.1% KDP + high-fat diet (KDP), and 5% guar gum + 0.1% KDP + high-fat diet (Mix) for 16 weeks. Water and feed were consumed ad libitum. At 16 weeks of rearing, the mices were dissected, and their organs were harvested for analysis. Gene expression analysis related to lipid metabolism in adipose tissue and cholesterol metabolism in liver were conducted. **Results:** Perirenal adipose tissue showed a significant decrease in the Mix group compared to the HF group. Lipid metabolism-related gene (*PPARγ, GPR43, Fasn, Acaca*) expression tended to increase in *PPARγ* and G*PR43* in the Mix group. Mix diet may improve of lipid metabolism. Furthermore, total cholesterol levels were significantly lower in the Mix group than in the HF group. Expression analysis of cholesterol metabolism-related genes (*ABCG5, ABCG8, BSEP, ABCC2, HMGCR, Cyp7α1,* and *LDLr*) in the liver was conducted. *Cyp7α1, HMGCR*, and *LDLr* expressions were decreased in the Mix group compared to HF group. This result suggests that cholesterol lowing effect of Mix may be involved in the inhibition of cholesterol synthesis.

Conclusion: Combined consumption of heat-treated KDP and guar gum significantly reduced perirenal adipose tissue weight and total cholesterol levels in high-fat diet-induced obese mice by improving lipid metabolism and inhibition of cholesterol synthesis.

Novel mung bean-derived peptides improve glucose metabolism by activating AMPK in diabetic KK-A^{y} mice

Biyun Zhang[1], Kentaro Kaneko[1], Maiko Shobako[1], Ken Shimizu[1], Kazuo Inoue[1], Kousaku Ohinata[1]

1. Kyoto University (Japan)

Background and objectives: Mung bean (*Vigna radiata* L.), a common food consumed particularly in Asia, is well-known for its nutritive values as well as for its roles in Chinese medicine. Mung bean protein, which can be produced at an industrial scale, is emerging as a candidate for new plant-based protein. In this study, we found that the enzymatic digest of mung bean protein exhibited glucose-lowering effect. We then investigated mung bean specifically derived peptides that could decrease blood glucose and the potential mechanisms.

Methods: Male healthy mice (ddY or C57BL/6N) treated with high-fat diet (HFD), and KK-A^{y} mice, a type II diabetic model, were used. To investigate the effects on glucose metabolism, the oral glucose tolerance test (OGTT) and the intraperitoneal insulin tolerance test (IPITT) were performed after intraperitoneal administration of samples. The peptides were chemosynthesised by F-moc strategy. AMPK phosphorylation in tissues from KK-A^{y} mice was measured by Wes, a capillary electrophoresis western analysis.

Results: The mung bean protein digest significantly lowered blood glucose levels in HFD-fed mice after glucose administration; however, the digest did not increase insulin sensitivity in IPITT. These results suggest that the digest could enhance glucose tolerance and therefore improve glucose metabolism in HFD-fed mice independent of insulin action. The candidate bioactive peptides were chosen based on the homology of mung bean protein with the LC-MS comprehensive peptide analysis of soy protein digest [1], together with the structure-activity relationship. Among candidate peptides, we found two peptides, LLLPHY and LAGEK, enhanced glucose tolerance in OGTT in HFD-fed mice. Moreover, the glucose intolerance of diabetic KK-A^{y} mice was significantly improved by both peptides. AMPK activation is well-known for insulin-independent modulation of glucose metabolism. Indeed, we found that both peptides significantly increased hepatic AMPK phosphorylation. Lastly, we investigated the enzymatic conditions to produce these peptides, and their presence in the digests was confirmed by LC-MS.

Conclusions: This study newly discovered peptides derived from mung bean protein that can improve glucose metabolism *in vivo* for the first time by activating AMPK.

The dietary isoflavone daidzein regulates the expression of pro-inflammatory and antioxidative genes in hepatocyte and macrophage co-culture

Wakana Nishimura[1], Kana Mizushima[1], Kaoruko Iida[1]

1. Ochanomizu University (Japan)

Background and objectives: Nonalcoholic fatty liver disease(NAFLD)is a disease in which there is significant lipid accumulation in the liver in the absence of excessive alcohol intake. Three major factors are thought to be involved in the progression of NAFLD: lipid accumulation, oxidative stress, and inflammation. Daidzein, a soy isoflavone, has been reported to exert protective effects on hepatic steatosis in animal models, however the exact mechanisms remain unclear. Therefore, we investigated the effects of daidzein on hepatocyte lipid accumulation, and on inflammation and oxidative stress caused by hepatocyte-macrophage crosstalk.

Methods: Mouse hepatocyte cell line Hepa1-6 and mouse macrophage cell line RAW264 were used. To evaluate the effect of daidzein on lipid accumulation, Hepa1-6 were treated with abmixture of palmitic acid (PA) and oleic acid (OA) with or without 50 μM daidzein, and the lipid content was assessed by Oil red O staining. To investigate the effect of daidzein on inflammation and oxidative stress, Hepa1-6 and RAW264, were co-cultured in same dishes and incubated with daidzein. Gene expression levels of inflammatory mediators and antioxidant enzymes were evaluated by RT-PCR and the protein expression levels of upstream signaling molecules were examined by Western blotting.

Results: In Hepa1-6 cells, daidzein had no effect on the intracellular lipid accumulation induced by addition of PA and OA mixture. In co-cultured cells, daidzein treatment significantly suppressed gene expression levels of inflammatory mediators, Inducible nitric oxide synthase (iNOS) and Interleukin-1 beta(IL-1ß), which were increased by co-culture itself. As a mechanism, the nuclear translocation of NFkB was suppressed by daidzein. In addition, daidzein treatment significantly increased the gene expression of the antioxidant enzymes Heme oxygenase 1 (HO-1), NADPH quinone oxidoreductase 1 (NQO1), and Superoxide dismutase (SOD). It is known that the transcription of these genes are promoted by activating Akt, which cause nuclear translocation of Nrf2. In co-cultured cells, daidzein significantly increased Akt activation and nuclear Nrf2 content.

Conclusions: These findings suggest that daidzein may prevent the progression of NAFLD by inhibiting inflammation via the NFkB pathway and enhancing antioxidant properties via the Akt/Nrf2 pathway.

Effects of selective fish oil consumption at end of the day on high-fat diet-induced overweight in mice

Hiroki Matsuyama[1], Nanaka Shibazaki[1], Hiroki Matsuzaka[1], Wataru Tanaka[1], Saori Watabe[1], Hiroyuki Sakakibara[1]

1. University of Miyazaki (Japan)

Background and objects: Animals, including rodents and humans, tend to preferentially select fatty foods for their good flavor and texture. However, it was unclear whether these preferences observed in the presence of plural fat-based diets indicates diurnal differences, and then affects weight gain. Therefore, we investigated the effects of selecting high-fat diets composed of soybean oil, lard, and fish oil on metabolic parameters in mice using a self-selection regimen from two diet boxes.

Methods: Four-week-old male C57BL/6 mice were given two diet boxes per cage: two 30% (w/w) soybean oil-based high-fat (SOY) diet boxes (w-SOY), a SOY-diet box and a 30% (w/w) lard-based high-fat (LARD) diet box (SOY-vs-LARD), and a SOY-diet box and a 30% (w/w) fish oil-based high-fat (FISH) diet box (SOY-vs-FISH). The mice were permitted free access to deionized water and both diet boxes. Diurnal food intake patterns were analyzed, and the individual diet boxes were weighed every 2 hours for 48 hours at week 7. After 8 weeks consumption, the blood biochemical parameters and fatty acid composition were analyzed.

Results: Mice preferred the LARD diet over the SOY diet and the SOY diet over the FISH diet, although the total energy intake was the same for all three groups. These preferences are likely due to the different fatty acid compositions, especially the omega-6/omega-3 ratio. The SOY-vs-LARD group gained significantly more weight than did the w-SOY and SOY-vs-FISH groups, indicating that daily selective consumption of high omega-6/omega-3 ratios from fat (lard) induces excess weight gain. Additionally, minimal but selective consumption of an omega-3 fatty-acid-rich FISH diet at the end of the active period increased the physiological fatty acid compositions of eicosapentaenoic acid and docosahexaenoic acid in the SOY-vs-FISH group, and their metabolic parameters were lower than the w-SOY group.

Conclusions: The results obtained in this study imply that consuming small amounts of fish oil at the end of the active period may help prevent excess weight. We are currently conducting the study on the effects of the mixing oils.

Effect of supplemented flaxseed oil with tocopherols and phytosterols on the mechanisms involved in the prevention of liver steatosis

Ignacio Scanarotti[1,2], Juliana Sain[1,2], Ana Clara Fariña[1], Luciana Vera Candioti[1,2], Claudio Bernal[1,2]

1. School of Biochemistry - Universidad Nacional del Litoral (Argentine), 2. CONICET (Argentine)

Background and objective: High fat (HF) intake has been associated with liver steatosis in humans and experimental animals, and we had demonstrated that flaxseed oil (FO) rich in α-linolenic acid (ALA) supplemented with a purified extract of oil deodorizer distillate (DD) rich in tocopherols and phytosterols attenuated the liver damage and triacylglycerol (TAG) accumulation. The aim of this preliminary study was to investigate some mechanisms involved on the liver steatosis attenuation by a FO supplemented or not with DD.

Methods: Male *Wistar* rats were fed (60-d) recommended (SO7: soybean oil-SO-, 7%) or HF (30%) diets containing SO or FO supplemented or not with 1% of DD (SO30, FO30, SO30DD and FO30DD diets, respectively). Liver TAG levels, fatty acids (FA) profile, *in vivo* VLDL-TAG secretion rate (TAG-SR), and mRNA levels of key lipogenic and oxidative enzymes and transcription factors, as well as, transport proteins.

Results: Among the most important changes, FO30 diet (vs SO30) reduced the hepatic TAG (-65%) levels, associated with an increased ALA, EPA and DHA incorporation, without significant differences in the hepatic TAG-SR and mRNA levels of β-oxidative genes. Notoriously, the supplementation with 1% of DD (FO30DD diet), resulted in a similar reduction of hepatic TAG levels (- % vs SO30) and incorporation of FA that those founded in FO30 diet, but increased (+500%) the mRNA levels of PPARα and CPT1a and reduced the mRNA levels of FATP2 and FATP5 (vs SO30 and FO30 diets).

Conclusions: The prevention of liver steatosis induced at high fat levels by flaxseed oil supplemented with a tocopherols and phytoesterols mixture could be related to an enhanced β-oxidation pathway and a reduction of the fatty acid uptake by the hepatocytes. Nonetheless, further studies are required to explain the mechanism involved in the beneficial effects of FO30 alone on liver steatosis. Flaxseed oil supplemented with tocopherols and phytosterols might play an important role as bioactive compounds preventing non-communicable chronic diseases like liver steatosis in humans.

Comparative Analysis of Differently Originated Blackcurrant(*Ribes nigrum*) Powder on the Antioxidant Activity and Phenolic Contents.

Sookyeong Hong[1], Hyun-Sook Kim[1]

1. Sookmyung Women's University (Korea)

Background and Objectives: Berries are known to have antioxidant effect of anthocyanins, phenols, and flavonoids from previous studies. Blackcurrant(*Ribes nigrum*), in particular, is known as one of the phytochemical-rich berries with high antioxidative effect. The aim of this study is to compare the antioxidant capacity and the contents of anthocyanin, phenol, and flavonoid in Blackcurrant powders from different origins, such as South Korea(KOR), Poland(POL), America(USA), present on the market.

Methods: The lyophilized Blackcurrant powders which were cultivated in POL, USA, and KOR was extracted by 50% EtOH(50mg/ml) under the same conditions. The antioxidant and free radical scavenging activities were investigated using DPPH and ABTS radical scavenging capacity assay, and total phenolic, flavonoid, and anthocyanin contents were determined by each of its own method using Blackcurrant ethanolic extracts.

Results: The result of ABTS assay was significantly higher in POL($p<0.01$), while DPPH assay was significantly higher in KOR($p<0.005$) than the other two. The highest amounts of anthocyanin, phenol, and flavonoid were all found in POL among 3 samples; The anthocyanin ($p<0.005$) and flavonoid ($p<0.005$) contents were significantly higher than other two, while phenolic content($p<0.005$) was only significantly higher than USA.

Conclusions: The Blackcurrant powder from POL may have the potential of highest antioxidant capacity and phytochemical contents among three of the powders used in this study. The further study in vivo mouse model of non-alcoholic fatty disease(NAFLD) is in progress to prove that antioxidant capacity of the phenolic contents of Blackcurrant powder can ameliorate ceremide synthesis in liver.

Evidence on a brain transport of anti-cognitive dipeptide, Tyr-Pro, after oral administration to mice

Lihong Cheng[1], Atsuko Yoshino[1], Yuki Nagasato[1], Fuyuko Takata[2], Shinya Dohgu[2], Mitsuru Tanaka[1], Toshiro Matsui[1]

1. Kyushu University (Japan), 2. Fukuoka University (Japan)

Background and objectives: Transportation of substances to the brain is strictly regulated by the blood-brain barrier (BBB). A dipeptide, Tyr-Pro (YP), capable of crossing the BBB in intact form [1] and improving impaired memory in amyloid β-injected Alzheimer's disease model mice [2], has a potential for cognitive prevention. However, no study has been reported on intact accumulation of the dipeptide into brain after oral intake. In the present study, we thus tried to clarify the bioavailability of YP, including brain transport, after the intake to mice.

Methods: A single oral administration of stable isotope-labeled YP ([$^{13}C_5$, ^{15}N] YP) was performed in male ICR mice and taken blood and brain at 0–2 h after the administration. Perfusion of cerebral vessels by physiological buffer was performed prior to the collection of brain. The amount of YP in plasma and brain were determined by an LC-qTOF/MS, in combination to a 3-aminopyridyl-N-hydroxysuccinimidyl carbamate (APDS) derivatization technique (405.1800 m/z > 285.1467 m/z<).

Results: A highly sensitive detection of isotope-labeled YP at > fmol/injection level was achieved by the APDS-aided LC-qTOF/MS analysis. The APDS-LC-qTOF/MS analysis on the plasma revealed that YP dosed at 10 mg/kg entered the blood in its intact form (T_{max}: 15 min, $T_{1/2}$: 9.82 min, C_{max}: 1.04 nmol/mL). In the brain we successfully detected the isotope-labeled YP at ~200 fmol/mg of whole brain at 15 min after the oral administration.

Conclusions: The present study provided the first finding that a dietary YP is an absorbable bioactive compound into the circulating bloodstream, and rapidly (15 min after the intake) reaches to the mouse brain parenchyma in intact form or without degradation.

PAB(T7-115)
AMPK negatively regulates RANKL-induced osteoclast differentiation by suppressing oxidative stress

Miori Tanaka[1,2], Hirofumi Inoue[1], Nobuyuki Takahashi[1], Mariko Uehara[1]

1. Tokyo University of Agriculture (Japan), 2. The Nippon Foundation Human Milk Bank (Japan)

Background and objectives: AMP-activated protein kinase (AMPK) is a crucial energy sensor of cellular metabolism in response to various metabolic stresses such as oxidative stress and inflammation. AMPK has been shown to stimulate the differentiation and proliferation of osteoblasts, but its role in osteoclasts remains unclear. Thus, this study determined the mechanistic connection between AMPK and osteoclast differentiation, and the potential role of AMPK in the anti-resorptive effects of several phytochemicals.

Methods: The murine macrophage RAW 264.7 cells were transfected with AMPK siRNA and treated with 50 ng/mL receptor activator of nuclear factor-kappa B ligand (RANKL). Tartrate-resistant acid phosphatase (TRAP)-positive multinucleated cells were counted by TRAP staining. We measured osteoclast-specific gene and protein expression by real-time PCR and western blotting. Moreover, involvements of signaling pathways such as mitogen-activated protein kinase (MAPK), nuclear factor-kappa B (NF-κB), and reactive oxygen species (ROS) in the effect of AMPK were analyzed.

Results: RANKL-induced osteoclast differentiation, osteoclastic gene expression, and activation of p38 MAPK, JNK, and NF-κB were promoted in cells transfected with AMPK siRNA. Knockdown of AMPK led to defective synthesis of heme oxygenase-1 (HO-1), an antioxidant enzyme involved in the suppression of oxidative stress. Furthermore, treatment with N-acetyl-L-cysteine (NAC) abolished osteoclast differentiation and MAPK/NF-κB pathways induced by AMPK knockdown. The AMPK activators, hesperetin, gallic acid, resveratrol, and curcumin, also suppressed osteoclast differentiation via the activation of AMPK.

Conclusions: Our data suggest that AMPK could effectively inhibit RANKL-induced osteoclast differentiation by suppressing oxidative stress. AMPK activation by dietary-derived phytochemicals may be a therapeutic strategy for reducing the risk of bone diseases.

Keyword: AMPK, osteoclast, oxidative stress, polyphenol

Difference of oleic acid effects on muscle fiber type in differentiated myotubes and isolated mature muscle fibers of mice

Yusuke Komiya[1], Shugo Iseki[1], Issei Yokoyama[1], Keizo Arihara[1]

1. Kitasato University (Japan)

Background and objectives: Skeletal muscle is important tissue which regulates the metabolism and locomotive ability. Bundles of numerous muscle fibers build the muscle tissue, however different kinds of muscle cells, such as satellite cell, myoblast, myotube, and muscle fiber, are present depending on the process of muscle formation. Myotubes are often used as representative in vitro models of muscle however we have reported the difference of contractile properties between myotubes and mature muscle fibers isolated from muscle tissue. In addition, there are two major classification of muscle fiber types, type 1 (slow-twitch oxidative) and type 2 fibers (fast-twitch glycolytic), according to contractile and metabolic properties. The muscle fiber type is regulated by exercising, however we revealed that dietary olive oil intake improves runnning endurance and muscle metabolism in mice. The present study was aimed to investigate the effects of oleic acid, abundant in olive oil, on muscle fiber type in differentiated myotubes and isolated mature muscle fibers in vitro.

Methods: C2C12 myoblast were differentiated in 2% HS-DMEM for 72 hours to form myotubes. The flexor digitorum brevis muscle of C57BL/6J male mice was harvested and incubated in 0.2% collagenase solution. The tisuue was triturated to single fibers and isolated fibers were cultured in 30% FBS-DMEM. 100 μM oleic acid was supplemented in culture medium of each cell. After 6-hour, total RNA was extracted and the mRNA expression was analyzed by real-time RT-qPCR.

Results: We found that the transcript levels of Myh7, Pdk4, Cpt1b, Angptl4, Cd36, and Ppargc1a were significantly upregulated in myotubes of oleic acid supplementation. In isolated muscle fibers, the transcript levels of Pdk4, Cpt1b, Angptl4, and Cd36 were significantly upregulated in oleic acid supplementation, however the expression of Myh7 and Ppargc1a did not change.

Conclusions: The central finding of this study was that oleic acid supplementation increased transcript levels of key genes related oxidative metabolism in both myotubes and isolated muscle fibers, however type 1 fiber marker (Myh7) was regulated only in myotubes. Our results indicate that oleic acids are more likely to affect to muscle fiber types in newly formed myotubes rather than mature muscle fibers.

Effects of Itadori (Fallopia Japonica) leaf extract using ethanol on colorectal cancer cells

Hao Luo[1], Kazuhito Takemoto[1], Masaki Iji[1], Akari Koresawa[1], Ganlin Tian[1], Takahiro Narukawa[1], Tomohisa Koyama[1], Hiroyuki Watanabe[1]

1. University of Kochi (Japan)

Background and objectives: Malignant neoplasms are the leading cause of death in Japan, with colorectal cancer accounting for the second highest mortality rate in the country. Recently, many polyphenols have been reported to have anticancer-like effects on colorectal cancer cells, and the prevention of cancer through the consumption of specific foods has been gaining attention. The stems of Itadori (Fallopia japonica) are consumed in Kochi Prefecture, and the leaves of the plant are rich in polyphenols (quercetin, rutin, neochlorogenic acid, and piceatannol). Therefore, in this study, effects of polyphenols contained in Itadori leaf extract were investigated on an established cell line derived from mouse colorectal cancer cells.

Methods: Mouse colorectal cancer cells, Colon-26, was used in the experiments. The medium used was RPMI 1640. The component extracted from dried Japanese knotweed leaves by using 80% ethanol was lyophilized and used. The extract was added to the medium and incubated at 37℃ in the presence of 5% Carbon Dioxide. Cell viability was then determined using the WST-8 method and the trypan blue dye exclusion test. Apoptosis was confirmed using the DNA ladder and caspase assays. The polyphenols quercetin, rutin, neochlorogenic acid, and piceatannol were added to the cells, and similar measurements were performed.

Results and Discussion: The addition of Itadori leaf extract at a concentration of 1 mg/mL or higher caused a significant decrease in cell viability in the WST-8 method. The DNA ladder assay showed DNA fragments at 250, 500, and 1000 μg/mL for piceatannol, and at 250 and 500 μg/mL for the other polyphenols. In the caspase assay, the addition of the Japanese knotweed extract, neochlorogenic acid, rutin, and quercetin significantly increased activity.

Conclusions: Itadori leaf extract had an apoptosis-inducing effect through its constituent polyphenols on an established cell line derived from mouse colorectal cancer cells.

Changes in response and saliva-related gene expression into amino acid stimulation in cell line A253.

Nanami Sakakibara[1], Mieko Aoki[2], Kyoichi Takao[3], Tetsuya Takao[1]

1. Fac. Human Life Enviro. Sci., Showa Women's Univ. (Japan), 2. Med. Enviro. Med., Kochi Univ. (Japan), 3. Med. Sch., Nihon Univ. (Japan)

Background and objectives: More than half of people over 65 years old sometimes feel dry mouth. Decreased saliva secretion is thought to be one of the causes of food intake reduction, malnutrition and decline in their QOL. Increased salivation by salivary gland stimulation have the potential to improve QOL. Cell line A253 from human salivary gland tumor was used to attempted to find metrics for salivary gland stimulation. We previously reported that the A253 expressed all 25 isoforms of hTAS2R, hT1R3 and alpha-Amylase, and also responded to some bitter compounds. The amino acids in foods have various tastes for example, bitterness and sweetness. In this study, we examined the responsiveness to amino acids and the expression of saliva-related genes using the A253.

Methods: $5x10^4$ cells/well of A253 strain were incubated in McCoy's 5A medium containing 10% FBS, 5% CO_2 for 24 hours at 37ºC. Stimulation of A253 with each of 20 amino acids was performed at concentrations up to 10 times the threshold, based on the threshold. Then, intracellular calcium concentration was measured by calcium imaging using Fluo-8. The expression levels of saliva-related genes stimulated with alanine, arginine, lysine, phenylalanine were measured by qRT-PCR.

Results: Among 20 amino acids, A253 responded to 14 amino acids; those are arginine, histidine, leucine, methionine, phenylalanine, isoleucine, tryptophan, alanine, glycine, proline, lysine, valine, glycine and cysteine. The expression level of AMYLA was changed by the stimulation with alanine, arginine, lysine and phenylalanine. Similarly, expression level of MUC7 was changed by the stimulation with alanine, arginine and lysine and ANO1 was changed with only alanine and arginine.

Conclusions: From above results, it was speculated that the expression of saliva-related genes in the A253 was dependent on the taste components, to which the cells responded. It is speculated that changes in the expression of these genes may be indicators of salivary gland stimulation. Clinical trials will need to be conducted to investigate the effects of taste substances on saliva production hereafter. This research was supported by a Grant-in-Aid from the Showa Women's University.

Dipeptide FP(Phe-Pro) improves cholesterol metabolism via PepT1 and appears in portal blood.

Arata Banno[1], Mako Yamamoto[1], Ryosuke Mori[1], Jilite Wang[1], Maihemuti Mijiti[1], Asahi Takeuchi[1], Ye Yuyang[1], Satoshi Nagaoka[1]

1. Gifu University (Japan)

Background and objectives: There have been no reports on *in vivo* active cholesterol-lowering dipeptide in any protein origin. We discovered a novel cholesterol metabolism-improving peptide FP (phenylalanine-proline) from 400 dipeptides for the first time in the world (1). In this study, we evaluated the cholesterol-lowering effects *in vivo* and *in vitro*, including in *PepT1* KO mice. In addition, we administered a single oral dose of FP to rats and quantified its concentration in portal plasma, using LC-TOF/MS analysis.

Method: The effect of FP on the cholesterol absorption system was analyzed in Caco-2 cells. Wistar male rats were fed on a high-fat, high-cholesterol diet and orally administered FP for 14 days to evaluate its effects on lipid metabolism. Wild-type C57BL/6J male mice and *PepT1* KO mice were fed on a high-fat, high-cholesterol diet and orally administered FP for 14 days to evaluate its effect on lipid metabolism. FP (600 mg/kg B.W.) was administered orally as a single dose to male Wistar rats, and portal blood sampling was performed before and after administration (15, 30, 60, and 120 min). The obtained plasma was subjected to LC-TOF/MS analysis, using the stable isotope FP ($[^{13}C_9, ^{15}N]$Phe-Pro) and the inducing reagent AccQ Tag.

Results: Cholesterol absorption was significantly reduced by FP in Caco-2 cells. FP induced a significant decrease in lipid metabolism-related mRNA levels. Serum total cholesterol of rats was significantly decreased and HDL-cholesterol was significantly increased. The jejunal ABCA1 mRNA level was also significantly decreased. In wild-type mice, cholesterol absorption, serum total cholesterol, liver cholesterol, and liver lipids were significantly decreased. From LC-TOF/MS analysis, the FP concentration detected in portal plasma was 0.485 nmol/ml at 30 minutes after administration.

Conclusions: In this study, we found that the cholesterol metabolism-improving effect of dipeptide FP is mediated by PepT1. Furthermore, 0.485 nmol/ml of FP was detected in rat portal vein plasma.

Keyword: Dipeptide, PepT1, ABCA1, Cholesterol, LC-TOF/MS

In vitro and *in vivo* inhibitory effects of Japanese black tea on postprandial blood glucose elevation

Yukari Hamura[1], Mihoko Moto[1], Ayaka Yagi[1], Honoka Yahagi[1], Ayumi Yamamoto[1], Asae Nakamura[1], Naoko Takamizawa[2], Kazunaga Yazawa[2], Masayuki Suzuki[3]

1. Wayo Women's University (Japan), 2. Waseda University (Japan), 3. Mitsui Norin Co., Ltd. (Japan)

Background and Objectives: Correcting postprandial hyperglycemia has been shown to be clinically effective in preventing the development and progression of insulin resistance and type 2 diabetes. Many approaches have been used to suppress absorption of carbohydrates by inhibiting digestive enzymes, such as α-amylase and α-glucosidase, to mitigate the elevation of postprandial blood glucose levels. We evaluated the α-glucosidase inhibitory activity of Japanese black teas *in vitro* and investigated their inhibitory effects on postprandial blood glucose elevation in human subjects.

Methods: α-glucosidase inhibitory activity of 11 species, 20 kinds of Japanese black tea were compared. *In vivo* study was randomized, placebo-controlled, crossover study. Thirty-two eligible subjects took Japanese black tea or water as a placebo with white rice as a test meal. Blood glucose was measured at 0, 30, 60, 90, 120 min after the meal, and we compared the changes between Japanese black tea group and placebo group.

Results: α-glucosidase inhibitory activity of Japanese black tea differed among different species and harvest area. There was correlation with the α-glucosidase inhibitory activity of Japanese black tea and the total polyphenol content. Even for the same species of leaves, the α-glucosidase inhibitory activity of black tea was higher than that of green tea. Japanese black tea suppressed the increase of blood glucose at 30 min after the meal, and the effect was especially marked in subjects whose postprandial blood glucose levels were higher at this time point.

Conclusions: These results suggest that intake of Japanese black tea reduced carbohydrate metabolism in the gastrointestinal tract, showing a lower postprandial blood glucose level in human subjects. Consequently, ingestion of Japanese black tea might be useful for preventing the development and progression of insulin resistance and type 2 diabetes.

The effect of Spirulina compounds on insulin sensitivity and renal function in patients with chronic kidney disease: a randomized double-blind placebo-controlled study

Shih Chien Huang[1], Ying Hung Tien[1], Yu Tung Tseng[1], Huey Liang Kuo[2], Yen Ping Lei[3]

1. Chung Shan Medical University (Taiwan), 2. China Medical University Hospital (Taiwan), 3. National Yang Ming Chiao Tung University (Taiwan)

Background/Objectives: Chronic Kidney disease (CKD) is considered a global public health problem, that causes high risk of mortality in cardiovascular diseases CVDs, and insulin resistance (IR) and uncontrolled hypertension is an early metabolic alteration in CKD patients. Spirulina is microalgae with nutritious ingredients and has potential effects on enhanced cardiovascular and metabolic health. Therefore, the aim of the present study was to investigate the effects of spirulina compounds on metabolic parameters in CKD patients.

Methods: In a double-blind, placebo-controlled clinical trial. we recruited 50 subjects with early CKD (CKD stages 2-3) in the outpatient clinic of China Medical University Hospital in Taiwan, Subjects were randomly assigned to four groups [group A: placebo (*n* = 10), group B*: Spirulina* 250 mg (*n*= 12), group C: *Spirulina* 500 mg + glutathione 200mg + vitamin C 200mg (*n* = 14), group D: *Spirulina* 500mg (*n* = 14)] and each randomized to receive 4 capsules of Spirulina or placebo daily for 12 weeks. The hematological parameters, anthropogenic indices were measured/ assessed at the 0 and 12th week.

Results: At baseline, there were no significant differences in a outcome variables among four groups. Insulin (16.9 ± 14.5 vs 12.2 ± 11.4 μIU/mL), HOMA-IR (4.4 ± 3.6 vs 3.3 ± 2.9) and triglyceride (178.3 ± 96.5 vs 133.9 ± 55.1 mg/dL) at baseline and week 12 in patients receiving group C supplementation. After 12 weeks, systolic blood pressure in patients receiving group B supplementation was significantly lower that of 6.6%. However, there was *no significant improvement* in renal *function among groups* (*P*>0.05) after intervention.

Conclusion: A Spirulina complex supplementation improved insulin resistance in patients with CKD stage 2-3 after the 12 week follow-up period.

Functional food ingredients reduce lung metastasis by using B16-BL6 melanoma cells

Sachi Shibata[1], Kohei Yamada[1], Shigeyuki Kon[1]

1. Fukuyama University (Japan)

Background and objectives: Some functional food ingredients have an inhibitory effect on angiogenesis, which was suggested to be related to cancer. We focused on the preventive effect on the metastases of lung cancer through functional food ingredients with an inhibitory effect of angiogenesis. In this study, we aimed to analyze the effect of some functional foods in a mouse model of murine melanoma employing the B16-Bl6 melanoma cell lines and C57BL/6 mice.

Methods: In the lung cancer metastasis model, B16-BL6 cells were intravenously injected into C57BL/6 mice. Functional food ingredients were fed to mice. The role of functional food ingredients, such as carnosic acid, pisiferic acid, oleoylethanolamide, and Japanese *Sake* cake, were examined. We conducted some behavioral experiments for brain function. The number of lung metastases and lung weights were measured at the end of the experiments. To further clarify the mechanism, integrin expression on B16-BL6 cells was examined by flow cytometry and cell adhesion assay. Cell adhesion analysis was performed using various integrin ligands coated plates.

Results: We found that ingestion of some functional food ingredients was suppressed in the metastasis of lung cancer. In the light/dark box test, the carnosic acid group showed an anxiolytic effect. Flow cytometry analysis revealed that carnosic acid and pisiferic acid suppressed α4 integrin expression on B16-BL6 cells. Furthermore, carnosic acid treatment led to the inhibitory effect for α4, α9, and RGD recognizing integrin-dependent cell adhesion.

Conclusions: Our study demonstrated the preventive effects of functional food ingredients on lung cancer metastasis via suppression of integrin expression.

Keyword: lung metastasis, B16-BL6 cells, integrin, carnosic acid

Effect of starch-degraded rice endosperm protein on obesity in mice fed a high fat and sucrose diet

Keita Tsuhara[1], Chihana Igarashi[2], Motoni Kadowaki[1,2], Masatoshi Kubota[1,2]

1. Graduate School of Engineering, Niigata Institute of Technology, Kashiwazaki, Niigata (Japan), 2. Faculty of Engineering, Niigata Institute of Technology, Kashiwazaki, Niigata (Japan)

Background and objectives: Rice is not only an energy source, but also an important protein source for Asian people. Some studies on the physiological functions of rice endosperm

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

protein (REP) have been reported. There are two types of REP isolates reported: the one prepared by an alkali-extraction method (AE-REP) and the other prepared by a starch-degradation method (SD-REP). Most of the studies about the physiological functions have been conducted using AE-REP. Obesity is a risk factor for many diseases such as diabetes and many studies about anti-obesity have been conducted using various food materials. There is no reports of SD-REP about obesity although it was reported that AE-REP had suppressive effects on obesity . Therefore, we clarified whether SD-REP, which was characterized by less digestibility of prolamin, had anti-obesity effects or not.

Methods: Six-week-old male C57BL/6 mice were divided into three groups, mice fed a high fat and sucrose casein diet (HC), a high fat and sucrose SD-REP diet (HR), and a normal casein diet (NC). Mice were fed each experimental diet for 10 weeks and the body weight (once a week) and the feed intake (every day) were measured. Feces were collected for 4 days before the end of the experiment and subjected to the fecal lipid excretion analysis. At the end of the experiment, the blood samples were withdrawn from the inferior vena cava and the viscera (liver, kidney, perirenal fat, epididymal fat, and mesenteric fat) were collected. The collected blood samples were subjected to the biochemical analysis.

Results and conclusions: The body weight in the HR group was significantly suppressed after 2 week, compared with one in the HC group. The perirenal, epididymal, and mesenteric fat weights were also significantly lower in the HR group. These results strongly suggests that SD-REP has suppressive effects on obesity. In addition, aspartate aminotransferase and alanine aminotransferase in the blood, which are typical liver dysfunction markers, were significantly lower in the HR group, inferring that SD-REP has protective effects on liver functions. Therefore, SD-REP may have the suppressive effects on obesity and liver dysfunctions.

Arctigenin-containing food materials prevent obesity by improving composition of gut microbiota in obese mice

Shimpei Watanabe[1], Akiko Ohno[1], Satoshi Yomoda[1], Satoshi Inamasu[1]

1. Kracie Holdings, Ltd. (Japan)

Background and objectives: Gut microbiota affect the health status of the host, with dysregulation in the gut environment being linked to various disorders. For example, the Firmicutes/Bacteroidetes (F/B) ratio and the amount of *Akkermansia muciniphila* in the microbiota have been closely linked to obesity. In this study, we evaluated the effects of an anti-obesity lignan compound, arctigenin (AG), and AG-containing food materials, on the gut microbiota in an obese mouse model.

Methods: C57BL/6J mice were fed a high-fat high-sucrose (HFHS) diet with AG, burdock sprout extracts (GSE), forsythia leaf extracts (RLE), and metformin (MF) for 8 weeks. The composition of gut microbiota and cecal content of short-chain fatty acids (SCFAs) were determined using 16S rRNA gene sequencing and high performance liquid chromatography, respectively. The qPCR was performed on the fecal samples used for 16S rRNA gene sequencing to determine the abundance of *A. muciniphila.*

Results: Body-weight gain was significantly suppressed in obese mice treated with AG, GSE, RLE, and MF compared with that in the HFHS group. Analysis of the gut microbiota revealed that the F/B ratio was significantly reduced in the AG-, GSE-, and RLE-treated groups in comparison with HFHS group. Furthermore, the copy number of *A. muciniphila* in the feces was significantly increased in obese mice treated with AG, GSE and RLE. In particular, the increase in *A. muciniphila* in the RLE group was remarkable compared to that in the AG and GSE groups. In addition, the amount of SCFAs in cecal content was significantly increased following AG, GSE, and RLE treatment.

Conclusions: Collectively, these results suggest that AG, AG-containing GSE, and RLE prevent obesity by inducing changes in the gut microbiota. The positive effect observed in the GSE group is considered to be exerted by the AG. In contrast, the effect of RLE may be related not only to AG but also to other polyphenols and dietary fiber. Therefore, AG should be further evaluated as a novel prebiotic for reducing obesity, as well as improving intestinal health. GSE and RLE are potentially useful raw food materials for AG consumption.

Keyword: Arctigenin, Obesity, Gut microbiota, Burdock sprout extracts, Forsythia leaf extracts

Palmitic acids suppress gene expression of myosin heavy chain via MyoD inactivation

Rikako Fujita[1], Izumi Matsuba[1], Kaoruko Iida[1,2]

1. Graduate school of Humanities and Sciences, Ochanomizu University (Japan), 2. The Institute for Human Life Innovation, Ochanomizu University (Japan)

Background and objectives: Sarcopenia is defined as the loss of skeletal muscle mass and strength, and known to cause physical disability, reduced quality of life and death. Aging and poor nutrition are known causes of sarcopenia, but recently fat accumulation due to obesity has also been considered as a cause. In particular, palmitic acids (PA) secreted from hypertrophied adipocytes is reported to induce myotube atrophy, however the underlying mechanism is still unclear. In this study, we therefore investigated the effect of PA on myoblast differentiation and myofiber maturation, which plays an important role in maintaining muscle mass, and the mechanism underlying these effects.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: C2C12 mouse myoblast cell line derived from mouse muscle satellite cells was used. After the cells were differentiated into myotubes, the cells were exposed to PA and the mRNA levels of myogenic regulatory factors (MRFs) and myosin heavy chain (MHC) were examined by real-time PCR. To confirm the effects of PA on promoter activity of MHC2b gene, we performed luciferase reporter assays using the reporter plasmid containing MHC2b gene promoter and the MyoD expression plasmid. **Results:** Treatment with 0.4 mM PA for 24 hours inhibited morphological differentiation of C2C12 myoblasts and significantly decreased the mRNA expression levels of MyoD, myogenin, and certain types of MHC, particularly MHC2b. In promoter assays, forced expression of MyoD, a transcription factor involved in MHC2b expression, significantly increased MHC2b promoter activity, but this increase in activity was significantly reduced by PA. Inhibition of MyoD phosphorylation on serine residues attenuated the inhibitory effect of PA on MHC2b promoter activity. Furthermore, PA-induced decrease in gene expression of MHC2b was restored by treatment with myriocin, a ceramide synthetase specific inhibitor.

Conclusions: These results indicate that ceramide synthesized from PA induces phosphorylation of MyoD, which may suppress the activity of this factor, thereby reducing the promoter activity of MHC2b gene and suppressing its expression.

Keyword: skeletal muscles, palmitic acids, myosin heavy chain (MHC), MyoD, promoter activity

PAB(T7-126)
Effect of imidazole-dipeptides deficiency on protein metabolism in skeletal muscle of exercise-loaded mice

Jiawei Wu[1], Toshihide Nishimura[1]

1. Kagawa Nutrition University (Japan)

Background and objectives: Imidazole dipeptides (IDs) such as carnosine and anserine have been reported to have antioxidant, anti-fatigue, and cognitive function recovery effects as supplementation, but its endogenous physiological function in the body are not clear. In the present study, wild-type (WT) mice and KO mice (carnosine synthase-gene deficient knock-out mice) were used for exercise-loaded experiment, and we aimed to clarify the effect of IDs deficiency on protein metabolism in skeletal muscle of exercise-loaded mice.

Methods: 30-week-old male WT mice and KO mice (n = 4 in each group) were forcibly exercised for 2 weeks. After the loading, tissues were extracted under general anesthesia with isoflurane and these weights were measured. The gene expression levels of factors related to muscle protein metabolism in the gastrocnemius muscle were measured by quantitative RT-PCR. The free amino acid concentration in gastrocnemius muscle was measured. Protein hydrolysis method was followed to measure the total amount of protein in gastrocnemius muscle.

Results: There was no significant difference in the mileage in exercise by treadmill between the WT and KO groups, and also no significant difference in muscle weight. The amount of exercise load in this experiment did not affect the performance. The analyses of the gene expression levels of protein metabolism-related factors in muscle showed that the levels of gene expression in mTOR, Cathepsin L, atrogin-1, and PGC1α in the KO group were significantly lower than those in the WT group by 30%-50%. The amount of proteins in mice of WT group tended to be higher than that of the KO group. It was presumed that IDs deficiency suppressed the syntheses of skeletal muscle proteins in skeletal muscle during loaded exercise. In the next step, the effect of the administration of imidazole dipeptides on protein metabolism in skeletal muscle in mice after exercise loaded should be investigated.

Conclusions: IDs deficiency affected the protein metabolism in skeletal muscle, suggesting IDs may regulate the protein metabolism of skeletal muscle.

Keyword: Imidazole dipeptide, Carnosine synthase knockout mouse, Protein metabolism, Skeletal muscle , Exercise loaded

PAB(T7-127)
Okra (*Abelmoschus esculentus* L.) as a potential source of functional food

Chalinee Tatiyanukul[1], Suzuno Shinohara[1], Hibiki Kubota[1], Wataru Tanaka[1], Hiroyuki Sakakibara[1]

1. University of Miyazaki (Japan)

Background and objective: In recent years, many people have become health conscious, and hence, many research groups are investigating to find the functional food candidates, which have the possibility to protect our body from the life-related diseases, such as diabetes and obesity. Okra (*Abelmoschus esculentus* L.) is widely spread in the world, including Japan, and has attracted attention for its functional properties. Okra has a slimy consistency when chopping. This stickiness is attributed to pectin, a water-soluble dietary fiber. In this study, two kinds of okra, normal okra (NO) and pectin-rich okra (PRO), were used as test samples, and their biological functions were evaluated.

Methods: Corn and onion, which were used as control food materials, were freeze-dried, in addition of NO and PRO. Freeze-dried samples powders were washed by ethanol and dried to obtain pectin fraction. Their water-soluble pectin amounts were analyzed using carbazole-sulfate method. The antioxidant activity and total polyphenol amounts were analyzed using 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging and Folin-Ciocalteu assay, respectively. Furthermore, antioxidative activity and polyphenol total content of pectin fractions from the PRO and NO were evaluated subsequently.

Results: The results showed that PRO indicated the significantly higher pectin amount than that of NO. PRO also

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

showed a significantly higher antioxidant activity and total polyphenol content compared to corn, onion, and NO. No significant differences were observed between pectin fractions from NO and PRO.

Conclusion: PRO has a significantly higher antioxidant activity, pectin, and total polyphenol amount compared to corn, onion, and NO. It could be possibly a potential source of functional food due to pectin amount and its antioxidant activity. Currently, we are conducting the study about the effects of pectin fraction from PRO on glucose absorption using *in vivo* assay system.

PAB(T7-128)
Effects of *Lactococcus* spp. on the lifespan and motility of *Caenorhabditis elegans*

Shino Takeuchi[1], Mohammad Shaokat Ali[1,2] , Eriko Kage-Nakadai[1]

1. Osaka City University (Japan), 2. Chattogram Veterinary and Animal Sciences University (Bangladesh)

Background and objectives: In studies using the nematode *Caenorhabditis elegans* (*C. elegans*) as a surrogate model, various lactic acid bacteria have been reported to ameliorate the longevity and motility of the nematode. This study was performed to elucidate the effects of *Lactococcus* spp. on the longevity and motility of *C. elegans* as a host.

Methods: The wild-type *C. elegans* (N2) was employed as the experimental animal. Synchronized L1 larvae were grown at 25°C on nematode growth media (mNGM) with a standard diet, non-pathogenic *Escherichia coli* OP50 (OP), until 3 days old to be used for experiments. For survival study, the larvae were separated into a control group (fed OP) and a test group (fed *Lactococcu*s spp.) when they reached adulthood at 3 days of age. The Kaplan-Meier method was used to compute survival rates, and variations in survival rates were identified with the log-rank test. For this study, three distinct *Lactococcus* species (i.e. *Lactococcus formosensis, Lactococcus taiwanensis*, and *Lactococcus kimuchii*) were employed. Because of the nematode avoidance of *L. formosensis* and *L. taiwanensis*, they were fed a 1:1 mixture with OP.

Results: Nematodes fed alone with *L. formosensis* had significantly lower longevity and motility than the control group. Aside from that, nematodes fed only *L. taiwanensis* had a shorter lifespan but enhanced motility. Furthermore, nematodes fed with a mixture of *L. taiwanensis* and OP or *L. kimuchii* and OP exhibited no difference in longevity but increased their motility significantly.

Conclusions: We intend to investigate gene expression in *L. kimuchii*-fed worms in the future and investigate the mechanism of improved motility.

Aesculetin blocks neutrophil elastase-mediated airway epithelial barrier disruption caused by inhalation of urban particulate matter

Young Eun Sim[1], Sin-Hye Park[1], Young-Hee Kang[1]

1. Hallym University (Korea)

Background and objectives: Particulate matter (PM), a mixture of solid and liquid air pollutant particles suspended in air, is the most harmful form of air pollution due to its ability to penetrate deep into the lungs and blood streams, causing diverse respiratory diseases. Neutrophil elastase (NE) is a major constituent of lung elastolytic activity and potently stimulates mucus secretion during airway inflammation. Aesculetin is a coumarin derivative that is known to have anti-inflammatory effects in the vascular and immune system. The current study investigated that naturally-occurring aesculetin attenuated NE-mediated urban PM10 (uPM10, particles less than 10 μm)-induced airway epithelial barrier dysfunction and tight junction disruption.

Methods: Mice were orally administrated with 10 mg/kg aesculetin and exposed to 6 μg/ml uPM10 for 8 weeks. To further explore the NE involvement in uPM10-induced epithelial junction disruption and inhibitory effects of aesculetin, bronchial epithelial BEAS-2B cells were treated with 1-20 µM aesculetin in the presence of 2 μg/ml uPM10 or 0.5 μg/ml NE.

Results: Oral administration of aesculetin attenuated NE accumulation and interleukin-1β secretion in the small airways inflamed by uPM10. Additionally, uPM10 markedly induced NE in bronchial epithelial BEAS-2B cells, which was dose-dependently inhibited by1-20 µM aesculetin. Expression of bronchial epithelial toll-like receptor 4 (TLR4) and epidermal growth factor receptor (EGFR) was highly enhanced within 2 h following treatment with 0.5 μg/ml NE. Interestingly, NE evoked a dual induction of EGFR at 24 h after exposure to NE. Such induction of both TLR4 and EGFR by NE was curtailed by treating 20 μM aesculetin to bronchial epithelial cells. It should be noted that uPM10 induced TLR4 and EGFR, which was hampered by aesculetin. Furthermore, aesculetin promoted the induction of epithelial tight junction markers including occludin-1 reduced by uPM10 and NE. The epithelial induction of TLR4 and EGFR was responsible for the disruption of bronchial tight junction. These results demonstrated that aesculetin blocked airway epithelial barrier disruption caused by uPM10 inhalation through inhibiting NE-stimulated TLR4 and EGFR.

Conclusions: Aesculetin may be a promising agent for restoring airway epithelial barrier integrity disrupted by urban coarse particulates.

Keyword: Aesculetin, urban particulate matter, neutrophil elastase, airway epithelial barrier integrity, airway epithelial tight junctions

Effect of tomato seed extract and its major saponins on epidermal barrier functions and steroidal anti-inflammatory effect

Shogo Takeda[1], Kenchi Miyasaka[1], Sarita Shrestha[2], Yoshiaki Manse[2], Toshio Morikawa[2], Hiroshi Shimoda[1]

1. Oryza Oil & Fat Chemical Co., Ltd (Japan), 2. Pharmaceutical Research and Technology Institute, Kindai University (Japan)

Background and objectives: Tomatoes *(Solanum lycopersicum)* are widely consumed around the world. As previous works regarding constituent study of tomato fruits, steroidal saponins have been isolated as lycoperosides and esculeosides. Among these saponins, orally administered esculeoside B isolated from tomato juice improved 2,4-dinitrochlorobenzene-induced type IV allergic dermatitis in mice. However, studies of tomato seeds on skin inflammation are limited. In this study, we have isolated 11 compounds, including solanocapsin type, spirosolan type, pregnan type, frostan type and spirostan type saponins and flavonoids from tomato seeds, to evaluated the effects on epidermal barrier functions and inflammation.

Methods: The screening for candidate compounds that improve epidermal barrier functions was assessed by measurement of mRNA expression of filaggrin, involucrin, serine palmitoyltransferase-2 (SPT2), ceramide synthase-3 (CerS3) and glucosylceramide synthase (GCS) on HaCaT cells. Epidermal barrier functions on the reconstructed human epidermal keratinization (RHEK) model were evaluated by measurements of transepidermal water loss (TEWL), ceramide contents in stratum corneum and mRNA expression of ceremide synthesis related enzymes including SPT2, CerS3, GCS, β-glucocerebrosidase (GBA), sphingomyelin synthase-2 and acid sphingomyelinase. On the other hand, the effect of lycoperoside H, the most abundant saponin in tomato seed, on atopic dermatitis (AD)-like symptoms was evaluated by oral administration to IL-33 transgenic (IL-33Tg) mice which is developed as AD model mice. In addition, binding ability to glucocorticoid receptor (GR) was evaluated by GR competitive assay.

Results: Among isolated compounds, all tomato seed saponins (10 µM) upregulated the mRNA expression of proteins related to epidermal hydration in HaCaT cells. These saponins (10 µM) except a pregnan saponin decreased TEWL in RHEK model and quantitative analysis of SC ceramide content revealed that 1 and 10 µM of lycoperoside H increased ceramide[NP] via upregulation of the mRNA expression of CerS3, GCA and GBA. On the other hand, oral administration of lycoperoside H (10 mg/kg) to IL-33Tg mice suppressed the deterioration of skin inflammation and TEWL. In addition, lycoperoside H suppressed infiltration of eosinophils and mast cells, and improves Th2/Th1 cytokine balance in the inflammatory skin region. GR competitive assay demonstrated that lycoperoside H partially binds to the glucocorticoid receptor.

Conclusions: Among 11 isolated compounds from tomato seeds, lycoperoside H was found to improve epidermal dehydration and suppress inflammation in AD mice by increasing ceramides in stratum corneum and anti-inflammatory activity.

Keyword: tomato seed, lycoperoside, steroidal saponin, ceramide, anti-inflammation

Acute and chronic administration of alpha-linolenic acid respectively potentiates nutrient-induced GLP-1 secretion in rats

Rino Kimura[1], Anri Sano[1], Tohru Hira[1]

1. Hokkaido University (Japan)

Background and objectives: Glucagon-like peptide-1 (GLP-1) is an incretin hormone that enhances insulin secretion leading to suppression of elevated blood glucose levels. Alpha-linolenic acid (ALA) co-administered with glucose is reported to promote GLP-1 secretion. However, the effect of a single administration of ALA, and chronic ingestion of ALA on GLP-1 secretion are unknown. In the present study, we examined the GLP-1 secretory response to a single oral administration of ALA, and the effects of long-term feeding of ALA-rich oil (perilla oil) on basal and postprandial responses of GLP-1 in rats.

Methods: ①Single oral administration study: Male Sprague Dawley rats (5 weeks old) were divided into three groups: dextrin group (4 g/kg body weight), ALA group (27.8 mg/kg body weight), and coadministration group. Blood samples were collected from the tail vein before and after the administration. ②Long-term feeding study: Rats were given either a control diet (C, soybean oil 7%) or a diet containing perilla oil (P, perilla oil 7%). Meal tolerance tests (MTT) were performed to evaluate postprandial GLP-1 responses to a liquid diet administration (15 kcal/kg body weight), at 2 and 4 weeks of feeding period. Rats were dissected 3 days after the 4 weeks-MTT, then, blood and tissue samples were collected.

Result: ①Plasma GLP-1 concentrations were increased by the coadministration of ALA and dextrin, but not by sole administrations. ②Postprandial GLP-1 response at the 4 weeks-MTT tended to be higher in the P group than in the C group. The AUC of GLP-1 concentration was higher, and the time for returning to basal GLP-1 concentrations (duration) was longer, in the P group than in the C group. After the experimental period (> 4 weeks), there were no differences in basal plasma GLP-1 concentration, GLP-1 content and proglucagon mRNA expression levels in the small intestine.

Conclusion: These results suggest that relatively small amount of ALA, not solely, but co-administered with carbohydrate exerts GLP-1 releasing effect, and that long-term ingestion of perilla oil enhances meal-induced GLP-1 secretory response. It is possible that dietary ALA enhances nutrient-sensing function of GLP-1-producing enteroendocrine cells.

Effects of interesterified fat between lard and medium-chain triacylglycerols on gut immunoglobulin A reactivity to gut bacteria and glucose metabolism

Emiko Katsumata[1], Takashi Yoshida[2], Mio Sasaki[2], Mao Teraoka[1], Taisei Miyamoto[1], Naoki Nishino[1], Takeshi Tsuruta[1]

1. Okayama University (Japan), 2. TAIYO YUSHI CORP. (Japan)

Background and objectives: We have previously demonstrated that excessive lard intake reduces the amount of immunoglobulin A (IgA) coating gut bacteria, and a reduction of IgA coating of gut bacteria may be related to abnormal glucose metabolism accompanied by excessive lard intake. In the present study, we evaluated the effect of lard with modified fatty acid composition on IgA coating of gut bacteria and glucose metabolism.

Methods: C57BL/6 mice were divided into 6 groups and fed lard, medium-chain triacylglycerols (MCT), or medium- and long-chain triacylglycerols (MLCT), which were interesterified fat between lard and MCT, at 7% or 30% w/w in a diet for 8 weeks, respectively (low-lard, high-lard, low-MCT, high-MCT, low-MLCT, high-MLCT group). Fresh feces were collected at week 8 and the IgA-coated fecal bacteria were stained with FITC-labeled anti-IgA antibody and propidium iodide. The average FITC intensity of IgA-coated bacteria was measured by flow cytometer and defined as amount of IgA coating a single fecal bacterium (IgA coating amount). Oral glucose tolerance test (OGTT) was performed to evaluate glucose tolerance. The fasting blood glucose and insulin concentration were measured to calculate the HOMA-IR index for the evaluation of insulin sensitivity.

Results: The IgA coating amount was significantly decreased in high-lard group as compared to low-lard group while no significant difference was observed among low-lard, high-MCT, and high-MLCT group. The incremental area under the curve of OGTT was significantly decreased in high-MCT and high-MLCT group compared to high-lard group. A similar tendency was observed in the HOMA-IR index. Pearson's correlation analysis showed a negative correlation between IgA coating amount and HOMA-IR index (P=0.06, r=-0.33).

Conclusions: Our findings demonstrate that a reduction of IgA reactivity to gut bacteria induced by excessive lard intake is alleviated by interesterification of lard with MCT. Furthermore, the alleviation effect of interesterified fat between lard and MCT on IgA reactivity to gut bacteria may relate to the improvement of abnormal glucose metabolism.

Effect of imidazole-dipeptides deficiency on spontaneous motor activity of mice

Ayane Seki[1], JIAWEI WU[1], Toshihide Nishimura[1]

1. Kagawa Nutrition University (Japan)

Background & Object: Carnosine and anserine are kinds of Imidazole dipeptides (IDs) which are abundant in vertebrate skeletal muscles. However, the physiological function of endogenous IDs in skeletal muscles is not still unclear. Our study was carried out to clarify the effects of deficiency of IDs on spontaneous motor activity of mice.

Methods: We experimented with the 21week old wild type mice (WT) and carnosine synthase gene defected mice (KO). Control diet (10kcal/fat) or high fat diet (60kcal/fat) were used as experimental foods. Food and water were provided *ad libitum* for 6weeks. Body weight was recorded twice a week. Mice were assigned into four groups such as control diet WT, control diet KO, high fat diet WT, and high fat diet KO. Spontaneous motor activity was recorded every minute for 24 hours with *Actimo* (SHINFACTORY Co.).

Result: In control diet group, there is no significant difference in body weight, food intake and water intake of mice between WT and KO groups. And spontaneous motor activity of mice in KO group tended to be higher than that in WT group *(p*=0.057). In high fat diet group, there is no significant difference in food intake and water intake of mice between WT and KO groups. Weight gain in KO group was significantly smaller than that in WT group during the experimental period ($p< 0.05$). Although there is no significant difference in the spontaneous motor activity of mice between WT and KO groups in the dark periods, the spontaneous motor activity of KO group in the light period was significantly higher than that of WT group ($p< 0.05$). This difference in the spontaneous motor activity between both groups seemed to be caused by that of body weight.

Conclusions: In high fat diet to mice, IDs deficiency seemed to affect the body weight gain of mice and enhance their spontaneous motor activity.

Effects of diurnal rhythms of ω-3 fatty acid synthesis pathway biological regulatory functions

Wataru Tanaka[1], Saori Watabe[1], Hiroki Matsuyama[1], Nanaka Shibazaki[1], Kayoko Shimoi[2], Hiroyuki Sakakibara[1]

1. University of Miyazaki (Japan), 2. University of Shizuoka (Japan)

Background and objectives: A daily consumption of high-fat diet induces overweight. On the other hand, ω-3 polyunsaturated fatty acids (PUFA), such as eicosapentaenoic acid (EPA) and docosahexaenoic acid has been reported to have an anti-obese effect. Recently, we have reported that EPA-rich fish oil intake at the end of the active phase maintained physiologically high EPA content using mice model, even if the intake was small. In the present study, we further evaluated that the effects of consumption timing on the physiological changes under the consumption of α-linolenic acid, which is PUFA physiologically converted to EPA.

Methods: On the first experiment, the liver samples were collected from male C57BL/6 mice every 6 hours for 24 hours, and analyzed the diurnal expression of genes concerning with fatty acid metabolism, including ELOVL Fatty Acid Elongase 2 (*Elovl2*) and *Elovl5*, which is factors related to the fatty acid synthesis system. Following, mice were consumed diet composed with ω-3 PUFA-rich perilla oil or ω-9 PUFA-rich olive oil for one week. The hepatic fatty acid composition and gene expression of *Elovl2* and *Elovl5* were analyzed.

Results: Hepatic gene expression of *Elovl2* and *Elovl5* exerted typical diurnal rhythm, with peak at the end of the active period. This diurnal rhythm was conserved on the mice consumed perilla oil, but not olive oil. EPA, which was little in perilla oil, was detected in the liver from mice consumed perilla oil, but almost detection limits in the mice consumed olive oil, which was a little of ω-3 PUFA including EPA. Interestingly, hepatic EPA amount was significantly higher at the end of the inactive period.

Conclusions: The results obtained in this study imply that the physiological system for fatty acid elongation has exert typical diurnal rhythm, and consequently EPA mounts after consumption of α-linoleic acid-rich oil might be affected from the consumption timing.

Keyword: ω-3 polyunsaturated fatty acids (PUFA), ELOVL, EPA, mice, perilla oil

PAB(T7-135)
Efficacy of dewaxed brown rice on the symptoms of seasonal allergic rhinitis; An open-label, randomized, parallel-group comparative pilot study.

Maya Uenobe[1], Hiroshi Yoshimura[2], Hiroyuki Inagawa[3]

1. The University of Nagano (Japan), 2. Nakagawa Hospital (Japan), 3. Control of Innate Immunity Technology Research Association (Japan)

Background and objectives: Dewaxed brown rice (DBR) is prepared by removing the outermost wax layer of brown rice. We have previously reported that DBR activates innate immune system macrophages and alleviates seasonal allergic rhinitis symptoms in mice. However, the effect on seasonal allergic rhinitis in humans has not yet been investigated. Therefore, we examined the effect DBR consumption on pollinosis symptoms in volunteers. recruited from the Nakagawa Hospital in Fukuoka.

Methods: In a parallel-group comparison trial, 28 participants who have experienced pollinosis symptoms in the past 2 years during the pollen season were divided into 2 groups. Participants consumed either white rice (WR, n=15) or DBR (n=13) for 5 months (December to April, 2 meals a day). Once a week during the trial, participants recorded symptoms (runny nose, sneezing, nasal congestion and itchy nose, itchy eyes, watery eyes) using the Japan Rhinitis Quality of Life Questionnaire No.1 (JRQLQ No.1). Medication use was recorded daily. Total nasal symptom medication score (TNSMS) and total ocular symptom medication score (TOSMS) were calculated. To evaluate the difference between symptom scores, the area under the curve (AUC) during the study period was calculated. Based on the AUC of TNSMS and TOSMS, the participants were classified as high or low responders. (Ethics Committee of The University of Nagano: E19-6).

Results: The baseline participant characteristics were not significantly different between the groups. During the pollen season (February to April), the medication score (MS) in the DBR group was significantly lower than in the WR group (Mann-Whitney U-test, $P < 0.05$). In assessing symptom independence, the AUC values for participants consuming DBR were significantly lower than those consuming WR (Fisher's exact test, $P < 0.001$, TNSMS, TOSMS).

Conclusions: Consuming DBR prior to pollen season was effective in reducing the TNSMS and TOSMS for seasonal allergic rhinitis compared to consuming WR. These results suggest that individuals with seasonal allergic rhinitis may be able to manage symptoms by consuming DBR regularly.

Comparison of intestinal absorption profiles of various apigenin glycosides in rats

Mika Kawamoto[1], Kaeko Murota[1]

1. Shimane University (Japan)

Background and Objectives: Flavonoids are widely distributed in plant foods and beverages. Most of the flavonoids have antioxidant and anti-inflammatory activities and are attracting much attention to their health beneficial effects on various disease prevention. In plant foods, flavonoids are present mainly in various glycosidic forms. The basic structure of flavonoid aglycone and the type of sugar moiety bound to one or more hydroxy groups strongly affect their bioavailability. We have investigated the intestinal absorption, lymphatic transport pathways, and metabolism of dietary flavonoids with various chemical structures, especially quercetin and its derivatives. In this study, we compared the bioavailabilities of apigenin derivatives with different glycosidic moieties in rats.

Methods: Apigenin and its glycosides, apigenin-7-O-glucoside (A7-O-G), apigenin-7-O-apioglucoside (apiin), apigenin-6-C-glucoside (isovitexin) and isovitexin-4'-O-glucoside (isosaponarin), were administered intraduodenally to the thoracic lymph-cannulated rats. The collected peripheral plasma, the lymph and the urine were analyzed by UV-HPLC with or without deconjugation treatment.

Results: When A7-O-G and apiin were administered, apigenin was detected in the plasma, the lymph and the urine with deconjugation treatment. The intact aglycone was also detected in the lymph and the urine only in smaller amount, indicating that most of the absorbed apigenin were present as its conjugates after hydrolysis of O-glycosidic bonds. In addition, A7-O-G was absorbed earlier after hydrolyzed by intestinal mucosal enzyme and apiin absorption was observed later probably after the deglycosylation by intestinal microbiota. The apigenin levels in the plasma and the lymph was highest after A7-*O*-G administration compared with apigenin aglycone and apiin administration. Meanwhile, apigenin aglycone was not detected either with or without deconjugation after administration of isovitexin and isosaponarin. Instead, small amounts of these C-glycosides were detected in the plasma and the lymph shortly after administration. Interestingly, a part of isosaponarin was converted to isovitexin in the small intestine.

Conclusion: These results indicate that the absorption amount and the metabolic pattern of apigenin differed, and the physiologically active metabolites may be dissimilar depending on the type of sugar moieties.

Keyword: apigenin, glycoside, intestinal absorption

Jasmine mixed tea's potential benefits against oxidative stress-related diseases.

Kheira Makreloufi[1], Kaeko Murota[1]

1. Shimane University (Japan)

Background and Objectives: Antioxidants have a potential to protect against oxidative stress-related multiple diseases, including cancer, diabetes, and neurodegenerative and cardiovascular diseases when consumed in a long-lasting way through food intake. Jasmine tea is a popular flower tea that has been reported to be effective in treating hypercholesterolemia in rats and preventing the elevation of serum and liver cholesterol as well as the atherogenic index. Other studies demonstrated that jasmine flavored green tea exhibited strong antioxidant and anticancer activities and the increase in scenting process did not significantly affect the antioxidant capacity. Our objective is studying jasmine tea's potential benefits against metabolic diseases, so as an initial step jasmine tea's polyphenolic content and antioxidant activity were investigated to estimate the potential preventive effect against oxidative stress.

Methods: We prepared extracts of jasmine green tea, jasmine black tea, green tea, black tea, or jasmine buds with boiling water. The antioxidant activity was estimated by the radical scavenging ability using DPPH technique. Folin Ciocalteu method was used to compare the polyphenolic content in each extract. HPLC method was used to analyze the polyphenolic contents in extracts.

Results: Jasmine green tea and green tea showed higher antioxidant activity and polyphenolic contents than black teas. Specific DPPH radical scavenging activity per polyphenolic contents were higher in green tea than in jasmine green tea. On the contrary, jasmine black tea showed higher specific activity than black tea. HPLC analysis showed that some polyphenols were enhanced after adding the jasmine scenting, whereas some polyphenols have been reduced. Polyphenolic contents found in the jasmine buds extract were not detected in jasmine green tea but slightly detected in jasmine black tea.

Conclusion: Jasmine scenting process could alter the polyphenolic content and the antioxidant activity on green tea and black tea in different ways. To find the contributor for the alteration of biological activities, using polyphenol standard and a handmade jasmine buds-tea mixture will be helpful for clarification, and eventually proposing various jasmine mixed teas that may have beneficial effects against oxidative stress-related diseases.

Keyword: Polyphenols, DPPH radical scavenging activity, jasmine tea, oxidative stress

Anti-cancer effects of Kencur extract on Ehrlich ascites tumor cells

Yutaro Sasaki[1], Isao Matsui-Yuasa[1], Akiko Kojima-Yuasa[1]

1. Graduate School of Human Life Science, Osaka City University (Japan)

Background and objectives: Kencur, a tropical plant of the *Zingiberaceae* family, is widely cultured in Asia and its rhizome is used as a spice in various traditional cooking. Previous studies have reported that Kencur prevents hypertension and diabetes. This study aimed to discover new physiological effects of Kencur by assessing the anti-cancer effect of Kencur extract on Ehrlich ascites tumor cells (EATC).

Methods: Kencur extract was prepared by extracting Kencur with 100% ethanol. EATC were incubated with or without Kencur extract (6.25, 12.5 or 25 μg/ml). The anti-cancer effect of Kencur extract was estimated using by Trypan blue exclusion, 2,7-dichlorofluorescin diacetate assay, 5-bromo-2'-deoxyuridine (BrdU) incorporation assay, real-time quantitative PCR, and western blotting. The components of the Kencur extract were analyzed by HPLC.

Results: The Kencur extract suppressed cell proliferation without reducing the cell viability of EATC. In addition, BrdU positive cells were reduced by Kencur extract. The main component of the Kencur extract was ethyl-4-methoxycinnamate (EMC), and EMC exhibited the same anti-proliferative effect as the Kencur extract. EMC decreased the expression levels of TFAM (transcription factor of mitochondrial DNA) and intracellular ROS production levels, and increased the expression levels of Pten (G1 arrest related gene). Furthermore, EMC decreased Ser62 phosphorylation levels of c-Myc, which is a transcriptional regulator of TFAM, by suppressing the expression levels of H-Ras. EMC also increased the expression levels of Mxi1, which inhibits the function of c-Myc.

Conclusions: This study revealed that Kencur extract and EMC exhibit anti-proliferative effect by blocking the G1/S transition of EATC. Furthermore, our results suggested that EMC increased the expression levels of Pten by decreasing mitochondrial-derived ROS levels via reduced transcriptional activity of c-Myc.

Keyword: Kencur, Ethyl-4-methoxycinnamate, Ehrlich ascites tumor cells (EATC), Anti-cancer, G1 arrest

Effect of the black vinegar drink containing peanut skin extract on glucose and lipid metabolism in high-fat diet-induced obese mice

Rino Higa[1], Riko Kato[1], Honami Ohta[1], Yukari Egashira[1], Akihiro Isoda[1], Seiji Suwa[2], Keita Imai[2], Shizuka Hirai[1]

1. Chiba University (Japan), 2. Yamasu Inc. (Japan)

Background and objectives: Obesity, which has been increasing all over the world in recent years, increases oxidative stress in our body and leads to the development of metabolic syndrome. Peanut skin is discarded in large quantities due to their low economic value in the peanut industry. However, peanut skin is an attractive material rich in antioxidant polyphenols. We have previously found that black vinegar containing peanut skin extracts have a very high polyphenol content. In this study, we investigated the effect of the black vinegar drink containing peanut skin on glucose and lipid metabolism in high-fat diet-induced obese mice.

Methods: Six-week-old male C57BL/6J mice were divided into three groups depending on the sample provided as a drink; water (control group), 40-fold dilution (low dose (LD) group) or 20-fold dilution (high dose (HD) group) of the black vinegar drink containing peanut skin. Mice were fed with a 60%kcal high fat diet for 19 weeks. Mice were sacrificed one week after the oral glucose tolerance test.

Results: The final body weight of LD and HD groups were significantly decreased compared with control group ($p = 0.01$ and $p = 0.05$, respectively).

Conclusions: The results of this study suggest that ingestion of black vinegar drink containing peanut skin may help to prevent high-fat diet-induced obesity and development of metabolic syndrome.

Infants may be exposed to quercetin and its metabolites *via* breast and formula milk

Nao Fujiwara[1], Rie Mukai[2], Akira Murakami[1], Akari Ishisaka[1]

1. University of Hyogo (Japan), 2. Tokushima University (Japan)

Background and objectives: Quercetin (QUE) is converted into various metabolites by mechanisms of drug metabolism. Blood and urine have so far been conventionally used to evaluate the bioavailability of QUE. However, it has recently been shown that flavonoids, including QUE, are also present in human breast milk[1]. It is important to note that previous studies have not elucidated the presence of aglycones in breast milk because they used deconjugation enzymes for analyses. In addition, the concentrations of flavonoids in the blood and breast milk of one individual have never been compared. In this study, we aimed to quantify QUE and its metabolites in biological samples of maternal and neonatal mice.

Methods: Both male and female ICR mice, divided into a control and a 1%-QUE-fed group, were allowed to mate and delivery. Breast milk was then collected from maternal mice once or twice by postnatal day 11-13, and then blood and urine from maternal and neonatal mice were obtained. Each sample was treated with or without the deconjugation enzyme sulfatase H-1. QUE and its metabolites were quantified by LC-QTOF-MS/MS analysis.

Results: QUE and its metabolites (isorhamnetin, QUE-3-glucuronide and QUE-3'-sulfate) were detected in breast milk, blood and urine of maternal mice in the QUE group. Interestingly, the concentrations of QUE in breast milk were estimated to be 7 times as high as those in blood. Besides, QUE was present in the blood and urine of neonates. Therefore, our results suggest that QUE was transferred from maternal to neonates *via* breast milk. In addition, we found that QUE aglycone was present in commercial infant formula.

Conclusions: In this study, we have demonstrated for the first time the presence of QUE and its metabolites in the biological samples of QUE-fed maternal mice and their infants. As QUE was also present in formula milk, infants may be exposed to QUE in both cases that they intake either breast or formula milk. The levels of drug-metabolizing enzymes of the QUE exposed infants are currently investigated.

Effect of soybean hull product on obesity and gut microbiome in high-fat diet induced obese mice

Hatsune Komaya[1], Minori Ogata[1], Ikuho Takao[1], Shizuka Hirai[1], Takuya Asaoka[2], Yuka Miki[2], Yukari Egashira[1]

1. Chiba University (Japan), 2. Showa Sangyo Co., Ltd. (Japan)

Background and objectives: In recent years, the global obesity population has increased rapidly. Obesity increases the risk of developing cardiovascular diseases, therefore it is important to prevent or ameliorate obesity. Soybean hulls are by-product produced during the processing of soybean products. Although soybean hulls contain a high content of dietary fibre, most of them are wasted. Several studies have reported that the intake of dietary fibre improves high-fat diet induced obesity and gut microbiome composition, however few studies have reported about the effect of soybean hulls on obesity and microbiome. Therefore, in this study, we investigated the effects of soybean hull product on obesity and gut microbiome in high-fat diet induced obese mice.

Methods: 7-week-old male C57BL/6J mice were fed a standard diet (ST), a high-fat diet (HFD), or HFD with 5% (w/w) or 10% (w/w) soybean hull product (5% or 10%) for 10 weeks. After 10 weeks of the respective dietary treatment, mice were sacrificed. For the measurement of fecal short chain fatty acids (SCFAs) contents and the analysis of gut microbiome composition, feces were collected at 10 weeks of treatment. The gut microbiome composition was analyzed by 16S rRNA gene sequencing.

Results: Dietary supplementation of 10% soybean hull product significantly reduced the body weight gains, weights of subcutaneous, epididymal, and perirenal adipose tissues compared to the HFD group. In 10% group, the content of major SCFAs such as acetate, propionate, and butyrate significantly increased. Furthermore, the overall gut microbiome composition changed with the dietary treatment, especially 10% group showed the significant increase of the relative abundance of potentially beneficial bacteria such as SCFAs producing bacteria.

Conclusions: Consumption of soybean hull product suppressed the weight gain and fat accumulation caused by a high-fat diet intake and altered gut microbiome composition. These results suggest that soybean hull product can be a functional food material which helps prevent high-fat diet induced obesity and utilize wasted food material.

Keyword: soybean hulls, obesity, gut microbiome, dietary fibre, SCFAs

Anti-cancer effect of nucleic acids and its mechanism

Mamia Furuta[1], Yutaro Sasaki[1], Keisuke Kiriyama[2], Mica Fujita[2], Keita Sutoh[2], Isao Matsui-Yuasa[1], Akiko Kojima-Yuasa[1]

1. Graduate School of Human Life Science, Osaka City University (Japan), 2. Fordays Company, Limited (Japan)

Background and objectives: It has been clarified that nucleic acids have various physiological activities such as catalysis of certain biochemical reaction and regulation of certain activity in cells. We have already reported that DNA-rich nucleic acid prepared from salmon milt (DNSM) has protective effect against ethanol-induced liver injuries in rats. In this study, we investigated that anti-cancer effect of nucleic acids.

Methods: We evaluated nucleic acids for its anti-tumor activity against the Ehrlich ascites tumor (EAT) *in vivo* and *in vitro*. EAT-bearing mice was used for *in vivo* system. DNSM and RNA as a sample, was ingested orally. For *in vitro* experiments, DNSM, RNA, or nucleosides such as adenosine, guanosine, 2-deoxyguanosine, cytidine and uridine were used. Cell viability, cell proliferation and cell cycle were analyzed. The expression levels of cell cycle-related genes and proteins were measured by real-time quantitative PCR and western blotting.

Results: When DNSM or RNA was added to the medium of EAT cells, RNA showed anti-cancer effect, but DNSM did not affect cell viability and proliferation. On the other hand, in *in vivo* experiments, oral administration of DNSM or RNA significantly reduced ascites in mice, suggesting the digestive products, which are created by the degradation of DNSM by nucleases in the intestine, showed anti-cancer effect. Furthermore, in order to reveal for the active component of the anti-cancer effect of nucleic acid, cell proliferation of EAT cells was measured. Among each nucleoside, guanosine and 2-deoxyguanosine significantly suppressed the cell proliferation via G1 arrest of cell cycle.

Conclusion: It was suggested that the active component of the anti-proliferative effect by nucleic acid is guanosine and 2-deoxyguanosine.

Keyword: Nucleic acids, Guanosine, Anti-cancer, Ehrlich ascites tumor (EAT) cells, G1 arrest

Valorization of *Prinsepia utilis* byproducts for alleviating anti-aging stress and skin revitalization

Pushpa kewlani[1], Laxman Singh[1], Indra Dutt Bhatt[1]

1. G.B. Pant National Institute of Himalayan Environment (India)

Background and objectives: The interest of the cosmetic industry in natural bioactive compounds for their use in nutricosmetic and cosmeceutical products is increasing. Natural products-based cosmetics reduce skin aging and inflammation and protect from UV radiation. As a result, nutricosmetics and cosmeceuticals are becoming innovative self-care products in the cosmetics market. Among others, wild edible fruits are gaining popularity due to their nutraceutical and cosmeceuticals properties; and *Prinsepia utilis* (*P. utilis*) is the case of this study as it is considered a good source of fatty acids, vitamins, bioactive compounds, and antioxidants. The present study aims to study the potential of *P. utilis* with regards to (i) extraction and characterization of oil and its antioxidant activity, and (ii) optimization of antioxidant polyphenolics of leftover oil residue using green extraction for possible applications in the nutricosmetics industry.

Methodology: The seed powder was extracted using hexane with soxhlet and analyzed using GC-MS. The leftover oil residue is optimized through Response Surface Model (RSM) using UAE. Standard methods were used for analyzing the antioxidant and anti-aging activity of the seeds and leftover oil residue.

Results: The GC-MS results highlight the presence of many health-promoting compounds, i.e., fatty acid, phytosterols, and tocopherols. The ABTS antioxidant activity of oil attained IC_{50} at 904.11 µg/ml, which is beneficial to inhibit the free radicals. Under optimum extraction conditions, total phenolics, flavonoids, tannins, and antioxidant activity were closed with the model predicted values. HPLC-PDA analysis detects ten polyphenolic compounds under optimized extraction conditions. The anti-aging activity indicated that extract is good in inhibition of tyrosinase (IC_{50} 1.81± 0.02 mg/ml) and hyaluronidase (IC_{50} 0.90±0.03 mg/ml) enzyme. The extract prevented UV damage and showed good sun protection (SP) value (11.00±0.03) at a dose of 1000µg/ml

Conclusion: The study provides the potential use of leftover residue in water, which can be used for higher antioxidant activity and alleviating oxidative stress. The oil residue can be utilized for skincare, nutraceuticals pills, and functional food.

Absorption and Tissue Distribution of 3-(4-hydroxy-3-methoxyphenyl) propionic acid, a flavonoid metabolite, in Rats

Ayano Soma[1], Chizumi Abe[1], Tint Ni Ni Tun[1], Yosuke Nishitani[2], Hiroyuki Kayaki[2], Hideaki Kawakami[2], Toshiro Matsui[1]

1. Kyushu University (Japan), 2. Maruzen Pharmaceuticals Company (Japan)

Background and Objectives: 3-(4-Hydroxy-3-methoxyphenyl) propionic acid (HMPA) is an end-product of flavonoids in the gut system by microbiota. Although the intake of flavonoids caused diverse physiological events, pharmacokinetics as well as bioactivity of their metabolite HMPA remain unclear. In this study, we thus tried to clarify the bioavailability of HMPA in Sprague-Dawley (SD) rats for further study regarding physiological potential of HMPA and/or its metabolites in accumulated organs.

Methods: A single oral administration of HMPA (10 mg/kg) was performed in 8-week-old male SD rats. Blood samples collected from the tale vain at 0, 0.25, 0.5, 1, 2, 4, and 6 h after the administration, following the collection of organs (the liver, kidneys, heart, lungs, soleus muscle, and abdominal aorta) at each sampling schedule. Blood and tissue samples were subjected to an LC-TOF/MS to determine HMPA and its possible metabolites of sulfated (HMPA-S) and glucuronided (HMPA-GlcA) conjugates.

Results and Discussion: An intact absorption of HMPA into SD rat circulating bloodstream was observed up to 6 h after the administration (10 mg/kg). The pharmacokinetics obtained in this protocol (T_{max}: 0.25 h, $T_{1/2}$: 0.18 h, C_{max}: 5.8 ± 0.8 nmol/mL) indicated a rapid absorption and disappearance of HMPA in blood system. LC-TOF/MS analysis of blood (plasma) samples also revealed the compatible absorption of HMPA conjugates (HMPA-S, 3.8 ± 0.4 nmol/mL; HMPA-GlcA, 1.3 ± 0.2 nmol/mL) to intact HMPA (5.8 ± 0.8 nmol/mL), suggesting a rapid and significant phase II-metabolism of HMPA before entering bloodstream. In target organs, HMPA (e.g., liver at 2 h: 0.33 ± 0.33 nmol/g-tissue) and HMPA-S (0.042 ± 0.023 nmol/g-tissue) were detected up to 6 h after administration, while no detection of HMPA-GlcA was observed after 4 h (liver at 2 h: 0.0014 ± 0.0014 nmol/g-tissue).

Conclusion: This study demonstrates that a flavonoid metabolite in the gut, HMPA, was rapidly absorbed and accumulated in circulating blood and organs for a long period of 6 h, along with sulfation and glucuronidation metabolism. The impact of this finding leads us to further study on their physiological roles in accumulated organs.

Keyword: flavonoid metabolite, bioavailability, absorption, distribution

Effects of curcumin and low carbohydrate diet on testicular antioxidant capacity, cell apoptosis and spermatogenesis in male mice

Chinyu Liu[1], Peishan Ke[1], Hsinyi Yang[1], Chihwei Tsao[2,3]

1. Department of Nutritional Science, Fu Jen Catholic University (Taiwan), 2. Division of Urology, Department of Surgery, Tri-Service General Hospital, National Defense Medical Center (Taiwan), 3. Division of Experimental Surgery Center, Department of Surgery, Tri-Service General Hospital, National Defense Medical Center (Taiwan)

Background and objectives: The aim of this study was to investigate the effects of Curcumin supplementation on low carbohydrate diet (LC) diet-induced metabolic dysfunction, testicular antioxidant capacity, apoptosis, inflammation and spermatogenesis in male mice.

Methods: Male C57BL/6 mice were fed normal diet (AIN-93M group, n=12) or LC group (fed with low carbohydrate diet, n=48) for 12 weeks and mice randomly chosen from the LC group were later kept original diet (LC group, n=12), changed into AIN-93M feed (LC/AIN-93M group, n=12) or ketogenic diet (LC/KD group, n=12) or ketogenic diet treated with curcumin (LC/KDCu group, n=12) for the final 6 weeks.

Results: A poor sperm morphology and the mean testicular biopsy score (MTBS) were observed in the LC and LC/KD groups, but this was eliminated by the normal diet or ketogenic diet with curcumin. The LC group exhibited a lower testicular testosterone level and a lower 17β-HSD activity and protein expression. The LC group exhibited enhanced apoptosis protein expressions in testis tissue, including Bax/BCl_2, cleaved caspase 3 and cleaved PARP, and higher inflammation protein expressions, NF-κB. The LC group exhibited a statistically-significant increasing in lipid peroxidation and decreased superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase level as compared with other groups. The LC diet induced hyperlipidemia in mice, which developed metabolic dysfunction and poor semen quality.

Conclusions: Overall, the results showed that a normal diet or ketogenic diet treated with curcumin attenuated oxidative stress and improved the semen quality reduced by the LC diet.

Keyword: low carbohydrate diet, curcumin, oxidative stress, male infertility, spermatogenesis

Bioavailability of organic acids and phenolic compounds by ingestion of *Hibiscus sabdariffa* BEVERAGE: effect on inflammation markers as a potential immunomodulator for sars-cov-2 disease

Luis Alejandro Reynoso[1], Edgar J. Mendivil[2], Sonia G. Sayago/Ayerdi[1]

1. National Institute of Mexico, Technological Institute of Tepic (Mexico), 2. Nutrition and Food Science Research Group. Department of Psychology, Education, and Health. ITESO, Jesuit University of Guadalajara (Mexico)

Background and objective: The severe acute respiratory syndrome (SARS-CoV-2) is characterized by an inflammatory response exacerbating cytokine production. The worldwide affected population is about 162,773,940 cumulative confirmed cases by WHO. *Hibiscus sabdariffa (HS)* is a common ingredient used in Mexican cuisine that has shown antioxidant, anti-inflammatory, anti-hypertensive, anti-microbial, anti-convulsant, and hypoglycemic properties. Due to its potential anti-inflammatory, *HS* might represent a potential coadjuvant treatment for SARS-Cov-2. This study aims to evaluate the bioavailability of the bioactive compounds in an *HS* shot-type beverage and its possible effect against acute infection SARS-CoV-2 disease.

Methods: An acute single-blind crossover trial with at least six days of washout period, in which twelve volunteers consumed a shot of 60 mL drink based on HS, agave fructans and mint, or a placebo. After consuming the beverages, participants received a Western diet, and blood samples were collected at 0, 0.5, 1, 2, 3, 4, 5, and 6h, as well as urine samples at 0, 3, 6, 12, and 24h. The bioavailability of antioxidant compounds in plasma and urine were evaluated by High-Performance Liquid Chromatography coupled to a mass spectrometer (HPLC-DAD-MS) (Agilent 1260).

Results: The *HS* beverage appear to be multifunctional, with the participation of different bioactive compounds identified as bioavailable; within the most abundant in plasma and urine were organic acids such as hibiscus acids, hydroxycitric acid, hibiscus dimethyl ester, and trimethylhydroxycitric acid. The cinnamic acids such as chlorogenic acid and gallic acid in plasma are some of the potentially bioavailable compounds that can interact with different biological targets to cause possible anti-inflammatory effects.

Conclusions: Many *in-vivo* and *in-vitro* studies have shown the immunosuppressive effect of aqueous *HS* beverages. The bioavailability of the bioactive constituents of HS needs to be considered, involving different bioactive agents which can interact with different biological targets to elicit the observed anti-inflammatory effects, which will serve to generate strategies to counteract COVID19 disease.

Bioactive compounds in the peel, arils, and juice of pomegranate fruits Punica granatum in Mexico

Ma. Claudia Castaneda Saucedo[1], Ernesto Tapia Campos[2], Jessica Del Pilar Ramírez Anaya[1], Sandra Teresita Martin del Campo Barba[3], Daniel Guajardo Flores[3], Adriana Cavazos Garduño[1], Julio Serrano-Nino[1], Diana Esmeralda Peregrino Villalvazo[1], Maria Luisa Pita López[1]

1. Universidad de Guadalajara (Mexico), 2. CIATEJ (Mexico), 3. Tecnológico de Monterrey (Mexico)

Background and objectives: The pomegranate (*Punica granatum* L) is a "superfruit" and is considered a nutraceutical food due to the large number of polyphenols that provide nutraceutical, organoleptic and antioxidant properties. This research aimed to evaluate the content of total phenols, anthocyanins, punicalagin, and antioxidant capacity by the ABTS, DPPH methods, and the peel, arils, and fruit juice of five varieties of pomegranates from southern Jalisco, Mexico.

Methods: The varieties included in this study were sweet pomegranates (Apaseo and Isais), sweet-sour (Wonderful), and sour (Chichona and Verde). Total polyphenol contents (TPC), mg gallic acid equivalents per 100g dry weight (mg GAE/100g DW) and Trolox equivalent antioxidant capacity (TEAC, µmol/g) by the ABTS and DPPH method, total anthocyanin content (TAC, mg cyanidin-3- glucoside equivalents per 100 g DW (mg CGE/100d DW) and punicalagin content (PC, mg/g DW) were evaluated.

Results: The results show that the varieties evaluated have a high TPC (805.9-5599 mg/GAE/100g DW), TEAC (582.89-1419.09 mM TEAC/100g DW), TAC (8.38-34.056 mg CGE/100g DW). The Chichona variety has the highest TPC, TEAC, and punicalagin, while the Wonderful variety has the highest total anthocyanins. The TPC (19206.3 mg/GAE/100 g DW) is statistically higher in the peel than in aril and juice with 869.4 and 286.4 mg/GAE/100 g DW, respectively. TEAC by the DPPH method also showed higher values in the peel than aril and juice 2533.70 vs. 149.95 and 42.19 mMol TE/100mg, respectively; similarly, the same trend was presented for TEAC by the ABTS method. In contrast, the total content of anthocyanins in juice and arils was the same with 18.2259 and 17.4766 mg CGE/100g DW, respectively, and the peel was obtained the lowest anthocyanins with a value of 1.5858 mg CGE/100g DW.

Conclusions: In conclusion, it is considered that the fruits of the pomegranate varieties evaluated show to be a powerful antioxidant, especially in the peel, reflected in higher TPC, TEAC, and punicalagin content, although anthocyanins presented higher values in arils and juices.

Antioxidant Activity, Total Phenolic Content and Organic Acids of Winter Melon Aqueous Extract

Che Anis Jauharah Che Mohd Zin[1], Wan Mohd Izani Wan Mohamed[1], Nurzalina Abdul Karim Khan[1], Wan Rosli Wan Ishak[1]

1. Universiti Sains Malaysia (Malaysia)

Background and objectives: Winter melon (*Benincasa hispida)* is one of the vegetable crops planted in dry lowland tropical areas. It is a species in the cucurbit family that is primarily grown for its fruits. Mostly in Asian countries, winter melon has been valued as a nutritious vegetable and traditionally applied to treat various ailments such as anti-ulcer, anti-inflammatory, anti-diarrheal, among others. This study aimed to determine antioxidant activity and total phenolic content at three edible fruit maturity stages and to identify the presence of polyphenolic compounds and organic acids in winter melon aqueous extract.

Methods: Malaysian-grown round fruits of winter melon were collected at 45, 56, and 70 days after planting. The fruit pulp was extracted in filtered water at 60℃ for 30 minutes and dried at 55℃ in an oven for 48 hours. Antioxidant activity and total phenolic content of the extract were determined by 2,2-diphenyl-1-picrylhydrazyl (DPPH) and Folin-Ciocalteu assays, respectively. The liquid chromatography quadrupole time-of-flight-mass spectrometer (LC-QTOF-MS) was used to identify compounds in the selected extract.

Results: Aqueous extract of winter melon fruit collected at day 56 exhibited significantly higher free radical-scavenging activity and total phenolic content compared to extract from fruits collected at day 45 and 70. There was a negative correlation between IC50 value and total phenolic content. A total of 15 compounds were identified in the extract of fruit collected at day 56 when subjected for further analysis using LC-QTOF-MS. Other than polyphenolic compounds like 6-gingerol, the extract was also found to be rich in organic acids namely citric acid, fumaric acid, and glutaric acid. The presence of these polyphenols and organic acids might be responsible for the antioxidant activity in winter melon aqueous extract. Citric acid is the most abundant compound identified. Inositol, a natural sugar, was also detected in the extract.

Conclusions: Overall, this study suggested good polyphenols, organic acids, and antioxidant activity potential in winter melon aqueous extract. Future research may focus on its application in nutraceutical and pharmaceutical sectors.

Keyword: antioxidant, maturity stage, organic acid, phenolic content, winter melon.

PAB(T7-149)
Intranasal administration of eugenol alleviates high-energy diet-induced cognitive impairment

Yuge Jiang[1], Jianjin Zhu[1], Yonghui Shi[1], Guowei Le[1]

1. Jiangnan University (China)

Background and objectives: High energy dietary intake may be harmful to cognitive, and nasal inhalation of spices is an effective means of acting directly on the brain. Eugenol is widely used to inflammation and dietary interventions for metabolic disorders. However, the protective effect of inhaled eugenol on cognitive functions is not fully clear. In this study, we evaluated the protective effect of inhaled eugenol on cognitive impairment through a high-energy diet animal model.

Methods: Fifty 6-week-old C57BL/6J male mice were divided into five groups (n=10/group): The Control group (Control) (Fed with a standard diet, AIN93), the Control +high dose eugenol group (Con-eu) (standard diet with 10 mL, 10mg kg^{-1} day^{-1} body weight, nasal drip of eugenol), the HFFD group (HFFD) (Diet 60% kcal from fat, 10% fructose in drinking water, 10 mL drip of saline), the Low dose eugenol group (LE) (HFFD diet with 10 mL, 5 mg kg^{-1} d^{-1} body weight nasal drip of eugenol), the high dose eugenol group (HE) (HFFD diet with 10 mL, 10 mg kg^{-1} d^{-1} body weight nasal drip of eugenol). After 14 weeks of eugenol administration, the degree of cognitive impairment in mice was assessed by water maze, open field, and new object recognition behavioral assays

Results: Nasal administration of eugenol significantly reduced weight gain and insulin resistance in HFFD-fed mice. Low doses of nasal administration of eugenol significantly prevented HFFD-induced neuronal loss and memory impairment. Immunofluorescence staining of hippocampal showed that apoptosis marker protein cleaved caspase-3 expression was significantly enhanced in HFFD group, whereas expression was significantly lower in the nasally administered eugenol group. Transcriptomic results showed that inhalation of eugenol significantly inhibited the expression of *Lnc-Snhg16* gene and increased the expression of anti-apoptotic gene BCL-2 by activating IRS/AKT phosphorylation. Flow cytometric results showed that 100 mM eugenol significantly ameliorated high glucose-induced apoptosis in hippocampal HT22 cells, and the ameliorating effect of eugenol on apoptosis was inhibited after si *LncSnhg16*.

Conclusion: Nasal administration of eugenol is a way to prevent high-energy density diet-induced cognitive impairments, which could be possibly explained by their mediating effects on insulin signaling in the brain.

Keyword: eugenol, nasal, inhalation, hippocampal apoptosis

Cyclic nigerosylnigerose attenuates colonic inflammation and abnormal glucose metabolism as well as promotes gut bacteria-specific IgA secretion in diet-induced obese mice

Takeshi Tsuruta[1], Taisei Miyamoto[1], Akiko Mizote[2], Mao Teraoka[1], Emiko Katsumata[1], Naoki Nishino[1]

1. Okayama University (Japan), 2. HAYASHIBARA CO., LTD. (Japan)

Background and objectives: Prolonged intake of a high-fat diet (HFD) impairs gut barrier function, which relates to exacerbation of low-grade inflammation and insulin resistance (IR) in peripheral tissues. Furthermore, HFD feeding reduces the amount of gut IgA coating gut bacteria and a reduction of IgA coating relates to HFD-induced IR. We previously showed that oral administration of cyclic nigerosylnigerose (CNN), a cyclic sugar, ameliorates gut inflammation symptoms and promotes IgA coating of gut bacteria. In this study, we investigated the effect of CNN, especially on gut inflammation, glucose metabolism, and gut bacteria-specific IgA secretion in diet-induced obese mice.

Method: Balb/c mice were divided into 3 groups including normal-fat diet (NFD)-fed group, HFD- fed group, and HFD-fed and CNN-administered (HFD+CNN) group. CNN-supplemented water (45 mg/mL) was given to HFD+CNN group. Before dissection, the fasting blood glucose and insulin concentration were measured to calculate the HOMA-IR index. At week 20, mice were sacrificed and the colonic tissues and fresh feces were collected. The *Tnfa* gene expression in the colonic tissue was measured by qPCR. The total amount of IgA coating fecal bacteria (μg/g feces) (a) was measured by immunoblotting. The fecal IgA concentration (μg/g feces) (b) was measured by ELISA. The ratio of (a) to (b) was calculated to predict how much amount of IgA was specific for gut bacteria.

Results: The HOMA-IR index was significantly lower in NFD and HFD+CNN group than HFD group. The gene expression of *Tnfa* was significantly lower in NFD and HFD+CNN group than HFD group. The fecal IgA concentration was significantly lower in HFD+CNN group than HFD group while the total amount of IgA coating fecal bacteria tended to be higher in HFD+CNN group. The ratio of (a) to (b) was significantly higher in HFD+CNN group than NFD and HFD group.

Conclusion: CNN attenuates colonic inflammation and abnormal glucose metabolism accompanied by long-term HFD feeding. CNN increases a ratio of IgA specific for gut bacteria in fecal IgA. It remains unclear whether gut bacteria-specific IgA induced by CNN contributes to the improvement of colonic inflammation and abnormal glucose metabolism.

Dietary oleic acid modulates satiety by mobilizing intestinal oleoylethanolamide signaling

Miki Igarashi[1,2], Kensuke Iwasa[2], Tsuyoshi Tsuduki[3], Ikuo Kimura[4,5], Kei Maruyama[2], Keisuke Yoshikawa[2]

1. Institute of Neurological Disorders (Japan), 2. Saitama Medical University (Japan), 3. Tohoku University (Japan), 4. Tokyo University of Agriculture and Technology (Japan), 5. Kyoto University (Japan)

Background and objectives: Oleoylethanolamide (OEA) is a lipid mediator with homeostatic functions in appetite regulation and fat metabolism through peroxisome proliferator-activated receptor-α. Accumulating data suggest that luminal oleic acid (OA) can be sensed by cluster of differentiation 36 expressed in gastroenterocytes and then converted to OEA via the N-acylphosphatidylethanolamine-dependent pathway, resulting in satiety induction.

Methods: In this study, we investigated how dietary fat or OA affects OEA biosynthesis and food intake in mice, using three diets—OA diet (38 mg OA/g diet, 7% fat, OAD), low OA diet (3 mg OA/g diet, 7% fat, LOAD), and high fat diet (200 mg OA/g diet, 36% fat, HFD).

Results: LOAD feeding caused reduction in jejunal OEA levels and increase in food intake compared with OAD feeding. This effect of LOAD was observed even on the first day of feeding. OEA treatment diminished the effects of LOAD feeding. Furthermore, lipid or OA infusion into the upper gut stimulated jejunal OEA production and reduced food intake. In contrast, HFD feeding reduced intestinal OEA production even though the diet contains 5 times more OA than OAD.

Conclusions: Collectively, these findings suggest that dietary OA induces meal satiety via intestinal OEA production, but the effects is depending on the total fat amount of the meal, indicating that balanced dietary fat intake is important in controlling feeding behavior through intestinal OEA signaling.

PAB(T7-152)

Discovery of novel human metabolites, dimethylated rosmarinic acids (DiMe-RAs), after oral intake of *Perilla frutescens purpurea* extract and their inhibitory activity on TRPV4

Akihiro Takamura[1], Masazumi Iwashita[1], Eri Ozeki[1], Kohjiro Hashizume[1], Ryuta Shioi[1], Naoya Kitamura[1], Akihiro Fujii[1], Takatoshi Murase[1], Kiyotaka Nakagawa[2]

1. Kao Corporation (Japan), 2. Tohoku University (Japan)

Background and objectives: Rosmarinic acid (RA) is a dietary polyphenol abundant in *Perilla frutescens purpurea* and known to exhibit various health-promoting effects. In recent years,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

polyphenol metabolites have attracted great interest as some of them showed higher biological potencies rather than the parent compounds. In a previous study concerning methylated RA, only a monomethylated RA (MonoMe-RA), which is methylated at phenolic hydroxyl group of RA, was reported as a metabolite after oral administration of RA in rat plasma; however, detailed methylation metabolism of RA and their biological activities have not been fully investigated. Therefore, we focused on the methylation behavior of RA and developed an analytical method to quantify methylated RAs including unidentified isomers of MonoMe-RA and dimethylated RA (DiMe-RA) as well as reported RA metabolites. Furthermore, as an example to demonstrate the functionality of the metabolites, inhibitory activities of methylated RAs were tested against TRPV4, which is recognized as a therapeutic target for treatment of inflammatory and neuropathic pain.

Methods: Synthetic standards of Mono/DiMe-RAs and a UHPLC-MS/MS method were prepared for quantification. A crossover study was conducted to examine the pharmacokinetics of *Perilla frutescens purpurea* leaf extract (PE) containing RA in healthy human volunteers. After a single oral dose of PE 442 mg containing RA 100 mg or placebo, the urine and plasma were collected from 0 to 24 h and quantitatively analyzed. Several Mono/DiMe-RAs were tested in an *in vitro* cellular assay to evaluate inhibitory activity on TRPV4.

Results: The quantification result of collected human plasma and urine showed metabolic production of DiMe-RAs after oral intake of PE as novel and prime metabolites, while 4,3'-DiMe-RA was the most abundant metabolite among them. In a biological assay, the DiMe-RA showed inhibitory potency on TRPV4.

Conclusions: The present research clarified human pharmacokinetics and metabolism of RA focusing on the methylated RA. Further physiological activities of methylated RAs will be investigated aiming to develop self-medication products such as functional foods. This study showed that the preparation of potential metabolites as original compounds would be a promising way to elucidate not only overall metabolism but also unknown biological activities of target compounds.

PAB(T7-153)
Use of Superfoods in Infants and Young Children Nutrition in Africa: a systematic review

Brenda AZ Abu[1], Daniel Boateng[2,3], Hibbah Osei-Kwasi[4]

1. Rochester Institute of Technology, College of Health Sciences and Technology, Wegmans School of Health and Nutrition, Rochester, New York (USA), 2. School of Public Health, Kwame Nkrumah University of Science and Technology, Kumasi (Ghana), 3. University Medical Center Utrecht, Utrecht University, 3508 TC Utrecht (Netherlands), 4. Department of Geography, the University of Sheffield, Sheffield S1 4DP (UK)

Background and objective: African communities have diverse complementary feeding options but also practices that may interfere with optimum child nutrition and growth. This review assessed the contributions of macronutrient, and micronutrients intake, nutritional status and long-term effects of superfoods (food with exceptional nutrient content) intake among African children 6-24 months.

Methods: We searched through PUBMED, EMBASE, CINAHL and African Index Medicus databases. Further, grey literature were extracted from Google scholar published articles. Population, intervention, control and outcomes (PICO) terms to create MeSH terms targeting children 6-24 months. The reporting of this review followed the PRISMA guidelines and was registered on Prospero [CRD42021240697].

Key findings: Out of 3,758 papers pulled, 24 papers from 10 countries published between 1999 to 2020. Overall, 18 of the papers used an experimental design and remaining 6 were observational studies. The most common superfoods used in child feed were soybeans flour, and orange-fleshed sweet potatoes. Soybean use was most associated with weight gain and length after 3 months of implementation. Soybean combined with other foods such as corn-soy blends, weight gain effects were still observed, however no significant gains were observed in length gain or stunting rates. Orange-fleshed potatoes significantly improved vitamin A intake and serum vitamin retinol levels. Only one intervention study reported on the use of hibiscus leaf intake and this had a low significant increase in length for age among children 6-24 months. Stunting rate in this population increased by 1.4% in the intervention compared to 5.1% in the control group. Similarly, spirulina incorporated in maize porridge in another study had an impact on length and weight gain and significantly reduced likelihood of developing coughs and child motor development such as walking alone without support at 15 months of age.

Conclusion: Superfoods such as soybean, spirulina and hibiscus used alone or added to grains in complementary foods have potential to increase anthropometrics indicators among young children, while sweet potatoes and hibiscus increased serum retinol levels and motor development. To obtain optimum benefits of superfoods in physical and motor development among young children a combination of these foods may be beneficial.

Anti-obesity effect of Kencur, *kaempferia galangal* L., extract

Nanami Tanoguchi[1], Yutaro Sasaki[1], Isao Matsui-Yuasa[1], Akiko Kojima-Yuasa[1]

1. Graduate School of Human Life Science, Osaka City University (Japan)

Background and objectives: Obesity is a major risk factor for various chronic diseases, such as diabetes, cardiovascular disease and cancer. Therefore, it is very important to find an effective way to prevent obesity. Kencur, a plant of the *Zingiberaceae* family, is mainly cultivated in Southeast Asian countries. It has been already reported that Kencur has antioxidant and anti-inflammatory effects. However, the anti-obesity effect of Kencur has not been yet clarified. Therefore, we investigated the anti-obesity effect as a new physiological activity of Kencur.

Methods: Kencur was extracted with 100% ethanol and concentrated to dryness using a vacuum evaporator. We investigated the effect and mechanism by which Kencur extract inhibits the differentiation of 3T3-L1 preadipocytes into adipocytes. 3T3-L1 preadipocytes were cultured for 8 days after adding a sample at a various stages of inducing differentiation. The amount of intracellular triglyceride (TG) and the activity of glycerol-3-phosphate dehydrogenase (GPDH), a rate-limiting enzyme of TG synthesis, were estimated. Furthermore, the expression levels of transcription factors, PPARγ, C/EBPα and C/EBPβ, involved in adipocyte differentiation were measured by Western blotting and real-time quantitative PCR.

Results: Kencur extract was analyzed with HPLC and found that the main component in Kencur extract is ethyl-4-methoxycinnamate (EMC). Kencur extract and EMC suppressed the TG accumulation and GPDH activity in a dose-dependent manner, suggesting that EMC acts as the active component for the effect of the Kencur extract. In addition, when EMC was cultured at different timings, TG accumulation was significantly suppressed by adding it 2 days after the induction of differentiation. Furthermore, the gene expression levels and protein expression levels of PPARγ, C/EBPα, and C/EBPβ were significantly reduced by the addition of EMC.

Conclusions: Our results showed that Kencur extract suppresses the TG accumulation in 3T3-L1 preadipocytes by reducing the expression of transcriptional factors that promote differentiation in the early stage of the differentiation process. These results suggest that Kencur extract is useful for anti-obesity.

Keyword: Kencur, 3T3-L1 preadipocytes, Ethyl-4-methoxycinnamate (EMC), Transcriptional factors, Anti-obesity

Milk fermented by lactic acid bacteria enhance dietary carotenoid bioavailability in humans in a randomized crossover trial.

Masashi Morifuji[1], Satomi Ichikawa[1], Masami Kitade-Miyayama[1], Yuki Manabe[2], Tatsuya Sugawara[2]

1. Meiji Co., Ltd. (Japan), 2. Kyoto University (Japan)

Background and objectives: Dietary carotenoids have beneficial health effects because of their antioxidant and anti-inflammatory properties. In humans, the bioavailability of β-carotene from carrots or spinach ranges from 3–16%. Therefore, it is important to increase the bioavailability of dietary carotenoids in order to maximize their potential for health effects. The aim of this study was to evaluate the effect of fermented milk on the bioavailability of dietary carotenoids in humans.

Methods: Three studies were conducted using a randomized, crossover method. The study subjects (N=16/study) consumed a test drink on two separate days with a two-week washout period. Subjects consumed a vegetable (carrot, tomato, or spinach) drink alone or with a fermented milk. Fermented milk was produced by incubating *Lactobacillus delbrueckii* subsp. *Bulgaricus* OLL1251 and *Streptococcus thermophilus* OLS3290 with 10% nonfat skimmed milk powder. Blood samples were collected before the test drink was consumed (0 h) and again 2, 4, 6, 8 h after ingestion. Aliquots of fresh plasma from each blood sample were processed to isolate the triacylglycerol-rich lipoprotein (TRL fraction) because the postprandial carotenoid content in the TRL fraction of plasma is elevated. Plasma carotenoid concentrations were quantified using a HPLC.

Results: A significantly higher $iAUC_{0\text{-}8\ h}$ for β-carotene, α-carotene, retinyl palmitate was observed in the TRL fraction of plasma when carrot + fermented milk was consumed compared with carrot alone (β-carotene: 1.8-fold change). For lycopene, the $iAUC_{0\text{-}8\ h}$ of the TRL fraction of plasma was significantly larger in the group that consumed tomato combined with fermented milk versus the groups that consumed tomato alone (6.5-fold change). The iAUC for lutein in all plasma fractions was significantly higher for the group that consumed spinach + fermented milk compared to the spinach alone group. A significantly larger $iAUC_{0\text{-}8\ h}$ for β-carotene and retinyl palmitate was observed in the TRL fraction of plasma when spinach + fermented milk was consumed compared with spinach alone.

Conclusions: Co-ingestion of β-carotene and fermented milk significantly increased dietary carotenoid bioavailability in humans. These findings may provide new methods to increase dietary carotenoid bioavailability.

Metabolites profile of sea grapes (*Caulerpa racemose*) soxhlet extract: A Study Untargated Metabolomic Profiling

Muhammad Yusuf[1], Fahrul Nurkolis[2], Happy Kurnia Permatasari[1], Nelly Mayulu[3], Nurpudji Astuti Taslim[4]

1. University of Brawijaya (Indonesia), 2. State Islamic University of Sunan Kalijaga (Indonesia), 3. Sam Ratulangi University (Indonesia), 4. Hasanuddin University (Indonesia)

Background and objectives: Sea grapes (*Caulerpa racemosa*) is a green seaweed that currently gaining attraction due to its potential health benefits. The identification of sea grapes' major constituents is required to profile its biological activities and therapeutic potentials. This study aims to analyze the metabolomics of sea grape Ethanolic-Soxhlet extract via liquid chromatography-high resolution mass spectrometry (LC-HRMS).

Methods: Fresh samples of Seagrapes underwent Ethanolic Soxhlet extraction and subsequently untargeted metabolomics analysis by LC-HRMS. Compounds were identified utilizing Compound Discoverer with mzCloud MS/MS Library.

Results: The Top 25 major constituents of sea grapes extract were identified. Betaine, a compound commonly used in homocystinuria treatment, was present as the top metabolite of sea grapes extract. Betaine was also proven to be effective to halt liver diseases progression including NASH and hepatitis C virus infection through anti-inflammatory effects. Other major compounds were yielding a variety of biological activities including Hexadecanamide, Diisobutylphthalate which is commonly used as plasticizers and adhesives, 2,2,6,6-Tetramethyl-1-piperidinol (TEMPO), and NP-008993.

Conclusion: Untargeted metabolomic profiling showed many bioactive compounds contained in sea grapes Ethanolic-Soxhlet extract. The major compounds in sea grapes extract showed various therapeutic potentials. Further research such as preclinical and clinical trials is required to explore the health benefits of sea grapes extract as functional properties.

PAB(T7-157)
The effect of turmeric oil on obesity and lipid metabolism in mice fed high fat diet

Takashi Arai[1], Sachiko Okue[1], Yori Ozaki-Masuzawa[1], Takashi Hosono[1], Taiichiro Seki[1]

1. Nihon University (Japan)

Objective: Obesity is a major risk factor of cardiovascular diseases. Obesity, along with hypertension, hyperlipidemia, and type 2 diabetes, causes so-called metabolic syndrome and accelerates atherosclerosis. Turmeric oil (TO), an essential oil derived from turmeric (*Curcuma longa*), is an attractive food material that is thought to have various physiological functions promoting our health. In this study, we examined the effect of TO on mouse obesity induced by high fat diet, and further the lipid metabolism in the mice to clarify the anti-obesity mechanism.

Methods: C57BL/6J mice were divided into (1) control group fed a high fat diet containing 40% kcal Lard and (2) TO group fed a high fat diet containing 0.5% TO. The mice were fed on the experimental diets for 4 weeks and then blood, liver and adipose tissues were collected for the biochemical analyses. C57BL/6J mice were divided into (1) control group (40% kcal Lard) and (2) 0.5% TO group. The mice were kept for 2 weeks on the experimental diets. Three days prior to termination, mice were intraperitoneally injected with 0.9% NaCl D_2O (0.035 mL/g b.w.) and drinking water was replaced with 8% D_2O water. The newly synthesized fatty acid fraction in the liver was analyzed with GC/MS for the assessment of *de novo* lipogenesis (DNL).

Results: Body weight gain was significantly suppressed in the TO group compared to the control group. Although the liver, spleen, and muscle weights were not different between the two groups, white adipose tissue weights and the triacylglycerol content in the liver were significantly reduced in the TO group. The expression level of thermogenic genes *Ucp-1* and *Cidea* in white adipose tissue tended to be increased by TO. On the other hand, the hepatic lipogenic genes, *Fasn* and *Scd1* were significantly reduced in the TO group. The DNL assessed by measuring palmitate, stearate and oleate was not influenced by TO administration.

Conclusion: TO suppress body weight gain independent with the expression of thermogenic genes and lipid metabolism.

Keyword: turmeric oil, obesity, lipid metabolism, thermogenic gene

PAB(T7-158)
Identification of gut microbiota-derived fatty acids which activate fatty acid oxidation in human intestinal organoids

Makoto Noguchi[1], Makoto Shimizu[1], Yu Takahashi[1], Shigenobu Kishino[2], Jun Ogawa[2], Yoshio Yamauchi[1], Ryuichiro Sato[1]

1. The University of Tokyo (Japan), 2. Kyoto University (Japan)

Background and objectives: Gut microbiota metabolites such as fatty acids modulate host energy and lipid metabolism. It has been recently reported that lactic acid bacteria had a unique saturation metabolism from polyunsaturated fatty acids (PUFAs) such as gamma-linolenic acid (GLA) to hydroxy- or oxo-fatty acids. Dietary intake of PUFAs has been recognized as beneficial for host energy homeostasis. However, roles of PUFA-derived metabolites produced by lactic acid bacteria in human are largely

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

unknown. Nuclear receptors (NRs) are transcription factors which are activated by lipophilic ligands and regulate energy metabolism. In this study, we explored microbiota-derived fatty acids which activate NRs and lipid metabolism in human intestinal organoids.

Methods: To identify NRs activated by microbiota-derived FAs, we performed a luciferase reporter assay. Direct bindings of FAs to NRs were analyzed using a competitive binding assay with radio isotope-labeled FAs. Human iPS cells-derived small intestinal organoids were used as human intestinal model. Gene expression was quantified by a real-time quantitative PCR. Fatty acid β-oxidation was examined by FAO Blue staining. BODIPY staining and cellular triglyceride quantification were performed to analyze triglyceride accumulation in human intestinal organoids.

Results: We found that 13(OH)GLA and 13(oxo)GLA selectively activated peroxisome proliferator-activated receptor δ (PPARδ), a nuclear fatty acid receptor. 13(OH)GLA and 13(oxo)GLA potently activated PPARδ than natural ligands such as DHA or EPA. A competitive binding assay revealed that 13(OH)GLA and 13(oxo)GLA, but not GLA, directly bound to PPARdδ. Treatment of human intestinal organoids with these FAs increased PPARδ target genes which activate fatty acid β-oxidation. Furthermore, these FAs decreased triglyceride accumulation in intestinal organoids.

Conclusions: We found that 13(OH)GLA and 13(oxo)GLA, metabolites of dietary GLA produced by lactic acid bacteria, are ligands for PPARδ. We also showed 13(OH)GLA and 13(oxo)GLA activate fatty acid β oxidation through PPARδ, and suppressed lipid accumulation in human intestinal organoids. Because excess accumulation of intestinal lipid causes several pathological effects, these FAs may contribute to alleviation and prevention of lifestyle-related diseases such as obesity.

Keyword: Gut microbiota, Lipid metabolism, Small intestine, Organoid, PPARδ

The absorption and metabolism of γ-oryzanol, a functional compound characteristic of rice bran, is different depending on its molecular species

Junya Ito[1], Yukiko Hayashi[1], Takumi Kokumai[1], Satoshi Maeda[1], Kazue Sawada[2], Hiroyuki Hashimoto[2], Kiyotaka Nakagawa[1]

1. Tohoku University (Japan), 2. Tsuno Food Industrial Co., Ltd. (Japa

Background and objectives: γ-Oryzanol (OZ) is a bioactive compound characteristically contained in rice bran. OZ is a mixture of ferulic acid (FA) esters of phytosterols (PS) and triterpene alcohols (TTA). Despite PS- and TTA-type OZ having strikingly different chemical structures, studies on their absorption and metabolism have been mostly done using a mixture of PS- and TTA-type OZ, thus their individual absorption and metabolic profile remained unclear. Hence, in this study, we investigated the absorption and metabolism of each major OZ molecular species in rice bran (i.e., PS-type OZ; campesteryl ferulate (Camp-FA) and β-sitosteryl ferulate (Sito-FA), TTA-type OZ; 24-methylenecycloartanyl ferulate (24MCA-FA) and cycloartenyl ferulate (CA-FA)).

Methods: Camp-FA and Sito-FA were synthesized via the silyl protection of the phenolic hydroxyl group of FA, followed by their condensation with campesterol and β-sitosterol and deprotection of the silyl group. 24MCA-FA was isolated from rice bran, and CA-FA was purchased commercially. Following a single oral loading of each sample (300 μmol/kg body weight) to SD rats (male, 12-week-old), blood was collected from the tail vein (0-12 hours) and subjected to analysis using the liquid chromatography-tandem mass spectrometry system.

Results and Discussions: In the PS-type OZ group (given the Camp-FA or Sito-FA), intact OZ and its metabolites (i.e., FA and FA conjugates) were detected in plasma, and its concentrations increased over time post-dosing. Meanwhile, in the TTA-type OZ group (given the 24MCA-FA or CA-FA), plasma levels of intact OZ increased over time, but interestingly, FA and FA conjugates were hardly detected. As mentioned above, previous studies, including ours, used the mixture of OZ for the evaluation of the absorption and metabolism of OZ. Thus, the differences of the metabolic profiles of molecular species of OZ remained unknown. In this study, our results clearly showed how the absorption and metabolism of OZ differ greatly between the PS-type and TTA-type OZ, indicating that the mechanisms of physiological functions of OZ may also be completely different between PS-type and TTA-type OZ. Therefore, further elucidation of their metabolic profiles is necessary to gain better understanding of the physiological functions of OZ.

Background and objectives: It is known that obesity induces a chronic inflammatory reaction, which causes lifestyle-related diseases such as diabetes, dyslipidemia, and heart disease. Therefore, it is suggested that the inhibition of inflammation

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

leads to suppressing the onset of the lifestyle-related disease. Vitamin E is a fat-soluble vitamin present in vegetable oils and nuts and has eight different naturally occurring forms. Four tocopherols (α-, β-, γ-, and δ-tocopherol) and four tocotrienols (α-, β-, γ-, and δ-tocotrienol). Among them, there are many reports on the function of α-tocopherol, but there are few reports on δ-tocopherol. In this study, we investigated about the anti-inflammatory effect of δ-tocopherol on adipose tissue in rats induced inflammation by lipopolysaccharide (LPS) administration.

Methods: We used male SD strain rats (3 weeks of old, n=25). Initially, the rats were fed a control diet (high-fat and high-sucrose diet) for 1week to allow them to adapt to the new environment. To avoid differences, the rats were then divided according to their average weight into four groups: the control (C; n=7), LPS (LPS; n=6), LPS+α-tocopherol (LPS+α; n=6), and LPS+δ-tocopherol (LPS+δ; n=6). After 4 weeks, all rats except C group were intraperitoneally administered 1 mg LPS / kg B.W. and rats of C group were administered PBS instead of LPS. After four hours, rats sacrificed under isoflurane anesthesia.

Results: Plasma glucose concentration of C group was significantly higher than that of LPS, LPS+α, and LPS+δ group. The gene expressions of TNF-α, IL-6, MCP-1 and IL-1β in perirenal fat of LPS group were remarkably higher than those of the C group. On the other hand, the gene expression of IL-1β in perirenal fat of LPS+δ group tended to decrease compared to the LPS group.

Conclusions: According to the above results, we suggested that δ-tocopherol has a potential power of anti-inflammation on adipose tissue of rats. Currently, we continue to examine about signal transduction of inflammation using adipocytes.

Keyword: vitamin E, δ-tocopherol, inflammation, obesity, adipose tissue

Development of Protein Bar as Supplementary Food Product for Tuberculosis (TB) Patients

Paul John Gonzales de Leon[1], Lauren Lalaine Lao[1], Ma. Christella Inumerable[1], Gayle Urrera[1], Joyelli Anne Ramos[1]

1. Philippine Nutri-Foods Corporation (Philippines)

Background and objectives: Tuberculosis (TB) is a major health problem. 554 cases of TB for every 100,000 Filipinos were recorded by the World Health Organization (WHO) — the highest TB incidence rate in Asia. Drugs used for treating TB reduce appetite and cause malabsorption of essential vitamins and minerals, affecting patients with comorbidities like undernutrition, anemia, and diabetes. There is no supplementation program for TB patients and thus this study aims to develop food products to help improve their nutritional status. A protein bar is a suitable form of food appropriate for distribution at 8,541 TB diagnostic and treatment facilities nationwide. It is ready-to-eat, caloric dense, and has a long shelf life.

Methods: Energy-dense whey protein concentrate (WPC) and isolated soy protein (ISP) were used together with functional ingredients like inulin and L-glutathione. Vitamins and mineral premix added meet 40% of the average recommended energy and nutrient intake (RENI) for males 35-64 years old. The bars were processed through a cold sheeting method and packed at 40g serving size to preserve the effectiveness of vitamins and functional ingredients that have been added. The most acceptable prototype sample in terms of texture, chewability, taste, and appearance was then subjected to consumer acceptability using paired preference tests over an existing brand in the market. The results were analyzed using a two-tailed F test at 95% significance level. The prototype exceeding the required amount of agreeing judges was subjected to shelf-life and nutrient analysis.

Results: The developed protein bar has around 500 calories per serving. It contains 22 micronutrients that are 40% above the RENI of an adult. It includes functional ingredients – inulin and L-glutathione that help reduce potential toxicity to anti-TB medications and cater to TB patients who are also hyperglycemic.

Conclusions: The protein bar can be suitable supplementary food for TB patients because of its high macronutrient and micronutrient content. It is conveniently packaged and can be distributed at scale. Guidelines for nutritional care in TB recommend consuming two bars per day per person in between meals to provide 1000 calories and 44 grams of protein daily.

PAB(T7-162)
Effect of perilla flavonoid apigenin on tryptophan-NAD metabolic key enzymes expression in LPS-stimulated microglial cells and its mechanism

Yukari Egashira[1], Dian Kurniati[1], Shizuka Hirai[1]

1. Chiba University (Japan)

Background and objectives: Flavonoid apigenin (AP) is abundantly present in various vegetables such as perilla. AP has anti-oxidant and anti-inflammatory effects. 2-Amino-3-carboxymuconate-6-semialdehyde decarboxylase (ACMSD) and Indole amine 2,3 dioxygenase (IDO) are metabolic key enzymes that play pivotal role in tryptophan degradation via kynurenine pathway. Tryptophan is converted to various metabolites such as NAD and quinolinate (QUIN). Excess production of QUIN leads to pathogenesis of neurodegenerative diseases. ACMSD and IDO affect QUIN production. Therefore, regulation of ACMSD and IDO may be effective to suppress QUIN production and the progression of neurodegeneration. In this study, we examined the effect of AP on ACMSD and IDO expression, inflammatory mediators and related inflammatory signal pathways including NF-κB pathways in lipopolysaccharide (LPS)-stimulated microglial cells.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: The MG6 cell line, derived from mouse microglial cells was used. Cells were cultured in dishes in Dulbecco's modified Eagle's medium with fetal bovine serum. MG6 cells were treated with LPS and/or AP for the detection of ACMSD expression, nitric oxide (NO) secretion and inflammatory cytokine production. NO concentration in the medium was measured by the Griess reaction method. Subsequently, ACM*SD* and *IDO* mRNA expression levels were measured by quantitative polymerase chain reaction. Related inflammatory mediators were also measured by enzyme-linked immunosorbent assay (ELISA). Protein expression levels were detected by Western Blot analysis.

Results: LPS suppressed ACMSD and enhance IDO expression, which may lead to increase QUIN concentration. However, AP recovered LPS-stimulated ACMSD and IDO expression. Furthermore, it also inhibited interleukin-6 (IL-6) and NO production. AP also inhibited degradation of IκBα.

Conclusions: AP recovered LPS-stimulated ACMSD and IDO mRNA expression and suppressed some inflammatory mediators, which may be mediated by inhibition of the NF-κB pathway in microglial cells. These results suggest that AP may be helpful for avoiding central nerve system inflammation.

Effect of urolithin on Japanese cedar allergic rhinitis in mice.

Nobuo Morishita[1], Sachie Nakatani[1], Hiromu Shimizu[1], Kazumi Hayashi[2], Katsuhiro Ishikawa[1], Natsuko Ozawa[2], Masatake Kudoh[3], Yuichi Ukawa[3], Kenji Kobata[1]

1. Graduate school of pharmaceutical sciences, Josai University (Japan), 2. Department of Pharmaceutical Science, Josai University (Japan), 3. DAICEL CORPORATION Healthcare SBU (Japan)

Background and objectives: Urolithin (U) compounds are known to be detected in blood after ingestion of ellagic acid (EA) contained in pomegranate and berries. It has been reported that some U compounds inhibit the degranulation of the mast cell line RBL-2H3. However, the in vivo allergic inhibitory effect of U has not been clarified. In this study, we first compared the degranulation inhibitory effects of each U compound on RBL-2H3 cells. Next, we examined the possibility that Urolithin A (UA) suppresses allergic reactions in a mouse model of cedar pollinosis.

Methods: After RBL-2H3 cells were primarily sensitized with dinitrophenyl IgE, degranulation inhibition activity of UA, UB, UC, UD, UH, and EA was tested with a secondary sensitization. Twenty-one 5-week-old BALB/c female mice were intraperitoneally injected with cedar pollen antigen on days 0, 7, and 14 as primary sensitization. From day 21 to 39, cedar pollen antigen was administered intranasally as a secondary sensitization. On day 27, the mice were divided into three groups: control (C), UA, and dexamethasone (Dex) groups. From day 28 to 39, the C group was treated with pure water, the UA group with 1 mg/animal of UA, and the Dex group with 0.1 mg/animal of Dex directly by oral gavage. Sneezing frequency was measured on the 39th day. On the 40th day, autopsies were performed and serum IgE levels (ELISA) and eosinophil counts (Diff-Quik staining) in nasal lavage fluid (NALF) were measured.

Results: In vitro, UC and UH at concentrations of 1 µM or higher, and UA and UB groups at concentrations of 10 µM or higher inhibited the release of β-hexosaminidase more than EA. In vivo, compared to group C, the number of sneezes and the number of eosinophils in NALF of UA were significantly reduced to the same level as those in the Dex group. Serum IgE levels were not significantly different among the groups.

Conclusions: UA did not affect IgE concentration in blood of pollinosis model mice, but suppressed sneezing caused by pollinosis through inhibition of eosinophil migration and degranulation.

Keyword: allergic rhinitis, cedar pollinosis, ellagic acid, urolithin, RBL-2H3 cells

PAB(T7-164)
Effect of catechol on Nrf2-mediated oxidative stress response gene.

Iori Adachi[1], Sachie Nakatani[1], Misuzu Saito[1], Kenji Kobata[1]

1. Graduate school of Josai University (Japan)

Purpose: Oxidative stress causes various diseases. Recent studies have shown that some food ingredients may induce oxidative stress response genes and enhance oxidative stress tolerance at the cellular level. Activation of the transcription factor Nrf2 is involved in the expression of various oxidative stress response genes. Catechol (CC) is produced from chlorogenic acid during the roasting process of coffee. It has been clarified that CC has an anti-inflammatory effect by Nrf2 intervention. In this study, we investigated the possibility that CC improves oxidative stress tolerance via Nrf2.

Method: HepG2 cells were used to evaluate the oxidative stress response. The HepG2 cells were pre-treated with CC for 6 days.CC was removed and H_2O_2 was added as an inducer of oxidative stress. Cell viability was determined by WST-1 assay. Intracellular ROS accumulation was measured using the fluorescent marker, DCFH-DA. RNA and protein were extracted from the CC-treated cells, and the expression levels of Nrf2 and oxidative stress response genes were measured. RNA was evaluated by the RT-PCR, and proteins were evaluated by Western blot.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Results: CC-treated cells increased H_2O_2-induced cell viability and significantly reduced ROS production compared to CC-untreated cells. As a result of comparing the expression of HO-1, TXNRD1, and γ-GSC of HepG2 supplemented with CC in advance, CC significantly increased the mRNA expression level and protein expression level in HepG2 cells. In addition, as a result of comparing the amount of Nrf2 in the nucleus of HepG2, the amount of Nrf2 in the nucleus increased as compared with the case where CC was not added.

Conclusion: As a result of this study, it was suggested that CC continuously induces the activation of Nrf2 in HepG2 and enhances the antioxidant action of the cells themselves via oxidative stress response genes.

Keyword: Oxidative stress, Antioxidant, pyrocatechol, Nrf2, Hepatocyte

PAB(T7-165)
Effects of urolithin A on osteoblast differentiation-related proteins.

Hikaru Kawano[1], Sachie Nakatani[1], Yasuhiro Horimoto[1], Masatake Kudoh[2], Yuichi Ukawa[2], Kenji Kobata[1]

1. Graduate School of Pharmaceutical Sciences, Josai University (Japan), 2. DAICEL CORPORATION Healthcare SBU (Japan)

Background and objectives: Urolithin A is a polyphenol that is metabolized by intestinal bacteria when ellagic acid is ingested and detected in the blood. It has been reported that ingestion of ellagic acid increases the bone mineral density in postmenopausal osteoporotic mice, but the low rate of transfer into the blood after oral ingestion of ellagic acid suggests that urolithin A is likely to be the active metabolite. However, the action of urolithin A on osteoclasts has not been investigated. We found that urolithin A inhibited the differentiation of hematopoietic stem cells into osteoclasts. In this study, we sought to determine the effect of urolithin A on the phosphorylation of c-jun N-terminal kinase (JNK) and extracellular signal-regulated kinase (ERK), which are upstream of NFATc1, the master transcription factor for osteoclast differentiation.

Methods: Bone marrow fluid from the femur and tibia of ddY 8-week-old mice was collected and seeded into dishes, one day later, floating cell mouse bone marrow-derived hematopoietic stem cells were collected and seeded at 12.5 x 10^4 cells/cm^2. Macrophage colony-stimulating factor (30 ng/mL) and receptor activator of nuclear factor kappa-B ligand (50 ng/mL), which are differentiation inducers for osteoclasts, were added and cultured at the same time as the seeding. Osteoclast differentiation was assessed by tartrate-resistant acid phosphatase (TRAP) staining, mRNA expression of osteoclast differentiation-related genes by RT-PCR, and protein expression by Western blotting.

Results: TRAP staining showed that urolithin A significantly inhibited osteoclast differentiation at a concentration of 10 µM, RT-PCR showed that urolithin A suppressed NFATc1, DC-STAMP, matrix metalloproteinase 9, cathepsin K, and TRAP. Western blotting results suggested that urolithin A reduced the expression level of p-JNK.

Conclusions: These results indicate that urolithin A may inhibit osteoclast differentiation by inhibiting JNK phosphorylation followed by suppressing NFATc1 expression.

Postbiotic of LP CBA L74 or Lactobacillus rhamnosus GG prevent gliadin induced activation of mTOR pathway and NFK-β activation in Caco-2 cells and intestinal organoids

Maria Vittoria Barone[1], Federica Nigro[2], Claudia Bellomo[1], Francesca Furone[1], Andrea Luigi Budelli[3], Roberto Nigro[3], Merlin Nanayakkara[1]

1. ELFID (European Laboratory for the Investigation of Food Induced Diseases), Department of Translational Medical Science, Section of Paediatrics, University Federico II (Italy), 2. I.T.P. Innovation and Technology Provider S.r.l (Italy), 3. DICMAPI, University of Naples Federico II (Italy)

Background and objectives: Celiac disease (CD) is an autoimmune disease characterized by an altered immune response induced by gliadin peptides that are not digested and by damage of the intestinal mucosa. Therapy for the disease is a lifelong diet without gluten. Alternative therapies for CD have been proposed, in particular one of this is focused on the destruction of gliadin peptides present in the food, while another approach has the goal of blocking the entry of peptides in the intestinal epithelium, preventing the activation of the immune response. Probiotics and postbiotics, substances produced through the metabolic activity of the microorganism, have characteristics that could be useful in both these areas. The aim of this study was to investigate whether the postbiotic of Lactobacillus paracasei (LP) and Lactobacillus rhamnosus GG (LGG) could prevent the action of gliadin peptides on mTOR, autophagy and inflammatory response.

Methods: We treated Caco-2 cells an intestinal cell line with gliadin peptic-tryptic digested peptides (PTG), or P31-43 alone, before and after postbiotic pretreatment with LP CBA L74 (LP CBA L74) or Lactobacillus rhamnosus GG (ATCC 53103) (1x10^9). As read out of inflammation we evaluated the levels by western blot (WB) analysis of pmTOR, p70S6k, p4EBP and pNFkβ. To study autophagy, we analysed LC3 and p62 levels by WB and immunofluorescence. We confirmed these data on intestinal organoids derived from celiac (CD) patients biopsies.

Results: Levels of phosphorylation of mTOR, p70S6k and p4EBP1 were increased after treatment of PTG and P31-43 indicating that intestinal epithelial cells responded to gliadin peptides activating the mTOR pathway. Moreover, we observed an increase of phosphorylation of NFKβ and a decrease of authophagy. Pre-treatment with postbiotic LP CBA L74 or

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Lactobacillus rhamnosus GG (ATCC 53103) prevented the mTOR pathway activation, the NFKβ phosphorylation and increased the autophagy. The increase of pNFkB after gliadin peptides treatment was confirmed in intestinal organoids from CD patients also in this case the postbiotic of LP and LGG are able to prevent these effects.

Conclusions: These preclinical studies are a good basis to plan clinical trials in celiac patients to prevent the pro-inflammatory effects of gliadin peptides.

Dietary ellagic acid retards atherosclerosis through ameliorating vascular inflammation and endothelial dysfunction in apolipoprotein E knockout mice

Sin-Hye Park[1], Young-Hee Kang[1]

1. Hallym University (Korea)

Background and objectives: Atherosclerosis particularly due to high circulating level of LDL is a major cause of cardiovascular diseases including myocardial infarction, heart failure, and stroke. Ellagic acid is a natural polyphenolic compound in fruits, vegetables, nuts, and wine, particularly rich in pomegranates and berries. Our previous study showed that ellagic acid exhibited anti-atherosclerotic activity *in vitro* by promoting cholesterol efflux from lipid-laden foam cells. The aim of this study is to investigate whether ellagic acid improves vascular endothelial function damaged in apoE knockout (KO) mice.

Methods: ApoE KO mice are highly susceptible to spontaneous hypercholesterolemia and atherosclerosis. In this study, apoE KO mice were fed Paigen's atherogenic diets for 10 weeks to induce severe atherosclerosis. Concurrently, ellagic acid was orally administrated to the apoE KO mice at the dose of 10 mg/kg for 10 weeks.

Results: Oral administration of ellagic acid reduced the number of eosinophils and basophils, and displayed lipid-lowering effects with a reduction of atherogenic index highly elevated by Paigen's diet in apoE KO mice. Ellagic acid diminished LDL-cholesterol highly elevated in apoE KO mice, whereas HDL-cholesterol was relatively enhanced. In addition, supplementing ellagic acid to Paigen's diet-fed mice lack of apoE gene substantially reduced plasma levels of C-reactive protein, soluble vascular cell adhesion molecule-1 (VCAM1) and interferon-γ but not of tumor necrosis factor-α, all involved in vascular inflammation. Staining with H&E and Oil red O showed that ellagic acid attenuated aortic plaque formation in apoE KO mice. Furthermore, ellagic acid diminished the expression of inflammatory biomarkers such as VCAM1, ICAM1, and p-selectin in aortic tissues, and enhanced the expression of endothelial function-related biomarkers such as nitric oxide synthase-2 and heme oxygenase-1.

Conclusions: Ellagic acid may be an athero-protective compound through alleviating vascular inflammation and ameliorating endothelial dysfunction.

Keyword: Ellagic acid, vascular inflammation, endothelial dysfunction, apoE knockout mice, atherosclerosis

PAB(T7-168)
Attempt to Evaluate Comfort Level Using EEG Before and After Sugar Intake: Examination of EOG by Principal Component Analysis

Mayu Fujita[1], Ayaka Yoshino[1], Kazuyoshi Ohashi[1], Ryota Akai[1], Harunobu Nakamura[2], Yoshimitsu Okita[1]

1. Shizuoka University (Japan), 2. Kobe University (Japan)

Background and objectives: It has been reported that sugar produces positive emotions in psychological questionnaire studies. However, some reports show no effect on mood, and others show increased depressed mood. Questionnaire surveys are not sufficient for subjective mood evaluation. Recently, electroencephalography (EEG), a simple measurement of central nervous system activity, has been used as an objective method for estimating mood. The Comfort Vector (CV) model based on the 1/f characteristics of alpha wave fluctuations in the frontal lobe is used as a mood evaluation index using EEG. In contrast, EEG is contaminated with Electrooculography (EOG). EOG-contaminated EEG makes the accuracy of the results of the CV model unstable. A method for removing EOG artifacts from EEG is proposed using principal component analysis (PCA). In this study, we propose a new CV model combined with PCA for objective and real-time evaluation of mood on sugar intake.

Methods: Two healthy young males participated in this double-blind crossover study. Experiments were conducted in the morning after a 12-hour fast. The subjects consumed fructose or placebo (sodium saccharin) with water. EEG and EOG were measured for 6 min 7 times before and every 10 minutes after intake with eyes closed at resting-state. The EEG and EOG signals were divided into 2.048-second segments, and the segments were graded based on the maximum amplitude of the EOG signals. PCA was applied to the EEG contaminated with EOG artifacts. Then, the analytical procedure for the CV model was performed.

Results: We report about the percentage of the region where the length of the vector in the second quadrant is greater than 50%. This percentage increased 20 min after intake for subject A and 10 min after intake for subject B in both intakes. Then, this

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

percentage did not increase or decrease 40–50 min after placebo intake, whereas it increased after fructose intake.

Keyword: Alpha wave fluctuation, Comfort Vector model, Electrooculography, Principal component analysis, Sugar

Conclusions: We conclude that the CV model with PCA can show the difference in the change in comfort level depending on the type of sugar.

PAB(T7-169)
In vitro Metabolism of 5,7,3',4'-Tetramethoxyflavone by Rat Liver Microsomes

Chiho Ohta[1], Hitomi Ogata, Masayo Deguchi[1], Nobuyuki Koga[1]

1. Nakamura Gakuen University (Japan)

Background and objectives: 5,7,3',4'-Tetramethoxyflavone (TMF) is one of the polymethoxyflavones that are abundant in the rhizomes of black ginger (*Kaempferol Parviflora*) and have been reported to show various biological effects such as inhibitory effect of P-glycoprotein, anti-inflammatory effect, cytotoxicity against cancer cell lines. Therefore, the metabolism of TMF was investigated using rat liver microsomes and the effects of typical cytochrome P450 (CYP) inducers, phenobarbital (PB), 3-methylcholanthrene (MC) and dexamethazone (DEX) were also examined.

Methods: TMF was incubated for 20 min at 37°C with rat liver microsomes, NADPH-generating system, $MgCl_2$ and 100 mM HEPES buffer (pH 7.4) under aerobic conditions. Rat liver microsomes were prepared from untreated, PB-treated, MC-treated and DEX-treated rats. After incubation, an ice-cold methanol was added to stop the reaction and the incubation mixture was centrifuged to remove the denatured protein. The supernatants obtained were applied to reverse phase HPLC and LC-MS for analyses of the metabolites.

Results: The liver microsomes from untreated animals metabolized TMF to one major metabolites (M2) and three minor metabolites (BM2, BM3 and M8). In untreated microsomes, M2 was mainly produced at a rate of 0.86 nmol/min/mg protein. BM2, BM3 and M8 were also produced at rates of 0.10, 0.09 and 0.03 nmol/min/mg proteins, respectively. In PB-, MC-, and DEX-treated microsomes, TMF was oxidized to give nine metabolites. PB- treatment showed an increase in M2 (about 2.8-fold that of untreated microsomes), and other metabolites (BM2, BM3 and M8) also increased 1.2-fold to 2.4-fold. MC-treatment decreased M2 to 60% of untreated micosomes, while five other metabolites (M1, M4, BM1, BM2 and BM3) significantly increased. DEX-treatment significantly increased M1, M3, M8, BM2 and BM3. As a result of LC-MS, eleven metabolites were determined to be a hydroxy (OH)-TMF (M3), three mono-demethylated TMF (BM3, M2, M5), four di-demethylated TMF (BM1, BM2, M6, M8), two OH・mono-demethylated TMF (M1, M7) and a OH・di-demethylated TMF (M4).

Conclusions: These results suggested that MC- and DEX-induced CYP, CYP1A and CYP3A enzymes, are important in TMF metabolism.

PAB(T7-170)
Antioxidant effect of yellow Chinese chives extract via elevation of the intracellular glutathione levels

Kayoko Kawakami[1], Kei Moriyama[1], Chie Moritani[1], Tadashi Hatanaka[2], Seiji Tsuboi[1]

1. Shujitsu University (Japan), 2. RIBS, Okayama (Japan)

Background and objectives : Oxidative stress is pivotal in any pathological processes and reducing the level of oxidative stress is implicated in prevention of diseases such as diabetes and cancer. Glutathione, the most abundant intracellular antioxidant, protects cells against reactive oxygen species induced oxidative stress. We previously demonstrated that yellow Chinese chives (*ki-nira*) increased the intracellular glutathione levels. This study aimed to investigate the protective effects of yellow Chinese chives on H_2O_2-induced oxidative stress in human hepatoblastoma cell line HepG2 and identify a compound that increases intracellular glutathione levels.

Methods: Yellow Chinese chives were minced in a food processor and extracted with 50% aqueous ethanol for 1 h. The liquid phase was evaporated and lyophilized to obtain a yellow Chinese chive extract (YCE). HepG2 cells were cultured with or without YCE and collected on indicated times to determine intracellular glutathione levels. We also evaluated the protective effect of YCE on H_2O_2-induced cytotoxicity in HepG2 cells using MTT assay.

Results: The treatment with YCE increased the intracellular glutathione levels in a dose- and time-dependent manner. Moreover, pretreatment of cells with YCE reduced the cytotoxicity caused by H_2O_2 in a dose-dependent manner. Nuclear factor erythroid 2-related factor 2 (Nrf2) and its downstream antioxidant enzymes are considered to protect cells against oxidative stress. Therefore, we investigated the expression of Nrf2 and its target antioxidant enzyme. YCE led to an increased expression of antioxidant enzymes, cystine uptake transporter, especially hemeoxygenase-1. YCE promoted Nrf2 nuclear translocation after 3 h. In order to determine the active component, purification of the active compounds using a Sep-Pak C18 cartridge and reversed-phase HPLC, led to the identification of (Z)-10-devinylajoene (Z)-4,5,9-trithiadeca-1,6-diene 9-oxide). In addtion, knockdown of Nrf2 inhibited the increase of the intracellular glutathione levels by (Z)-10-devinylajoene.

Conclusions: These results indicate that YCE exerts a protective effect against oxidative stress by modulating glutathione levels and anti-oxidative enzyme expression *via* the Nrf2 pathway. We identified (Z)-10-devinylajoene as a

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

compound that increases intracellular glutathione levels from the yellow Chinese chives.

Keyword: yellow Chinese chives, glutathione, nuclear factor erythroid 2-related factor 2 (Nrf2)

PAB(T7-171)
Niclosamide activates the AMP-activated protein kinase complexe containing β2 subunits independently of AMP sensitivity

Tsukasa Suzuki[1], Momoko Kojima[1], Yu Matsumoto[3], Ken-Ichi Kobayashi[2], Jun Inoue[1], Yuji Yamamoto[1]

1. Tokyo University of Agriculture (Japan), 2. Notre Dame Seishin University (Japan), 3. Komazawa Women's University (Japan)

Background and objectives: AMP-activated protein kinase (AMPK) is a major regulator of cellular energy homeostasis. AMPK is a highly conserved serine/threonine kinase, composed of a catalytic α subunit and β and γ regulatory subunits. Each AMPK subunit has multiple isoforms (α1/α2, β1/β2, γ1/γ2/γ3), which can be combined to form multiple heterotrimeric complexes. For the AMPK activation, phosphorylation of Thr172 of the α catalytic subunit is essential. Furthermore, increased cellular AMP and ADP induce allosteric activation of AMPK by binding to the γ subunit and preventing dephosphorylation of Thr172. Activated AMPK phosphorylates many substrates and promotes catabolic processes to maintain cellular ATP concentrations while inhibiting anabolic processes. Thus, AMPK activators are important therapeutic targets for metabolic syndrome. In recent studies, niclosamide (5-chloro-salicyl-(2-chloro-4-nitro)anilide), an FDA-approved anthelmintic, improved blood glucose levels in mice via AMPK activation and niclosamide is thought to activate AMPK by increasing the AMP/ATP ratio through mitochondrial uncoupling. However, the details of its action remain unclear. The purpose of this study is to determine how niclosamide activates AMPK and whether the activation occurs in an AMP-independent manner.

Methods: To evaluate niclosamide for the activity of AMPK in cultured cells, we treated HEK293T cells with niclosamide and measured phosphorylation of Thr172 on the AMPK α subunit and phosphorylation of ACC. To examine the effect of niclosamide on AMP-insensitive AMPK complex, HEK293T cells were expressed with AMPK γ subunit mutant (D90A).

Results: We found that niclosamide also activates AMPK complexes containing AMP-insensitive γ subunits. We further examined AMPK activation by niclosamide in combination with α1/α2 and β1/β2 subunits and found that the β2-containing AMPK complex is activated. This effect was suppressed by replacing the Ser108 residue in the β2 subunit with alanine.

Conclusions: Niclosamide has a novel AMP-independent AMPK activation mechanism. In addition, unlike A-769662, a direct AMPK activator, niclosamide specifically activates AMPK via the AMPK β2 subunit. In skeletal muscle, exercise specifically activates the AMPK α2β2γ3 complex and improves metabolism via phosphorylation of AMPK substrates. Therefore, niclosamide may be effective as an AMPK activator targeting skeletal muscle.

Keyword: AMPK, Niclosamide, Diabetes

Infant curcumin intake enhances antioxidant by upregulating Nrf2 in the kidneys of fructose-loaded female pups exposed to undernutrition during fetal and infancy

Shin Yamaoka[1,2], Kotomi Sasaki[3], Shin Sato[1,3]

1. Aomori University of Health and Welfare Graduate School (Japan), 2. Akita Nutrition Junior College (Japan), 3. Aomori University of Health and Welfare (Japan)

Background and objectives: Excessive intake of fructose induces oxidative stress in the kidney. Moreover, excess fructose suppresses the expression of NF-E2-related factor 2 (Nrf2), a transcription factor involved in antioxidant regulation. Curcumin plays a role in activating Nrf2 in the kidney, increasing heme oxygenase-1 (HO-1) and superoxide dismutase (SOD) expression levels, and alleviating oxidative stress. However, little is known regarding the effects of infancy curcumin intake. We investigated whether infancy curcumin intake upregulates Nrf2 and suppresses oxidative stress in the kidney due to fructose-loading.

Methods: Pregnant Wistar rats received diets containing 20% (NP) or 8% (LP) casein, in addition to 0% or 0.25% curcumin (Cur)-containing LP diets (LP/LP and LP/Cur) during lactation. At weaning, the pups were fed distilled water (W) or 10% fructose solution (Fr) and accordingly divided into four groups: NP/NP/W, LP/LP/W, LP/LP/Fr, and LP/Cur/Fr. Body weight and food and water intake were measured during breeding. At 13 weeks, glucose (Glc), triglyceride (TG), urea nitrogen (BUN), creatinine (Cr), and malondialdehyde (MDA) levels in the plasma and protein expression of Nrf2, HO-1, superoxide dismutase 1 (SOD1), and superoxide dismutase 2 (SOD2); glutathione (GSH) level; and glutathione peroxidase (GPx) activity in the kidney of female pups were examined.

Results: No significant difference was found in body weight between the LP/LP/Fr and LP/Cur/Fr groups at 13 weeks of age. At 12 weeks of age, food and water intake of the LP/LP/Fr and LP/Cur/Fr groups decreased significantly compared to that of the NP/NP/W and LP/LP/W groups, respectively. Glc, TG, and MDA levels in the plasma were significantly lower in the LP/Cur/Fr than in the LP/LP/Fr group; however, BUN and Cr were not significantly different between the groups. Nrf2, HO-1, and SOD1 protein expression; GSH levels; and GPx activity in the kidney were significantly higher in the LP/Cur/Fr than in the LP/LP/Fr group.

Conclusions: Infant curcumin intake may upregulate Nrf2 in the kidney, enhance antioxidant regulation, and suppress oxidative stress due to fructose-loading.

Gut microbial short-chain fatty acids-mediated olfactory receptor 78 stimulation promotes anorexigenic gut hormone peptide YY secretion in mice

Akari Nishida[1], Junki Miyamoto[2], Hidenori Shimizu[1], Ikuo Kimura[1]

1. Kyoto University (Japan), 2. Tokyo University of Agriculture and Technology (Japan)

Background and objectives: Olfactory receptor 78 (Olfr78), which is also known as a receptor for short-chain fatty acids (SCFAs) produced via gut microbial fermentation from indigestible polysaccharides such as dietary fibers, is expressed in the enteroendocrine cells of the colon. However, the role of Olfr78 in gut hormone secretion remains unknown. Here, we aimed to investigate the function and mechanism of action of Olfr78 in vivo and in vitro.

Methods: We assessed the expression of Olfr78 in several tissues, affinity of Olfr78 to various monocarboxylates, and the secretion of anorexigenic gut hormone peptide YY (PYY) via Olfr78 using various molecular and biochemical techniques.

Results: Olfr78 was abundantly expressed in the colon and mouse enteroendocrine cell line STC-1 and showed specific affinity to SCFAs such as acetate and propionate, but not butyrate, in a monocarboxylate ligand screening assay using a heterologous expression system. Acetate promoted PYY secretion in STC-1 cells via Olfr78-protein kinase A signaling, whereas the effects were abolished by Olfr78 RNA interference. Colonic SCFAs production via oral administration of fructo-oligosaccharide significantly increased plasma PYY levels, whereas this effect was abolished in Olfr78-deficient and germ-free mice.

Conclusions: These results suggested that the SCFA receptor Olfr78 is important for anti-obesity and anorexigenic effects of the gut microbiota and dietary fibers (Nishida et al. *Biochem Biophys Res Commun*. 2021).

Keyword: SCFAs, Olfr78, gut microbiota, PYY, GPCRs

Curdlan intake changes gut microbial composition, short-chain fatty acid production, and bile acid transformation in mice

Mayu Yamano[1], Keita Watanabe[1], Yuki Masujima[1], Ryuji Ohue-Kitano[1], Ikuo Kimura[1]

1. Kyoto University (Japan)

Background and objectives: Indigestible polysaccharides, such as dietary fibers, benefit the host by improving the intestinal environment. Short-chain fatty acids (SCFAs) produced by gut microbial fermentation from dietary fibers exert various physiological effects. The bacterial polysaccharide curdlan benefits the host intestinal environment, although its effect on energy metabolism and SCFA production remains unclear. Hence, this study aimed to elucidate the effect of curdlan intake on gut microbial profiles, SCFA production, and energy metabolism in a high-fat diet (HFD)-induced obese mouse model.

Methods: We first assessed changes in gut microbial composition, SCFA production, and glucose homeostasis following curdlan supplementation in HFD-fed mice. Additionally, we examined the fecal primary and secondary BAs to clarify the relationship between curdlan intake and plasma GLP-1 increase in addition to SCFA.

Results: Gut microbial composition of fecal samples from curdlan-supplemented HFD-fed mice indicated an elevated abundance of Bacteroidetes, whereas a reduced abundance of Firmicutes was noted at the phylum level compared with that in cellulose-supplemented HFD-fed mice. Moreover, curdlan supplementation resulted in an abundance of the family Bacteroidales S24-7 and Erysipelotrichaceae, and a reduction in Deferribacteres in the feces. Furthermore, curdlan supplementation elevated fecal SCFA levels, particularly butyrate. Although body weight and fat mass were not affected by curdlan supplementation in HFD-induced obese mice, HFD-induced hyperglycemia was significantly suppressed with an increase in plasma insulin and incretin GLP-1 levels.

Conclusions: Curdlan supplementation elevated fecal bile acid and SCFA production, improved host metabolic functions by altering the gut microbial composition in mice [Watanabe and Yamano (co-1st author) et al. *Biochem Biophys* Rep. 2021].

Phytochemical Screening of Local Lombok Island *Moringa Oleifera Leaf* Powder as Diabetes Therapy Through IRS-1- Expression Regulation

Aladhiana Cahyaningrum[1], Dian Handayani[2], Djoko Wahono Soeatmadji[3], Masruroh Rahayu[4], Surya Hadi[5]

1. Brawijaya University (Indonesia), 2. Brawijaya University (Indonesia), 3. Brawijaya University (Indonesia), 4. Brawijaya University (Indonesia), 5. Mataram University (Indonesia)

Background and objectives: Moringa *(Moringa oleifera*) is a plant that can grow regardless of the season, so it is easy to obtain, relatively inexpensive, and can thrive in almost all parts of Indonesia, including Lombok Island, West Nusa Tenggara province. *Moringa oleifera* leaves are sources of polyphenolic compounds such as flavonoids and phenolic acids, that can function as antidiabetics. This study aims to identify the chemical compounds contained in *Moringa oleifera* from Lombok Island and predict its role as a therapy for diabetes mellitus.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: Phytochemical screening was conducted using the predict spectrophotometric method, while the amino acid analysis was done using the UPLC method. In silico was performed to predict the compound contents in *Moringa oleifera* and to describe its role in certain biological processes.

Results: Analysis of Pa (probability "to be active") using the Pass Server approach predicted that *Moringa oleifera* could be used for diabetes treatment (Pa values of 0.387 and 0.446), since it has significant role as anti-inflammatory (Pa value of 0.707) and antioxidant (Pa value of 0.839). Analysis by using the STITCH program showed that quercetin is one of the flavonoids found in *Moringa* leaves that effect the expression regulation of IRS-1. The phytochemical screening results show that *Moringa oleifera leaf* powder from Lombok Island contained polyphenols, flavonoids, tannins and quercetin, in where polyphenols is the most compound contained (864.09 mgGAE/100 g). Of 15 kinds of amino acids in *Moringa oleifera* powder, the highest number of amino acids is L-Glutamic Acid (22012.14 mg/kg).

Conclusions: *Moringa oleifera* leaf powder from Lombok Island contains polyphenols, flavonoids, tannins ,quercetin, and amino acids. Quercetin is predicted to have the ability as a diabetes therapy by regulating the expression of IRS-1.

Keyword: Moringa oleifera, phytochemical screening, in silico, diabetes mellitus.

PAB(T7-176)
Anti-proliferation effect of *S*-allyl-L-cysteine sulfoxide in garlic against cutaneous tumor, melanoma

Yusuke Yamaguchi[1], Toshiki Ando[1], Tomoaki Yazaki[1], Hiroyuki Hara[1], Hitomi Kumagai[1]

1. Nihon University (Japan)

Background and objectives: Melanoma is a malignant tumor in the skin, causing 55,000 deaths annually around the globe. Because few treatment options have been available, melanoma is a life-threatening disease once it spreads. Therefore, it is required to prevent the proliferation of melanoma cells in the early stage. Garlic is known as an anti-cancer food. The major effective components are reported to be lipophilic sulfides such as diallyl trisulfide, and diallyl disulfide which are enzymatically produced from S-allyl-L-cysteine sulfoxide (ACSO) when garlic is cut or crushed. However, having strong garlic odor, these sulfides are difficult to be applied as food ingredients. On the other hand, ACSO, a garlic-odor precursor, is odorless, highly water-soluble, and enhances good tastes. We have already found that ACSO possesses various pharmacological effects such as anti-platelet aggregation and hepatoprotective effects *in vivo*. Here, we investigated if ACSO would suppress the proliferation of melanoma cells.

Methods: ACSO was orally administered to C57BL/6J mice after subcutaneous injection of mouse melanoma B16F1 cells. Then, tumor volume and LDH activity in the blood, an indicator of melanoma progress, were measured. Anti-proliferation effect of ACSO was also investigated using B16F1 melanoma cells and normal NHEM melanocytes. ACSO was added to these cells and then the cell viabilities were measured using MTT assay.

Results: Orally administered ACSO significantly suppressed tumor growth of melanoma and the increased in LDH activity compared with those of mice administered distilled water as a vehicle. In addition, ACSO decreased cell viability of melanoma cells, but did not affect that of melanocytes.

Conclusions: Considering that ACSO is reported to be absorbed from the small intestine to the blood, our results indicate that orally administered ACSO was delivered to the skin tumor and suppressed the proliferation of melanoma cells without affecting normal melanocytes. ACSO has the potential to be used as a food material to prevent melanoma proliferation.

Intake of soymilk-okara powder for 12 weeks decreases body fat and increases body muscle in Japanese adults: A single-arm intervention study

Akihiro Maeta[1], Masahiro Katsukawa[2], Yaeko Hayase[2], Kyoko Takahashi[1]

1. Mukogawa Women's University (Japan), 2. Kikkoman Food Products Company (Japan)

Background and objectives: Okara is a by-product of soymilk manufacturing and a rich source of protein and dietary fiber. Some animal model reports suggested that okara intake might increase lipid catabolism and decrease anabolism. Moreover, in a mouse model experiment diets supplemented with okara altered cecal microbiota. However, there are few reports of dietary okara intake for the long term in healthy humans. This study investigated whether dietary okara intake in the long term affects the body composition and the gut microbiota flora in healthy Japanese adults.

Methods: 46 participants (women: 43) were enrolled. All the subjects ingested 15g of okara powder (Soymilk-okara powder, Kikkoman Soyfoods Company, Japan) every day for 12 weeks. The subjects' body composition was assessed per 4 weeks. At baseline and after intervention for 12 weeks, fecal microbiota percentages were measured (Techno Suruga Laboratory Co., Ltd., Japan).

Results: The median total soymilk-okara powder intake during the intervention for 12 weeks was 1182g. All the subjects ingested more than 720g (15 g/day×4 days/week×12 weeks). There was no difference in nutritional intakes and exercise habits before and after the intervention. The weight of body muscle significantly increased, and the percentage of body fat significantly decreased at 4, 8, and 12 weeks after the intervention than at baseline. The percentages of *Coriobacteriaceae, Lactobacillales, Clostridium cluster IV* and *Clostridium cluster XI* in feces significantly decreased at 12 weeks after the intervention than at the baseline. Conversely, the

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

percentages of *Bacteroides* in feces significantly increased at 12 weeks after the intervention than at the baseline. Therefore, the *Firmicutes* group / *Bacteroidetes* group ratio in feces significantly decreased at 12 weeks after the intervention than at the baseline.

Conclusions: A dietary intake of 15g of soymilk-okara powder for 12 weeks induced a decrease in body fat, an increase in body muscle, and a change in fecal microbiota flora.

Metabolite profiling and antioxidant activity of early immature durian (*Durio zibethinus* L.) fruit

Putthamas Pewlong[1], Supaart Sirikantaramas[1]

1. Chulalongkorn University (Thailand)

Background and objectives: Early immature durian (*Durio zibethinus* L.) fruit (30-45 days after anthesis with 6-12 cm in length) is currently considered as an agricultural waste from durian cultivation. This is because the fruit at this stage in large quantity are pruned out to preserve the quality (taste and size) of the fruit left on the trees. Therefore, the aim of the present study was to investigate the metabolite profile of early immature durian fruit.

Methods: GC-MS and HPLC-Q-TOF-MS/MS procedures were used to perform metabolite profiling of early the immature durian fruit. In addition, HPLC analysis was used to quantitively analyzed major bioactive compounds. DPPH and FRAP assays were prepared to evaluate antioxidant activity of the extract.

Results: Four groups of primary metabolites (sugars, organic acids, amino acids, and miscellaneous) were annotated using GC-MS, meanwhile HPLC-Q-TOF-MS/MS analysis revealed a few dominant secondary metabolites. Subsequently, we quantitively analyzed procyanidin B2, procyanidin C1 and (-)-epicatechin using HPLC and suggested them as major bioactive compounds. Moreover, the results of DPPH and FRAP assays showed that the extract had a greater antioxidant activity than ascorbic acid.

Conclusion: These results point out several aspects that the early immature durian fruit can be potentially exploited as an accessible source of bioactive ingredients with strong antioxidants for foods, cosmetics, or pharmaceutical industries.

PAB(T7-179)
Investigation of mannooligosaccharides from coffee administration and synergistic effect with vitamin D3 on calcium absorption in rats

Toshio Kumao[1], Takashi Hashimoto[1], Izumi Hoshino[1], Kazuto Ozaki[1]

1. Ajinomoto AGF, INC. (Japan)

Background and objectives: We confirmed that mannooligosaccharides (MOS) derived from coffee have promotive effects on calcium absorption in the large intestine, and short-chain fatty acids (SCFA) in the large intestine are thought to be the cause of these effects. Vitamin D3 (VD3), on the contrary, is known to aid calcium absorption in the small intestine, and the Japanese government has approved it for use in nutritionally functional meals. The synergistic effects of MOS and VD3 on calcium absorption in Sprague–Dawley (SD) rats were examined in this study.

Methods: This study was carried out with the approval of the Ethics Committee of Ajinomoto General Foods, INC. For 14 days, SD rats (5 weeks old) were fed the control diet (CFR-1; CLEA Japan INC.) and water *ad libituim*. During the experimental period, MOS (200 mg/kg body weight) or VD3 (2 µg/kg body weight) or both MOS and VD3 were orally administered to the rats daily. The SD rats were given a calcium solution (500 mg/kg body weight) on the 14th day, 15 min after each item was given, and urine was collected for 12 h. The calcium content of the urine was determined.

Results: MOS or VD3 administration resulted in a substantial increase in urine calcium when compared to the control ($p < 0.05$ in both). In comparison to the control, MOS + VD3 treatment resulted in a significant increase. However, there was no statistically significant difference in MOS + VD3 administration and MOS or VD3 administration.

Conclusions: In this study, MOS administration had enough effects on calcium absorption. However, the synergistic effects of VD3 and MOS were not confirmed in this study.

Establishment of a culture-based porcine intestinal microbiota model (TUSIMM: Tohoku University Swine Intestinal Microbiota Model)

Yuji Tsujikawa[1,2,3,4], Masahiko Suzuki[1,2], Taiga Sakuma[2,3], Mitsuki Sakurai[2,3], Md Shahid Riaz Rajoka[2,3], Iwao Sakane[1], Itsuko Fukuda[4], Ro Osawa[4], Haruki Kitazawa[2,3]

1. Central Research Institute, ITO EN, Ltd (Japan), 2. Graduate School of Agricultural Science, Tohoku University (Japan), 3. CFAI, Graduate School of Agricultural Science, Tohoku University (Japan), 4. Graduate School of Agricultural Science, Kobe University (Japan)

Background and objectives: The effects of dietary components on the gut microbiota are examined through human intervention studies. However, these investigations are difficult to execute due to their high expenses and ethical considerations. As a result, porcine is employed as a substitute model, but for the same reasons, its usage should be limited. Up to date, only a few semi-continuous or continuous in vitro models have been constructed, which are sophisticated and do not accurately recreate the fecal microbiota. Therefore, the objective of this study was to establish an optimal model system for porcine by seeking a culture medium that can reproduce the porcine fecal flora with high accuracy in a simple batch model.

Methods: Semi-fluid general anaerobic medium (GAM) or GAM supplemented with 0.5 g/L glucose (GAM+G) was distributed into vials and converted to anaerobic conditions by using a combination of N_2, CO_2, and H_2 gas. Each of the three porcine fecal samples was diluted with lyophilized anaerobic bacteria protectant and incubated for 30 hours at 37 °C. Bacterial flora analysis was then performed by using next-generation sequencing and real-time PCR for 16S rRNA genes in feces and culture medium. In addition, the concentration of short-chain fatty acids was also determined by using high-performance liquid chromatography (HPLC).

Results: Real-time PCR suggested that the culture in GAM tended to have lower numbers of Clostridium leptum subgroup and Prevotella and higher numbers of Enterobacteriaceae than fecal samples as compared with the cultures in GAM+G. The principal component analysis (PCA) by next-generation sequencing showed that the culture in GAM+G was plotted closer to fecal samples than the culture in GAM. Furthermore, the HPLC suggested that the short chain fatty acids concentration in the culture in GAM+G was closer to fecal samples than the culture in GAM.

Conclusion: It has been demonstrated that batch culture of pig feces in GAM+G employing vials is capable of reproducing the swine fecal flora to a significant extent. We are also investigating other medium to more closely mimic the porcine fecal flora, as well as culturing in an anaerobic chamber to build a more straightforward culture model

Protective effects of rice peptide against oxidative injury through activation of Nrf2 signaling pathway

Chie Moritani[1], Kayoko Kawakami[1], Hiroshi Shimoda[2], Tadashi Hatanaka[3], Seiji Tsuboi[1]

1. Shujitsu University (Japan), 2. Oryza Oil and Fat Chemical Co. Ltd (Japan), 3. RIBS Okayama (Japan)

Background and objectives: Maintenance of balance between cellular ROS generation and antioxidant defense mechanisms is important for normal cellular function. Glutathione is the most abundant non-protein thiol antioxidant, which contributes to the maintenance of cellular redox balance. We previously showed that commercially available Oryza Peptide-P60 derived from rice increased the intracellular glutathione levels. This study aimed to evaluate the antioxidant potential of this peptide and assess its mechanism of action.

Methods: The commercial rice peptide Oryza Peptide-P60 was a gift from Oryza Oil and Fat Chemical Co., Ltd.HepG2 cells were incubated with and without Oryza Peptide-P60 (5 mg/mL). Further, intracellular glutathione levels were measured, and protein and mRNA levels of antioxidant enzymes were quantified. The concentrations of reduced and oxidized glutathione were determined simultaneously by HPLC with fluorescence detection. Relative mRNA levels were estimated using quantitative RT-PCR. HepG2 cells were treated with and without Oryza Peptide-P60 followed by exposure H_2O_2 or acetaminophen (APAP), and then cytotoxicity was evaluated by lactate dehydrogenase activity released from damaged cells in the culture medium.

Results: Pretreatment of HepG2 cells with Oryza Peptide-P60 reduced the cytotoxicity caused by H_2O_2 or APAP (ca. 48% and ca. 12% of the cytotoxicity in Oryza Peptide-P60 pretreated group compared with H_2O_2 - or APAP- treated groups, respectively) through the restoration of glutathione homeostasis. Moreover, Oryza Peptide-P60 elevated the mRNA level of γ-glutamylcysteine synthetase, which is the rate-limiting enzyme in glutathione synthesis, by ca. 3-fold at 8 h, and also increased the level of mRNAs encoding other antioxidant enzymes. Furthermore, Oryza Peptide-P60 promoted nuclear factor erythroid 2-related factor (Nrf2) synthesis, a crucial regulator for antioxidant enzymes, nuclear translocation by ca. 2-fold after 8 h. Conversely, knockdown of Nrf2 inhibited the increase in the intracellular glutathione levels and suppressed the induction of antioxidant enzymes expression by Oryza Peptide-P60.

Conclusions: Oryza Peptide-P60 induced the synthesis of glutathione and antioxidant enzymes through activation of the Nrf2 pathway, leading to the suppression of oxidative stress-induced cytotoxicity in HepG2 cells. This study suggested that Oryza Peptide-P60 contained crucial peptides with substantial antioxidant activities.

Influence of daily supplementation of royal jelly on skeletal muscle force, fatigue and training effect

Daiki Watanabe[1], Katashi Nagamatsu[2]

1. National Cerebral and Cardiovascular Center (Japan), 2. Morikawa Kenkodo (Japan)

Background and objectives: Royal jelly (RJ), a natural secretion of worker honey bee, has been used as a health food. RJ is thought to improve skeletal muscle response to exercise. In this study, we examined the effects of daily RJ supplementation on skeletal muscle performance and training effects.

Methods: Nine-weeks-old male rats were assigned to control and RJ groups, and rats in RJ group were given 500 mg/kg/day RJ for 4 weeks. In either group, planta flexor muscles of left legs were subjected to endurance training and the muscles of right legs were used as untrained muscle. Under anesthesia, left leg of rat was attached to foot holder connected to force transducer. Contractions of planta flexor muscles were elicited by electrical stimulation and the force produced by these muscles were measured *in vivo*. Using this experimental system, muscles of left legs were repeatedly contracted every 5 sec for 60 min at 3 days/week for 4 weeks (endurance training). Two days after the end of training, force and fatiguability were measured in right (untrained) and left (trained) legs. Two days after the measurements, gastrocnemius (GAS) muscle, a major contributor of force production, was excised and used for analyses of citrate synthase activity and glycogen content. The data sets were statistically tested by two-way ANOVA for repeated measure and Holm-Sidak post-hoc test was subsequently used.

Results: RJ supplementation increased the force at 100 Hz but not at 20 Hz regardless training. The fatiguability was improved by endurance training but RJ supplementation exerts no effect on this improvement. Citrate synthase activity was increased by endurance training and post-hoc test indicated the significant difference between untrained and trained muscles only in RJ group. Muscle glycogen content was increased by endurance training.

Conclusions: Daily RJ supplementation 1) increases maximal force and 2) probably enhances mitochondrial biogenesis but the extent is too little to improve fatiguability.

PAB(T7-183)
Effect of Dietary Tamogitake (Pleurotus cornucopiae) on Lipid and Glucose Metabolisms in Rats and Mice

Rintaro Uchino[1], Haruka Tano[1], Shoho Bien[1], Jun Shiratsuchi[2], Akihiro Kawatani[3], Shizuka Hase-Tamaru[1], Shoko Nishizono[4]

1. Fukuoka Institute of Technology (Japan), 2. Tomuso Corporation (Japan), 3. Athree Corporation (Japan), 4. Sojo University (Japan)

Background and objectives: Tamogitake (Oyster mushroom) is an edible mushroom, which contains ergothioneine, a sulfur-containing amino acid, and has been used as a functional food for its potent antioxidant activity. In this study, we investigated the effects of dietary Tamogitake and ergothioneine on lipid and glucose metabolisms in animal models.

Methods: In experiment 1, four-week-old male Sprague-Dawley rats were fed AIN-76 based diets containing 5% Tamogitake dried-powder supplemented with or without 0.5% cholesterol for 4 weeks. In experiment 2, 4-week-old male C57BL/6J mice were fed the same diets containing 5% Tamogitake or 0.05% ergothioneine with 0.5% cholesterol for 4 weeks. Lipid and glucose parameters were measured, and quantitative real-time RT-PCR was performed for hepatic gene expression levels of HMG-CoA reductase and cholesterol 7a-hydroxylase, the rate-limiting enzymes in cholesterol synthesis and bile acid synthesis, respectively. In experiment 2, fecal lipid excretion was also measured.

Results: In experiment 1, administration of 5% Tamogitake had no adverse effects on food intake or growth; however, relative liver weights were significantly decreased in rats fed diets containing Tamogitake with or without dietary cholesterol. Serum and hepatic cholesterol and hepatic triglyceride levels were also reduced by Tamogitake feeding. No apparent effects of dietary Tamogitake on hepatic mRNA abundances of HMG-CoA reductase and cholesterol 7 a-hydroxylase were observed. Serum insulin level was significantly elevated by dietary cholesterol, while it was significantly lowered, with or without cholesterol, by dietary Tamogitake. On the hand, serum glucose concentration remained unchanged in these dietary conditions. In experiment 2, lowering effect of dietary Tamogitake on hepatic cholesterol was reproduced, but this effect was not observed in mice fed the ergothioneine-containing diet. Dietary Tamogitake and ergothioneine did not affect hepatic triglyceride level. The fecal excretions of bile acid and free fatty acid were remained unchanged by dietary Tamogitake and ergothioneine. Serum insulin level was decreased 48% by dietary Tamogitake and 72% by dietary ergothioneine.

Conclusions: These results suggested that Tamogitake has a beneficial effect on lipid and glucose metabolisms in animal model, and the lipid-lowering effects of Tamogitake might not be attributed to the ergothioneine.

Keyword: Tamogitake (Golden Oyster Mushroom), lipid metabolism, ergothioneine, rats, mice

Comparing the effects of cecal fermentation characteristics of raw and autoclaved-frozen white sorghum in rats

Ryuji Nagata[1], Takuto Nozoe[1], Samanthi Pelpolage[1], Naoki Fukuma[1], Michiyo Hoshizawa[2], Tetsuo Hamamoto[2], Kyu-Ho Han[1], Michihiro Fukushima[1]

1. Obihiro University of Agriculture and Veterinary medicine (Japan), 2. U.S. Grains Council (Japan)

Objective: Sorghum *Sorghum bicolor* L.) is a cereal rich in native resistant starch (RS). Similar to dietary fiber, RS also reaches the colon, where it is fermented by colonic microbiota, yielding short-chain fatty acid (SCFA). Among the five types of RS designated by the differences in physical and chemical properties, most raw starches are considered to be of RS type 1 and type 2. Generally, starches in cereals are consumed after a thermal treatment that enhances the digestibility. In the contrary, several recurrent cooking-cooling cycles are known to improve the RS content through the formation of retrograded starch (RS type 3). On the other hand, thermal cooking of sorghum has also shown to decrease the protein digestibility. Based on these grounds, this study aimed to assess the biochemical aspects of cecal fermentation of native and acclaimed RS in white sorghum in rats.

Methods: White sorghum grains were subjected to cooking (grains: water=1:2 (w/v)) by autoclaving (121℃, 20 min) and then freeze-dried. RS content in each sorghum sample was as follows (g/100 g sample): raw white sorghum (RAW), 11.6; white sorghum after one autoclave-freeze cycle (AC1), 3.64; white sorghum after three autoclave-freeze cycles (AC3), 5.81. Male Fischer 344 rats (7-week-old) were fed one of the four experimental diets (control (CON); 30% (w/w) RAW; 30% AC1, and 30% AC3; AIN-93G diet guidelines) for 4 weeks. Cecum was excised on the final day of the feeding period.

Results: Cecal pH in the AC1 and AC3 groups was lower than the CON and RAW groups. Cecal acetate, n-butyrate, and total SCFA concentrations were higher in the RAW, AC1, and AC3 groups, compared to the CON group. Further, the cecal n-butyrate concentration in the AC1 group was higher than the RAW group, while the molar proportion of n-butyrate was higher in the AC1 and AC3 groups compared to the CON and RAW groups. Cecal lactate concentration was higher in the AC1 and AC3 groups than the CON group, and was positively correlated with cecal IgA levels.

Conclusions: Autoclaved-frozen white sorghum exhibited better cecal fermentation characteristics, when compared with the raw white sorghum. On the other hand, the fermentation characteristics of AC1 and AC3 were comparable.

Keyword: sorghum, autoclaving, resistant starch, n-butyrate

Water in oil emulsion system modifies absorption profile of green tea catechins in the body and also masks their bitter taste: Evaluation in human subjects

Arata Hashimoto[1], Ayaka Miyashita[2], Junya Ito[2], Isabella Supardi Parida[2], Takashi Ichinose[3], Kiyotaka Nakagawa[2]

1. FUJI OIL CO., LTD (Japan), 2. Tohoku University (Japan), 3. FUJI OIL HOLDINGS INC. (Japan)

Background and Objectives: Catechins are the type of flavonoids present in green tea leaves and are known to have some physiological effects such as antioxidant and anticancer activities. On the other hand, their rapid excretion from the human body and the strong bitter taste are challenges for the effective use of catechins. To overcome these challenges, we attempted to use the water in oil (W/O) emulsion system for catechins, as this has been thought to be associated with the excretion rate and the masking tastes of compounds. Therefore, this study was aimed to evaluate the ability of the W/O emulsion system in moderating the rapid excretion of catechins and masking their bitter taste in humans.

Methods: Catechins in W/O emulsion (W/O-catechin) consists of green tea extract (mainly (−)-epigallocatechin gallate, EGCG), soybean oil, and surfactant. Water-dispersed catechins (W-catechin) were prepared by dissolving the green tea extract in water. In a crossover trial with a one-week washout period, healthy volunteers (n = 12) were given ten grams of either W/O-catechin or W-catechin. Blood samples were collected at 0, 1, 3, 6, 8, 12, and 24 hours after sample ingestion, and plasma catechin levels were measured using the liquid chromatography-tandem mass spectrometry (LC-MS/MS). Each subject also rated sample's bitterness using the Visual Analog Scales (VAS).

Results: From the results of LC-MS/MS analysis, the peak of EGCG was clearly detected not only in W-catechin group but also in W/O-catechin group. Interestingly, the area under the curve of plasma EGCG levels were relatively similar in subjects given W/O-catechin and W-catechin, moreover, EGCG was absorbed more gradually and remained for a longer time in the bloodstream when delivered using W/O emulsion system. Based on the VAS results, the bitterness of the catechin was also reduced in W/O-catechin. Overall, our results demonstrated the benefits of using the W/O emulsion system to extend the residence time of catechins in the body and mask its bitterness, allowing its widespread application for therapeutic purposes in the future.

Keyword: tea catechins, W/O emulsion, absorption, bitter taste masking

The impact of fish oil and/or probiotics intervention on vaginal microbiota in overweight and obese pregnant women

Noora Houttu[1], Kati Mokkala[1], Wisam Tariq Saleem[1], Seppo Virtanen[2,3], Ella Koivuniemi[1], Outi Pellonperä[1,4], Kristiina Tertti[1,4], Anne Salonen[2], Leo Lahti[1], Kirsi Laitinen[1]

1. University of Turku (Finland), 2. University of Helsinki (Finland), 3. Helsinki University Hospital (Finland), 4. Turku University Hospital (Finland)

Background and objectives: Obesity may cause perturbations in vaginal microbiota and thereby increases the risk for adverse pregnancy outcomes. The objective was to investigate the impact of long-chain polyunsaturated fatty acids (LC-PUFA, fish oil) and/or probiotics on the vaginal microbiota in overweight and obese pregnant women.

Methods: Overweight and obese pregnant women were randomly allocated into four intervention groups to consume capsules of fish oil and/or probiotics (fish oil+placebo, probiotics+placebo, fish oil+probiotics and placebo+placebo) from early pregnancy onwards. The fish oil capsules consisted of 2.4 g of n-3 LC-PUFAs (1.9 g docosahexaenoic acid and 0.22 g eicosapentaenoic acid), and probiotics capsules *Lacticaseibacillus rhamnosus* HN001 (formerly *Lactobacillus rhamnosus* HN001) and *Bifidobacterium animalis* ssp. *lactis* 420, 10^{10} colony-forming units each. Vaginal samples were collected at early (n=112) and late pregnancy (n=116) and were analysed for vaginal microbiota using 16S rRNA gene amplicon sequencing.

Results: When the active groups were compared to the placebo group, there was a lower abundance of potential pathobionts, namely *Ureaplasma urealyticum* in the fish oil group, *Ureaplasma*, *U. urealyticum* and *Prevotella disiens* in the probiotics group, *Dialister invisus* and *Prevotella timonensis* in the combination, i.e. fish oil+probiotics, group. α-Diversity did not differ between the groups at late pregnancy but it increased in fish oil group during pregnancy, whilst no difference was observed in the other groups from early to late pregnancy.

Conclusions: The results suggest that dietary intervention with probiotics and/or fish oil may have beneficial effect on vaginal microbiota composition, by lowering the abundance of potential pathobionts that have been previously related to adverse pregnancy outcomes such as bacterial vaginosis and preterm birth. However, the vaginal microbial diversity, which has been linked to vaginal dysbiosis, was increased in the fish oil group over the course of pregnancy. Further larger randomized trials are called for to clarify the findings.

Keyword: Vaginal microbiota, Fish oil, Probiotics, Pregnancy, Obesity

Eggshell membrane-induced keratinocyte differentiation is associated with PKC or/and PI3K-Akt signaling

Tetsuro Kataoka[1], Kyohei Furukawa[1], Masaya Kono[1], Yukio Hasebe[2], Huijuan Jia[1], Hisanori Kato[1]

1. The University of Tokyo (Japan), 2. ALMADO Co., Ltd. (Japan)

Background and objectives: Skin aging is one of the hallmarks of the aging process that causes physiological and morphological changes. We previously indicated that eggshell membrane powder (pESM) suppresses the skin thinning in interleukin-10 knockout mice, and enzymatically digested ESM (eESM) promotes cell differentiation in Neonatal Normal Human Epidermal Keratinocytes (NHEK-Neo) cells. Furthermore, the transcriptome analysis indicated that calcium signaling is upregulated in both experiments. However, it is unclear how ESM regulate calcium signaling. In this study, we focused three signaling pathway (protein kinase C (PKC), phosphatidylinositol-3-protein kinase B (PI3K-Akt), and Notch signal), which are reported to be regulated by extracellular calcium, and performed in vitro experiment.

Methods: NHEK-Neo cells were cultured with KBM™ Gold™ medium with or without 0.5, 1, 2, and 4 mg/ml of eESM. Gene expression was measured by qPCR and protein expression was measured by Western blotting. GF 109203X as PKC inhibitor and LY 294002 as PI3K inhibitor were used to investigate the relationship between above signaling and cell differentiation.

Results: The supplementation of eESM significantly increased expression of *KRT1, KRT10, IVL and KRT13*, which are differentiation markers, and changed cell morphology. And these effects on gene expression was dose-dependent manner. The expression of *HES1* and *ROCK1*, which are downstream of Notch signaling, was not altered by eESM supplementation. In contrast, the expression of genes related to PKC signaling such as IRF6, GRHL3 and OVOL1 were significantly upregulated at a concentration of 4 mg/ml eESM. Western blotting showed that the expression of Akt increased in a dose-dependent manner, and a significant upregulated at a concentration of 4 mg/ml eESM. Furthermore, the addition of GF 109203X and LY 294002 suppressed eESM-induced increase in expression of *KRT1, KRT10* and *IVL.*

Conclusions: This study indicates that eESM promote keratinocyte differentiation possibly via PKC or/and PI3K-Akt signaling pathway. And these findings could contribute to effective utilization of eggshell membrane as, an underutilized resource, especially in skin aging.

Keyword: Eggshell membrane, Keratinocyte differentiation, Skin aging, PKC, PI3K-Akt

Low methionine highland barley whole grains improve glycemic homeostasis in mice fed a high-fat diet

Chuanxing Feng[1], Yuge Jiang[1], Jianjin Zhu[1], Xue Tang[1], Yonghui Shi[1], Guowei Le[1]

1. Jiangnan University (China)

Background and objectives: Methionine restriction (MR) can improve blood glucose homeostasis, redox state, alleviate inflammatory response. However, the application of MR theory to real life still needs a lot of research. Research shows that highland barley can improve blood glucose, and it has the lowest methionine content in grains. Its effect on improving blood glucose may be related to its low methionine content. Therefore, this study investigated the effect of low methionine content in highland barley on improving blood glucose.

Methods: C57BL/6J mice were fed a control diet (CON, 0.86% methionine), highland barley high-fat diet (HBHF, 0.17% methionine), or highland barley high-fat with additional methionine diet (HBHFmet, 0.86% methionine) for 25 weeks. Blood glucose, plasma inflammation, lipid, total antioxidant capacity, mRNA related to liver gluconeogenesis, pancreatic function, and skeletal muscle glucose metabolism were mainly measured.

Results: The blood glucose, plasma TG, TC, LDL-C, HDL-C, TNF-α, IL- β, and antioxidant level (T-AOC) of mice fed with HBHF were maintained at normal levels. And mRNA related to liver gluconeogenesis, pancreatic function and skeletal muscle glucose metabolism were also remained at normal levels. However, these beneficial effects were attenuated after supplementation with methionine to normal levels (0.86%). Compared with the CON and HBHF groups, blood glucose, plasma TG, TC, LDL-C, TNF-α and IL-β in HBHFmet group were significantly increased, HDL-C and T-AOC levels were decreased significantly. G6Pase, PEPCK and Foxo1 mRNA were significantly increased in the liver. MafA, PDX and Bcl-2 mRNA were decreased significantly in pancreas, while bax and caspase-3 were increased significantly. The mRNA related to glucose metabolism (Pi3K, Akt, Gsk-3β, IRS-1, GLUT4, PKM, HK2) in skeletal muscle were reduced significantly. These results indicated that the HBHFmet had impaired pancreatic function, increased liver gluconeogenesis and decreased skeletal muscle glucose utilization, resulting in increased blood glucose. After supplementing methionine, the protective effect of low methionine on blood glucose homeostasis in high-fat diet mice was weakened.

Conclusions: Highland barley can keep blood glucose stabilization, partly due to its low methionine content.

Keyword: Methionine restriction, highland barley, blood glucose, high-fat diet

PAB(T7-189)
Sulforaphane promotes Sterol Regulatory Element-binding Proteins (SREBPs) precursor degradation and suppresses the activity of SREBP

Manami Kodaka[1], Shingo Miyata[2], Yuki Matsunaga[1], Keita Takeda[1], Ryo Katsuta[1], Ken Ishigami[1], Tsukasa Suzuki[1], Yuji Yamamoto[1], Ryuichiro Sato[2], Jun Inoue[1]

1. Tokyo University of Agriculture (Japan), 2. The University of Tokyo (Japan)

Background and objective: Sterol regulatory element-binding proteins (SREBPs) are transcription factors that regulate various genes involved in cholesterol and fatty acid synthesis. Sulforaphane (SFaN) is an isothiocyanate derived from cruciferous vegetables, such as broccoli, cauliflower, and kale. SFaN reportedly acts through nuclear factor erythroid 2-related factor 2 (Nrf2) transcription factor activation to induce phase II detoxification enzymes, such as NAD(P)H-quinone oxidoreductase 1, glutathione S-transferases, and heme oxygenase.SFaN is also reportedly effective in atherosclerosis, diabetes, and obesity treatment. However, the underlying mechanisms of these SFaN effects are not fully understood.

Methods: Using a luciferase reporter gene assay with the fatty acid synthase (FAS) gene promoter region, we identified SFaN as a natural food component that inhibit SREBP. To investigate the effect of SFaN on SREBP protein and function, we treated human hepatoma Huh-7 cells with 100uM SFaN. Next, we generated SREBP deletion mutants to determine whether SFaN increases ubiquitination of SREBP and to identify the site of ubiquitination.

Results: When Huh-7 cells were treated with SFaN, SFaN reduced SREBP proteins in a time- and concentration-dependent manner by promoting the degradation of the SREBP precursor. This SFaN-mediated SREBP degradation was partly inhibited by MG132, a proteasome inhibitor. Investigations using deletion mutants revealed that the C-terminal region is crucial for the SFaN-mediated SREBP-1a precursor form reduction and ubiquitination. We also found that such SREBP-1 degradation occurs independently of the SREBP cleavage-activating protein (SCAP) and the Keap1-Nrf2 pathway. Several small molecules have been reported to regulate SREBP activity, but the regulatory mechanisms differ among them. At present, it remains unclear what causes this difference. In addition, SFaN administration to obesity model animals shows an anti-obesity effect, with a decrease in serum cholesterol and TG levels. The mechanism by which SFaN exerts these beneficial effects is also still unclear, but the Keap1-Nrf2 pathway is one of the most likely candidates. This study suggests possibilities other than the Keap1-Nrf2 pathway, and further studies are required on these.

Conclusions: This study identifies SFaN as an SREBP inhibitor and provides evidence that SFaN could have major potential as a pharmaceutical preparation against hepatic steatosis and obesity.

Suppressive effect of UV-irradiated Red perilla on hepatitis induced by carbon tetrachloride in mice

Ryo Wakabayashi[1], Dian Kurniati[1], Ryohei Umeda[1], Eiji Goto[1], Natsuko Kagawa[1], Shizuka Hirai[1], Yukari Egashira[1]

1. Chiba University (Japan)

Background and objectives: Hepatitis has become a global health problem. Carbon tetrachloride (CCl_4) has been widely used to establish hepatic injury in experimental animals. CCl_4 also causes oxidative stress in animals. Red perilla (*Perilla frutescens* [L.] Britton var. *crispa f. purpurea*) displays various biological activities with its bioactive compound. Moreover, ultraviolet (UV) increasing antioxidant activity. However, the protective effect of UV-irradiated red perilla against CCl_4-induced hepatotoxicity has not been clarified. This study investigated the effect of UV-irradiated red perilla on liver injury stimulated by CCl_4 *in vivo*.

Methods: Male 9-week-old ICR mice were randomly divided into four groups. The untreated group (N) and CCl_4-treated model group (C) received 0.5% carboxymethyl cellulose-NA (CMC-Na) without UV-irradiated red perilla by oral gavage once a day for a week. The low-dose (UL) and high-dose (UH) UV-irradiated red perilla groups were administered red perilla extract that has irradiated by UV light at a dose of 25 or 100 mg/kg body weight, respectively, oral gavage once a day for a week. One hour after the last treatment, the C, UL and UH groups were intraperitoneally injected with 10 mL of CCl_4 (0.2% in olive oil) per kg body weight, while the N group received an equivalent volume of olive oil. After 24 h of CCl_4 treatment, all mice were sacrificed under anesthesia. Hepatotoxicity was assessed by measuring serum levels of total bilirubin, alanine aminotransferase (ALT), aspartate aminotransferase (AST), and Lactose Dehydrogenase (LDH) using standard methods.

Results: High and low dose of UV-irradiated red perilla significantly ameliorated CCl4-induced hepatotoxicity by decreasing the serum level of ALT, AST and LDH.

Conclusions: UV-irradiated red perilla cultivated in a plant factory with artificial light provides hepatoprotection against CC14-induced liver injury in mice. UV-irradiated red perilla would be beneficial in protecting against several diseases related to oxidative stress.

Improvement of storage stability of vegetable oils by using rice bran oil

Shota Koishi[1,2], Ami Okuda[2], Takahiro Inoue[2], Ryunoshin Kono[2], Shigeo Nakajima[2], Halida Rahmania[1], Yurika Otoki[1], Shunji Kato[1], Kiyotaka Nakagawa[1]

1. Tohoku University (Japan), 2. Tsuno food industrial Co., Ltd. (Japan)

Background and objective: Rice bran oil (RBO) is widely used due to its good flavor for cooking and its characteristic antioxidants such as gamma-oryzanols and tocotrienols. To take advantage of these benefits, RBO is sometimes blended to other edible oils. We have shown that addition of RBO to other oils such as rapeseed oil improves the storage stability [1,2], but the detail effect by adding RBO are still not clear. In this study, we investigated the effect and mechanism of blending RBO with linseed oil to improve the storage stability.

Methods and results: Linseed oil mixed with various proportion of RBO were stored at either 60℃, 40℃, or 25℃, then the peroxide value (POV) and aldehydes (propanal and acrolein; major components of unpleasant odor caused by oil deterioration) were measured. The POV and aldehydes were decreased with increasing RBO proportion, especially at 40℃ and 25℃. These values were decreased significantly even with only 10% RBO addition. Furthermore, the linseed oil with 10% RBO addition stored at 40℃ suppressed the carbonyl value and hence maintained the amount of unsaturated fatty acids.

Conclusions: The addition of RBO to linseed oil greatly improved its oxidative stability, especially bellow 40℃. Together with our previous study[1,2], we considered that adding RBO to oil (e.g., linseed oil and rapeseed oil) improves its oxidative stability, probably due to high antioxidant activity of RBO. Many companies have been trying to extend the shelf life of food products and reduce food loss to achieve the Sustainable Development Goals (SDGs). The knowledge from above results will contribute to the achievement of SDGs from the perspective of oils and fats.

Identification Of a Cytokine Storm Inhibitor From a Golden Berry Leaf.

Akira Yano[1], Shota Uesugi[1], Sayaka Yuki[1], Mayuka Hakozaki[1], Yuko Kanno[1], Akiko Shiraishi[1]

1. Iwate Biotechnology Research Center (Japan)

Background: In COVID-19, pneumonia with a strong inflammatory response and inflammatory reactions in blood vessels throughout the body contribute to the severity of the disease. These local and systemic inflammations are thought to be caused by a cytokine storm with overexpression of IL-6, which is believed to be involved in the increase of tissue inflammatory responses mediated by IL-17 and TNFα. Th17 is also known to be involved in various immune diseases. Methods: Solvent extraction was performed from 500 agricultural, forestry, and marine products from the Tohoku region of Japan to construct the food extracted library. Using epithelial fibroblast HeLa cells, we prepared an inflammation model system in which IL-6 overexpression was induced by administration of IL-17 and TNFα, and searched for food-derived components that inhibit IL-6 expression.

Results: 114 polar solvent extracts were selected from the library and screened. As a result, we succeeded in finding 7 anti-inflammatory materials. Among them, the MeOH extract of golden berry (*Physalis peruviana*) leaves had IC_{50} = 4.97 μg/ml. Estimation of anti-inflammatory components by crude fractionation and LC-MS/MS was performed, and a known anti-inflammatory component, 4-beta hydroxywithanolide E (4β-HWE), was identified. 4β-HWE had an IC_{50} = 0.21 µM (0.11 µg/ml). and the content in the extract suggested that it was a major cytokine storm suppressor.

Conclusions: A potent cytokine storm suppressor, 4β-HWE, was identified from a golden berry leaf.

Keyword: Golden berry leaf, Physalis peruviana, 4-beta hydroxywithanolide E, IL-6, cytokine storm

PAB(T7-193)
Functional analysis of LXR during muscle injury and regeneration

Hayataka Takase[1], Makoto Shimizu[1], Ikuyo Ichi[2], Yoshio Yamauchi[1], Ryuichiro Sato[1]

1. The University of Tokyo (Japan), 2. Ochanomizu University (Japan)

Background and objectives: Skeletal muscle regeneration is an important response to muscle injury and damage which are caused by overload, drugs, and inflammation. It is known that the ability of skeletal muscle regeneration is decreased during aging. Because skeletal muscle mass and strength are important factors to maintain a quality of life, we explored a novel regulator which is activated during muscle injury or regeneration. We found that expression of target genes of LXR, liver X receptor, a nuclear oxysterol receptor, are upregulated during muscle injury. In this study, we analyzed how LXR is activated and how LXR regulates muscle injury.

Methods: Mice were injected with cardiotoxin, a muscle damage inducer. Skeletal muscle was harvested on 3 and 5 days after injection. Mouse muscle cell line C2C12 cells were differentiated using medium containing 2% horse serum. Differentiated C2C12 myotubes were treated with LPS, lipopolysaccharide, mimic muscle damage. Gene expression was analyzed using real-time quantitative PCR. Myotube diameters of C2C12 myotubes were analyzed after immunostaining of myosin heavy chain.

Results: Expression of LXR target genes including ABCA1 were potently upregulated in skeletal muscle injected with cardiotoxin. A mass spectrum analysis revealed that some oxysterols which may activate LXR were significantly increased. LPS-induced inflammation using C2C12 myotubes were used as an *in vitro* model of muscle injury. During inflammation, LXR activation by a synthetic LXR agonist T0901317 increased myotube diameters. LXR increases both phosphorylation of Akt and protein synthesis in C2C12 myotubes.

Conclusions: This study revealed that nuclear oxysterol receptor LXR is activated during muscle regeneration. Increased synthesis of oxysterols may contribute to LXR activation. LXR also increases protein synthesis in C2C12 myotubes. These results suggest a novel regulatory mechanism of muscle injury and regeneration by LXR.

Keyword: skeletal muscle, LXR, oxysterol, muscle injury, muscle regeneration

Identification of components derived from Pacific krill oil that improve glucose and lipid metabolism

Haruka Tatamisashi[1], Hirofumi Dohi[1], Tomoki Oshita[1], Natsuki Itoh[1], Seiji Kurozumi[2], Yukari Egashira[1], Shizuka Hirai[1]

1. Chiba University (Japan), 2. Koyo Chemical Co., Ltd. (Japan)

Background and objectives: Obesity is known to induce insulin resistance through hypertrophy of adipocytes, causing type 2 diabetes. Activation of peroxisome proliferator-activated receptor (PPAR) γ, a ligand-activated transcription factor, is known to induce adipocyte differentiation and improve glucose intolerance. The oil extracted from Pacific krill that inhabits the North Pacific Ocean (Pacific krill oil: PKO) is rich in functional components such as ω3 fatty acids, phospholipids, and astaxanthin. We have previously found that PKO improves glucose and lipid metabolism in mice, which may involve activation of PPARγ. In this study, we attempted to identify the components that activate PPARγ in PKO.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Methods: First, PKO was partitioned with n-hexane and water. Further separation of the components in hexane fraction was performed using high performance liquid chromatography (HPLC). The effect of each fraction obtained by HPLC on PPARγ transcriptional activity was evaluated by luciferase reporter assay using CV-1 cells. The isolated PPARγ activating component was subjected to structural analysis by liquid chromatography-mass spectrometry (LC-MS) and nuclear magnetic resonance (NMR).

Results: The component that activates PPARγ in PKO was contained in the hexane fraction. As a result of repeated fractionation of the hexane fraction by HPLC and luciferase reporter assay, we obtained a fraction containing a single peak and showing PPARγ transcriptional activity. Structural analysis of this fraction by LC-MS and NMR presumed that this component was 11 (Z) -eicosenoic acid.

Conclusions: 11 (Z) -eicosenoic acid was identified as a candidate for PPARγ agonist in PKO. It was suggested that 11 (Z) -eicosenoic acid in PKO may increase small-sized adipocytes through activation of PPARγ and improve glucose and lipid metabolism.

Protective effects of D-β-hydroxybutyrate on diabetic nephropathy and myopathy in mice

Kenshu Miyata[1], Mayu Horii[1], Tolulope Peter Saliu[1], Ayane Kudo[1], Jun Tsubota[2], Thanutchaporn Kumrungsee[1], Noriyuki Yanaka[1]

1. Hiroshima University (Japan), 2. Osaka Gas Co. (Japan)

Background and objectives: Diabetes mellitus causes not only chronic hyperglycemia, but also some types of complications in kidney, skeletal muscles, and other tissues. Diabetic nephropathy (DN) is a syndrome characterized by inflammation and structural changes with a reduction of glomerular filtration rate in diabetic kidney. Recent studies showed the renal dysfunction is possibly related to impaired energy production such as reduced ATP production in the diabetic kidneys. Ketone bodies have been considered to cause diabetic ketoacidosis, however, recent paper showed that SGLT2 inhibition protects from DN by endogenous ketone body synthesis. In this study, we investigated the protective effect of dietary ketone body D-β-hydroxybutyrate (DBHB) on diabetic nephropathy in a streptozotocin (STZ)-induced diabetic mouse model and further tested the protective effect of DBHB on diabetic myopathy.

Methods: C57BL/6J mice were injected intraperitoneally with 125mg/kg STZ for two consecutive days, and three days after the STZ administration, these mice were divided into two groups, the diabetic group (DM) maintained in 0.9% NaCl water and DBHB group (KB) maintained in a DBHB water with an equal Na amount. DBHB was provided from Osaka Gas (OKETOA D-BHB). Kidney and skeletal muscle were isolated and subjected to RNA and histological analyses.

Results: DBHB supplementation showed less kidney mass. mRNA analyses showed that the expression levels of inflammation- and fibrosis-related genes are down-regulated in the kidney of KB group and that energy metabolism- and muscle atrophy-related genes in the skeletal muscle were significantly improved in KB group, even though there was no difference in blood glucose level between two groups.

Conclusions: This study suggests that DBHB supplementation can improve diabetic nephropathy. We will further test the protective effect of DBHB on diabetic myopathy and show a possibility that dietary DBHB protects from diabetic complications.

Auraptene, a citrus polyphenol attenuates an aortic aneurysm formation through the suppressing osteoclastogenesis in the artery in Ca-PO_4-induced mouse model.

Yuichiro Takei[1], Mamoru Tanaka[2], Yukiko Sumida[1] Hiroyuki Watanabe[1]

1. University of Kochi (Japan), 2. Chubu University (Japan)

Background and objectives: The mortality rate of aortic aneurysm is severely high not only in the West but in Asia including Japan. Generally, a typical therapy for this disorder is a surgical approach, and the effective medicine hasn't still been existed. Recently, we found that osteoclasts expressed in lesions of the patients with aortic aneurysm and anti-osteoporosis drug bisphosphonate could suppress aneurysm formation. However, bisphosphonate frequently has side effects like a BRONJ, bisphosphonate-related osteonecrosis of the jaw and gastroenteropathy. Thus, other internal medical way is still required. No report has been discussed about the effect of a food factor which ameliorates osteoporosis, on aneurysm formation. Here, we unveiled the preventing function of auraptene, a citrus polyphenol to aneurysm formation via anti-osteoclastogenic property.

Methods: Mouse macrophage RAW264.7 cells were used for investigating the effect of auraptene on osteoclastogenesis. For the osteoclast differentiation analysis, 7,000 cells were plated at each well into 96-well plate and stimulated with 100 ng/ml recombinant human sRANKL with or without 20 mM auraptene. Five days after stimulation, osteoclasts were detected by tartrate-resistant acid phosphatase (TRAP) staining. Western blot analysis evaluated expression of a secretary matrix metalloprotease (MMP)-9, which is a well-known contributor for aneurysm formation. Auraptene (40 mg/kg/day) were orally

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

injected twice a day into 7 weeks-old ddY male mice from 1 day before Ca-PO_4 surgery as an experimental aneurysm model. At 7 days after surgery, the mice were dissected, and maximum diameters of the arterial lesion was measured. Obtained arterial samples were frozen-sectioned and analyzed by using TRAP staining, and von Kossa staining to detect an ectopic calcification. Because the calcification of blood vessel is a trigger to accelerate osteoclastogenesis in artery.

Results: Auraptene inhibited osteoclast differentiation of RAW264.7 cells through, followed by decreasing MMP-9 secretion. *In vivo* analysis showed auraptene reduced expansion of arterial diameter but had no effect on vascular calcification by inducing Ca-PO_4 surgery.

Conclusion: Auraptene attenuated Ca-PO_4 induced aneurysm through suppression of osteoclastogenesis in artery, suggesting that this citrus polyphenol counted on as a therapeutic supplement for aortic aneurysm.

PAB(T7-197)
Vitamin A-responsive LGR6 promotes myoblast differentiation

Rina Tatsumi[1], Mayu Yamguchi[1], Tomoya Kitakaze[1], Naoki Harada[1], Ryoichi Yamaji[1]

1. Osaka Prefecture University (Japan)

Background and objectives: Skeletal muscles are formed through a complex process that involves differentiation. Therefore, it is important to understand the process of myoblast differentiation in maintaining and enhancing the skeletal muscle health. The active form of vitamin A, all-trans retinoic acid (ATRA), promotes myoblast differentiation via retinoic acid receptors (RAR) that function as transcription factors. However, limited information is available on the target genes of RARs that regulate myoblast differentiation. We previously demonstrated that the expression of leucine-rich repeat-containing G protein coupled receptor 6 (LGR6) is upregulated in response to ATRA in skeletal muscle cells[1]. The purpose of this study was to obtain information on the expression mechanism of LGR6 expression by ATRA and the role of LGR6 in myoblast differentiation involved in skeletal muscle formation.

Methods: Murine C2C12 myoblasts were induced to differentiate into myotubes in the presence or absence of ATRA. The effect of RAR agonists on Lgr6 mRNA expression was assessed. Furthermore, C2C12 myoblasts were transfected with Lgr6 siRNA and induced to differentiate.

Results: In the presence of ATRA, *Lgr6* mRNA expression was transiently increased by 3 h after myoblast differentiation and then decreased to its basal levels by 12 h after induction of differentiation. The RAR-specific pan-antagonist AGN193109 completely inhibited the ATRA-induced increase in *Lgr6* mRNA expression. The RARα agonist AM580 and RARγ agonist BM961 increased *Lgr6* mRNA expression. The *Lgr6* mRNA expression during differentiation transiently increased earlier than the mRNA expression of myogenin (*Myog*; a myogenic transcription factor), myomaker (*Mymk*), and myomerger (*Mymx*; factors that promote myoblast fusion). Furthermore, *Lgr6* knockdown decreased the differentiation and fusion indices, and reduced the *Myog, Mymk,* and *Mymx* mRNA expression. Furthermore, exogenous LGR6 overexpression increased the *Myog, Mymk*, and *Mymx* mRNA expression 3 h after inducing differentiation.

Conclusions: The present study suggests that ATRA up-regulates Lgr6 mRNA expression via RARα and RARγ and indicates that LGR6 is transiently required to promote the early stage of myoblast differentiation.

Keyword: skeletal muscle, vitamin A, LGR6, myoblast differentiation, murine C2C12 myoblast

Extracts from *Chlorella vulgaris* induce rapid proliferation of muscle cells in serum-free condition

Jayeesha Ghosh[1], Yuji Haraguchi[2], Akiyama Yoshikatsu[2], Kumiko Yamanaka[2], Toru Asahi[1], Yoichi Nakao[1], Tatsuya Shimizu[2]

1. Waseda University (Japan), 2. Tokyo Women's Medical University (Japan)

Background and objectives: World population will grow from 7.2 billion today to 9.6 billion in 2050 along with a strong demand for meat in 2050 projected to grow by 73 and 58 percent, respectively (FAO, 2011). To overcome the shortage of meat and milk production, artificially cultured meat has created quite a stir. However culturing mammalian cells require large volume of expensive culture media (Dulbecco`s modified Eagle`s medium) and serum (Fetal bovine serum) to sustain in-vitro cell culture. For now, almost 50 L of media is required to produce 1 kg of cultured meat and the expense ranges from 3000-4000. Hence, coming up with an alternative source of serum supplement is necessary to reduce the cost of cell culture. This research aims at establishing an alternative mammalian cell culture medium that is cheap and eco-friendly. Micro-algae have an immense application in the pharmaceutical and nutraceutical industries, biodiesel and wastewater management system. It is a fundamental part of food consumption as well. Hence, we aim at extracting growth factors and functional metabolites from micro-algae and apply on mammalian myoblast cell culture to enhance the proliferation rate.

Methods: We found extracts obtained from *Chlorella vulgaris* through ultrasonication method has a potential to influence myoblast cell proliferation. In order to investigate further, the extract was purified and the compounds soluble in water (CW) was collected by utilizing our new separation method.

Results: We found some astounding results. Compounds soluble in water (CW) has a capability to proliferate mammalian cells, C2C12 cells, without fetal bovine serum (FBS). These

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

mammalian cells showed high proliferation rate, comparable to the cell proliferation using DMEM supplemented with FBS. Currently, we are identifying the components present in CW as well its effect on signal transduction process on myoblast cells.

Conclusion: Hence, with further research and optimization of CW components we will introduce CW as an eco-friendly, cheaper alternative growth promoting supplement to the scientific community. It will not only boost the cultured meat industry but will also have a huge impact on various fields of biosciences like regenerative medicine, gene/cell therapies, production of biopharmaceutical and antibody therapeutics.

Sargassum macrocarpum exhibits anti-IgE-mediated allergic activity by suppressing IgE secretion by U266 cells and inhibiting degranulation of RBL-2H3 cells.

Hiroko Okuda[1], Seiya Shinoda[1], Mitsuhiro Sekiguchi[1], Sogo Nishimoto[1]

1. Ishikawa Prefectural University (Japan)

Background and objectives: The number of people suffering from allergic diseases is increasing, especially in developed countries. Therefore, anti-allergic ingredients in natural product have been attracting attention. While the brown algae *Sargassum macrocarpum* has low food value and is currently considered an underutilized resource, it is abundant in available resources because it forms large colonies. Few studies have examined the anti-allergic activity and exact mechanism of action of *Sargassum macrocarpum*. Seaweed are widely known to have a variety of pharmacological ingredients. Therefore, the present study investigates the anti-allergic effect of an ethanol extract from *Sargassum macrocarpum* (SME).

Methods: SME was obtained by ethanol extraction of dried *Sargassum macrocarpum* collected in Tsukumo Bay. Further, SME was fractionated and purified to isolate the compound. The cells were pre-treated with various samples for 24h. We evaluated IgE secretion and IgE gene expression in U266 cells. For *in vitro* model of IgE-mediated mast cell degranulation, DNP-IgE-sensitized RBL-2H3 cells challenged with DNP-HSA. The β-hexosaminidase release rate of RBL-2H3 cells was measured.

Results: SME reduced IgE secretion from U266 cells in a dose-dependent manner. At 1.25 μg/mL, IgE secretion was suppressed by about 80%. On the other hand, no significant decrease in IgE gene expression was confirmed by the addition of SME. Furthermore, SME suppressed the release of β-hexosaminidase in DNP-IgE-sensitized RBL-2H3 cells. We identified anti-allergic candidate substances in SME.

Conclusions: It was suggested that SME inhibited the secretion of IgE produced in plasma cells to the extracellular space. In addition, SME inhibited the release of inflammatory mediators by suppressing the degranulation of mast cells. These results in this study suggests that SME has an anti-IgE-mediated allergic effect.

PAB(T7-200)
Improvement of lipid metabolism by piceid, a glycoside of resveratrol

Hono Inaoka[1], Mizuki Ito[1], Rino Nakazawa[1], Hiroyasu Inoue[1], Rieko Nakata[1]

1. Nara Women's University (Japan)

Background and objectives: Resveratrol, a phytoalexin and antioxidative polyphenol found in red wine and various plants, is associated with a reduced risk of cardiovascular diseases. We reported that resveratrol activates nuclear receptor PPARα, β/δ and γ, which are considered molecular targets against lifestyle-related diseases by regulating lipid and carbohydrate metabolism, in cell-based reporter assay and the intake of resveratrol improves lipid metabolism in mice through PPARα-dependent mechanism. Based on these dates, we have been working on PPARs as potential molecular targets of resveratrol. On the other hand, piceid, a glycoside of resveratrol, is also found in red wine and various plants and may exert various physiological effects as well as resveratrol. In this study, we examined improvement of lipid metabolism by piceid and involvement of PPARα.

Methods: Male wild type (C57BL/6J) and PPARα-knockout mice (7 to 9-week-old) were fed the normal diet (AIN93-G) or the same diet supplemented with 0.4% piceid. After 8 weeks of feeding, blood sample and tissues were harvested for each analysis. Moreover, we also tested anti-atherosclerosis by administering piceid with a normal diet to male apolipoprotein E knockout mice (8 to 10-week-old). After 12 weeks, aorta was collected and stained with oil red O for pathologic analysis.

Results: Eight-week intake of piceid with a normal diet was decreased plasma triglyceride levels in the wild-type but not in PPARα-knockout mice. Hepatic expression of lipid metabolism-related genes such carnitine palmitoyltransferase 1, cyp4a14, acyl CoA oxidase and fatty acid binding protein 1 was upregulated in PPARα-dependent or -independent manner. Moreover, we also found the increase of plasma HDL-cholesterol, the decreases of plasma total and non-HDL cholesterol, and the suppression of lipid accumulation in aorta by feeding piceid in apolipoprotein E knockout mice. These effects were not found in apolipoprotein E/PPARα double knockout mice.

Conclusions: The intake of piceid improved lipid metabolism partially via PPARα. The effects of piceid were similar to resveratrol. These findings indicate that piceid will afford beneficial effects of preventing lifestyle-related diseases.

Keyword: Piceid , Resveratrol, Lipid metabolism, PPAR

Effects of sugar cane juice non-sucrose fraction on starch induced hyperglycemia on mice

Hibiki Kubota[1], Suzuno Shinohara[1], Tsutomu Arimura[2], Nanaka Shibazaki[1], Wataru Tanaka[1], Shigekatsu Kimura[2], Daigo Yokoyama[1], Hiroyuki Sakakibara[1]

1. University of Miyazaki (Japan), 2. Daito Seito Co., Ltd (Japan)

Background and objects: The sugar cane juice non-sucrose fraction is commonly referred to as molasses and is produced as a byproduct of sugar extraction from sugar-making raw materials made by concentrating sugar cane juice. It is attracting attention as a new functional food material because of its rich mineral and polyphenol content and bio-regulatory functions such as antioxidant and anti-inflammatory activities. In this study, we investigated that the effects of sugar cane juice non-sucrose fraction (SJNoS) (81.9% solids, 40.4% total sugar) on starch induced hyperglycemia using oral starch tolerance test (OSTT), and further speculated their active ingredients and mechanisms.

Methods: Male ICR mice under overnight fasting were orally administrated 20% water soluble starch with or without SJNoS, and then their blood glucose levels were analyzed at individual time points (0, 30, 60, 120, 180 min) using glucose meter. SJNoS was fractionated into water soluble fraction (W-Fr), ethanol insoluble fraction (Et-Fr), ethyl acetate soluble fraction (EAc-Fr), and hexane soluble fraction (Hx-Fr) by two-phase distribution. The effects of individual fraction on starch induced hyperglycemia using same model described above. In addition, the inhibitory effects of SJNoS and individual fraction on α-amylase and α-glucosidase activities were measured using *in vitro* methods.

Results: Starch administration increased blood glucose levels, reaching a peak at 60 minutes after administration. On the other hand, simultaneous administration of SJNoS markedly suppressed this increase, and the area under the curve at 240 minutes after administration was significantly suppressed. Simultaneous administration of each fraction and starch showed an inhibitory effect in both W-Fr and Et-Fr groups. SJNoS significantly inhibited the α-glucosidase activity, but not α-amylase. Similar results were observed in both W-Fr and Et-Fr.

Conclusions: These results suggest that SJNoS has the potential to suppress postprandial hyperglycemia via α-glucosidase inhibition.

PAB(T7-202)
Impact of short-term isolation stress on urinary stress hormone excretion

Orie Muta[1], Minayu Odaka[1], Yasuyuki Fujii[1], Taiki Fushimi[1], Naomi Osakabe[1]

1. Shibaura Institute of Technology (Japan)

Background and objectives: Exposing stressors on mammals, stress hormones are secreted from adrenal glands to blood, consequently excreted into urine. Catecholamines or cortisol (corticosterone in rodents) are produced by the activation of sympathetic adrenomedullary axis (SAM axis) or hypothalamic-pituitary-adrenal axis (HPA axis). By the determination of urinary stress hormone levels, it can estimate the state of stress in the animals. In the previous studies, urine collection from the rodents for measuring stress hormone levels was carried out by a single housing mouse. On the other hand, mouse in single-housing exposes potent social isolation stress, consequently showing depression and anxiety-like behavior. In this study, we compared the levels of urinary stress hormone between mice in single- or pair-housing to verify the validity of the conventional evaluation methods.

Methods: A mouse (single-housing group) or two mice (pair-housing group) was housed in metabolic cages for 4 days. Each day during that period, they were weighed, and collected their daily urine into a tube filled with 6N hydrochloric acid. Urinary noradrenaline and adrenaline were determined by HPLC equipped with an electrochemical detector, and their final metabolites, vanillylmandelic acid (VMA) were determined by UPLC-MS/MS. Urinary corticosterone levels were measured using ELISA kit. The level of stress hormone excretion was corrected by urinary creatinine levels.

Results: Compared with the pair-housing group, the bodyweight of the single-housing group significantly decreased from day 1, and this change was not recovered during the experimental period. The total amount of catecholamines and corticosterone excreted into urine for 4-days was markedly increased in the single-housing group compared to the pair-housing group.

Conclusions: Significantly decreasing body weight and increasing urinary catecholamine and corticosterone in the single-housing group compared with the pair-housing group. It was found that short-term social isolation stress activated the HPA and SAM axis and increased the excretion of stress hormones. Therefore, when verifying the effects of the bioactive compounds on sympathetic nerve activity (e.g. capsaicin), using the urine collected by pair-housing is more appropriate than single-housing.

Anti-proliferative effect of germinated djulis (*Chenopodium formosanum*) in human colorectal cancer cells

Mei-Chi Hsieh[1], Qian Xiao[1], Chia-An Shen[1], Hung-Yu Shih[1], Chun-Kuang Shih[1,2,3]

1. School of Nutrition and Health Sciences, Taipei Medical University (Taiwan), 2. School of Food Safety, Taipei Medical University (Taiwan), 3. Master Program in School of Food Safety, Taipei Medical University (Taiwan)

Background and objectives: Colorectal cancer (CRC) is one of the most common cancers in the world. Djulis (*Chenopodium formosanum*) is a plant native to Taiwan, which contains more dietary fiber, phytochemicals and minerals than commonly consumed cereals. Djulis has been shown to prevent pre-cancerous colorectal lesions. Germination is an extensive way to increase the nutritional value of seeds because it produces physiologically active components and increases bioavailability of nutrients. This study was conducted to investigate the effect of germinated djulis (GD) and ungerminated whole djulis (WD) on CRC and to elucidate its possible mechanisms.

Methods: WD was soaked in warm water at 40°C for two hours, germinated at 25°C for 72 hours, and then collected as GD. Both WD and GD were ground into powder, extracted with water at 25°C, dried and analyzed for γ-aminobutyric acid (GABA), total phenolic content (TPC) and total flavonoid content (TFC). The extracts were intervened in HT-29 human CRC cells to investigate their anti-cancer activity.

Results: GD had significantly higher extraction rate and GABA content than did WD. In contrast, TPC and TFC were significantly higher in WD compared with GD. GD showed a stronger inhibitory activity on HT-29 cells than did WD. WD significantly increased the expression of pro-apoptotic Bcl-2-associated X (BAX) in HT-29 cells, while the expression of anti-apoptotic B-cell lymphoma family 2 (Bcl-2) did not differ between WD and GD groups.

Conclusions: Germination may increase the extraction rate, GABA content and anti-CRC effect of djulis. However, apoptosis is not the major mechanism of germinated djulis for inhibiting the growth of CRC cells.

Analysis of immunomodulatory and anti-allergic functions of *Cyclopia* extracts

Hitoshi Shimbo[1], Yutaka Miura[1], Makoto Hattori[1], Elizabeth Joubert[2,3], Tadashi Yoshida[1]

1. Tokyo University of Agriculture and Technology (Japan), 2. Agricultural Research Council (South Africa), 3. Stellenbosch University (South Africa)

Background and objectives: The number of patients suffering from immune disorders such as allergies, ulcerative colitis, cancer, and infectious diseases is increasing. Although drugs have been developed to alleviate symptoms, fundamental cure has not been established. On the other hand, food factors with immunomodulatory activity show promise in preventing and treating such diseases. While immunomodulatory foods are attracting attention in this way, we are focusing on *Cyclopia species* indigenous to South Africa that have been used as an herbal tea, honeybush tea, for many years. Honeybush tea has been reported to have beneficial health effects such as antioxidant, anticancer, and antimutagenic properties. Therefore, in this study, we aimed to analyze the immunomodulatory and antiallergic effects of *Cyclopia* extracts.

Methods: *Cyclopia* extracts were dissolved in drinking water and given to ovalbumin (OVA)-specific T cell receptor transgenic mice (DO11.10). The mice were then fed a diet containing OVA, and blood was collected to prepare serum. The serum was used for antibody production assays. The splenocytes of the mice were prepared and subjected to flow cytometry to analyze the induction of Treg cells. DO11.10 mice were also administered OVA by inhalation to make an allergy model and the effect of *Cyclopia* extracts on allergic symptom was evaluated.

Results: Aqueous and 40% EtOH-water extracts of *Cyclopia genistoides, Cyclopia subternata*, and *Cyclopia maculate* were tested and the 40% EtOH-water extracts of *C. genistoides* and *C. subternata* showed to have the most promising immunomodulatory functions in the *in vitro* screening assay. The *in vivo* study clearly showed that oral administration of the two extracts to DO11.10 mice significantly enhanced antibody production and induction of regulatory T cells simultaneously, consistent with the results of *in vitro* studies. Furthermore, the *Cyclopia* extracts suppressed systemic anaphylactic symptoms in the OVA-inhalation murine model of allergy.

Conclusions: *Cyclopia* extract is expected to be a promising ingredient with immunomodulating and anti-allergic functions.

Effects of dietary β-conglycinin on energy expenditure and lipid metabolism in Otsuka Long-Evans Tokushima Fatty (OLETF) rats

Koji Kawabeta[1,2], Kazunori Koba[1]

1. University of Nagasaki (Japan), 2. Nagasaki International University (Japan)

Background and objectives: Beta-conglycinin (β-CON), one of the major components of soy protein (SOY), has been shown to lower body fat mass and lipid levels. The effects could be partly associated with an increase of serum adiponectin concentration. Since adiponectin was demonstrated to control energy metabolism, the feeding of β-CON could also modulate energy consumption. In the present study, therefore, we examined how β-CON affected energy expenditure and lipid metabolism in obese Otsuka Long-Evans Tokushima Fatty (OLETF) rats.

Methods: The 14% high-fat diets were prepared according to the AIN-93G formula, containing either 20% casein (CAS), or the CAS replaced with SOY or β-CON at the proportion of 50%. The animals (5 week-old) were fed with the diets for 6 weeks. On day 35, the respiratory quotient was measured to calculate energy expenditure. After the feeding period, blood was collected from the abdominal vena cava and serum was prepared. The liver, white and brown adipose tissues and soleus muscle were excised.

Results: Total energy consumption in the β-CON group was significantly higher than that in the CAS and SOY groups, concomitant with an increase of serum adiponectin level. Final body weight in the β-CON group was significantly lower than that in the CAS and SOY groups, while food consumption was comparable among the groups. The expression of genes related to energy metabolism (i.e. peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1α) and carnitine palmitoyltransferase 1b (CPT1b) in the soleus muscle and uncoupling protein 1 (UCP1) in the brown adipose tissue) was higher in the β-CON group than in the CAS and SOY groups. The mesenteric adipose tissue weight was also significantly lower in the former than in the latter. Dietary β-CON compared with CAS decreased triglyceride concentration in the liver, being associated with a decrease of fatty acid synthesis and an increase of fatty acid β-oxidation in the liver.

Conclusions: The results suggested that dietary β-CON was involved in energy expenditure to improve lipid metabolism through an increase of serum adiponectin concentration in OLETF rats.

Keyword: β-conglycinin, energy expenditure, adiponectin

PAB(T7-206)
Verification of the anti-obesity effect of mixed probiotic (*Bifidobacterium animalis ssp. lactis* and *Lactobacillus rhamnosus*) in high-fat diet-induced obese mice

Hayoon Kim[1], Sumin Kang[2], Gwangwoong Go[3]

1. Hanyang university (Korea), 2. Hanyang university (Korea), 3. Hanyang university (Korea)

Background and objectives: Obesity has become a worldwide health problem with severe complications such as type 2 diabetes and cardiovascular diseases. *Bifidobacterium animalis* ssp. *lactis* (Bf141) and *Lactobacillus rhamnosus* (Lb102) have been proven to prevent metabolic diseases. This study aimed to screen the anti-obesity effect of mixtures of *Bifidobacterium animalis ssp. Lactis* (Bf141) and *Lactobacillus rhamnosus* (Lb102).

Methods: Four-week-old C57BL/6N mice were administered the mixture of Bf141 and Lb102 (50% Bf141, 30% Lb102, and 15% maltodextrin) with a high-fat diet (60% kcal from fat) for eight weeks. Mice were randomly assigned into three groups; 1) the control group (only distilled water), 2) the low group (2.5×10^9 CFU), and 3) the high group (10×10^9 CFU). Water and diet were fed *ad libitum.*

Results: The mixed probiotic did not alter the adiposity, including body weight and fat in tissue. Liver weight was not changed, which is the center of lipid synthesis. Furthermore, the lipid content in feces, an indicator of lipid digestion and absorption, is not modified. Serum triglycerides and total cholesterol levels are also not significantly different.

Conclusions: These findings imply that the mixed probiotic (Bf141 and Lb102) does not have an anti-obesity effect in high-fat diet-induced obese mice. In a future study, it is necessary to design various mixing conditions and concentrations to demonstrate the effect of mixed probiotics on obesity.

PAB(T7-207)
Identification of a food-derived molecule which induces the anti-obese hormone FGF21

Makoto Shimizu[1], Yoshio Yamauchi[1], Ryuichiro Sato[1]

1. The University of Tokyo (Japan)

Background and objectives: Fibroblast growth factor 21 (FGF21) is a hepatokine which regulates energy metabolism. FGF21 has several beneficial effects including an increase of energy expenditure and weight loss, indicating that FGF21 acts as an anti-obese hormone. In the liver, expression of FGF21 is

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

induced by a variety of nutritional and stress signaling. We previously reported that endoplasmic reticulum stress potently induces FGF21 expression through an activation of transcription factor ATF4. A multiple ATF4-binding sites are present in the promoter region of FGF21 gene, suggesting that FGF21 is a highly sensitive target of ATF4. In this study, we explore food-derived molecules which activate ATF4-FGF21 pathway to identify anti-obese food ingredients.

Methods: A luciferase reporter assay of ATF4 using HEK293 cells was performed for a screening of food derived molecules (>300). An analysis of endogenous expression was investigated using real-time quantitative PCR or western blotting. Knockdown experiments were performed by siRNA transfection using human hepatoma cell line HepG2.

Results: Using the ATF4-driven reporter assay for screening a food derived molecule, we identified bergamottin, a furanocoumarin present in grapefruits, as an ATF4 activator. Bergamottin increases endogenous expression of both ATF4 and FGF21 in HepG2 cells. ATF4 is known to be activated by translation upon stress signaling through four eIF2α kinases (PERK, GCNS, HRI, and PKR). Experiment using siRNA or inhibitors showed that bergamottin activates ATF4 through PERK. Bergamottin does not induce endoplasmic reticulum stress which is upstream signal of PERK, suggesting an existence of another mediators. From series of experiments, we identified that Rheb, an interacting protein of PERK, is an important mediator of bergamottin signaling. In addition to bergamottin, we found some other furanocoumarins including dihydroxybergamottin activate ATF4-FGF21 pathway.

Conclusions: This study revealed a natural inducer of the anti-obese hormone FGF21. Because FGF21 has several beneficial effects on energy metabolism, bergamottin may be a candidate of a functional food ingredients to inhibit metabolic syndromes.

Cyanidin Inhibits Adipogenesis in 3T3-L1 Preadipocytes via the PLC-IP_3 Pathway and Intracellular Ca^{2+} Signaling

Phutthida Kongthitilerd[1,2], Elise Barras[3], Weiqiong Rong[3], Ansleigh Thibodeaux[3], Madison Rigdon[3], Shaomian Yao[3], Sirichai Adisakwattana[1], Tanyawan Suantawee[1], Henrique Cheng[3]

1. Chulalongkorn University (Thailand), 2. Burapha University (Thailand), 3. Louisiana State University (USA)

Background and objectives: Cyanidin is the most abundant anthocyanidin found in red-purple fruits and has antioxidant, antidiabetic, and anti-obesity properties. However, the mechanisms that cause the anti-adipogenic impact have not been fully identified. The aim of this study was to elucidate the anti-adipogenic mechanism of cyanidin through the inhibition of adipogenesis in preadipocytes.

Methods: Mouse 3T3-L1 preadipocytes were cultured in an adipogenic medium supplemented with cyanidin. Adipogenesis, cell viability, and adipogenic gene expression were evaluated using Oil Red O staining, MTT assay, and RT-qPCR, respectively. Cyanidin's mechanism of action was studied via intracellular Ca^{2+} signaling using real-time Ca^{2+} imaging analysis.

Results: The results showed that the addition of cyanidin (1-50 μM) to the adipogenic medium inhibited adipogenesis and downregulated the expression of adipogenic marker genes (PPARγ, C/EBPα, adiponectin, and aP2), with no effect on cell viability after 4 days of treatment. Furthermore, exposure to cyanidin concentrations up to 100 μM for 1 hour did not affect cell viability. The results of real-time Ca^{2+} imaging analysis indicated that cyanidin (30-100 μM) increased intracellular Ca^{2+} signals. Pretreatment of cells with U73122 (a PLC inhibitor) and 2-APB (an IP_3 receptor blocker) inhibited the intracellular Ca^{2+} signals by cyanidin. In addition, the depletion of endoplasmic reticulum Ca^{2+} stores by thapsigargin (TG) also abolished the cyanidin-stimulated Ca^{2+} signals.

Conclusions: Our findings demonstrate that cyanidin activates the PLC-IP_3 signaling pathway to stimulate intracellular calcium signals, which inhibits adipogenesis and the expression of adipogenic genes. This study has revealed for the first time the underlying mechanism of the anti-adipogenic effect of cyanidin through activated intracellular Ca^{2+} signaling.

Keyword: Cyanidin, Adipogenesis, Gene expression, PLC-IP3 pathway, Ca2+ signaling

Non-destructive analysis of lignan in sesame oil

Yurika Otoki[1], Shiori Watanabe[1], Kenichi Miyazaki[2], Kiyotaka Nakagawa[1]

1. Tohoku University (Japan), 2. Takemoto Oil and Fat Co., Ltd (Japan)

Background and objective; Lignan is one of the most important functional component in the sesame oil with strong antioxidant activity, so understanding its content is a key to maintain its quality. Although HPLC, general method to determine lignan concentration, is selective and sensitive, it is time-consuming and somewhat cumbersome. On the other hand, as a simple and rapid non-destructive analysis of foods and agricultural products, Fourier transform near-infrared spectroscopy (FT-NIR) has been attracting attention and widely used due to its high transmittance. In sesame oil, NIR analysis of major component such as fatty acid composition has been reported so far, but analysis of trace functional components such as lignan has been rarely performed. Therefore, in this study, we aimed to develop a non-destructive quantitative analysis method for lignans contained in sesame oil using FT-NIR.

Methods; 150 of sesame oils with different lignan concentrations were used. Lignans (sesaminol, diasesamine, sesamin, episesamin and sesamolin) were measured by HPLC. Sesame oil was placed in an 8 mm vial (6.6 mm i.d. vial) and its

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

NIR absorption spectra (12500 cm^{-1} - 4000 cm^{-1}) was obtained by FT-NIR spectrometer (MPA, Bruker Optic). Both spectra of background and sample were integrated with 128 scans with 8 cm^{-1} resolution. Based on the obtained spectral data and the quantitative values obtained by HPLC, a calibration model was created by the partial least square (PLS) regression. The prediction model was verified by cross-validation method and the accuracy of the model was confirmed by the determination coefficient (R^2), residual predictive deviation (RPD), and root mean square error (RMSE), respectively.

Result and Conclusions; Each PLS prediction model to determine sesaminol, diasesamin, sesamin, episesamin and sesamolin by FT-NIR was successfully developed. In developed PLS model, the R^2 and RMSE were 0.91-0.99 and 0.016-0.041, respectively. The accuracy of the calibration model was confirmed by enough RPD (3.3-11.1). Therefore, the simple and rapid non-destructive analysis of each characteristic lignan in sesame oil was achieved by FT-NIR even its component is a trace amount and chemical structure is similar. This method will be contribute to keep the sesame oil quality in the industrial process.

Keyword: Sesame oil, lignan, FT-NIR, non-destructive analysis

Effect of mung bean peptides on maintenance of muscle mass

Yasukiyo Yoshioka[1], Yukiko Imi[2], Kyuichi Kawabata[2], Katsumi Shibata[2], Hitoshi Ashida[3], Junji Terao[2], Noriyuki Miyoshi[1]

1. University of Shizuoka (Japan), 2. Konan Women's University (Japan), 3. Kobe University (Japan)

Background and objectives: Musculoskeletal disorders have become a big problem in the super-aging society in Japan. The maintenance of muscle mass is one of the preventive measures for extension of healthy life expectancy. The functional evaluation of the peptide of mung bean is not sufficient on the maintenance of skeletal muscle mass. Therefore, in this study, we searched for mung bean peptides that contribute to the maintenance of skeletal muscle mass and elucidated their mechanism.

Methods: The mung bean peptide was digested with pepsin, trypsin and chymotrypsin from its protein powder and subjected to gel-filtration column chromatography, weak anion exchange column chromatography, high-performance liquid column chromatography and mass spectrometry to purify and identify the peptides. To examine the effect on skeletal muscle mass, mouse fibroblasts C2C12 differentiated into myotubes were used. The myotubes were treated with several concentration of mung bean peptides and subjected to SUnSET method and western blotting for protein synthesis. To evaluate preventive effect of the mung bean peptides against muscle atrophy, the myotubes were treated with the mung bean peptides and stimulated with 1 μM dexamethasone for 24 h and then subjected to western blotting. Competitive assay with molecular probes of the peptides was performed to assess the mung bean peptides competition for dexamethasone-glucocorticoid receptor binding.

Results: Treatment of mung bean peptides increased protein synthesis in C2C12 myotubes. The peptides induced the phosphorylation of mTOR and p70S6K. Furthermore, the peptides inhibited dexamethasone-induced the expression of ubiquitin ligases, MuRF1 and Cbl-b via suppression of glucocorticoid receptor translocation. Its mechanism is competitive inhibition against dexamethasone by directly bind to the glucocorticoid receptor.

Conclusions: It was revealed that mung bean peptide contributes to the maintenance of skeletal muscle mass by promoting protein synthesis and suppressing proteolysis.

Keyword: mung bean peptide, muscle mass

Determination of the bioaccessibility of compounds with antioxidant activity from orange juice subjected to an *in vitro* digestion system

Blanca Edelia Gonzalez-Martinez[1], Karen Itzel Amaya Barbosa[1], Jesus Alberto Vazquez Rodriguez[1], Abad Arturo Lopez-Hernandez[1]

1. Universidad Autonoma de Nuevo Leon (Mexico)

Background and objectives: Citrus fruits, among which the orange (*Citrus sinensis)* stands out, have a high commercial value both fresh and in the food industry. Vitamin C is their most recognized nutrient, but they also provide phenolic compounds of vital importance to improve human health due to their antioxidant properties. However, during the digestion process, food components are constantly exposed to different physicochemical and biochemical conditions and, consequently, the bioavailability and bioactivity can be affected. The objective of the study was to determine the bioaccessibility of the phenolic profile and vitamin C in orange juice subjected to an *in vitro* digestion system.

Methods: *In vitro* digestion of orange juice was performed. Porcine pepsin was used in gastric phase (pH=2 with HCl). For intestinal phase, porcine bile and pancreatin were used (pH=5.3 with NaOH). For bioaccessible phase, the membranes were filled with NaHCO (pH=7 with NaOH). The determination of total polyphenols in samples was carried out following the Folin-Ciocalteu method and the antioxidant activity, by the DPPH and FRAP methods. The profile of phenolic compounds and the content of vitamin C was determined by high performance liquid chromatography (HPLC).

Results: The content of vitamin C, after *in vitro* digestion, decreased by 84% (only 16% of the total quantified in the juice was preserved). Of the total polyphenol content, 37% was preserved and, regarding antioxidant activity, 14 and 12% bioaccessibility was observed for DPPH and FRAP, respectively. The highest concentration of phenolic compounds was narirutin,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

followed by hesperidin, kaempferol, hesperitin, naringenin and quercetin. On the other hand, the highest bioaccessibility was found in hesperitin and the lowest in hesperidin (93 and 3%, respectively).

Conclusions: Although the hesperidin content is high, its percentage of bioaccessibility was the lowest compared to the other phenolic compounds analyzed. The bioaccessible portion of vitamin C and the total antioxidant activity of orange juice is less than 20% of the content in the food. Therefore, it is necessary to perform *in vivo* experiments to provide relevant information on the real experience of the consumption of citrus beverages.

Evaluation of the antihypertensive activity of chia seed extracts (*Salvia hispanica*)

Abad Arturo Lopez-Hernandez[1], Ana Sofia Ortega-Villarreal[1], Manuel Lopez-Cabanillas Lomeli[1], Elizabeth Solis Perez[1], Blanca Edelia Gonzalez Martinez[1]

1. Universidad Autonoma de Nuevo Leon (Mexico)

Background and objectives: Hypertension is a chronic disease and a major public health problem that represents third of adult population worldwide and it is considered a major risk factor for cardiovascular disease. In this context, there is a growing interest in finding alternatives that improve its prevention and treatment. The aim of this study was to evaluate the in vitro angiotensin-converting enzyme (ACE) inhibitory activity of phenolic compounds present in ethanolic and methanolic *Salvia hispanica L*. (chia) seed extracts.

Methods: Chia seeds used in this project were cultivated in Mexico. Extracts were made with 50 g of chia in 250 mL of methanol or ethanol and were macerated during 48 h and were concentrated by rotary evaporation. Chia seed extracts were subjected to acid hydrolysis process to break the glycosidic bond between the aglycone (compound in free form) and its sugar to be quantified in both forms. The major phenolic compounds were quantified by high performance liquid chromatography (HPLC). ACE inhibitory activity was determined by *in vitro* enzyme assay using the hypuryl-L-histidyl-L-leucine (HHL) reagent as substrate.

Results: Myricetin was the main phenolic compound found in both extracts, followed by chlorogenic and caffeic acid, myricetin, quercetin and kaempferol. Most of them were found in conjugated form (50 and 73 % for ethanolic and methanolic extract, respectively). Extracts exhibited inhibitory ACE activity, IC_{50} values of extracts were 7.1 and 2.1 mg/mL for ethanolic and methanolic extract, respectively.

Conclusions: Methanolic extract presented the highest concentration of phenolic compounds and an *in vitro* inhibitory ACE activity three times superior compared to ethanolic extract. These results may suggest that the phenolic compounds contained in chia seed extracts have the potential to be used in the development of adjuvant agents in the treatment of hypertension, presenting the advantage of being derived from a food matrix.

Comprehensive proteome analyses revealed the signal transduction of skeletal muscle hypertrophy

Mizuki Morisasa[1], Eriko Yoshida[2], Mina Fujitani[3], Kenji Uchida[2], Taro Kishida[3], Tsukasa Mori[1], Yasuro Furuichi[4], Yasuko Manabe[4], Nobuharu L Fujii[4], Naoko Goto-Inoue[1]

1. Nihon University (Japan), 2. Nippon Suisan Kaisha, Ltd. (Japan), 3. Ehime University (Japan), 4. Tokyo Metropolitan University (Japan)

Background and objectives: Skeletal muscle comprise approximately 40% of the total body weight, and play fundamental roles in energy metabolism. They can adapt intramuscular metabolism to suit various environmental conditions for maintaining homeostasis. We set two different experimental models, fish protein feeding model and treadmill training model, to investigate the mechanism relying on muscle hypertrophy using proteome analysis. These results will show us how to improve muscle atrophy such as sarcopenia.

Methods: We made two different models; fish protein feeding model and treadmill training model. For fish protein-feeding model, the rats were throughout the seven-day feeding experiment with fish protein and casein. For treadmill training model, the mice were randomly assigned to one of the two experimental groups: sedentary control and training groups. The training group mice were subjected to chronic exercise on a treadmill for 60 min at 14–20 m/min, 5 days per week, for eight-week. After experiment, the animals were sacrificed, and the gastrocnemius muscle was excised. Gastrocnemius muscles were cut into pieces and homogenized after adding a lysis buffer to extract total protein. For comprehensive proteome analyses, we used iTRAQ-based systems, and western blotting analyses demonstrated to confirm the protein expression.

Results: We analyzed the total proteins extracted from muscle from both rats and mouse by LC-MS and detected and identified over 20,000 proteins based on the UniProt ID. To calculate the quantitative differences, we calculated the fold changes of the expressed proteins using isotope tags. Ingenuity pathway analysis was conducted to speculate the activated signaling pathways, and pathways related to the proliferation and differentiation of muscle cells were observed. Western blotting analyses clearly showed that suggested pathways were really changed.

Conclusions: Comprehensive proteome analyses demonstrated the upregulation of protein synthesis via protein kinase Akt/mTOR signaling in both models. Using this approach, we could speculate upstream molecules as well as protein expression differences. We would like to apply this approach for

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

screening of novel nutritional factors and/or pharmaceuticals to demonstrate the beneficial effects for skeletal muscles.

Dual roles of protein hydrolysates from purple rice bran in early stages of carcinogens-induced liver and colon carcinogenesis in rats

Rawiwan Wongpoomchai[1], Aroonrat Pharapirom[1], Sirinya Taya[1], Akkasit Jongjareonrak[1], Kenji Sato[2]

1. Chiang Mai University (Thailand), 2. Kyoto University (Japan)

Background and objectives: Increased health awareness among consumers has supported the use of plant-protein hydrolysates to reduce the risk of degenerative diseases. The hydrolysate of purple rice bran glutelin exhibited antioxidant, antimutagenic and anti-inflammatory activities; however, there has been a lack of published studies on cancer prevention in animal experimtents. This study aimed to investigate cancer chemopreventive effects of glutelin and hydrolysates obtained during the production of purple rice bran protein hydrolysates in carcinogens-induced liver and colon carcinogenesis in rats and the relevant molecular mechanisms.

Methods: Defatted purple rice bran was soaked in NaOH to obtain an alkali soluble fraction that was further adjusted by pH to precipitate glutelin (GTL). The alkali soluble fraction and GTL were digested by alcalase under optimal conditions to obtain whole protein hydrolysate (WPH) and glutelin hydrolysate (GH) together with non-glutelin hydrolysate (NGH). All samples were spray-dried using maltodextrin as a carrier. Rats were injected with diethylnitrosamine, a hepatocarcinogen, and 1,2-dimethylhydrazine, a colorectal carcinogen, and orally administered GTL and various hydrolysates for 10 weeks. The end-point markers were hepatic GST-P positive foci and colonic aberrant crypt foci (ACF). Cell proliferation and apoptosis in the liver and colon were analyzed by immunohistochemistry. The expression of apoptotic and inflammatory genes was detected using Real-time PCR.

Results: Testers did not induce GST-P positive foci and ACF in the liver and colon of rats. Both GTL and GH could inhibit preneoplastic lesions in the liver and colon; however, only GH effectively suppressed colonic ACF. Interestingly, WPH and NGH promoted colonic ACF formation in carcinogen-initiated rats. GTL and GH decreased the number of PCNA positive cells, a cell proliferation marker, in liver and colon tissues. Moreover, GH increased the number of apoptotic hepatocytes and colonocytes and reduced inflammatory gene expression. WPH and NGH enhanced the expression of some proinflammatory cytokines, including IL-6, in carcinogen-treated rat colons.

Conclusion: Protein hydrolysate of purple rice bran contained both anticarcinogenic and carcinogenic peptides as protein sources. A specific protein, glutelin, could be the source of liver and colon cancer chemopreventive peptides.
Accordingly, the identification of these anticarcinogenic and carcinogenic peptides are now under investigation.

Keyword: Anticarcinogenicity, Cancer Chemoprevention, Glutelin, Protein hydrolysate, Purple rice bran.

Effect of theogallin on cognitive function in mice

Kwanwoo Lee[1], Yushi Otsuka[1], Yoshinori Fujimura[1], Hirofumi Tachibana[1]

1. Department of Bioscience and Biotechnology, Kyushu University (Japan)

Background and objectives: Theogallin is an ingredient in green tea, but little is known about bioactivity. Therefore, we investigated the effect of theogallin on cognitive function in mice.

Methods: 64-week-old (aged) C57BL/6J mice were oral administrated using theogallin (10 mg/kg b.w.) daily for 7 days. Then, we evaluated cognitive ability using novel object recognition test. Effect of theogallin on hippocampal neurogenesis and neuroplasticity was assessed by western blot analysis to measure protein level of doublecortin (DCX), a stage-specific marker of adult neurogenesis, and cognition related proteins, such as early growth response 1 (EGR1), brain-derived neurotrophic factor (BDNF), and activity-regulated cytoskeleton-associated protein (Arc). Also, the expression of alzheimer's disease related proteins, beta-secretase 1 (BACE1) and phosphorylation of tau, was measured in hippocampus.

Results: Theogallin improved the cognitive function of old mice in the novel object recognition test, and up-regulated expression of hippocampal neuroplasticity-related proteins, such as BDNF, EGR1, and Arc. Interestingly, the expression of DCX was also upregulated in hippocampus. In addition, it downregulated the expression of BACE1 and phosphorylation of tau.

Conclusions: Taken together, our findings provide evidence for a novel effect of theogallin on cognitive function. Also, theogallin is considered to a beneficial ingredient that works for up-regulated proteins of cognitive ability, adult neurogenesis for neuronal precursors and migrating neuroblasts, and downregulated expression of alzheimer's disease related proteins.

PAB(T7-216)
Screening for inhibitors of lipid accumulation from Mango kernels.

Takahiro Fujimaki[1], Chikako Sato[1], Rei Yamamoto[1], Sayo Watanabe[1], Hikaru Fujita[1], Hidehiko Kikuno[1], Masayuki Sue[1], Yoshitaka Matsushima[1]

1. Tokyo University of Agriculture (Japan)

Backgroud and objectives: Obesity is defined as an excessive weight gain and abnormal fat accumulation, which is considered the major risk factor for chronic metabolic diseases such as type 2 diabetes. The obesity epidemic has paid attention to adipose tissue and the development of fat cells, termed adipogenesis. Therefore, control of adipogenesis accompanied by fat accumulation may prevent chronic metabolic diseases. In this study, we aimed to isolate anti-obesity agents from mango (*Mangifera indica L.)* kernels that inhibit intracellular lipid formation in 3T3-L1 adipocytes.

Methods: Effect of compounds isolated from mango kernels on lipid accumulation in 3T3-L1 adipocytes was evaluated by Oil Red O staining. cell viability was measured by MTT assay. Adipogenesis-, lipid synthesis-, and lipolysis- related gene were observed using RT-PCR and western blot.

Results: Ethyl gallate and ethyl digallate, 1,2,3,4,6-penta-O-galloyl-β-D-glucose (PGG) and 3-O-digalloyl-1,2,4,6-tetra-O-β-D-glucose (HGG) were isolated from mango kernels, and were obseved to be inhibited lipid accumulation regardless of the cytotoxicity. Furthermore, ethyl digallate, PGG, and HGG significantly suppressed the mRNA expression of adipogenic transcription factors such as C/EBPα and PPARγ. However, ethyl gallate did not affect the expression of these transcription factors.

Conclusions: Our findings reveal compounds present in mango kernels that inhibit lipid accumulation, thus providing potential therapy for obesity.

Keyword: 3T3-L1, obesity, mango seeds

PAB(T7-217)
The impact of pterostilbene on the interplay between epigenetics and metabolism in hepatocellular carcinoma

Cayla Sayaka Boycott[1], Megan Beetch[1], Katarzyna Lubecka[2], Barbara Stefanska[1]

1. University of British Columbia (Canada), 2. Medical University of Lodz (Poland)

Background and objectives: Disruption to metabolic status can lead to aberrant activity of epigenetic machinery and is often associated to diseases. In fact, many pieces of evidence indicate that epigenetic reprogramming are essential events in hepatocellular carcinoma (HCC), a primary liver cancer often implicated with disrupted metabolism. Interestingly, a dietary bioactive compound, pterostilbene (PTS), has been shown to restore disrupted metabolism in diseases by regulating activity of AMP-activated protein kinase (AMPK), a protein that monitors cellular energy. Relevantly, AMPK is often dysregulated in cancers and has previously been shown to negatively regulate gene silencing mediated by histone methylation, a form of epigenetic regulation. Herein, we investigated the effects PTS has in an *in-vivo* and *in-vitro* model of HCC and determined its impact on AMPK activity, histone modifications, and transcription of genes involved in carcinogenesis.

Methods and results: We incorporated PTS into a HCC-inducing diet and found significant attenuation in development of HCC in rats. Genome-wide transcriptional analysis on PTS supplemented rat livers revealed upregulation of several genes associated with tumor-supressing activities such as *Aldh1l1*, compared to the HCC-induced livers. *ALDH1L1* was also upregulated in PTS-treated HepG2 cells compared to control (ethanol), as we examined using quantitative reverse-transcription PCR (qRT-PCR). We quantified protein levels of active AMPK, and found that PTS significantly upregulated active phosphorylated form of AMPK. Due to the implication of AMPK in histone methylation, we then looked for changes in H3K27me3, a histone modification implicated in gene silencing, and H3K9ac, a marker of gene activation using chromatin immunoprecipitation followed by qPCR (qChIP). Remarkably, we found a significant decrease in H3K27me3 and an increase in H3K9ac marks at the promoter of ALDH1L1, implicating the open chromatin structure, which may, at least partially explain the upregulation of ALDH1L1.

Conclusion: PTS-induced activation of AMPK was correlated to changes in H3K27me3 and H3K9ac mark, accompanied by upregulation of ALDH1L1 in HCC. We will further investigate this relationship by quantifying changes to histone methylation in PTS-treated cells upon inhibition of AMPK.

Effects of mannooligosaccharides derived from coffee on mineral absorption in ovariectomized rats

Takashi Hashimoto[1], Izumi Hoshino[1], Ichiro Asano[1], Kazuto Ozaki[1], Toshio Kumao[1]

1. Ajinomoto AGF, Inc. (Japan)

Background and objectives: It has been reported that indigestible oligosaccharides have beneficial effects on the absorption of minerals and bone. Therefore, it was expected that mannooligosaccharides derived from coffee (MOS) has the same effect on mineral absorption as several oligosaccharides.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Furthermore, it has been reported that women are more prone to osteoporosis after menopause because of the decreased secretion of female hormones involved in bone metabolism. Therefore, we used ovariectomized rats as the osteoporosis model and investigated the effects of MOS on mineral absorption and bone mass in them.

Methods: This study was carried out with the approval of the Ethics Committee of Ajinomoto General Foods, Inc. Ovariectomized Sprague–Dawley rats (female, 4-week-old) were used and were fed a control diet and a 2.5% or 5% MOS containing diet *ad libitum* for 29 days. At 9–11 days and 27–29 days, mineral balance tests (Ca, Mg, and P) were performed. Every day, feces and urine were collected and weighed. Food intake, mineral content in the diet, and mineral excretion in feces and urine were used to calculate the apparent mineral absorption rate and retention rate. Weight, pH, and SCFA in the cecal contents were measured after the cecum was removed. Weight, ash weight, calcium content, and breaking energy were all assessed after the femur was removed.

Results: Mineral valance test: Ca and Mg absorption significantly increased in the 2.5% and 5% MOS group as compared with the control group ($p < 0.05$). Cecal contents: Content weight and SCFA in the cecum significantly increased in the 2.5 and 5.0% MOS group as compared with the control group ($p < 0.05$). pH in the cecum significantly decreased in the 2.5% and 5.0% groups as compared with the control group ($p < 0.05$). Bone: Bone weight and ash content were similar in the 2.5% and 5.0% MOS group as compared with the control group. Ca content was significantly higher in 5.0% MOS group ($p < 0.01$), and breaking energy was significantly higher in 2.5% MOS group ($p < 0.05$).

Conclusions: In ovariectomized rats, MOS consumption was beneficial in promoting mineral absorption.

Keyword: mannooligosaccharides, mineral absorption, ovariectomized rat

Seed peptide lunasin ameliorated inflammation and glucose uptake in 3T3-L1 adipocytes and C2C12 myotubes in the obese microenvironment

Ching-Ching Chiang[1], Ching-Ya Huang[1], Chi-Hao Wu[1], Chia-Chien Hsieh[2]

1. National Taiwan Normal University (Taiwan), 2. National Taiwan University (Taiwan)

Background and objectives: Obesity, a global health crisis, is manifested with impaired energy homeostasis and chronic low-grade inflammation. Food-derived proteins and peptides have been identified to have multiple bio-functions that alleviate diseases, including metabolic complications. Lunasin, a natural seed peptide, acts with multiple bioactivities, including anti-cancer, anti-inflammation, anti-oxidation, and immune regulation. This study aimed to investigate the effects of lunasin on inflammatory regulation and glucose utilization in C2C12 myotubes and 3T3-L1 adipocytes under obese condition.

Methods: Cells were treated with synthetic lunasin and lunasin-enriched soy protein isolate (LES) to compare the bioactivity of lunasin, C2C12 myotubes were stimulated by the palmate acid (PA) and 3T3-L1 adipocytes were stimulated by the tumor necrosis factor-α (TNF-α) to mimic the obese microenvironment.

Results: The results have shown that C2C12 myotubes treated with lunasin have lower monocyte chemoattractant protein-1 (MCP-1) and interleukin 6 (IL-6) secretions under the PA condition. In glucose utilization, lunasin improved glucose uptake and glucose consumption regardless of whether insulin was present or not. Lunasin increased glucose transporter 4 (GLUT4) expression in both spontaneous and PA condition without insulin present. In 3T3-L1 adipocytes, LES treatment has shown to increase glucose uptake in the spontaneous and TNF-α challenge with insulin conditions, but synthetic lunasin had no such effects.

Conclusions: These findings demonstrated that lunasin suppressed obesity-related inflammation and then ameliorated glucose update and GLUT4 expression, suggesting that lunasin is a promising regulator for glucose utilization in myotubes and adipocytes in the obese microenvironment.

Keyword: Lunasin, Adipocyte, Myotube, Inflammation, Glucose utilization

Conflict of Interest Disclosure: There is no conflict of interest.

The hemodynamics effect of single or repeated doses of cyanidin-3-glucoside

Taiki Fushimi[1], Shiori Oyama[1], Ryo Koizumi[1], Yasuyuki Fujii[1], Naomi Osakabe[1]

1. Shibaura Institute of Technology (Japan)

Background and objectives: Cyanidin-3-glucoside(C3G) is one of the most abundant anthocyanidins in plants. Several intervention trials and subsequent meta-analyses have also suggested that anthocyanins reduce the risks of cardiovascular diseases. Ingestion of anthocyanidin shows the beneficial impact on the vascular system in general, but the relationship between the promotion of endothelium function induced by a single dose of anthocyanin and hypotensive activity induced by long-term ingestion of anthocyanin remain unclear. In the present study, we examined the impact of C3G on micro- or systemic circulation following a single or repeated dose .

Methods: (Single oral dose study) We examined the changes of cremaster muscle arterial blood flow by the method of laser doppler for 60 minutes following a single oral dose of vehicle or 1 mg/kg (C3G[1]). After the measuring period, the aorta was excised, we determined phosphorylation of Akt and endothelial nitric oxide synthase (eNOS) by the method of western blotting.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

(Repeated oral dose study) We measured the blood pressure by the tail cuff method following 14-days repeated gavage administration of 1 mg/kg C3G We measured the expression of eNOS in the aorta by the method of western blotting. In addition, we made frozen slice of soleus taken from the animals. We observed the expression of dapi, laminin, and CD31which is an angiogenesis marker by the method of immunohistochemically.

Results: (Single oral dose study) We observed the increase of blood flow soon after administration of C3G, and this change was continued during measurement period. The ratio of phosphorylated Akt were significantly increased taken 60 min after a single oral dose of C3G.
(Repeated oral dose study) Mean blood pressure was decreased on day 7 and day 14 after repeated administration of C3G, with slight increasing aortic eNOS level. The expression of CD31 in soleus were significantly increased by C3G with increasing cross-sectional area of soleus.

Conclusions: These results suggested the possibility that increased blood flow by an oral dose of C3G, resulting in the promotion of angiogenesis within skeletal muscle, consequently reducing blood pressure.

PAB(T7-221)
Induction of cell death by egg-derived sphingomyelin in rat hepatoma cells

Chiharu Iwase[1], Naoto Hatanaka[1], Yutaka Miura[1]

1. Tokyo University of Agriculture and Technology (Japan)

Background and objectives: Sphingomyelin (SPM) is one of amphiphilic sphingolipids which is composed of ceramide and phosphocholine. It is abundant in animal food products, such as eggs and milks. We have previously shown that egg-derived SPM induces cell death specifically in hepatoma cells, and that the mechanism of cell death is neither apoptosis nor necrosis. In this study, we aimed to clarify the details of the mechanism of cell death induced by SPM using rat ascites hepatoma cell AH109A.

Methods: Micellar egg-derived SPM was added to AH109A, and cell viability was measured by the WST-8 method. The intracellular reactive oxygen species (ROS) levels were examined by DCFH-DA. To confirm that SPM-induced cell death is a ferroptosis, the effects of ferroptosis inhibitors: Deferoxamine and Ferrostatine-1, were examined. Intracellular labile iron pool (LIP) level was also measured using Calcein-AM.

Results and Conclusions: Cell death was inhibited by simultaneous addition of α-Tocopherol with egg-derived SPM. Chelation of ferric iron with EDTA had no effect on cell death, whereas chelation of ferrous and ferric iron with deferoxamine inhibited cell death, suggesting that the chelation of ferrous iron may influence the cell death induced by egg-derived SPM. When ferrous or ferric iron was added, cell death was accelerated only for ferrous iron, suggesting the involvement of ferrous iron. In addition, cell death was inhibited by the ferroptosis inhibitors: Deferoxamine and Ferrostatine-1, and the lipid ROS level was increased by the addition of SPM, strongly suggesting that SPM-induced cell death may be a type of ferroptosis. Furthermore, comparison of intracellular LIP level between AH109A and other cells of which cell deaths were not induced by SPM revealed higher LIP level in AH109A, indicating the involvement of intracellular LIP level in SPM-induced cell death.

Keyword: sphingomyelin, ferroptosis, cell death, cancer, hepatoma

PAB(T7-222)
Anti-inflammatory effects of honeybush extracts and identification of effective ingredients

Kanta Kusumoto[1], Kaho Shiraishi[1], Dalene de Beer[2], Elizabeth Joubert[2], Yutaka Miura[1]

1. Tokyo University of Agriculture and Technology (Japan), 2. Agricultural Research Council (South Africa)

Background and Objectives: We have been studying the health-promoting effects of honeybush (*Cyclopia subternata*), an herbal tea plant indigenous to South Africa. Previously, we had reported the anti-inflammatory effects of *C. subternata* extract in a UV-irradiated mouse model. In this study, *C. subternata* extracts and their fractions, were examined for their anti-inflammatory and skin-protective effects using Normal Human Dermal Fibroblasts (NHDF) and DNFB-induced dermatitis model mice. Fractionation was used in an attempt to enhance the anti-inflammatory activity.

Methods: NHDF were incubated with honeybush extracts or their fractions for 24 hours, whereafter IL-1β (1 ng/mL) was added to induce inflammation. Total RNAs were prepared and the expression levels of the inflammation-related genes, i.e., COX-2, IL-6 and MMP1, were measured by real-time PCR. *Cyclopia subternata* were extracted with hot water or 40% ethanol and an n-BuOH and an aqueous fraction was prepared by liquid-liquid fractionation. For in the *in vivo* study, hairless mice were divided into two groups: a DNFB-applied group and a non-applied control group, and a half of each group was orally treated with honeybush extract. We measured skin moisture content, TEWL and dermatitis symptoms, and assessed the histology of the skin.

Results and conclusion: The aqueous fraction of the honeybush extract inhibited the expression of COX-2 in NHDF, whereas the n-BuOH fraction showed a relatively weak inhibitory effect, suggestion that the aqueous fraction had a stronger anti-inflammatory activity than the n-BuOH fraction. In the *in vivo* study, inflammatory symptoms, epidermal thickening and dermatitis induced by DNFB were suppressed by both the aqueous and n-BuOH fraction of the honeybush extract. The aqueous fraction, but not the n-BuOH fraction, also significantly improved the skin moisture content. Both the *in vitro* and *in vivo*

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

results suggested that the aqueous fraction of honeybush had a relatively stronger skin protective effect than the n-BUOH fraction, so compounds contained in the aqueous fraction may have strong anti-inflammatory effect.

The effect of collagen-derived dipeptide prolyl-hydroxyproline on chondrocytes under hypoxic conditions

Yoshifumi Kimira[1], Takahiro Sato[1], Yuya Tezuka[1], Yuna Shiobara[1], Yoshihiro Osawa[1], Hiroshi Mano[1]

1. Josai University (Japan)

Background and objectives: Collagen peptides are used as functional food ingredients, and their effects on joints have been reported in recent years. It has been shown that collagen peptides inhibit differentiation into calcified cartilage, and the active body of collagen peptides has been found to be prolyl hydroxyproline (Pro-Hyp). Physiologically, there are no blood vessels in articular cartilage, and cartilage exists in a hypoxic environment. The effects of Pro-Hyp on hypoxic chondrocytes have not been clarified. This study examined the effect of Pro-Hyp on the hypoxia-mimetic state of the progenitor chondrocyte cell line ATDC5.

Methods: Cobalt chloride ($CoCl_2$) 200 µM and Pro-Hyp 0.001 mM to 1 mM were added to ATDC5 cells 24 hours after seeding, and the number of cells cultured for 24 and 48 hours was measured and used as an index of chondrocyte proliferation. ATDC5 cells were cultured with 200 µM of $CoCl_2$ and 0.01 mM to 1 mM of Pro-Hyp when cell density reached 100% confluency after seeding, ALP staining after 4 days of culture and Alcian blue (AB) staining after 12 days of culture were used as indicators of chondrocyte differentiation.

Results: Compared to the control group that only underwent medium exchange, the number of cells in both the $CoCl_2$ alone and $CoCl_2$ and Pro-Hyp simultaneously added groups decreased. Compared to the control group that only underwent medium exchange, $CoCl_2$ alone decreased ALP activity and AB staining area, while the simultaneous addition of $CoCl_2$ and Pro-Hyp inhibited the decrease in ALP activity and AB staining area in a Pro-Hyp concentration-dependent manner.

Conclusions: In this study, we found that the addition of Pro-Hyp suppressed the decrease in ALP activity and AB staining area in ATDC5 under hypoxia-mimetic conditions induced by $CoCl_2$, and that the addition of Pro-Hyp Pro-Hyp may maintain the differentiation of chondrocytes under hypoxic conditions.

Roasted whole-grain barnyard millet enriched diet attenuates metabolic syndrome-related risks in high-carbohydrate high-fat-fed rats

Siti Raihanah Shafie[1], Mazni Syamim Mohd[1], Nurul Husna Shafie[1], Fairus Ahmad[2]

1. Universiti Putra Malaysia (Malaysia), 2. Universiti Kebangsaan Malaysia (Malaysia)

Background and objectives: Obesity and metabolic syndrome have become major public health concerns, contributing to many comorbidities worldwide. Data showed that metabolic syndrome affects 20-25% of the adult population, globally. In combating obesity and metabolic syndrome, a lifestyle change that includes a healthy balanced diet is considered the most important initial step. Incorporation of functional foods in the diet is part of healthy dietary regimes in treating obesity and metabolic syndrome. Millet is one of the economically essential cereals that contain a high nutritional value that has the potential to give innumerable health benefits. Several studies indicated that barnyard millet contains a high source of protein including essential amino acids, carbohydrates, dietary fiber, polyphenols and micronutrients. However, there is a limited study that has highlighted the potential of whole barnyard millet consumption against metabolic syndrome. Thus, this study aimed to determine the effect of roasted whole-grain barnyard millet flour on metabolic parameters in rats with diet-induced metabolic syndrome.

Methods: Male Wistar rats (n = 7) were fed on a 10% addition of roasted whole-grain barnyard millet flour to a modified high-carbohydrate high-fat diet (HM) for the final eight weeks of a 16-week protocol. The control rats (n = 7) were fed with high-carbohydrate high-fat diet (HF) for 16 weeks. The rats were monitored for changes in adipose tissue mass, blood pressure, lipid profiles and histological hepatic structure.

Results: After 16 weeks of diet regime, the intervention rats' group HM showed significant differences ($P<0.05$) in adipose tissue mass, blood pressure, total cholesterol and triglycerides levels compared to the HF group. Decrement in the lipid droplet accumulation in the liver was also observed in HM rats compared to HF rats.

Conclusion: The results demonstrated that roasted whole-grain barnyard millet supplementation could be one of the potential functional foods, specifically in reversing metabolic syndrome disease.

Identification and characterization of lipid-lowering peptides from oil palm kernel protein hydrolysate

Sui Kiat Chang[1]

1. Universiti Tunku Abdul Rahman (Malaysia)

Background and objectives: Plant proteins play essential roles in human nutrition. Oil palm fruit is the most important oilseed crops globally where its kernel is obtained as waste after palm oil production. Our previous study demonstrated that oil palm kernel hydrolysate (OPKH) obtained after protease hydrolysis showed strong lipid-lowering properties by reducing apolipoprotein B100 (apoB100) secretion in HepG2 cells. Hence, this study aims to purify and identify the lipid-lowering peptides from OPKH.

Methods: First, the OPKH was purified by ultrafiltration, followed by reversed-phase (analytical) and semi-preparative HPLC to collect the bioactive peptide fractions. The effects of bioactive peptides isolated from OPKH protease hydrolysate on apolipoprotein B (apoB100) secretion was assessed using HepG2 cells as a model. Cell viability was measured using 3-(4,5-dimethylthiazol-2-yl)-5-(carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium (MTT) assay. Subsequently, cellular triglycerides (TG), cholesterol ester (CE) and apoB100 levels were determined using ELISA assay kits according to manufacturer's instructions. Next, the amino acid sequences of the lipid-lowering peptides were identified by ESI/MS/MS coupled with Q-TOF LC/MS and PEAKS studio software using de novo sequencing.

Results: Seven active fractions (F1-F7) were collected and purified from the oil palm kernel protease hydrolysate. Fraction F4 showed the highest lipid-lowering properties by reducing apoB100 secretion, cellular TG and CE levels. Fraction F4 was collected and re-chromatographed on the same analytical column where two sub-fractions (F4a and F4b) were obtained. Two lipid-lowering peptides, His-Phe-Asp-Ser-Ile (HFDSI) and Leu-Thr-Thr-Leu-Asp-Ser-Glu (LTTLDSE) were identified using LC-MS/MS. The molecular masses of the peptides, HFDSI and LTTLDSE were 618.25 and 777.37 Da, respectively. These bioactive peptides were not cytotoxic to HepG2 cells.

Conclusion: Bioactive peptides purified from the oil palm kernel protein hydrolysate demonstrates the potential as a nutraceutical to be utilized as lipid-lowering functional foods. Further in vivo studies will be conducted to verify the lipid-lowering properties of these bioactive peptides and the bioactive fractions.

Effect of hot water extract of defatted perilla seed residue on bone metabolism

Hiroyuki Asano[1], Masataka Kitaji[2], Sogo Nishimoto[1,2]

1. Ishikawa Prefectural University Graduate School (Japan), 2. Ishikawa Prefectural University (Japan)

Background and objectives: Perilla seed oil has many reported benefits as a health contributing food. However, most of the defatted perilla seed residue after oil extraction is disposed of as industrial waste. Recently, we found that perilla seed extract regulates bone metabolism by enhancing bone formation in osteoblasts and inhibiting bone resorption in osteoclasts. In this study, we explored the detailed mechanism of action in regulating bone metabolism in osteoclasts, and in addition, we examined the effect of perilla seed extract *in vivo* by the administration of it to osteoporosis model mice.

Methods: Samples were made by hot water extraction of defatted perilla seed residue and lyophilized. Osteoclasts were differentiation-induced bone marrow cells derived from mouse femur and tibia. The expression levels of various genes involved in osteoclastogenesis were measured and examined by qPCR. In addition, after creating an ovariectomized osteoporosis model mouse, the mice were orally administered extract of perilla seed daily. After 28 days of administration, the uterus and femur were harvested for uterus weight and dry bone weight measurements, as well as length measurements of trabecular bone structures.

Results: Defatted perilla seed hot water extract was found to significantly suppress the expression of downstream genes along with the suppression of NFATc1 gene expression. *In vivo* evaluation showed no significant increase in uterine weight in mice treated with perilla seed extract however, an increase in dry bone weight was confirmed. Furthermore, loss of trabecular bone area was observed after OVX treatment. But trabecular bone area inside the bone was significant recovery in mice treated with perilla seed extract.

Conclusions: Defatted perilla seed hot water extract does not exhibit estrogenic effects. However, it was found to be effective in reducing bone resorption ability by suppressing the expression of the NFATc1 gene expression, an essential factor for osteoclastogenesis. These functions suggest that perilla seed extract can ameliorate OVX-induced osteoporosis symptoms.

PAB(T7-227)
Quality characteristics of chicken stock with different plant ingredients

Lim SeoungCheol[1], Shin Yujin[1], Kim Bokyung[1], Park MiHwa[1], Jung Kyoungim[1], Kim Inkyung[2], Kim Mihyang[1]

1. Silla University (Korea), 2. Full-JungSung Corp (Korea)

This study was conducted for the purpose of improving the nutritional content and taste of chicken stock due to the addition of various plant materials. Apples, lemons and tomatoes were used as the main plant materials for chicken stock and 9 major nutrients were analyzed to examine changes in the nutritional composition of chicken stock. In order to evaluate the preference, sensory evaluation was performed using a five-point scale method. The crude protein content by Kjeldahl method was 2.53 g/100 g when apples were added alone (A), and 2.45 g/100 g when apples and tomatoes were added (AT). In contrast, the crude protein content of the apple, tomato and lemon (ATR) stock was 3.30 g/100 g. The crude protein content of ATR was increased by 134% compared to AT. As a result of analyzing the 9 major nutrients in the stock to which ATR was added, the crude protein content of the ATR-added group was 3.40 g/100 g, whereas that of the non-added group was 1.90 g/100 g, which increased by about 1.8 times. As a result of the amino acid analysis, the contents of glutamic acid, aspartic acid and various essential amino acids were increased in the group with the addition of ATR compared to the group without the addition of ATR. As a result of comparing with commercially available chicken stock using a five-point scale method for evaluation of preference, the ATR-added group showed the highest score in color, smell, and taste. In chicken stock, the addition of apple, tomato and lemon increased the content of various essential amino acids along with the increase of the crude protein content, and showed excellent results in terms of taste. Most commercially available products have high MSG and sodium content, but the chicken stock developed in this study is expected to be used as a health-oriented product that can replace existing products.

Anti-inflammatory effects of RAW264.7 cells stimulated with lipopolysaccharide and antioxidant activities of *Terminalia ferdinandiana*

Shin Yujin[1], Lim Seoungcheol[1], Lee Chong[1], Kim Bokyung[1], Park MiHwa[1], Kim Mihyang[1]

1. Silla Universtity (Korea)

Terminalia ferdinandiana (TF) contains various minerals and vitamins and is known as a fruit rich in phytochemical. In this study, the antioxidant activity of TF and its effect on the change in active free radical removal ability and IL-1β content in LAW264.7 cell were examined. In addition, after adding TF to foods such as beverages, yogurt, and salad dressing, sensory evaluation was conducted to explore the possibility of developing functional foods. As a result of measuring the DPPH radical scavenging ability, the activities of the hot water extract (TFH) and the ethanol extract (TFE) at 100 μg/ml concentration were 96.46% and 97.34%, respectively. In the SOD-like activity, when the concentration of TF extracts were 5 to 100 μg/ml, the activity was increased in a concentration-dependent manner. In particular, at a concentration of 100 μg/ml, the activity of each extract was 21.77% and 15.28%, respectively. In addition, ABTS radical scavenging activity, increased in a concentration-dependent manner when it was 5 to 100 μg/ml. Total polyphenol content of TFH and TFE showed a content of 30.96 mg/g and 224.48 mg/g, respectively. In the cytotoxicity test, 0 to 500μg/ml showed no toxicity. After LPS treatment on LAW264.7 cells, the ROS level was lowered in the group that added the TFH, indicating that TF had a protective effect from oxidative stress. Furthermore, the IL-1β content showed a significant increase compared to the LPS untreated group when LPS was treated, but the content IL-1β decreased when TFH was treated with 5 μg/ml and 100 μg/ml, indicating an anti-inflammatory effect. Sensory evaluation was conducted to examine whether there was a change in preference by adding TF to yogurt, powder yogurt, and dressing products. When 1.25 μg/ml of TF was added, there was no significant difference in taste and aroma compared to existing products. These results indicate that functionality can be improved without affecting existing foods, and the possibility of being used as an antioxidant material can be expected as it can be applied to various food developments in the future.

Arousal inducing ability of procyanidin and caffeine, the difference to the mechanism of action

Yasuyuki Fujii[1], Jun Sakata[1], Kazuki Sakata[1], Taiki Fushimi[1], Shu Taira[2], Naomi Osakabe[1]

1. Shibaura Institute of Technology (Japan), 2. Fukushima University (Japan)

Objectives: We have previously confirmed that following a single dose of cinnamtannin A2 (A2, epicatechin tetramer) activates neural activity in the mouse hypothalamus. It is known that sleep-active neurons located in the hypothalamus regulate the sleep-wake cycle. In this study, we compared arousal inducing ability between A2 and caffein in mice following a single oral dose.

Methods: After a 2-week habituation period, mice were orally administered A2(25 or 100 µg/kg) or caffeine (1, 100 mg/kg) and their behavior was observed for 180 min in an open field. Mouse behavior was analyzed in MATLAB using a program developed to quantify travel distance and time spent in central or corner area. We also observed noradrenaline levels in brain using by imaging mass spectrometry following a single oral administration 25 μg/kg A2. In addition, mRNA expression of noradrenalin synthase and transporter were detected using by *in situ* hybridization.

Results: While mice in the vehicle group showed sleep behavior after the exploratory period, mice in caffeine group exhibited a significant increase in travel distance to keep awake for 180 min. This result suggested that observation of spontaneous behavior in the open field can be evaluated to indirectly arousal. Caffeine increased travel distance dose-dependent manner. On the other hand, 25 µg/kg A2 group showed a significant increase in the spontaneous behavior, but this change disappeared in the 100 µg/kg group. Significant noradrenaline signals were observed in the locus coeruleus, brainstem, and hypothalamic preoptic area soon after A2 administration. While the expression of noradrenaline synthase and transporter mRNAs was only observed in the locus coeruleus. These results suggested that the feeding stimulus of A2 fires the locus coeruleus-noradrenaline system and projects noradrenaline to the sleep-active neuron in the preoptic area of the hypothalamus.

Conclusions: It is known that the locus coeruleus, the input site of A2, expresses not only promoting receptors but also inhibitory autoreceptors, the α2 adrenergic receptors (α2ARs). A high dose of A2 activates α2AR, consequently abolishing the promotion of arousal. The mechanism of A2 differs from that of caffeine, an adenosine receptor inhibitor.

Keyword: Epicatechin tetramer, Caffein, Arousal, Locus coeruleus

PAB(T7-230)
Transformation of major ginsenosides into minor ginsenosides in ginseng by pickling in salted rice malt paste

Manabu Sugimoto[1], Nobutada Murakami[2]

1. Okayama University (Japan), 2. Functional Food Creation Research Institute Co., Ltd. (Japan)

Background and objectives: Production of minor ginsenosides from major ginsenosides in ginseng, the root of *Panax ginseng*, has been approached through using microbial and enzymatic reactions. However, these methods require commercial or self-purified major ginsenosides as a substrate, or culture medium or purified enzyme solutions. Therefore, they are limited by costs and the working process used for implementation. To enhance the contents of minor ginsenosides in ginseng at low labor and cost, fresh ginseng was pickled in a salted rice malt paste to transform major ginsenosides to minor ginsenosides.

Methods: Fresh 1-year-old and 6-year-old ginsengs were pickled in the salted rice malt paste fermented using *Aspergillus kawachii* in the dark at 23°C for 28 days. The pickled ginsengs were minced, homogenized in 80% ethanol, and incubated at 80°C for 14 h. The solution filtered and evaporated to remove ethanol was used as a ginseng extract.

Results: The extracts of 1-year-old and 6-year-old ginsengs pickled in the salted rice malt paste for 28 days contained minor ginsenosides F2 and CK in addition to major ginsenosides Rb1 and Rd by HPLC analysis. The ratios of Rb1, Rd, F2, and CK in the extracts of pickled 1-year-old and 6-year-old ginseng were, respectively, 40:39:7:14 and 35:45:8:12, whereas those in the extracts of fresh 1-year-old and 6-year-old ginseng were, respectively, 68:32:0:0 and 72:28:0:0. The respective amounts of F2 and CK in the 1-year-old ginseng pickled in the salted rice malt paste were 5.0 and 6.0 μg/g; those of pickled 6-year-old ginseng were, respectively, 3.0 and 2.0 μg/g.

Conclusions: Fresh 1-year-old and 6-year-old ginsengs, which had major ginsenosides Rb1 and Rd but had neither minor ginsenosides F2 and CK, were pickled in the salted rice malt paste with *A. kawachii*. The extracts showed production of F2 and CK, and changed the ratio of Rb1, Rd, F2, and CK in ginseng, demonstrating that pickling fresh ginseng in the salted rice malt paste is a simple and useful means of producing minor ginsenosides F2 and CK and changing the relative contents of ginsenosides in ginseng.

Elucidation of novel γ-oryzanol species in rice bran oil and processed foods containing rice bran oil

Kazue Sawada[1], Junya Ito[2], Yusuke Ogura[3], Hiroyuki Hashimoto[1], Kiyotaka Nakagawa[2]

1. Tsuno Food Industrial CO., LTD. (Japan), 2. Tohoku University (Japan), 3. The University of Tokyo (Japan)

Introduction: γ-Oryzanol (OZ) is a functional ingredient in rice bran. OZ in rice bran is mainly composed 24-methylenecycloartanyl ferulate (24MCA-FA), cycloartenyl ferulate, campesteryl ferulate, and β-sitosteryl ferulate. However, in the case of "rice bran oil" (RBO, a purified oil from rice bran), we found that the content of 24MCA-FA was low while two additional novels of OZ species were potentially detected. In this study, we focused more about the presence of two novel OZ species in RBO and determined their chemical structures. On top of that, the quantification of two novel OZ species and other OZ species in commercial RBO and processed foods cooked with RBO have been conducted.

Methods: Rice bran and RBO were analyzed by HPLC-UV-IT-TOF. The two novel OZ species were isolated from RBO using liquid–liquid extraction, flash-chromatography, and HPLC-UV with C18 column and C30 column. The structures of two novel OZ species were determined by NMR. Six kinds of commercial RBO and some processed foods cooked with RBO (potato chip and rice cracker) were analyzed using HPLC-UV-IT-TOF, and the amount of two novel OZ species and other OZ species were quantified.

Results and Discussions: In rice bran, only 24MCAFA was detected in the negative mode XIC of *m/z* 615.4429. In RBO, in addition to a small amount of 24MCAFA, two novel OZ species were detected as major peaks in the negative mode XIC of *m/z* 615.4429. NMR analysis revealed that the two novel OZ species isolated from RBO were cyclobranyl ferulate (CB-FA) and cyclosadyl ferulate (CS-FA). When the quantification of OZ species in commercial RBO and processed foods cooked with RBO was conducted, CB-FA and CS-FA, like other OZ species, were certainly contained in all RBO and processed foods. It was suggested that people might have often consumed CB-FA and CS-FA from RBO and/or processed foods.

Effect of D-Serine intake in ataxia model mice

Naoki Takayanagi[1], Hidehiko Beppu[2], Hisahide Takahashi[2]

1. Tokaigakuen University (Japan), 2. Fujita Health University (Japan)

Background and Objectives: We maintained an ataxia model mouse (Wob/t) with degeneration and shedding of cerebellar Purkinje cells, accompanied by intoxicated gait and tremor. Cerebellar atrophy of Wob/t is caused by degeneration and shedding of cerebellar Purkinje cells beginning ten days after birth. In recent years, D-amino acids have been detected in vivo and in particular, D-Serine has been reported to be important in NMDAR-mediated cerebellum development. Brain-derived neurotrophic factor (BDNF) is a secretory protein that affects the survival and development of neurons. Decreased BDNF expression in the cerebellum of individuals with SCA1 has been reported. Additionally, BDNF has been reported to increase with exercise and medication. Therefore, we researched the effect of D-Serine intake in ataxic model mice, particularly in relation to BDNF expression and gait.

Methods: Wob/t was divided into a D-Serine intake group (DS-Wob/t; n = 5) and a control group (Wob/t; n = 8). The time to fall in the rotarod test (2-20 rpm) was compared to evaluate gait. BDNF levels were measured in the cerebellum up to six months of age.

Results: There was a significant increase in the fall time in the rotarod test, between the control (35.7 ± 4.5 s) and the DS-Wob/t group (105.3 ± 6.3 s). BDNF expression levels in the cerebellum of the DS-Wob/t group were higher than the control group.

Conclusions: D-Serine intake improved coordination and enhanced BDNF levels in the cerebellum. Therefore, it is suggested that D-Serine may have delayed the progression of cerebellar pathology.

Keyword: Wob/t, Ataxia model mouse, D-Serine, BDNF

PAB(T7-233)

Effects of trigonelline on human renal glomerular endothelial cell function

Yuri Nonoshita[1], Yuji Minami[1], Katsuko Kajiya[1]

1. Kagoshima University (Japan)

Background and objectives: Renal glomerulus, a bundle of capillaries lined by delicate fenestrated endothelia, plays an important role in urine production. Human renal glomerular endothelial cells (HRGECs) are the first barrier in ultrafiltration. HRGEC dysfunction causes glomerular diseases such as glomerulonephritis or glomerulosclerosis, ultimately leading to

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

kidney failure. Therefore, it is important to conduct research on the protection of HRGECs. While searching for various agricultural products that improve vascular function, we found Sakurajima daikon, a special product in Kagoshima prefecture, Japan. The functional compound contained in Sakurajima daikon was identified as trigonelline. We hypothesized that trigonelline may delay the progression of renal failure if it can improve the function of the renal glomerulus. We investigated the effects of trigonelline on vasoactive substances [vasodilator nitric oxide (NO) and vasoconstrictor endothelin-1 (ET-1)] in HRGECs.

Methods: The activation of endothelial NO synthase (eNOS) by phosphorylate of Ser1177 and expression of ET-1 in HRGECs were assessed by western blotting and flow cytometry. Bradykinin, acetylcholine, and vascular endothelial growth factor were used as positive controls. HRGECs were subsequently treated with trigonelline for specific time at various concentrations. The effects of trigonelline on the expression levels of phosphorylated eNOS and ET-1 were also investigated.

Results: The expression of phosphorylated eNOS and ET-1 in HRGECs was confirmed. The concentration- and time-dependent effects of trigonelline on eNOS activation were also confirmed. In addition, trigonelline effect on ET-1 production was evaluated.

Conclusions: Trigonelline tended to activate eNOS in HRGECs, suggesting that it increases NO production. Our study suggests that trigonelline protects glomerulus and prevents glomerular diseases. Further detailed studies are needed to understand and improve overall kidney function.

Keyword: Trigonelline, Nitric oxide synthase, Endothelin-1, Renal glomerular endothelial cells, Sakurajima daikon

Study on the functionality of the stem Tadeai(*Polygonum tinctorium* Lour:PTL)

Maki Kondo[1]

1. Shikoku University (Japan)

Background and objectives: Tokushima Prefecture ranks first in Japan in terms of Tadeai(indigo) cultivation area and yield. We have confirmed that rats treated with a 1%PTL leaf-added diet suppress weight gain, decrease intra-abdominal fat weight, decrease serum lipids, and PTL leaves have a preventive effect on lifestyle-related diseases. PTL is an annual plant, and leaves are used for dyeing and edible use. Half of the PTL cultivated is stems, stems are discarded every year. In this study, we examined the functionality of PTL stems in order to examine the utilization of discarded stems.

Methods: 12-weeks-old mature Wistar male rats were divided into 4 groups, AIN-93G was administered(Group C), and AIN-93G was supplemented with 5%PTL stem powder(Group S), AIN-93G with lard added to 30% fat diet(Group HF), 30% fat diet with 5%PTL stem powder added(Group HFS), each diet and water administered *ad libitum* for 6 weeks. One or two fresh feces were collected at 3 and 6 weeks after administration. On the day before sacrifice, only water was administered as a 24-hours fast, the abdomen was opened under anesthesia, blood was collected, and various components were measured using this serum. In addition, intra-abdominal fat, each organ, and the contents of the cecum were collected and the wet weight was measured. We analyzed and compared the intestinal or cecum bacterial flora.

Results: There were no differences in body weight change, food intake, organ weight between the each groups. Comparing serum triacylglycerols in group C and group S, it was significantly reduced by about 30% in group S. There was no difference in the intestinal flora in the cecum. Diversification of fecal bacterial flora by ingestion of stems which became more pronounced at 6 weeks of ingestion of PTL stem powder. Especially in group S, the intestinal flora of feces tended to resemble the cecum.

Conclusion: *Faecalibacterium*, which is expected as a next-generation probiotic, was present in the 6-weeks feces of some rats in group S, suggesting that PTL stem powder may function as a prebiotic.

Ellagic Acid Prevents Binge Alcohol-Induced Leaky Gut and Liver Injury through Modulating Gut Microbiome Change

Dong-Ha Kim[1]*, Moon-Chang Baek*[1]*, Young-Eun Cho*[2]*, Do-Kyun Kim*[3]*, Jin-Hyeon Hwang*[3]

1. Kyungpook National University (Korea), 2. Andong National University (Korea), 3. Jeonbuk National University (Korea)

Back Ground & Objectives: 1Alcoholic liver disease (ALD) is a major liver disease worldwide and can range from simple steatosis or inflammation to fibrosis/cirrhosis, possibly through leaky gut and systemic endotoxemia. We recently reported that a pharmacologically high dose of pomegranate extract prevented binge alcohol-induced gut leakiness and hepatic inflammation by suppressing oxidative and nitrative stress. Herein, we investigate whether a dietary antioxidant ellagic acid (EA) contained in many fruits, including pomegranate and vegetables, can protect against binge alcohol-induced leaky gut, endotoxemia, and liver inflammation.

Methods: 6-week-old female C57BL/6J mice were subjected to oral administration of a daily dose of 60 mg/kg EA, freshly prepared by suspension in water just before treatment, based on the calculation for physiologically and clinically relevant doses. Control mice were treated similarly by daily oral administrations with a vehicle. After EA pretreatment for 14 consecutive days, different groups of mice were exposed to 3 oral doses of binge alcohol or dextrose at 12 h intervals and euthanized 1 h after the last ethanol dose for collecting various tissues and plasma, the same as recently described.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Results: Pretreatment with EA significantly reduced the binge alcohol-induced gut barrier dysfunction, endotoxemia, and inflammatory liver injury in mice by inhibiting gut dysbiosis and the elevated oxidative stress and apoptosis marker proteins. Pretreatment with EA significantly prevented the decreased amounts of gut tight junction/adherent junction proteins and the elevated gut leakiness in alcohol-exposed mice.

Conclusion: Taken together, our results suggest that EA could be used as a dietary supplement for alcoholic hepatitis patients.

Keyword: binge alcohol, ellagic acid, gut microbiota, intestinal barrier dysfunction, endotoxemia

PAB(T7-236)
Exploring food-derived ingredients that up-regulate LDL receptor expression

Naoki Kaname[1], Takahiro Fujimaki[1], Kaito Fujimura[1], Ken Ishigami[1], Tsukasa Suzuki[1], Yuji Yamamoto[1], Jun Inoue[1]

1. Tokyo University of Agriculture (Japan)

Background and objectives: Atherosclerotic cardiovascular disease is a major cause of morbidity and mortality worldwide. Elevated plasma low-density lipoprotein cholesterol (LDL-C) level is a prominent risk factor for atherosclerosis and coronary heart disease. The LDL receptor (LDLR) is a single transmembrane protein that is mainly expressed in the liver and is known to internalize LDL-C in the blood into cells. Therefore, increased expression of this protein is expected to reduce the risk of developing atherosclerosis. We have previously explored food-derived ingredients that up-regulate LDLR expression by luciferase reporter assays using the LDLR gene promoter region, and found several compounds including piperine and kaempferol (1, 2). In this study, we aimed to find functional ingredients that up-regulate the expression of LDLR from waste parts of agricultural products to add value to agricultural products and make effective use of them. After examining about 50 waste samples of agricultural products, we found that cherries (Sato Nishiki) axes contain ingredients that up-regulate LDLR gene promoter activity. Therefore, in this study, we focused on the axes of Sato Nishiki and aimed to identify the active ingredient.

Methods and Results: Sato Nishiki axes were extracted with 50% ethanol at 80°C for 1 hour, further separated using ethyl acetate and water, and the organic and aqueous layers were collected. The organic layer was further fractionated into a total of 100 fractions by reversed-phase HPLC fractionation, and fraction assays showed that some fractions were active. To isolate and identify the compounds in the fractions that were especially active, we performed by using HPLC, LC/MS, and NMR analyses. The results revealed that it is a glucoside of a certain flavone.

Conclusion: We have succeeded in identifying a compound that increases LDLR promoter activity in the Sato Nishiki axes. Analysis of the mechanism of its flavone-mediated LDLR up-regulation action is currently in progress.

Effect of enzyme-assisted extraction on nutritive value, bioactive compounds, and bioactive properties of date (*Phoenix dactylifera* L.) juices

Nattapol Tangsuphoom[1], Carolina Santoso[1], Uthaiwan Suttisansanee[1], Chitraporn Ngampeerapong[2]

1. Mahidol University (Thailand), 2. Maejo University (Thailand)

Background and objectives: Date palm (*Phoenix dactylifera* L.) has become an economical crop in Thailand. Date fruits of Barhi cultivar contain large amount of sugars and various bioactive compounds. Enzyme-assisted extraction is widely used to improve the quality and functional properties of fruit juices. This study aimed to compare the nutrients, bioactive compounds, and bioactive properties of date juices extracted without and with the aid of carbohydrases.

Methods: Deseeded Barhi date fruits were blended with water at 1:1 ratio. Juice extraction was performed at 45°C for 3 hours either with the aid of Pectinex® or Viscozyme® at the enzyme-to-substrate ratio of 1%, or without any enzyme. Nutritive value was analyzed according to AOAC Official Methods of Analysis. Total phenolic content (TPC) was determined using Folin-Ciocalteu method. Types and concentrations of phenolic acids, flavonoids and carotenoids were identified using HPLC. Antioxidant activities were assessed by DPPH, FRAP, and ORAC assays. Inhibitory activities on carbohydrate digestive enzymes were determined using *in vitro* calorimetric assays.

Results: Date juice obtained from enzyme-assisted extraction, particularly with Viscozyme, contained more moisture but less dietary fiber and sugars than that extracted without enzyme. TPC, DPPH, and FRAP values differed slightly among the three samples. Extraction with Viscozyme increased ORAC value of date juice from 585.31 to 913.26 µmol Trolox equivalent/100 mL. Enzyme-assisted extraction lowered the amounts of caffeic, syringic, p-coumaric, and synaptic acids but increased the amounts of ferulic and vanillic acids in date juice. For flavonoids, enzymatically extracted date juices contained more apigenin and isorhamnetin but less hesperidin, quercetin, and kaempferol. Carotenoids including lutein, α-carotene and β-carotene in date juices were unaffected by the application of enzyme. Enzyme-extracted date juices showed about five times greater inhibition of α-amylase than that extracted without enzyme, while the inhibitory effect on α-glucosidase were similar.

Conclusions: Enzyme-assisted extraction could be an alternative method to produce date juice with improved

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

antioxidant activities through ORAC assay, and strong antidiabetic properties through the inhibition of α-amylase.

Construction of a screening system for food compounds with anti-inflammatory effect to resore inflammation-induced suppression of UCP-1 expression in brwon-like adipocytes.

Hisako Takahashi[1], Sayuri Narahara[1], Hiromi Miwa[1], Hiromu Morimoto[1], Miori Tanaka[1], Hirofumi Inoue[1], Tsuyoshi Goto[2], Teruo Kawada[2], Mariko Uehara[1], Nobuyuki Takahashi[1]

1. Tokyo University of Agriculture (Japan), 2. Kyoto University (Japan)

Background and objectives: Obesity is the excessive accumulation of fat in adipose tissues. The adipocytes that compose adipose tissues are classified into three types: white, beige, and brown adipocytes, of which beige and brown adipocytes are called "brown-like adipocytes". Brown-like adipocytes are heat-producing cells that convert energy obtained by consuming stored fat into heat, and their activation is expected to lead to anti-obesity. Uncoupling protein-1 (UCP-1) is responsible for heat production in brown-like adipocytes, thus increasing UCP-1 expression leads to anti-obesity. On the other hand, chronic inflammation caused by obesity suppresses the UCP-1 expression, which means that heat production in brown-like adipocytes is suppressed under obese conditions. Therefore, it is expected that taking food compounds with anti-inflammatory effects will restore UCP-1 expression in brown-like adipocytes. Therefore, we attempted to develop a screening system for anti-inflammatory compounds with such restoration of UCP-1 expression.

Methods: It has been reported that LPS-activated macrophage culture supernatant (conditioned medium (CM)) suppresses UCP-1 expression. Thus, we attempted to construct a system to evaluate anti-inflammatory function of food compounds using CM. Mouse macrophages, RAW264.7 cells, were stimulated by LPS. The LPS-containing medium was replaced with fresh medium, and 24 hours later the medium was used as CM. Food compounds were added 24 hours before the replacement with fresh medium (still present during the LPS-stimulation). Twenty-four hours after the addition of the prepared CM to 10T1/2 adipocytes, UCP-1 expression was examined by quantitative RT-PCR.

Results: The activation of macrophages was evaluated by using gene expression of inflammatory cytokines as an indicator, and RAW264.7 macrophages were effectively activated by treatment with 1.0 mg/mL LPS for 3 hours. While control CM suppressed UCP-1 expression in 10T1/2 adipocytes, CM of anti-inflammatory food compound-treated RAW264.7 significantly restored the suppression of UCP-1 expression.

Conclusions: Some food ingredients with anti-inflammatory effects increase UCP1 expression at the basal level, thus it is difficult to evaluate only the recovery of UCP1 expression by anti-inflammatory effects. However, this CM-using system constructed in this study can evaluate only the anti-inflammatory effects on UCP-1 expression.

Nutritional optimization and starch and protein digestibility of smart pasta made with gluten free African cereal and legume flours

Pauline Penel[1], Clothilde Vannier[1], Sophie Drogue[2], Denis Cassan[2], Marie-Josephe Amiot-Carlin[2], Claire Bourlieu-Lacanal[2], Valerie Micard[1]

1. Institut Agro Montpellier (France), 2. INRAE (France)

Background and objectives: Nowadays, malnutrition is a major public health issue. This reflects energy and macro and micronutrient imbalances. Among strategies to fight malnutrition, governmental food programs, fortification and nutritional optimization of staple food can be alternatively or concomitantly adopted. Pasta is one of the most popular staple foods. Traditionally made from wheat, its formulation has been improved by including legumes inside. The next effort for improving its formulation would be to use raw materials from climate-smart crops. Our study takes place in the European H2020 Innofood Africa project federating European and African countries on the development of climate-smart crops and their use in the context of a balanced diet. It aims to develop new nutritionally optimized pasta made from gluten free African raw materials adapted to the climate transition e.g. drought resistance, low input requirement.

Methods: Raw materials are cowpea, faba bean and bambara legume flours; teff, finger millet and amaranth cereal grain flours and additional nutritious raw materials such as orange fleshed sweet potato and amaranth leave flours. Nutritional and antinutritional composition of all flours were determined (protein, amino acids content, starch, sugar, fibres, vitamins, minerals, phytic acids, trypsin inhibitor). This constituted a data base for nutritional optimization of pasta by mathematical programming. In order to cover adults needs, the following criteria were selected: an amino acid chemical score above 110 taking into account process and cooking losses, an omega 6/omega 3 ratio closest to 5, a fiber quantity for 100g of pasta less than 25g, quantities of iron, zinc, B9 vitamin and beta carotene at less equal to recommendations and minimization of anti-nutritional factors.

Results: The best formulations covering the nutritional requirements, mainly based on cowpea, teff, amaranth leaves flours, have been selected. They were processed by a classical low temperature extrusion followed by a low temperature drying

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

preserving their nutritional qualities. They have been characterized and compared with classical 100% durum wheat semolina pasta for their textural and culinary properties and their nutritional composition. The *in vitro* protein and starch digestibility was carried out to determine the impact of formulations on the nutritional potential of pasta.

Conclusion: new nutritionally equilibrated, gluten free and smart for climat pasta have been obtained.

Keyword: sustainable food, nutritional optimization, pasta, extrusion

Mid-term effects of unpolished rice vinegar beverage consumption on oral flora and salivary proteins

Yosuke Maruyama[1], Mana Ideguchi[3], Takumi Nishiuchi[2], Isao Kanbayashi[3]

1. Nayoro city University (Japan), 2. kanazawa University (Japan), 3. Hokkaido University of Education Sapporo (Japan)

Background and objectives: Long-term (4 weeks or more) vinegar consumption has been reported to beneficial effects for obesity people to reduce body weight, body fat and serum triglycerides. On the other hand, long term vinegar consumption induced dental erosion. The transient vinegar intake (intake after 3-12 hour) has been reported to have oral clearance and antibacterial effects. In contrast, the mid-term (about intake over a week) effects are largely unknown. Based on previous findings, we hypothesize that medium term intake of acetic acid may activate the oral immune system and affect the secretion of antimicrobial proteins Therefore, we have investigated the effects at mid-term intake on the local oral immune response by analyzing salivary proteins and oral flora.

Methods: We used unpolished rice vinegar beverage (URVB) (750 mg acetic acid /500 ml) for vinegar intake group and water (bottled water) for control group. In URVB group (N=9, female undergraduate student), they took 250 ml URVB twice a day before a meal for one week. In control group (N=10, female undergraduate student), they took 250 ml water twice a day before a meal for one week. The saliva was collected at 0, 1, 3, 5, 7 days after start of administration. The sampling was performed just before URVB or water intake at dinner time. For 16S rRNA amplicon sequencing, DNA was extracted from 500 ul saliva and 5 ng of DNA was used for PCR. For Shotgun proteomics, 10 ug of saliva protein was used.

Results: Analysis of the saliva flora 0, 1, and 7 days during URVB intake showed a difference between 0 and 7 days in chao1 and observed futures ($P<0.05$), and no difference was observed between 0 and 1 day. Furthermore, clostridia bacteria were decreased at 7days in class level. As a same, *clostridiales* and *rhodobacterales* bacteria were decreased at 7 days in order level. On the other hands, *bacillales* bacteria were increased at 7 days in order level.

Conclusions: One week of continuous URVB intake affected salivary bacterial flora, suggesting that mid-term intake acetic acid modulates oral responses.

PAB(T7-241)
Safety Evaluation and Chondroprotective Functionality of *Salviae plebeia*

Hae-Jin Park[1], Mi-Rae Shin[1], Seong-Soo Roh[1]

1. Daegu Hanny University (Korea)

Backgroud and objectives: Salviae Plebeia (SP) contains numberous chemical components and is reported to exert various pharmacological activities such as antioxidant, anti-inflammatory, antimicrobial, analgesic, hypoglycemic, antiviral, anti-tumor, and hepatoprotective effects. Even though it has these various effects, its scientific proof remains uncertain the effect and underlying mechanism about joint damage. Accordingly, the present study was designed to evaluate the therapeutic effects and possible underlying mechanism of SP on osteoarthritis (OA).

Methods: OA animal model was induced via intra-joint injection of monosodium iodoacetate (MIA) 50 uL with 80 mg/mL in SD rat. Excluding the normal group, OA-induced mice were divided into 4 groups (control, INDO, SPL, SPH). The drug concentrations were indomethacin 5 mg/kg, SP 500 mg/kg, and SP 1,000 mg/kg, and were administered orally once a day for 2 weeks. After drug supplementation, the effects of SP were measured with serum analysis, western blotting, and histopathological staining.

Results: SP administration improved hind limb overload and it led to relieve pain. Moreover, it suppressed oxidative related factors. The NF-κB inactivation though the inhibition of IκBα phosphorlyation significantly decreased both inflammatory mediators such as COX-2 and iNOS and cytokines such as TNF-α, IL-1β, and IL-6. Whereas, anti-inflammatory cytokines like IL-4 and IL-10 were shown to increase. In addition, SP administration exerted a protective effect on ECM by reducing the expression of collagen degradation factors including MMP-1, -3, -13 and by increasing TIMP-1.

Conclusions: SP may possess the effect of delaying the progression of osteoarthritis and protecting cartilage. Accordingly, the present study may provide a scientific basis the chondroprotective effect of SP on MIA induced osteoarthritis.

Effects of Ascorbic acid on bone metabolic indicators in vitro and in vivo

Kim Mihyang[1], Lim Seoungcheol[1], Shin Yujin[1], Park Mihwa[1], Jung Kyongim[1], Kim Bo-Kyung[1]

1. Silla Universtity (Korea)

L-ascorbic acid (AsA) is known to affect bone formation by participating in collagen synthesis in animals. Osteoporosis is caused by collagen loss which is reversible. This study was intended to examine the effect of AsA on bone formation in cellular and animal models by analyzing bone metabolic indicators.

As osteoblasts, MC3T3-E1 cells were used and cultured with various concentrations of AsA during the cell differentiation period. To examine the effect of AsA on bone formation, ALP activity and bone calcification assays were performed. In addition, the effect of AsA on the expression of osteoblast differentiation-related proteins was also examined. In animal experiments, ovariectomy was performed to induce bone loss, and AsA was administered for 7 weeks. ALP activity and CTx and NTx Ⅰ content in serum were measured. The content of collagen in bone and cartilage were analyzed.

AsA treated cells showed a significant increase in ALP activity, an early indicator of bone calcification, compared to the control group. ASA promoted mineralization, which is a late stage of osteoblast differentiation. In addition, AsA increased the expression levels of collagen I and the expression of ALP and RUNX2 was increased by treatment with AsA 10μg/ml, and the expression of BSP and OPN was also increased. In ovariectomized animals, ALP, an indicator of bone formation, increased by ASA administration, but concentrations of CTx and NTx, indicators of bone resorption, decreased. The collagen content was increased in the AsA-administered groups compared to control group. From the above results, it was found that AsA has the effect of promoting factors related to bone formation and reducing factors related to bone resorption. These results indicate that it can be used as a material that can alleviate symptoms such as osteoporosis in the future.

Docosahexaenoic acid-containing diets inhibits decline kidney functions by reducing oxidative stress and inflammation at early stage of chronic kidney disease on 5/6 nephrectomized rats

Hiroki Muramatsu[1], Naoe Akimoto[1], Katsuhiko Yajima[1], Michio Hashimoto[2], Masanori Katakura[1]

1. Josai University (Japan), 2. Shimane University (Japan)

Background and objects: The kidneys are responsible for excretion of metabolites, maintenance of pH, adjustment of blood pressure, and regulation of body fluid volume. Therefore, it is very important to keep kidney functions. Arachidonic acid (ARA), an ω-6 polyunsaturated fatty acid (PUFAs), is involved in development and maintenance of the renal function. Docosahexaenoic acid (DHA), an ω-3 PUFAs, has anti-inflammatory effects. Previous study, increasing urinary albumin excretion 16 weeks after nephrectomy, it was attenuated by ARA or/and DHA containing diet fed 5/6 nephrectomized rats. The purpose of our study was to assess the effects of PUFAs on the early stage of chronic kidney disease (CKD).

Method: Male Sprague Dawley were randomly divided into Control group, ARA group, DHA group, and ARA+DHA group. Rats were removed 5/6 kidney and they were feed continuous for 4 weeks. rats were removed 5/6 kidney and they were feed continuous. Rats were housed in individual metabolic cage and were collected urine for 24 hours. 4 weeks after surgery, plasma and kidneys were collected for biochemical and histological analysis.

Results: Indoxyl sulfate (IS), one of the causes of uremia, reactive oxygen species (ROS), and tumor necrosis factor – α (TNFα) as inflammation cytokine in kidney were increased by nephrectomy, it was attenuated by feeding DHA containing diet. ROS and TNFα levels in the kidney at 4 weeks significantly negative correlated with creatine clearance; positive correlated with urinary albumin levels. The cause of albumin excretion in urine is glomerular damages. Histological analysis revealed that vacuolization of kidney tissue, proliferation of mesangial cells, and growth of mesangial substrates such as glomerular damages were increased in kidney section 4 weeks after nephrectomy. These damages were attenuated by DHA containing diet.

Conclusion: These results suggest that the DHA diets inhibits progress the early stage of CKD by decreasing oxidative stress and inflammation.

Effect of omega-3 fatty acid supplementation on sleep quality in healthy subjects.

Kaori Yokoi-Shimizu[1,2], Kenichi Yanagimoto[1], Kohsuke Hayamizu[2]

1. Nippon Suisan Kaisha, Ltd. (Japan), 2. Yokohama University of Pharmacy (Japan)

Background and objectives: Omega-3 fatty acids have various functions, and one of these functions, an effect of sleep quality, has recently been shown to be effective in clinical studies. In some meta-analyses for children, omega-3 fatty acid could have the benefit of improving sleep quality. It is said that affected by aging for over 45 years old, the actual time of sleep is shorter. This study investigated the effect of omega-3 fatty acids on improving sleep quality in subjects aged 45 years or older, whose sleep quality is deteriorating.

Methods: This study conducted a randomized placebo-controlled, double-blind, parallel groups design. 66 healthy Japanese men and women were randomly assigned to receive 0.48g X 6 capsules per day of omega-3 fatty acid (DHA 576 mg, EPA 284 mg per day, omega-3 group, n=33) or corn oil (control group, n=33) for 12 weeks. Before and after intervention, the OSA sleep inventory MA version (OSA-MA) and sleep quality test using a sleep scanning mat device were conducted.

Result: In omega-3 group, factor Ⅲ (frequency dreaming) scores in the OSA-MA significantly improved compared to control group. And sleep efficiency from sleep quality tests was also high compared to control group.

Conclusions: It was found for the first time that omega-3 fatty acids have the benefit of the sleep quality in only middle-aged and older subjects, and even at lower doses than those found in the previous study. Further investigation about mechanisms of improving sleep quality by taking omega-3 fatty acids are required.

Conflict of Interest Disclosure: This research was conducted with a research fund from Nippon Suisan Kaisha, Ltd., which the author belongs to.

PAB(T7-245)
Homocarnosine as a novel food factor increases brain GABA and homocarnosine levels

Jason Dumaguing Braga[1], Thanutchaporn Kumrungsee[1], Mikako Sato[2], Yukihiro Sugawara[2], Noriyuki Yanaka[1]

1. Hiroshima University (Japan), 2. NH Foods Ltd. R&D Center (Japan)

Background: Gamma-aminobutyric acid (GABA) is an important neurotransmitter. Dysregulation of brain GABA levels links to depression-anxiety behaviors and brain diseases such as epilepsy and Alzheimer's disease. Recently, various GABA-rich foods and supplements have been developed for ameliorating those neurological disorders. In addition to GABA, a GABA-containing peptide homocarnosine (GABA-L-histidine) is found at high concentrations in the brain and its biological antioxidant effect has been expected. Therefore, we proposed that homocarnosine can be a potential functional food for increasing brain GABA and homocarnosine. However, this hypothesis is challenging because there are unclear points regarding homocarnosine supplementation such as blood stability and permeability across the blood-brain barrier.

Objective: To determine if oral homocarnosine administration can increase GABA and homocarnosine levels in blood and the brain.

Methods and Results: ICR mice were orally given homocarnosine (2.12 g/kg body weight) through gavage method for 4 weeks. Carnosine and GABA as the homocarnosine derivative and substrate, respectively, were used as comparisons. Peptide and amino acid levels in plasma and brain were measured by using liquid chromatography-mass spectrometry. As expected, in the control group, GABA was present in trace amount (0.18 ± 0.06 µM), while homocarnosine was not detected. By giving orally homocarnosine, GABA, and carnosine, plasma GABA was significantly increased (0.33 ± 0.10, 0.40 ± 0.09, and 0.30 µM ± 0.09, respectively, vs. control, P< 0.05). However, only homocarnosine administration could significantly increase brain GABA levels (1.33 ± 0.08 (control) vs. 1.67 ± 0.28 µmol/g, P = 0.016). Both homocarnosine and carnosine administrations significantly increased its own levels in the brain (230 ± 66 (control) vs. 500 ± 114 (homocarnosine) nmol/g, P = 0.0003 and 103 ± 35 (control) vs. 156 ± 36 (carnosine) nmol/g, P = 0.021). GABA administration significantly increased brain homocarnosine levels (230 ± 66 (control) vs. 384 ± 47 nmol/g, P = 0.0009), but not carnosine levels.

Conclusion: This study demonstrates that oral homocarnosine administration can increase GABA and homocarnosine levels in both blood and the brain. The finding will lead to the development of nutritional interventions for increasing brain GABA and homocarnosine for promoting brain health.

The effects of lactate treatment on neuronal differentiation and gene expression profiles in human and mouse neuroblastoma cell lines.

Yidan Xu[1], Joji Kusuyama[1], Ryoichi Nagatomi[1]

1. Tohoku University (Japan)

Background and objectives: Lactate serves as the major glucose alternative and adequate energy supply in brain and involved in neuronal functions including neuroplasticity and memory consolidation. Lactate is accumulated in fetal brain during gestational stage, indicating the key roles of lactate for brain development and neuronal differentiation. Recent reports show that lactate functions as a signaling molecule to regulate gene expression and protein stability. However, the roles of lactate signaling in neuronal cells remains unknown.

Methods: Here, we investigated the effects of lactate on neuronal differentiation of mouse and human neuroblastoma cells. SH-SY5Y cells, a human neuroblastoma cell line, were induced to differentiate by retinoic acid with or without 30 mM lactate for 1-6 days. RNA-seq was performed in lactate-treated SH-SY5Y and Neuro2a, mouse neuroblastoma cell line.

Results: Intracellular concentration of lactate was significantly increased by lactate supplementation. 30 mM Glucose treatment did not affect intracellular lactate levels. Lactate stimulation promoted the neuronal differentiation characterized by neurofilament-H and beta-tubulin 3 positive area, length and continuous growth rates of neurites outgrowth at day 4 and 6, and increased protein expression of neuronal maker including neuron specific enolase at day 17. NDRG family member 3 (NDRG3), a lactate-stabilized protein against proteasomal degradation, was highly expressed by lactate treatment. We found 900 differentially expressed genes (DEGs) between lactate-treated and untreated SH-SY5Y and 6447 DEGs between lactate-treated and untreated Neuro2A. Scatter plot analysis showed a good correlation of SH-SY5Y and Neuro2A (correlation coefficient r=4.14). Over representation analysis of the highly ranked human-mouse gene pairs showed the pathways upregulated by lactate treatment including extracellular matrix organization, integrin cell surface interactions, hemostasis, neutrophil degranulation and response to elevated platelet cytosolic calcium. The pathways downregulated by lactate treatment including eukaryotic translation initiation, response of eIF-2-alpha kinase (GCN2) to amino acid deficiency, selenoamino acid metabolism, regulation of expression of slits and Roundabouts, signal recognition particle dependent co-translation protein targeting to membrane. Furthermore, neuronal system pathway was also significantly upregulated in lactate-stimulated SH-SY5Y and Neuro2a.

Conclusions: Our study demonstrates the promotive effects of neuronal cell differentiation and multiple regulatory roles in neural function of human and mouse neuroblastoma cells.

PAB(T7-247)

Effect of red bean paste intake on the maintenance of instantaneous power and endurance during exercise of university student athletes.

Hitomi Fukuda[1], Michiko Katsukawa[1], Satoko Aoto[1], Kanae Yamagami[1], Hiromi Shinno[1]

1. Tezukayama Gakuin University (Japan)

Background and Objectives: The components of red bean paste are specialized for carbohydrate. Accordingly, people who play sports such as marathon take red bean paste to supplement carbohydrate during exercise. Therefore, we investigated the effect of red bean paste intake on the maintenance of instantaneous power and endurance during exercise among university student athletes.

Methods: The red bean paste contained energy; 100 kcal, prptein;1.3 g, fat; 0.1 g, carbohydrate; 24.0g and salt; 0.15g respectively, per 55g of packet. University student athletes were ingested the red bean paste at the beginning or end of exercise load. In the physical data measurement, the instantaneous force was measured by repeated side jumps, and the endurance was measured by a 20m shuttle run (round-trip endurance running). The blood glucose level was measured using a self-monitoring device.

Results: Intake of red bean paste in the beginning of exercise, their instantaneous power and endurance remained unchanged. However, intake of this paste in the end of exercise, which had a significant effect of endurance. A group which was less than 95 times in shuttle run was significant increase in the times of shuttle run, and blood glucose levels was increased. When red bean paste was ingested, the peak blood glucose level was slower and the concentration was lower than that of sugar solution.

Conclusions: During exercise, sugar consumption becomes active and the blood glucose level drops faster, so by taking red bean paste about 10 minutes before the endurance declines due to fatigue. It is thought that sugar is supplemented and the blood glucose level rises, which is expected to improve endurance. In addition, since the rise in blood glucose level is milder than that in sugar solution drinks containing white sugar, high-concentration sugar is used without raising the blood glucose level to a level that causes insulin shock due to the effects of dietary fiber and polyphenols contained in red bean paste. It was suggested that red bean paste could be taken.

Protein-energy nutritional status of moderately low protein intake-sago diets compared to sufficiently protein intake-rice diets in well-nourished lowlanders in Papua, Indonesia

Yasmin A Syauki[1,2], Aki Ogawa[3], Uli Rina Pelegia Simanjuntak[2], Ingrid Gloria Mangiwa[2], Miki Doi[1], Suzumi Kageyama[1], Rikako Inoue[1], Nurpudji A Taslim[2], Yasuyuki Irie[1]

1. Okayama Prefectural University (Japan), 2. Hasanuddin University (Indonesia), 3. Konan Women's University (Japan)

Background and objectves: Protein inadequacy is prevalent in developing countries because of the high consumption of starchy staple foods. Sago, as a staple food in Papua Province, was eaten with less protein. This study aimed to analyze the nutritional status of protein-energy in well-nourished adults of the moderately low protein in-take (MLP)-sago group compared to the sufficient protein intake (SP)-rice group, in lowland Mimika, Papua.

Methods: This cross-sectional-analytic study was conducted on 50 participants. Twenty-four-hour food recall, body composition, albumin, and complete blood count were used to assess the nutritional status. Results: There were no differences in the body compositions and albumin levels between the MLP-sago and SP-rice groups. Multivariate linear regression showed that the mean corpuscular volume (MCV) (β = -0.524, *P* = 0.007) was a predictive factor for albumin in the sago group, while in the rice group, hemoglobin (β = 0.354 *P* = 0.089) and white blood cell counts (β = 0.396, P = 0.059) were predictive factors.

Conclusions: The MLP-sago and SP-rice groups exhibited no differences in the body and visceral protein; however different predictors of albumin were found be- tween the groups, suggesting an adaptive mechanism in the MLP-sago group to maintain normal albumin levels.

Hepatoprotecive effects of *Lycium barbarum leave's* ethanol extracts in non-alcoholic fatty liver disease models and HepG2 cell

Sun Yung Ly[1], Han Sol Lee[1]

1. Chungnam National University (Korea)

Background and objectives: The purpose of this study was to explore the efficacy of the material to develop a food material for the treatment of NAFLD usingan animal model of non-alcoholic fatty liver disease (NAFLD).

Methods: The material used in the experiment was extract of *Lycium barbarum's* leaves (LBL) with chlorophyll removal. This material has also been reported to have excellent anti-oxidant and anti-microbial activity in our previous study. In this study, we estimated the anti- fatty liver disease effect of LBL in NAFLD animal model and in HepG2 cell induced trilyceride accumulation with palmitate.

Results: There was no difference in serum TG and total cholesterol concentrations, and ALT and AST activities were significantly decreased compared to the control group. Compared to the liver tissue of the control group, the size and number of fat cells were significantly decreased in the LBL-treated group. Both TG and TC contents of liver tissue were significantly decreased in the LBL-treated group compared to the control group. As a result of WST assay measurement in HepG2 cells, toxicity was not observed up to a concentration of 1000 μg/mL. As a result of ORO staining, compared with the control group, fat accumulation was reduced in a concentration-dependent manner in the LBL group. It had a concentration-dependent effect and showed anti-fatty liver efficacy.

Conclusions: The ethanol extract of *Lycium barbarum*'s leaves from which chlorophyll has been removed appears to have anti-fatty liver efficacy, and the potential for development as a functional material was confirmed.

Keyword: *Lycium barbarum*'s leaf, Hepatoprotecive effects , non-alcoholic fatty liver disease

Adenosine Derivatives-Enriched Cordyceps militaris Extract Shows ENT1-mediated Transport and Induces Autophagic Cell Death via AMPK-mTOR Signaling Pathway

So Young Yoon [1], Anders M Lindroth [2], Soyoung Kwon [1], Soo Jung Park [3], Yoon Jung Park[1]

1. Ewha Womans University (Korea), 2. National Cancer Center (Korea), 3. Woosuk University (Korea)

Background and objectives: Cordyceps militaris Extract (CME) is mainly composed of adenosine derivatives, including 3'-deoxyadenosine, as known as cordycepin. The cytotoxic effects of CME and cordycepin have been reported, but the underlying molecular mechanism is yet clear. In this study, we analyzed the molecular mechanism of CME and cordycepin to have their cytotoxic effects in vitro and vivo.

Methods: Human ovarian cancer cells (A2780, SKOV3, OVCAR3, and TOV112D) were treated with CME or cordycepin for 48 h to perform three separate viability assays. To evaluate

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

the cytotoxic effect of CME and cordycepin in vivo, BALB/c nude mice were injected subcutaneously in the back next to the right hind leg with A2780 cells. A low and high dose of CME, cordycepin (25 mg/kg) or PBS were intraperitoneally injected for 12 days. Candidate macromolecular targets of adenosine derivatives (cordycepin and N-(2-hydroxyethyl)adenosine) in CME were predicted using the SwissTargetPrediction tool. Cellular signaling pathways were observed by docking experiments and signal transduction proteins with nitrobenzylthioinosine (NBTI), SCH 58261, PSB 603, Compound C, and 5-Iodotubercidin (5'-ITU). The relevance of potential targets to ovarian cancer was explored using publicly available web-based data (cBioPortal and Human Protein Alas).

Results: CME and cordycepin treatments effectively resulted in cancer cell death by showing significant reduction of cell viability and tumor sizes in xenograft mice. Inhibition of ENT1 suppressed the cell death, while that of Adenosine receptor 2A and 2B did not alter cell viability regardless of their effects on cAMP production. The results suggested that functional ENT1 transporting CME and cordycepin into the cytosol was required for effects of CME and cordycepin. The uptaken CME and cordycepin increased phospho-AMPK and inhibited mTOR activity, and subsequently led to autophagic cell death. Inhibition of AMPK reversed effects of CME and cordycepin on cell viability, indicating that AMPK activation mediated CME and cordycepin effects. According to the in-silico data, AMPK β and γ subunit genes among the seven AMPK subunit genes showed significant correlation between survival probability and mRNA expression level in cancer patients.

Conclusions: Our data suggest that adenosine derivatives may be an effective therapeutic intervention through ENT1-AMPK-mTOR.

Effect of a ginger-containing beverage on peripheral circulation and cold sensitivity in healthy subjects

Asumi Wano[1], Masaki Taga[1], Yuiko Tsuruno[1], Naoko Inamura[1], Reiko Takanashi[2], Takehiko Kaneko[1]

1. Wayo Women's University (Japan), 2. Wayo Women's University (Japan)

Background and objectives: Various functional foods such as ginger are expected to improve peripheral circulation. One of the Japanese beverages made from wine vinegar, ginger juice, and molasses is also used as a seasoning. We examined the effects of two weeks of drinking this product on peripheral circulation.

Methods: Sixteen healthy participants (age, 64.8 ± 13.0 y: 2 males and 14 females) were recruited. They were required to drink a ginger-containing drink daily for 14 days. The following experiments were performed on days 1 and 14. Capillaries were observed near the nail matrix of the index finger of the hand using capillary microscope (SC-10, At co., Ltd, Osaka). Associated analysis software was used to examine the number, length, thickness, and clouding of capillaries. On the scheduled date, changes in skin temperature of the back of hands and index finger tips were assessed 20 minutes after drinking beverage using Thermography camera (FLIR E85, Teledyne FLIR LLC, U.S.A). Taste preferences such as bitter, sweet, salty, sour and umami were evaluated after 14days. We also used a self-administered questionnaire to ask about peripheral coldness and numbness.

Results: The most highly rated taste was sourness, followed by umami and sweetness. In the observed field of view, the capillary microscope showed an increase average number of capillaries and their total length. In 4 of the 14 evaluable cases (28.6%), the number of sites with elevated peripheral skin temperatures increased after 14 days. According to the questionnaire survey, both peripheral coldness and numbness were evaluated better after drinking.

Conclusion: Drinking tested beverage made from wine vinegar, ginger juice, and molasses for 14 days may contribute to improved peripheral circulation and cold sensitivity.

Anti-allergic effect of onopordopicrin containing Japanese leaf burdock

Honoka Ishikawa[1], Akihiro Maeta[2] , Kyoko Takahashi[2]

1. Mukogawa Women's University Graduate School (Japan), 2. Mukogawa Women's University (Japan)

Background and objectives: Japanese leaf burdock *Arctium lappa* is a one of specialty vegetables at Osaka. The stems and leaves of Japanese leaf burdock are edible and are often fried (Kakiage), sauteed and simmered. Japanese leaf burdock has a strong anti-allergic effect. Furthermore, we revealed that the anti-allergic compound in Japanese leaf burdock was onopordopicrin (OPP). OPP is classified as the sesquiterpeneoid germacranolide and has some functions such as anti-ulcerogenic, anti-inflammatory, anti-bacterial and anti-proliferative activities. We investigated the anti-allergic mechanism of OPP.

Methods: The leaves of Japanese leaf burdock were freeze-dried and extracted with 70% ethanol. The extract was fractionated by the ethanol stepwise (10%, 20%, 40% and 80%) method using an HP-20 column. Moreover, the 80% ethanol eluted fraction was refined by preparative thin-layer chromatography and high-performance liquid chromatography due to purify OPP. The suppression of degranulation after the allergen stimulation and the Ca^{2+} ionophore (A23187) were evaluated by the inhibition of β-hexosaminidase releases in a rat

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

basophil leukemia cell which could initiate IgE–FcεRI interactions and subsequently induce a model reaction of type I allergic responses. Moreover, after the allergen stimulation, the inhibition of Ca^{2+} influx into cells and the suppression of inflammatory mediator releases were measured.

Results: The purified OPP elicited a concentration-dependent inhibition of degranulation after the allergen stimulation. Furthermore, the degranulation by A23187 also were suppressed by the purified OPP. However, the purified OPP did not inhibit the Ca^{2+} influx into cells after the allergen stimulation. The supernatant concentrations of tumor necrosis factor-α, prostaglandin D_2, and leukotriene B_4 after the allergen stimulation in the purified OPP were lower than those in a control.

Conclusions: Future, we'll clarify the effect of OPP to the intracellular signal transduction after an allergic reaction.

Keyword: antiallergic components, onopordopicrin, RBL-2H3 cell

Epigallocatechin gallate enhances ghrelin secretion from the gastrointestinal tract and increases NPY gene expression in the hypothalamus

Hideyuki Sone[1], Aki Takizawa[1], Yurika Goto[1], Ayaka Watanabe[1], Shin Kamiyama[1]

1. University of Niigata Prefecture (Japan)

Background and objectives: Epigallocatechin gallate (EGCG) is a catechin (natural polyphenol) found in green tea that has many biological functions; some studies have shown that EGCG suppresses feeding and reduces body weight in mice and rats. However, there are no detailed studies on the effects of EGCG on peripheral feeding-regulating hormone release. Therefore, we examined how EGCG affects the release of peripheral feeding-regulating peptides.

Methods: C57BL/6j mice were used as experimental animals, and 200 μg of EGCG was administered intraperitoneally. Blood was collected from the tail vein 20, 60, and 180 min after administration. Plasma concentrations of insulin, leptin, cholecystokinin, and ghrelin were measured by enzyme immunoassay. The hypothalamus was removed from the brain and gene expression of NPY and POMC were measured by real-time RT-PCR. In addition, the direct effects of EGCG on cholecystokinin and ghrelin secretion were examined by gastrointestinal perfusion.

Results: Plasma cholecystokinin and ghrelin concentrations were significantly reduced and increased, respectively, by EGCG compared to controls, but there were no differences in plasma insulin and leptin between the groups. Hypothalamic NPY mRNA level was increased 2-fold by EGCG, but POMC mRNA level was not altered. In gastrointestinal perfusion, ghrelin secretion was significantly increased by EGCG, but cholecystokinin secretion was not clearly altered.

Conclusions: These results indicate that EGCG enhances ghrelin secretion from ghrelin-producing cells in gastrointestinal tract and increases NYP gene expression in the hypothalamus, suggesting a feeding-promoting effect of EGCG.

Keyword: Epigallocatechin gallate, ghrelin

PAB(T7-254)
Effects of Alaska pollack protein intake on skeletal muscle mass and strength in healthy older women

Eriko Yoshida[1], Hiroyasu Mori[2]>, Yasunobu Tokuda[3], Kenji Uchida[1]>, Munehide Matsuhisa[2]

1. Food Function R&D Center, Nippon Suisan Kaisha (Japan), 2. Diabetes Therapeutics and Research Center, Institute of Advanced Medical Sciences, Tokushima University (Japan), 3. Hyogo Himeji Welfare Community, Nonprofit Organization (Japan)

Background and Objects: We have reported that the effect of Alaska pollack protein (APP) compared with whey and soybean protein intake on fast-twitch muscle hypertrophy in animal studies. However, the effect of long-term intake of APP on the increase in skeletal muscle mass, muscle strength, and physical function in the elderly has not been clarified so far. The purpose of this study is to evaluate the effects of APP intake on skeletal muscle mass, muscle strength, and physical performance among healthy community-dwelling older Japanese women.

Methods: In this double-blind randomized controlled trial, healthy women > 64 years old aged were allocated into two groups: the an APP intake intervention group and the a whey protein intake placebo (PLA) control group. Participants ingested the test protein meals (4.5 g of protein per serving) daily for 24 weeks. Baseline and intervention between-group differences were evaluated at 4, 12, and 24 weeks, including changes in skeletal muscle mass index (SMI) and muscle strength.

Results: There were no between-group differences in the nutritional status, total energy, total protein, and or food intake at baseline and at 12 and 24 weeks. A significant group-by-time interaction was identified for SMI (12 weeks, Pp=0.029; 24 weeks, Pp=0.013) and knee extension strength (12 weeks, Pp=0.012; 24 weeks, Pp=0.021) at 12 and 24 weeks. At 12 and 24 weeks of the intervention, the rate of change increased in the SMI, and knee extension strength was significantly higher in the APP group than in the PLA group (SMI: 12 weeks, pP=0.030; 24 weeks, pP=0.011; knee extension strength: 12 weeks, pP=0.010; 24 weeks, pP=0.015).

Conclusion: Daily APP intake can increase skeletal muscle mass and lower-extremity muscle strength in healthy older women more than whey protein intake. Therefore, APP intake can be proposed to prevent sarcopenia in older adults.

Hydroxylated soy isoflavones exhibit anti-diabetic properties via the inhibition of alpha-glucosidase and sodium-dependent glucose transporter SGLT1

Kai Luersen[1], Keita Chikamoto[2], Ilka Gunther[1], Takahiro Furune[2], Daisuke Nakata[2], Yukiko Uekaji[2], Naoto Hiramatsu[3], Yoshiyuki Ishida[2], Keiji Terao[2], Gerald Rimbach[1]

1. University of Kiel (Germany), 2. CycloChem Bio Co., Ltd (Japan), 3. Toyo Hakko Co., Ltd (Japan)

Background and objectives: The prevalence of type 2 diabetes (T2DM) is increasing globally. Controlling postprandial hyperglycemia by dietary means is crucial for the prevention of T2DM. Blood glucose levels are determined by various factors including food constituents and food matrix, carbohydrate hydrolyzing enzymes (e.g. alpha-amylase, alpha-glucosidase), glucose transporters and hormones. Although there is some evidence that soy-derived isoflavones such as genistein and glycitein may exhibit antidiabetic properties, little is known to what extent their corresponding hydroxylated metabolites including 8-hydroxy genistein (8OHGen) and 8-hydroxy glycitein (8OHGly) may affect glucose metabolism. Hydroxylation of isoflavones mainly occurs via food fermentation as well as phase I metabolism in the liver.

Materials and Methods: Alpha-amylase and alpha-glucosidase inhibitory activity of a soy isoflavone extract rich in 8OHGen (34% of total isoflavones) and 8OHGly (9 % of total isoflavones) was determined *in vitro* by applying a disc and spectrophotometric assay, respectively. Acarbose was used as a positive control. By mounting Caco2 cells on Ussing chambers we determined the effect of the soy isoflavone extract on sodium-dependent glucose uptake via the glucose transporter SGLT1. Phlorizin was used as a positive control.

Results: *In vitro* alpha-amylase activity was not changed due the soy isoflavone extract. However, we observed a concentration-dependent inhibitory effect of the soy isoflavone extract on alpha-glucosidase activity with statistical significance at a concentration of 10 µg/ml. The IC_{50} value of the isoflavone extract was estimated to be 78.6 µg/ml. Compared to the positive control acarbose (IC_{50} = 493 µg/ml) the soy isoflavone extract was six times more potent in inhibiting alpha-glucosidase. Adding the hydroxy-isoflavone-rich extract at a concentration of 1 µg/ml to Caco2 cells substantially lowered the glucose-induced short circuit current from 9.24 ± 1.73 to 3.63 ± 0.70 µA/cm^2 in the Ussing chamber experiments. This represents a SGLT1 inhibition of approximately 60%.

Conclusion: Our data indicate that a soy isoflavone extract rich in 8OHGen and 8OHGly exhibits potent antidiabetic properties by inhibiting alpha-glucosidase and SGLT1 *in vitro*. Present *in vitro* data should be verified in *appropriate in vivo* studies including laboratory rodents and humans.

Keyword: soy, isoflavones, hydroxylation, bioactivity, glucose metabolism

Inhibitory effects of amber extract on mast cell-mediated allergic reactions

Redoyan Refli[1], Reiko Takeda[1], Kazuma Okazaki[2], Marie Sekita[2], Kazuichi Sakamoto[1]

1. University of Tsukuba (Japan), 2. Kohaku Bio Technology Co., Ltd (Japan)

Background and objectives: Amber is a fossilized tree resin and has been traced in traditional medicines used in Russia and China. In the recent studies, amber extract has been shown the potential to treat and prevent Alzheimer's disease, inflammation-related diseases, and obesity-related diseases. Allergic diseases are inflammatory diseases that have become a global clinical health problem. However, there is still a limited report about amber extract functionality on allergic diseases. Therefore, in this study we aim to evaluate the anti-allergy effects and investigate the mechanism of anti-allergy function of amber extract on RBL-2H3.

Methods: The RBL-2H3 cells were treated with different type of concentration of amber extract. The toxicity of amber extract was conducted using MTT assay test. The RBL-2H3 cell were stimulated with the allergens, PMA/A23187. β-hexosaminidase is used as a marker to measure the efficacy amber extract in preventing mast cell activation and degranulation. ROS generation was also evaluated. The effect of amber extract on cytokines key mediators' production (IL-4, COX-2, p -38, Akt, and JNK) were also investigated.

Results: The result showed that amber extract up to 50 µg/mL has no cytotoxic effect on the RBL-2H3 cells. Treatment with amber extract have significantly suppressed the release of β-hexosaminidase in the dose dependent manner especially at 50 µg/mL concentration. Furthermore, amber extract suppressed the significantly increased amount of intracellular ROS stimulated by PMA/A23187. We also found that amber extract inhibited the increase levels of allergy associated cytokines (IL-4 and COX-2) in a dose dependent manner. In addition, amber extract tends to inhibit the increase of p-38, Akt, and JNK production.

Conclusion: Amber extract was found to suppress the release of β-hexosaminidase and the increased of ROS generation. Amber extract significantly inhibited the increase levels of allergy associated cytokines. Amber extract tends to inhibit the increase of p-38, Akt, and JNK production (MAPK's key mediator). MAPKs phosphorylation are also crucial events in the allergic inflammation response. Taken together, these results suggest that amber extract exerts anti-allergic effects by inhibition of MAPK phosphorylation. These results indicate that amber extract may be a promising new anti-allergic inflammatory agent

Protein Content and Amino Acid Profile of *Moringa oleífera* leaf and Its Protein Concentrate

Ahmad Syazrin Roslan[1], Nur Haleeda Elias[1], Amin Ismail[1]

1. University Putra Malaysia (UPM) (Malaysia)

Background and objectives: Protein is the major macronutrient present in the primary building block of body tissues and an essential nutrient for human body development. Apart from animal sources, plant proteins started gaining attention as a potentially healthier alternative to cover the daily protein recommendation (Richter et al., 2015; Chéreau et al., 2016). *Moringa oleífera*, also known as horseradish tree, is a native plant of India that has been widely introduced to other Asian countries such as Thailand, Malaysia, and the Philippines. The leaves of the plant are reported to have a high nutrient composition of protein, essential amino acids, and other bioactive compounds which can improve human health status (Mishra et al., 2020). Hence, this study focuses on determining the protein content and amino acid profile of raw and cooked *M. oleífera* leaves, and its leaf protein concentrate (LPC).

Methods: Protein content analysis was done using the Kjeldahl method (AOAC, 2000). The crude protein content is expressed as a percentage (%). Amino acids profile was quantified using HPLC with Fluorescence Detector (Azilawati et al., 2015). The amount of essential and non-essential amino acids were expressed as milligram per gram of sample (mg per g). One Way ANOVA with Tukey's posthoc test was used to determine significant differences in protein content between samples.

Results: The protein content of the samples was determined and statistical analysis showed a significant difference between the samples. LPC has the highest protein content (42.4 % ± 0.5869), followed by raw (35.75 % ± 1.378), and cooked leaves (30.38 % ± 0.536). The amino acid profile of the samples was determined. The most abundant essential amino acid detected in raw and cooked leaves was Lycine (84.22 mg in raw sample and 85.05 mg in cooked sample), and Leucine (97.14 mg in LPC). Methionine has the lowest amount detected in the samples. The most abundant non-essential amino acid detected was Glutamic acid while Cysteine was the lowest.

Conclusion: These findings highlight the importance of *M. oleífera* leaves as a source of protein, with particular nutritional significance because they may fulfill the protein and energy requirements of humans.

Lipid metabolism improving effect of fermented tea made by mixing of unripe Satsuma mandarin (*Citrus unshiu*) an third cropped green tea leaves in rats

Daiki Umed[1], Komei Hotta[1], Shizuka Hase-Tamaru[1], Aoi Tsuchihashi[2], Bungo Shirouchi[2], Kazunari Tanaka[2]

1. Fukuoka Institute of Technology (Japan), 2. University of Nagasaki (Japan)

Background and objectives: Satsuma mandarin is most consumed citrus fruit in Japan. Unripe and inedible Satsuma mandarin (USM) is unutilized and discarded despite USM is rich in flavanone glucosides such as hesperidin and narirutin exerting the improvement effect of lipid metabolism. On the other hand, green tea is also most popular beverage in Japan. Third cropped green tea leaves (TGT) is poor quality, so linger on the market. To make effective use of these unused resources, we have manufactured and developed novel tea leaves made by mixing and fermenting of USM and TGT. In the previous study, we revealed that the hot water extract of the mandarin tea leaves, mandarin tea beverage (MTB), has anti-obesity effect in mice. In this study, we investigated the effect of quantitative administration of MTB on lipid metabolism in rats.

Methods:To obtain MTB, 2 g of mandarin tea leaves were extracted with 100 mL of hot water for 5 minutes. Male Sprague-Dawley rats (4-5 weeks old) were fed diet ad libitum prepared according to AIN-93G composition containing 15% of fat and 0.5% of cholesterol for 1 month. Meanwhile, 2.5mL/100g body weight of water or MTB were administrated every other day. At the end of feeding period, energy expenditure derived from exhaled gas were measured for 24 hours by a mass spectrometer for biogas analysis. After anatomization, serum lipid, glucose, hormones involved in obesity, and lipase activity were analyzed with commercial kits. Hepatic lipid and glycogen levels and lipid excretion into feces were also measured.

Results: Body weight and white adipose tissue weight tended to decrease by MTB treatment. Administration of MTB significantly lowered hepatic cholesterol and triglyceride concentrations, serum cholesterol levels, and serum lipase activity. Serum bile acid level and liver functional markers (AST and ALT) tended to lower. The consumption of carbohydrates as energy during the feeding (dark period) was promoted by MTB administration.

Conclusions: These results suggested that MTB could prevent hepatic lipid accumulation and exert cholesterol-lowering effect. Suppression of lipolysis and promotion of carbohydrate consumption may contribute to anti-obesity effect of MTB.

Active compounds of *Petasites japonicus* Maxim. flower bud extract suppress postprandial blood glucose elevation in mice

Miki Hiemori-Kondo[1], Maho Yamaguchi[1], Yuuna Haruki[1], Mika Nii[2]

1. Tokushima Bunri University (Japan), 2. Tokushima Agriculture, Forestry and Fisheries Technology Support Center (Japan)

Background and objectives: Although extracts from *Petasites japonicus* exhibit a variety of biological activities, information regarding its antihyperglycemic effects is scarce. Thus, we investigated the inhibitory effects of an 80% ethanol extract of *P. japonicus* flower buds on postprandial hyperglycemia and identified its active compounds

Methods: We prepared an 80% ethanol extract from the powder of freeze-dried flower buds harvested in Tokushima, Japan, in spring 2017. We performed *in vivo* analysis using male Institute of Cancer Research mice to determine the suppressive effects of this extract on blood glucose elevations. Furthermore, we examined the suppressive effects of the active compounds present in fractions, obtained using the liquid–liquid extraction technique, which were then isolated using high-performance liquid chromatography, and identified and quantified via liquid chromatography-mass spectrometry. We also examined the effects of the extract against α-glucosidase prepared from rat small intestine acetone powder with maltose or sucrose as a substrate. Additionally, we compared the contents of the active compounds in extracts from flower buds, stems, and leaves.

Results: Compared with the control, oral administration of the flower bud extract (1,000 mg equivalent of powder/kg body weight) significantly suppressed blood glucose elevations before and simultaneously with glucose, maltose, or sucrose loading. The area under the curve for blood glucose levels was also significantly decreased. Moreover, simultaneous administration of the extract with starch significantly decreased glucose levels. The active compounds were identified as 5- *O*-caffeoylquinic acid, fukinolic acid, and 3,5-di-*O*-caffeoylquinic acid, and they inhibited α-glucosidase against maltose and sucrose. The highest concentration of these active compounds was in the flower buds, followed by leaves and stems.

Conclusions: Three compounds in the extract of *P. japonicus* flower buds were identified as potential suppressors of postprandial blood glucose elevation. They could help maintain glycemic control in cases of hyperglycemia and are potential candidates for the treatment or prevention of diabetes. Furthermore, the leaves of *P. japonicus* are a good source of these active compounds, representing a high-yielding unused resource.

Selenoprotein P regulates resistance to iron-dependent cell death by modulating selenium homeostasis in hepatocytes

Kotoko Arisawa[1], Moeka Natori[1], Yoshiro Saito[1]

1. Tohoku University (Japan)

Background and objectives: Selenium is an essential micronutrient responsible for antioxidant function, and its disruption of homeostasis is known to be a factor in lifestyle-related diseases such as type 2 diabetes. Selenoprotein P (SeP) is a major selenium-containing protein in human plasma and is mainly synthesized in the liver. It functions as a selenium-transporter to maintain antioxidative selenoenzymes in several tissues and plays a key role in selenium-homeostasis and antioxidative defense. Recent studies suggest that patients in the early stages of nonalcoholic steatohepatitis (NASH) have elevated levels of selenium and SeP in their blood, but its physiological significance is not clear. In this study, we focus on the liver as a major producing organ of SeP and elucidate pathophysiological function of the protein.

Methods: We established SeP-knockout HepG2 cells (SeP KO cells) using CRISPR/Cas9 system. Using these SeP KO cells, we compared the expression of major selenoproteins such as GPx1, 4, TrxR1 and SeP to that of SeP wild-type cells by western blotting and quantitative PCR. In vivo analysis was performed by generating SeP KO mice and analyzed the expression of those selenoproteins in the mice liver. We also examined whether SeP KO cells and mice are resistant to cell death caused by the ferroptosis inducers. Intracellular lipid peroxide and free iron production were observed using fluorescent probes to clarify the mechanism of resistance to ferroptosis in SeP KO cells.

Results: We found that knockout of SeP gene causes induction of GPx in hepatocytes *in vitro* and *in vivo*. Interestingly, ferroptosis-induced toxicity was reduced in SeP knockout HepG2 cells. Lipid peroxidation was decreased in SeP KO cells, as expected from the increase in GPx with antioxidant capacity.However, free iron, which promotes the fenton reaction, was also reduced unexpectedly.

Conclusions: These results indicate that genetic suppression of SeP was protective against peroxidative reactions in hepatocytes. It suggests that oversecretion of SeP might be negatively associated with antioxidative properties of liver via the regulation of selenium and iron homeostasis.

Identification of antioxidant components in purple cauliflower (*Brassicaceae oleracea var. botrytis)*

Yuu Saruta[1], Yuuki Maekawa[1], Miki Hiemori-Kondo[1]

1. Tokushima Bunri University (Japan)

Background and objectives: White cauliflower is a commonly consumed vegetable belonging to the *Brassicaceae* family and has several bioactive components. Colored cauliflowers contain high levels of plant pigments that have potent nutritional and health-promoting properties owing to their antioxidant activity. This study aimed to reveal the antioxidant components in purple cauliflower, a variety that differs from white cauliflower.

Methods: Purple and white cauliflowers harvested in Tokushima Prefecture in March 2022 were freeze-dried and powdered in a miller. Extracts were prepared from the powder in acetone/water/acetic acid mixture. Antioxidant activity of the extracts was determined using 1, 1-diphenyl-2-picrylhydrazyl (DPPH) radical scavenging assay. Purple cauliflower extract was fractionated using high-performance liquid chromatography to investigate antioxidant components, and the fractions that inhibited DPPH radical scavenging activity were determined. The isolated components in the active fractions were analyzed using liquid chromatography-tandem mass spectrometry and identified by comparing the ultraviolet-visible and mass spectral data from previous reports.

Results: The antioxidant activities of the purple and white cauliflower extracts were 65.1 ± 4.2 µmol of trolox equivalent/g of dry weight and 49.7 ± 5.0 µmol of trolox equivalent/g of dry weight, respectively. Two active peaks with maximum absorptions at 520 nm were observed in the chromatogram of the purple cauliflower extract. In positive mode mass spectrometry, the signal for one peak was m/z 1005, which produced the daughter ions m/z 961, 757, 535, 491, and 287. The other peak with m/z 859 produceed daughter ions of m/z 535, 491, and 287. These results indicate that anthocyanins, cyanidin 3-(coumaryl-caffeyl)glucoside-5-(malonyl)glucoside and cyanidin 3-sophoroside-5-(malonyl)glucoside, are the two antioxidant components. In addition, glucoiberin, a well-known antioxidant component, was detected.

Conclusions: Purple cauliflower extract had a higher antioxidant activity than white cauliflower extract. This study revealed that cyanidin 3-(coumaryl-caffeyl)glucoside-5-(malonyl)glucoside, one of the typical anthocyanins in purple cauliflower, is associated with the higher antioxidant activity of purple cauliflower extract, along with glucoiberin.

Fabrication and characterization of a novel H/J aggregates astaxanthin/ bovine serum albumin/ chitosan nanoparticles

Yingyuan Zhao[1,2], Shiying Xie[1], Qi Song[1], Di Chen[1], Ruifang Li[1], Ye Zhang[1], Hiroaki Oda[2]

1. Henan University of Technology (China), 2. Nagoya University (Japan)

Background and objectives:Astaxanthin is a hydrophobic carotenoid with various beneficial biological activities. Its use as a bioactive food and pharmaceuticals, however, is limited by its low-water solubility and chemical instability. Due to the terpene unsaturated structure, astaxanthin can self-assembly form H aggregates and J aggregates with different bioactive in certain conditions. Here, our research provided a new method for fabricating aggregates astaxanthin-loaded nanoparticles based on bovine serum albumin and chitosan nanocarriers for improvement of bioavailability

Method: The optimum preparation conditions of aggregates astaxanthin/ bovine serum albumin/chitosan nanoparticles (ABC-NPs) were studied. The properties and formation mechanism of ABC-NPs were characterized by dynamic light scattering (DLS), transmission electron microscopy (TEM), UV-vis spectra, Fourier transform infrared spectroscopy (FTIR) analysis, fluorescence spectra, and circular dichroism (CD).

Results: The resultant ABC-NPs with H-type aggregates astaxanthin (H-ABC-NPs) and J-type aggregates astaxanthin (J-ABC-NPs) were precise fabricated by molecular self-assembly and rotary evaporation, which effectively increase the water dispersibility and stability of astaxanthin. The H-ABC-NPs and J-ABC-NPs were both spheres with particle size around 320 nm 380 nm and positive surface zeta potentials around 25mV 32 mV, respectively. The UV-vis absorption band peaks λ_{max} at 388 nm and 565 nm exhibited the existence of two different H-aggregates and J-aggregates in ABC-NPs, respectively. H-aggregates were the face-to-face structure where the conjugated chains were closely packed and parallel oriented to each other, and J-aggregates were the head-to-tail structure where the aggregates were loosely packed and the coupled aggregates were weak. Moreover, the proposed formation mechanism of ABC-NPs was illustrated mainly by non-covalent interactions.

Conclusions: H-type aggregates and J-type aggregates astaxanthin were novelty capsulation in chitosan and bovine serum albumin (BSA) nanocarriers by molecular self-assembly. Both H-ABC-NPs and J-ABC-NPs were subspherical structure with the average hydrodynamic size less than 400 nm with positive charge. In addition, the encapsulated H or J aggregates astaxanthin exhibited relatively high encapsulation efficiency (both above 90%). Further work is underway to access the bioavailability of H-ABC-NPs and J-ABC-NPs *in vitro* and *in vivo*,which would be favor to the application of novel bioactives delivery systems in the field of nutrient and medicine.

Actual conditions and issue identification regarding health foods for women who wish to become pregnant

Yasuyo Wada[1], Hiroharu Kamioka[2], Misa Shimpo[3], Mikiko Shimada[4]

1. National Institute of Public Health (Japan), 2. Tokyo University of Agriculture (Japan), 3. The University of Nagano (Japan), 4. Kiryu University (Japan)

Background and objective: The number of infertility treatments has been increasing in recent years and will be partially covered by insurance starting in 2022, and the number of women who wish to become pregnant is expected to increase further in the future. Because the success rate of fertility treatment is not high, women who wish to become pregnant use all means other than infertility treatment. In particular, they often choose health supplements and other health products. However, there have been few reports on the actual conditions of what kind of health foods are being consumed by the women who wish to become pregnant, including those undergoing infertility treatment. Therefore, the purpose of this study was to clarify the actual situation and issues regarding health foods for pregnant women.

Methods: A web-based research company conducted a survey of pregnant women's attitudes and behaviors toward health foods. The survey was conducted by screening 20,000 women aged 25-39, married, and childless, of whom 900 were taking steps to conceive, had never been pregnant, and were currently consuming health foods.

Results:The age of the subjects was 33.6 ± 5.0 years, and they consumed two or more health foods as their age increased. The monthly cost per month spent on health foods increased with increasing age, and the cumulative cost for health foods to date also showed an increasing trend with increasing age. The percentage of respondents who knew or had heard of the "Dietary Guidelines for Pregnant and Nursing Mothers Starting Before Pregnancy" provided by the Ministry of Health, Labor and Welfare was 35%. Forty-one percent of the respondents were completely unaware of the classification of health foods. Folic acid was the most common nutrient consumed, while vitamin K was considered important by the younger generation. Forty-four percent of the respondents stated that the purpose of taking health foods was to increase the probability of pregnancy, and the percentage increased with age, while those who stated that it was for the health of the fetus in case of pregnancy were more likely to say it was for the health of the fetus at younger ages.

Conclusions: The study clarified the actual situation and issues related to health foods targeted at women who wish to become pregnant. The information necessary for pregnant women to select safe health foods was clarified, which may lead to the establishment of risk communication measures to ensure safety.

Effects of soy isoflavones, resistant starch and antibiotics in a letrozole treated polycystic ovary syndrome (PCOS) animal model

Shinji *Okada[2], Ryo Inoue[3], Mina Fujitani[4], Tomoko Ishijima[2], Taisei Shibutani[2], Keiko Abe[2,5], Taro Kishida[4], Geethika Savindhi Gammeddegoda Liyanage[2,1]*

1. School of Science, Business Management School (BMS) (Sri Lanka), 2. The University of Tokyo (Japan), 3. Setsunan University (Japan), 4. Ehime University (Japan), 5. Kanagawa Institute of Industrial Science and Technology (KISTEC) (Japan)

Background and Objectives: Polycystic ovary syndrome (PCOS) is the most common endocrine disorder found in women of their reproductive age. PCOS classical symptoms; menstrual irregularity, hyperandrogenism and polycystic ovaries have shown correlations with gut microbiota. In recent studies, various dietary interventions have been used as novel therapeutic approaches for PCOS. The main objectives of our study were to investigate if soy isoflavones, their metabolites are key effectors in lowering the severity of PCOS symptoms and if leaky gut is an important effector of PCOS pathogenesis.

Methods: 5 weeks old female SD rats were divided into 7 groups (n=8). PCOS-like symptoms were induced in 6 groups through oral gavage of letrozole for 3 weeks with simultaneous diet treatments. Control (C) and PCOS (L) groups received a control diet. LS, LR, LSR groups received diets with 0.05% soy isoflavones, 11% RS and a combination of both. LA and LSA groups were treated with an antibiotic cocktail and received the control and soy isoflavone based diets, respectively.

Results: LSR group contained a high concentration of soy isoflavones and equol and displayed a reduction in the severity of menstrual irregularity and polycystic ovaries. Bacterial genera such as, *Blautia*, *Dorea* and *Clostridium* were positively correlated with menstrual irregularity suggesting their effect in the significant reduction of the severity of menstrual irregularity in the resistant starch treated LR group. Compared to control group, L group contained a significantly high proportion of genes responsible for bacterial invasion into intestinal epithelial cells. The mRNA expression level of occludin was significantly high in the LSR group. Moreover, resistant starch treatment significantly increased butyric acid concentration. Antibiotic cocktail treated LA and LSA groups displayed leaky gut status with a significantly high Lipopolysaccharide Binding Protein (LBP) concentration and showed no considerable effects on reducing PCOS-like symptoms.

Conclusion: Soy isoflavone metabolites and resistant starch, together with gut microbiota modulations, decreased the severity of PCOS-like reproductive features by improving the gut barrier and through the effects of butyric acid. In conclusion, we suggest that dietary interventions and gut microbiota modulations could be effectively used in reducing the severity of PCOS reproductive features.

Role of urinary sodium excretion by *Saccharina japonica* extract in normotensive and hypertensive rats

Saki Maruyama[1], Yukiko Segawa[1,2], Ayaka Harui[1], Kanae Yamamoto[1], Hiroko Hashimoto[1,2], Tomoko Osera[1,3], Nobutaka Kurihara[1]

1. Kobe Women's University (Japan), 2. Osaka Seikei College (Japan), 3. Toyo University (Japan)

Background and objectives: One of the foods used for Japanese cuisine "Washoku" is brown algae, including *Saccharina japonica* (SJ). The extract of SJ (SJE, so-called "Dashi") is often used for soup stock. We previously demonstrated that the intake of SJ and SJE decreases blood pressure (BP) in 2-kidney, 1-clip hypertensive (2K1C) rats, while their intake does not decrease BP in normotensive rats. It is reported that intake of sodium alginate oligosaccharide and potassium, which are contained in SJE, increased urinary sodium excretion (UNaE). However, to our knowledge, it has not been reported the effect of SJE intake UNaE. In this study, we investigated the effects of SJE intake on UNaE in normotensive and hypertensive rats.

Methods: Male Sprague-Dawley rats (6 weeks) were treated with sham operation (SHAM) or clipping the left renal artery (2K1C). After surgery, rats were received a control diet (C) or a diet containing SJE with a normal-salt (0.7% NaCl) for 6 weeks. The amount of SJE used in the diet was extracted from the same amount of SJ in the 5% (w/w) SJ diet, which was previously observed with antihypertensive effects. Systolic BP (SBP) was measured by a tail-cuff method every week. At the end of the protocol, mean arterial pressure (MAP) was measured in each rat under anesthesia. In the last week, 24 hours of urine was collected through a simple metabolic cage to measure UNaE.

Results: Six weeks after the surgery, SBP was significantly higher in 2K1C-C than in SHAM-C (156±4 vs 131±2 mmHg, $P< 0.001$), and a significant decrease in 2K1C-SJE (143±2 mmHg) compared with 2K1C-C ($P< 0.05$). There was no significant difference between SHAM-C and -SJE (131±2 mmHg). The data of MAP were similar to SBP. UNaE was significantly higher in 2K1C-C than in SHAM-C (52.3±1.4 vs 44.2±2.4 mg/day, $P< 0.05$). SJE induced an increase in UNaE in both SHAM (64.2±3.4 mg/day, $P< 0.05$) and 2K1C (60.3±2.9 mg/day, $P< 0.05$). SJE intake increases Na^+ excretion into the urine in SHAM and 2K1C rats, and it may participate in lowering BP in a hypertensive state.

Conclusion: UNaE by SJE intake may contribute to alleviating BP-rise in hypertensive rats.

Comparison of bioactive compounds of sea grape extract (*Caulerpa racemosa*) on soxhletation extraction method and maceration-evaporation method

Noor Rezky Fitriani[1], Fahrul Nurkolis[1], Reza Sukma Dewi[1], Dian Aruni Kumalawati[1], Aldy Rahman Dharma Putra Sanjaya[1], Yan Nurrezkytaku A[1]

1. State Islamic University of Sunan Kalijaga (Indonesia)

Background and objectives: Sea grapes (*Caulerpa racemosa*) are easily found in various regions in Indonesia, including in the waters of Sumatra, Java, and North Sulawesi. This algae has properties as cytosine, antidiabetic, anti-inflammatory, and has a high antioxidant content of phenol groups. This study aimed to analyze the differences in the content of bioactive compounds in sea grape extract in the soxhletation extraction method and the maceration-evaporation method.

Methods: The making of sea grape extract (*Caulerpa racemosa*) begins with the process of cleaning and drying the sample, then it is ground into powder. Sea grape powder was extracted by soxhletation and maceration using 96% ethanol as solvent. The soxhletation process was carried out at a temperature of 70-80°C until it reached 3 cycles, while the maceration process was carried out for 3 x 24 hours and concentrated using a rotary evaporator.

Results: The result obtained in each extraction method was further determined for vitamin C content and total phenol content by UV-Vis spectrophotometer, and antioxidant activity was tested using the DPPH (1,1-diphenyl-2-picrylhydrazil) method. The results showed that the average vitamin C content of sea grape extract in the soxhletation method was 130 mg/100 g and the maceration-evaporation method was 830 mg/100 g. The average yield of total phenol content of sea grape extract with soxhletation and maceration-evaporation methods, respectively, was 96.95 mg GAE/g extract and 116.95 mg GAE/g extract. Meanwhile, sea grape extract with the soxhletation method had an antioxidant activity with an IC_{50} value of 55,489 g/ml, while sea grape extract using the maceration-evaporation method was 249,637 g/ml. Sea grape extract using the soxhletation method contains lower bioactive compounds than the maceration method because it passesthrough heating at high temperatures which make the compounds were easily damaged.

Conclusion: Based on this study, it can be concluded that the sea grape extract using the maceration method has a higher content of bioactive compounds than the sea grape extract using the soxhletation method. Thus, the extraction of sea grapes by the maceration method can be used to produce optimal content of bioactive compounds.

Protective effect of tea polyphenol and catechins on acrylamide induced cardiometabolic risk

Xuzhi Wan[1], Wei Jia[1], Pan Zhuang[1], Yu Zhang[1]

1. Zhejiang University (China)

Background and objectives: Polyphenolic antioxidants have been suggested to mitigate acrylamide formation during the thermal processing of food. However, their role in protecting the toxicity of exposure to acrylamide and the mechanism of action regarding profile alteration of biomarkers and metabolome remains unclear. The objective of this study was to evaluate the protective effect of tea polyphenol (TP) and catechins as its major antioxidant ingredients on the toxicity of acrylamide via the changes in biomarkers from metabolic profile analysis based on human and animal studies.

Methods: A total of 65 adults were randomized into four groups. Seventeen participants were served a personalized bag of potato chips with a placebo capsule, and the rest were required to consume the identical potato with the varied dose of TP capsule. Moreover, nontargeted urinary metabolomics analysis in acrylamide induced rats administered with and without catechins was conducted using ultra-high performance liquid chromatography linked with a quadrupole-orbitrap high-resolution mass spectrometry.

Results: Our present results showed that supplementation of TP and catechins promoted the excretion of N-acetyl-S-(2-carbamoyl-2-hydroxyethyl)- L-cysteine (GAMA) in urine. We also observed that epigallocatechin gallate (EGCG)/epicatechin (EC) intervention effectively decreased the conversion of acrylamide to glycidamide in rat blood. Metabolomics analysis showed acrylamide-induced metabolic disorders were improved via EGCG/EC supplement including glycolipid metabolism (Alanine, aspartate and glutamate metabolism and D-Glutamine and D-glutamate metabolism) and energy metabolism (tricarboxylic acid cycle). Besides, the EGCG supplement showed an evident effect on the cardiometabolic risk of exposure to acrylamide by regulating the critical metabolites, including phenylalanine and hippuric acid in phenylalanine metabolism.

Conclusions: Our finding revealed that TP and catechins supplement attenuated the toxicity of exposure to acrylamide by promoting the mercapturic acid detoxification pathway and thus increased urinary GAMA levels, which further led to lower HbGA levels in vivo. Moreover, we uncovered that EGCG/EC could improve the acrylamide-induced metabolic disorders in glutamate metabolism and tricarboxylic acid cycle by nontargeted urinary metabolomics analyses. Our findings shed light on the natural antioxidants that could be a therapeutic ingredient for preventing acrylamide-induced toxicity.

Intestinal absorption of heptapeptide QDGYMPW with anti-muscle atrophy effect in cells and rats

Kiyomi Ono[1]>, Weilin Shen[1], Reiko Nakao[2], Takeshi Nikawa[2], Toshiro Matsui[1]

1. Kyushu University (Japan), 2. Tokushima University (Japan)

Background and Objectives: Ubiquitination of growth factor receptors in muscle may cause muscle atrophy in bedridden and microgravity environments. As Cblin-like peptide (DGYMP) and QDGYMPW have an ability to inhibit the ubiquitination, the intake of these oligopeptides would be effective for prevention of muscle atrophy, while their bioaccessibility remains unclear. In this study, we thus tried to clarify the transportability of both peptides across Caco-2 cell monolayers and absorbability in Sprague-Dawley (SD) rats.

Methods: Synthetic DGYMP and QDGYMPW were used for 60 min-Caco-2 cell transport experiments at the concentration of 1 mM and for oral administration experiments to 8-week-old SD rats at a dose of 100 mg/kg. Basolateral solution collected at a time-schedule of 15, 30, 45, and 60 min and plasma samples from the tail vein, collected at 0, 15, 30, 45, and 60 min after the administration, were subjected to a LC-TOF/MS in positive ESI mode.

Results and Discussion: In Caco-2 cell transport experiments, DGYMP and QDGYMPW were detected from the basolateral side, with apparent permeability coefficients of and $3.2 \pm 0.4 \times 10^{-7}$ cm/s and $2.5 \pm 0.1 \times 10^{-7}$ cm/s, respectively. In oral administration experiments of both oligopeptides to SD rats, the heptapeptide QDGYMPW was successful detected in intact form at 15 min after the administration in rat circulatory bloodstream, and reached to a significant plasma level of 1.33 ± 0.32 pmol/mL-plasma at 60 min. Both *in vitro* and *in vivo* experiments revealed that the penta- and heptapeptides are an absorbable oligopeptide form.

Conclusion: This study provides the finding that anti-muscle atrophic oligopeptides can be intactly absorbed in the body.

Blueberry and Raspberry powders mitigate Caco-2 cell monolayer permeabilization induced by TNF-α through the modulation of the inflammatory and oxidative stress process

Mirko Marino[1], Samuele Venturi[1], Marco Rendine[1], Patrizia Riso[1], Marisa Porrini[1], Cristian Del Bo'[1]

1. University of Milan (Italy)

Background and objectives: The impairment of the intestinal permeability (IP) leads to a low-grade and systemic inflammation which represents a risk for chronic diseases development. It has been postulated that polyphenol-rich foods such as berries, may play a beneficial effect against an increased IP. The aim of the present study was to evaluate the effect of blueberry (BB) and raspberry (RB) on Caco-2 cell monolayer permeabilization, inflammation and oxidative stress.~

Methods: Caco-2 cell monolayer permeabilization was evaluated by using Transwell model, measuring transepithelial electrical resistance (TEER) and paracellular transport of FITC (Fluorescein-5-isothiocyanate)-dextran in the absence/presence of TNF-α pro-inflammatory stimulus (10 ng/ml) and with or without the supplementation of BB and RB powders tested at different concentrations (1 and 5 mg/ml) for 24 hours. The total polyphenols (TPs) content ranged from 12 to 60 µg/ml for RB and from 55 to 275 µg/ml for BB, while total anthocyanins (ACNs) content ranged from 3 to 15 µg/ml for RB and from 11 to 55 µg/ml for BB. The expression of tight junction (TJ) proteins, inflammatory (IL-6 and TNF-α) and oxidative stress (8-hydroxy 2 deoxyguanosine) markers were measured in the supernatants or cell lysate in accordance to the instructions reported in the ELISA kits.

Results: The results have documented that the incubation with BB and RB powders mitigated the loss of Caco-2 cell barrier integrity induced by TNF-α, reported as increased values in TEER and reduced values in FITC. However, this activity was dose and product dependent. In addition, a positive modulation of protein involved in IP such as claudin-1 and occludin was documented. Finally, BB and RB powders were able to counteract inflammation and oxidative stress.

Conclusions: Our findings suggest the potential role of BB and RB to counteract *in vitro* an impairment of IP induced by TNF-α as pro-inflammatory stimulus. This beneficial effect seems to be potentially carried out through a modulation of the expression of TJ proteins, and a reduction of the oxidative stress and inflammation.

Antifibrotic and tumor microenvironment modulating effect of date palm fruit (*Phoenix dactylifera L*) extracts in pancreatic cancer

Younis Baqi[1], Reem Al-Alawi[1,2], Mohammed S.S. Al-Hamdani[2]

1. Sultan Qaboos University (Oman), 2. Deutsches Krebsforschungszentrum (Germany)

Background and objectives:Date palm tree (*Phoenix dactylifera L.*) is one of the oldest crops in Southwest Asia and North Africa. In addition to, dates can be grown in Australia, southern Africa, South America, Mexico, and the United States. Date palm tree belongs to Arecaceae family (Angiosperms, monocotyledon) consisting of about 200 genera and more than 2,500 species. The aim of this study is to prepare and fractionate natural product extracts of the edible part of date fruit. The extracts and its fractions were investigated for antifibrotic and antiproliferative activities in tumor necrosis factor (TNF) stimulated PSCs.

Methods: Maceration method was employed to prepare four different extract of the date fruit utilizing a single solvent system including water, ethanol, acetone, and ethyl acetate. Column chromatography technique was used to fractionate the ethyl acetate crude extract using methanol/dichloromethane solvent system. PSCs were imaged using a Leica DM IRBE microscope. FN1 and α-SMA were determined using immunoblotting analysis. The antiproliferative activity of the date fruit extracts was determined based on the Resazurin assay, and DCFH-DA was used to measure the reactive oxygen species (ROS).

Results: Date fruit fractions reduced fibrosis, decreased PSC activity and reversed the PSCs' fibrotic phenotype. The results indicate the presence of a compound or mixture of compounds, which promote the reversal of PSCs to their quiescent state, detectable by suppression of the secretion of α-SMA.

Conclusion: The findings suggest a new approach for targeting pancreatic cancer through the modulation of PSC activity, thereby possibly enhancing the effect of known anticancer drugs. Moreover, date palm fruit appears to have chemopreventive activity protecting from pancreatic and probably other types of cancer.

The impacts of piperine on body composition and skeletal system

Ichiro Kaneko[1], Minori Uga[2]

1. University of Hyogo (Japan), 2. Tokushima University Graduate School of Biomedical Sciences (Japan)

Background and objectives: Several components in spice inhibit cytochrome P450 (CYP) isozyme activity. CYP3A4, a xenobiotic enzyme, is mainly expressed in the liver and intestine. A CYP3A4 mutation (gain-of-function) was recently reported to cause vitamin D-dependent rickets. Vitamin D is an important nutrient for bone and muscle function. Therefore, we hypothesized that certain spices could potentially contribute to maintain skeletal mass or function through vitamin D metabolism in the liver or intestine.

Methods: We compared the effect of curcumin or piperine, capsicin on CYP3A4 activity using a Luciferin-IPA assay. We also tested those vitamin D receptor-mediated transcriptional activity using a mammalian-2 hybrid assay. To clarify its physiologic activity, mice (C57BL/6J) were orally administrated piperine (20 mg/kg body weight) 3 times per week from 4 weeks to 10 weeks of age. Muscle mass was measured after mice performed the wire-hang test. Body composition was evaluated by micro-computed tomography. The calcium and phosphate concentration was measured using a Calcium-E Test or Phospha-C Test kit, respectively.

Results: Piperine administration significantly inhibited CYP3A4 activity in HEK293 or HCT116. Piperine also recovered the vitamin D receptor-mediated transcriptional activity inhibited by CYP3A4 overexpression. Mice administered piperine exhibited no change in body weight or food intake, but had a significantly lower subcutaneous fat mass. Piperine did not affect muscle mass, but the wire-hang time (indicating muscle strength) was significantly longer than that of control mice. In mice administered piperine, phosphate excretion was significantly increased and calcium excretion tended to increase. No change was detected in the plasma calcium and phosphate levels, or bone mineral density.

Conclusions: Piperine might inhibit vitamin D catabolism in the intestine (local action), thereby affecting calcium and phosphate absorption. Moreover, piperine is important for muscular strength without inducing muscle hypertrophy. Therefore, it may be beneficial toward preventing frailty and maintaining skeletal function. Further studies are needed to clarify the detailed molecular mechanisms of its actions. The effects of piperine in osteoporosis or muscle atrophy models will be evaluated in subsequent studies.

Effect of ingestion of powdered sword bean (*Canavalia gladiate*) on blood glucose levels in healthy young women.

Tomoko T. Asai[1], Shunsuke Higaki[2], Yukiko Sumida[3], Tomohisa Koyama[3], Masaki Taga[4], Yuichiro Takei[3], Takashi Murakami[3], Reiko Inai[1,3]

1. Nara Women's University (Japan), 2. Hokkaido Bunkyo University (Japan), 3. University of Kochi (Japan), 4. Wayo Women's University (Japan)

Background and objectives: Recently, it has been suggested that sword bean (*Canavalia gladiate*) has an anti-inflammatory effect and is expected as a functional food. In this study, to investigate the effect on healthy subjects who ingested the sword bean-powdered tea (hereinafter: sword bean) for 1 week, we compared the data from the time point before sword bean intake (described below as Before ingestion) with those from 1 week after ingestion of sword bean (After ingestion).

Methods: Healthy female volunteers (20-24 years, average body weight 57.9 kg) were separated into three groups (n = 3-5). Each group ingested 0.6, 1.2, 6.0 g of sword bean per day (0.2, 0.4, 2.0 g/meal), respectively. Sword bean was ingested before each meal (three meal per day) for a week. We analyzed biochemical examinations such as salivary IgA measurements and oral glucose tolerance test and assessed stress levels and body composition at Before- and After ingestions, respectively.

Results: There were no significant differences in body composition and biochemical tests between Before- and After ingestions. Stress indicators of After ingestion tended to be lower than those of Before ingestion in all groups. Postprandial blood glucose levels and the $AUC_{0\text{-}120}$ in After ingestion indicated a reducing trend compared to those in Before ingestion in all groups, showing the significant differences at 60 min after eating in the ingestion of 1.2 g per day and for fasting in the ingestion of 6.0 g per day ($p< 0.05$).

Conclusions: The results of present study indicated that intake of sword bean might suppress the levels of fasting and postprandial blood glucose, suggesting that the ingredients of sword bean enhance the ability to control blood glucose levels.

Estimation of the lipase inhibitory effects of the different herbal tea extracts

Mohammad Ariful Islam Bhuiya[1], Toshiya Matsumoto[2], Pinky Karim Syeda K. Fatema[2], Keisuke Yoshikiyo[2], Kaeko Murota[2]

1. Tottori University (Japan), 2. Shimane University (Japan)

Background and objective: Obesity has become a worldwide health problem and is the main risk factor for developing all types of metabolic disorders. Excess accumulation of body fat in obesity could be caused by many factors like sedentary lifestyle, consumption of high-fat diet, genetic predisposition and imbalanced energy metabolism. It is reported that suppressing lipase activity reduces hydrolysis of triglycerides into monoglyceride and fatty acids that helps for reducing fat absorption through the small intestine. Herbal teas contain various potentially bioactive phytochemicals and, in this study, their effects against obesity were investigated by estimating the polyphenol content and pancreatic lipase inhibitory effects.

Methods: Persimmon leaf tea and Manchurian wild rice (Makomo) leaf tea and others, which are made in Shimane prefecture, were prepared by hot water extraction. Polyphenol content was estimated by Folin-Ciocalteu methods with gallic acid as standard. To estimate the lipase inhibitory effects, porcine pancreatic lipase was reacted with triolein as standard substrate with or without tea extract and the liberated fatty acid were determined with GC-MS.

Results: It was observed that in these tea extracts polyphenol content were dependent on the amount of tea leaves and the heating time for extraction. When these herbal teas with similar polyphenol contents were compared, persimmon leaf tea showed the strongest inhibitory effect than other teas. The activity of persimmon leaf tea was dependent on its polyphenol content, whereas the effect of Makomo leaf tea was not correlated with its polyphenol content. There were also other teas found that showed potential for inhibiting pancreatic lipase.

Conclusion: Persimmon leaf tea showed to be highly active for reducing dietary fat digestion, indicating to be potentially beneficial for anti-obesity. Further study is necessary to reveal what compound is responsible for such effects. Makomo leaf tea and others will be also investigated further to estimate their potentials

PAB(T7-274)
Characterization and Isolation of Lactic Acid Bacteria Probiotic Candidates from Fermented Meats

Elvina Parlindungan[1], Gabriele A Lugli[2], Marco Ventura[2], Douwe van Sinderen[1], Jennifer Mahony[1]

1. University College Cork (Ireland), 2. University of Parma (Italy)

Background and objectives: With increasing public awareness for healthier lifestyle, there is growing market demand for functional foods/supplements which contain probiotics. Probiotics lactic acid bacteria (LAB) are defined as live microorganisms which confer health benefits to the host when administered in adequate amounts. The purpose of this study was to screen for novel probiotic candidate(s), as probiotic features and health benefits conferred, which are known to be strain-specific.

Methods:The biodiversity of 106 LAB isolates sourced from fermented meats was investigated using 16S rRNA and GTG_5 PCR fingerprinting. Antagonistic activity and production of organic acids were investigated against 22 distinct strains. Antibiotic susceptibility, hydrophobicity, auto-aggregation capacity, ability to withstand simulated gastric juice (0.3% pepsin), bile salt (0.3%), phenol (0.2 & 0.5%) and NaCl (1.5 to 3.5%) were assessed to select for probiotic candidates. Presence of bacteriocin-associated gene clusters and probiotic gene markers were analyzed. Two-way ANOVA verified with Tukey's multiple comparison tests was performed; a p-value of < 0.05 was considered statistically significant.

Results: *Lactiplantibacillus plantarum* was the most dominant species in the fermented meats. *L. plantarum* strains were found as the strongest lactate producer (106 mM to 158 mM). *L. plantarum* strains effectively inhibited all bacteria and fungal indicator strains tested. *L. coryniformis* subsp. *torquens* and *L. plantarum* displayed significantly greater hydrophobicity (31.2 to 42.2%) compared to *L. plantarum*, *L. sakei* and *P. acidilactici* (4.9 to 18.1%). *L. plantarum* strains showed highest auto-aggregation levels (63.6 to 69.0% at t = 24 h), highest tolerance to 0.3% bile salts, simulated gastric juice, phenol, and salt compared to strains of other species. Overall, *L. plantarum* 41G was identified as the most robust probiotic candidate possessing probiotic gene markers (*bsh*, *fbp*, *mub*) and also a bacteriocin producer.

Conclusions: Novel proposed probiotic candidate *L. plantarum* 41G was successfully isolated, characterized and potentially could be further developed into functional foods. This strain was the most susceptible to antibiotics (compared to other isolates belonging to the same species), with moderate hydrophobicity and auto-aggregation value, high tolerance to bile salt, phenol and NaCl stress, while it was also able to survive simulated gastric juice conditions for 2 to 3 h incubation.

Mori Cortex radicis extract protected against diet-induced neuronal damage by suppressing the AGE-RAGE/MAPK signaling pathway in C. elegans and mouse model

SoHyeon You[1], Hyunna Jung[1], Gun-Hee Kim[1]

1. Duksung Women's University (Korea)

Background and objectives: Metabolic syndrome (MetS) is a cluster of obesity, hypertension, high cholesterol levels, and hyperglycemia. Many studies have concluded a diet rich in sugary drinks and saturated fat elevates the risks of obesity, metabolic disorders, cardiovascular disease, and cognitive abnormalities. *Mori cortex radicis* (MCR), the root bark of *Morus alba* L., is a well-known herbal medicine in Asian countries and has been used for more than 1000 years to treat diabetes

Methods: In the present study, we investigated the effect of MCR on the underlying mechanisms of MetS and the risk of AD factors using *C. elegans* and a mouse model.

Results: In glucose-induced *C. elegans*, MCR attenuated metabolic disorder by inhibiting lipid and advanced glycation end products (AGEs) production, reducing oxidative stress, and preventing cognition and behavioral deficits. In high fat/liquid sugar-induced MetS mice, MCR intervention improved metabolic alterations and spatial memory. Furthermore, MCR in diet suppressed AGEs deposit and RAGE expression, improved the antioxidant system, and decreased pro-inflammatory cytokine levels in mouse hippocampus. This was accompanied by downregulation of the MAPK (p38, ERK, and JNK) pathway, which consequently protected against brain damage by suppressing BACE-1, APP, Tau, and βA.

Conclusion: These findings may be valuable for those investigating crosstalk between MetS and neurodegenerative disease progression or the effect of MCR on the AGE-RAGE/MAPK pathway.

Background and objectives: 3-Phosphoglycerate dehydrogenase (Phgdh) is the first committed enzyme in the *de novo* L-serine (L-Ser) biosynthetic pathway. Mice with systemic inactivation of *Phgdh*gene show severe intrauterine growth retardation, leading to embryonic lethality (Yoshida et al, 2004). In immortalized mouse fibroblasts (KO-MEFs) established from the above KO mouse embryos, we observed that L-Ser depletion led to impaired sphingolipid metabolism and cell death (Esaki et al, 2015; Sayano et al, 2016). Simultaneously, gene expression analysis revealed that a marked induction of genes involved in cholesterol and phospholipid metabolism occurred at the early stage of L-Ser deficiency in KO-MEFs (Hamano et al, 2016). In the present study, we aimed to clarify a possible mechanistic link between altered lipid metabolism and cell injury in L-Ser depleted KO-MEFs.

Methods: KO-MEFs and KO-MEFs^{+Phgdh} were cultured in L-Ser-supplemented or -depleted medium for 6 or 24 hours. Then, we conducted comparative lipidomic analysis by LC-TOFMS and DNA microarray analysis. Gene expression data were analyzed further by Ingenuity Pathway Analysis, and expression levels of identified differentially expressed genes were verified by QRT-PCR.

Results: Lipidomic analysis revealed that L-Ser depletion led to increases in cholesterol together with lysophospholipids and fatty acids. Microarray analysis showed a marked upregulation of gene expression involved in lipid metabolism and inflammatory response including proinflammatory cytokine interleukin-6 (IL-6). Since such lysophospholipids include proinflammatory lipid mediators activating the IL-6 signaling, we examined whether IL-6-Jak/Stat cascade was altered in L-Ser-depleted KO-MEFs. The gene expression analysis confirmed transcriptional activations of IL-6 and its downstream target genes upon L-Ser deficiency.

Conclusions: These observations indicate that cellular L-Ser deficiency promotes lipid remodeling via the degradation of membrane phospholipids, which may cause cell injury via the production of proinflammatory lipid mediators and the activation of proinflammatory IL-6 signaling.

Keyword: L-serine deficiency, cholesterol, lipid metabolism, interleukin-6

PAB(T7-277)
Antioxidant and Prebiotic activity of Pectin from banana peel as a health-promoting ingredient.

Nattida Chotechuang[1], Punyapat Utitphon[1], Punyanuch Maneepong[1], Chanchai Boonla[1]

1. Chulalongkorn University (Thailand)

Background and objectives: Pectin is a non-starch polysaccharide widely used in the food industry as a gelling agent, thickening agent, stabilizer and fat substitute, and in pharmaceutical industries as the bioactive components, plus in biomedical application for tissue engineering and drug delivery. It is also a dietary fiber that has biological functions. Pectin can be found in food by-products such as citrus peel, apple pulp and banana peel. Banana is a common food worldwide, but the peel is often discarded. This research aimed to extract pectin from banana by-products and identify its properties which have the potential to be functional foods.

Methods: Pectin was extracted from banana peels (BP), banana stem (BS) and orange peels (OP), sources of commercial pectin, by using solvent and acidic water extraction. All samples were characterized for their chemical properties (the degree of esterification (DE) and anhydrouronic acid (AUA) content), antioxidant activity (using ABTS and FRAP methods), and prebiotic activity.

Results: The BP pectin and BS pectin were categorized as low methoxyl pectin with the DE 37.08 ± 1.72% and 33.91 ± 1.34%, respectively, while OP pectin was high methoxyl pectin (76.50%). The BP, BS and OP pectin had an AUA contents of 46.30 ± 0.43%, 40.05 ± 3.74% and 65.63± 2.54%, respectively. The antioxidant activity of BP pectin was significantly ($p < 0.05$) higher than those of pectin from BS and OP according to both ABTS and FRAP methods. For the prebiotic activity, the survival of *Lactobacillus paracasei* and *Bifidobacterium lactis Bb12* in pomegranate juice with BP pectin added for 14 days were significantly higher (6.20 ± 0.02 and 5.71 ± 0.004 log CFU/ml, respectively), than those without pectin (4.24 ± 0.04 and 4.18 ± 0.14 log CFU/ml, respectively).

Conclusion: Pectin from BP was low methoxyl pectin which could be used as gelling agent, emulsifier and thickener in food industries. It also had high antioxidant activity and prebiotic activity. Therefore, BP could be considered as a potential raw material for the production of value-added pectin which has health-promoting attributes.

Melinjo (*Gnetum gnemon L.*) seed extract improves sleep quality in diet-induced obesity mice

Akira Terao[1], Mao Sato[1], Chiaki Sugiura[1], Haochen Ma[1], Nobuaki Okumura[2]

1. Tokai University, School of Biological Sciences (Japan), 2. Institute for Bee Products and Health Science, Yamada Bee Company Inc. (Japan)

Background and objectives: We investigated the effect of dietary melinjo (*Gnetum gnemon L*) seed extract (MSE) on sleep architecture in high-fat diet (HFD)-induced obese mice.

Methods: Forty C57BL/6J male mice were fed different diets for 17 weeks: normal diet (ND), ND with 1% MSE (ND+MSE), HFD, and HFD with 1% MSE (HFD+MSE). Body weight and sleep architecture were examined in all mice after the study period.

Results: The body weight of HFD-fed mice increased by 50% compared to that of ND-fed mice. Although HFD did not affect the amount of non-REM (NREM) sleep, the average duration of NREM sleep bout was significantly shortened, and the number of NREM sleep bout was significantly increased. These findings indicate fragmented NREM sleep and altered sleep architecture in HFD-fed mice. Dietary MSE did not affect body weight or sleep architecture in the ND+MSE-fed mice. In contrast, the body weight and sleep architecture of HFD+MSE-fed mice were almost identical to those of ND-fed mice, indicating that dietary MSE completely blocked HFD-induced weight gain and sleep fragmentation.

Conclusions: Our data provide compelling evidence that MSE is a novel and promising dietary supplement that restores obesity-induced impaired sleep architecture.

Keyword: sleep quality, diet-induced obesity, Melinjo (Gnetum gnemon L.)

Bioavailability of kawakawa (*Piper excelsum*) tea metabolites in healthy human volunteers

Ramya Jayaprakash[1], Farha Ramzan[1], Jennifer Miles-Chan[2], Meika Foster[1,3,4], Chris Pook[1], Richard Mithen[1]

1. Liggins Institute, Waipapa Taumata Rau - The University of Auckland (New Zealand), 2. Human Nutrition Unit, School of Biological Sciences, Waipapa Taumata Rau- The University of Auckland (New Zealand), 3. Edible research Ltd (New Zealand), 4. AuOra Ltd, Wakatū Incorporation (New Zealand)

Background and objective: Interest in functional foods has led to the scientific investigation of the chemistry of *Piper excelsum* or kawakawa due to its therapeutic use by Māori in Aotearoa New Zealand. Certain phytochemicals in kawakawa have been reported to influence nutrient uptake and to have anti-inflammatory activity. We report the first human study to investigate the bioavailability of potential biologically active metabolites in healthy individuals following kawakawa tea consumption.

Methods: A pilot study (BOKA T) was undertaken to investigate the bioavailability of compounds derived from kawakawa leaves and which are present in hot water leaf extracts ('tea'). Healthy participants were randomized to consume either kawakawa tea (1g/250mL or 4g/250mL) or hot water. A follow-up study to assess the impact of kawakawa tea ingestion on postprandial glucose metabolism in healthy human volunteers (TOAST) was conducted in which participants consumed a tea (4g/250mL) or hot water. Non-targeted and targeted high-resolution LC-MS/MS metabolite analyses were undertaken on plasma and urine samples collected at regular intervals from both BOKA T and TOAST. Targeted analyses included six compounds known to occur within kawakawa tea, namely myristicin, elemicin, fagaramide, pellitorin, yangambin and vitexin, and for which authentic standards were available.

Results: Known kawakawa metabolites were not observed in plasma and urine samples in unmetabolized or unconjugated forms. Thirty urinary metabolites were significantly associated with kawakawa tea consumption in a dose-dependent manner, of which eight were also present in plasma, with others detectable in plasma at trace levels. The plasma and urinary metabolites derived from kawakawa are likely to have arisen by biotransformation by the gut microbiota and phase 1 and 2 metabolisms, such as those from myristicin and elemicin.

Conclusion: Kawakawa tea is well tolerated by the participants after an overnight fast. Analysis of urine indicates that several kawakawa metabolites are bioavailable. These metabolites may provide biomarkers for kawakawa consumption as well as provide an indication of which kawakawa metabolites may underlie the reported therapeutic properties of this traditional herbal medicinal plant. Further studies are required to elucidate the pathways for the transformation and metabolism of kawakawa leaf metabolites.

Comparison of blood and urine concentrations of equol in healthy males and females by LC-MS/MS method and examination of factors affecting equol production

Remi Yoshikata[1], Khin Zay Yar Myint[1], Junichi Taguchi[1]

1. Midtown Clinic Medical Corporation (Japan)

Backgrounds and objectives: Equol is an active metabolite of daidzein, one of the soybean-derived isoflavones. It is produced by the action of intestinal bacteria and has an estrogenic effect. Equol producers were associated with mild menopausal disorder, good bone density and lipid profile, low risk of breast cancer and prostate cancer. However, different individuals have different metabolism of isoflavones, especially equol. In this study, we aimed to investigate the relationship between blood and urine equol concentrations and their relationships with other parameters, such as sex, age, endocrine function, glucose metabolism, lipid metabolism, and renal function.

Methods: We simultaneously measured the equol concentrations from the blood and urine of 466 healthy men and women (292 men and 174 women) aged between 22 and 88 (mean age 55) years who had given informed consent. Equol concentrations were determined by LC-MS/MS method. Equol producers were defined as those whose log ratio of urinary equol and daidzein concentration or log (equol/daidzein) was -1.42 or higher.

Results: Among 466 cases, 195 were equol producers (42%). The proportion of equol producers in females was larger than that in males (39% versus 47%). There was no significant difference in the urine/blood ratio of equol concentration between producers and non-producers in both males and females. PSA levels in men were significantly lower in equol producers (0.8 v.s. 1.0 ng/ml, p=0.004), especially in those in their 40 s (0.82 vs. 1.13 ng/ml, $p < 0.001$) and 60 s (0.64 vs. 1.02 ng/ml, $p < 0.001$). The proportions of equol producers were lower among those with high PSA levels (4.4% vs. 5.1%, p=0.068). In addition, a significant proportion of men with high LDL cholesterol levels were equol non-producers (48.9% vs. 36.8%, p=0.043), and equol non-producers tended to have lower HDL cholesterol and higher uric acid levels.

Conclusions: The equol-producing ability tended to be higher in females, suggesting a relationship between estrogen and equol-producing ability. There was no difference in urinary excretion due to equol-producing ability in both males and females. Male equol-producers had significantly lower PSA levels, suggesting reduced risk of prostate disease. They also have low blood lipids and uric acid levels.

Effects of Alaska pollack protein intake on skeletal muscle mass and strength in older people requiring for nursing care

Kenji Uchida[1], Hiroyasu Mori[2], Yasunobu Tokuda[3], Eriko Yoshida[1], Munehide Matsuhisa[2]

1. Nippon Susisan Kaisha, Ltd. (Japan), 2. Tokushima University (Japan), 3. Hyogo Himeji Welfare Community (Japan)

Objective: In Japan, the population of individuals above 75 years of age, i.e., the super-aged population, is increasing. This will increase the requirement for nursing care for older people due to frequent sarcopenia-related complications caused by malnutrition and inactivity. Alaska pollack fast muscle protein (APP) consumption increases gastrocnemius muscle weight and fast muscle fiber in rats. In clinical trials, APP intake for approximately three months increased skeletal muscle and strength in healthy older people and women in their twenties. However, the effects of APP on the skeletal muscle of older people requiring nursing care are unclear. We investigated the effects of APP intake on skeletal muscle mass, muscle strength, and physical function in older people requiring nursing care in a single group before and after 12 weeks of APP intake.

Methods: Twenty-one elderly volunteers requiring nursing care (level 1–3) participated in the study. The test meal (5 g protein per serving; APP: 4.5 g) was provided once a day for 12 weeks. The skeletal muscle mass index (SMI) of the extremities, secondary outcomes of body weight, lower leg circumference, grip strength, and maximum walk speed were evaluated before and after (four and 12 weeks) the intervention.

Results: During the study, six volunteers dropped out; thus, only 15 were included for analysis. The median age of the participants was 86 years, and 10 presented with sarcopenia. The median BMI before the intervention was 21.9 kg/m^2. The intake rate of the test meal was 75.9%. No significant changes were observed for each outcome after four weeks. After 12 weeks, SMI, body weight, and grip strength increased significantly ($p < 0.05$), whereas walk speed did not increase.

Conclusion: APP intake (4.5 g once daily) for 12 weeks increased skeletal muscle mass and strength in the older population, requiring long-term care.

Keyword: Alaska pollack protein, skeletal muscle mass, muscle strength, older adults, sarcopenia

PAB(T7-282)
Comparison of effects on lipid metabolism of different fats and oils in high-fructose and high-glucose diets in rats

Kunihiro Kishida[1], Kouhei Nagai[1], Hayato Ihara[2]

1. Kindai University (Japan), 2. Wakayama Medical University School of Medicine (Japan)

Background and objectives: Excessive intake of fructose has been reported to be associated with the development of metabolic syndrome. The physiological effects of fats and oils differ greatly depending on the fatty acids they contain. This study compared the effects of different fats and oils in high-fructose and high-glucose diets in rats.

Methods: We conducted 2 feeding studies. In Experiment 1, rats were divided into 4 groups and fed a high-fructose diet containing fish oil (HFFO) or soybean oil (HFSO) and a high-glucose diet containing fish oil (HGFO) or soybean oil (HGSO) for 4 weeks. In Experiment 2, rats were similarly divided into 4 groups and fed a high-fructose diet containing lard (HFLD) or medium-chain triglycerides (HFMCT) and a high-glucose diet containing lard (HGLD) or medium-chain triglycerides (HGMCT) for 4 weeks. To analyze the significance of sugar type and fats and oils type, a two-way ANOVA was used with Tukey's multiple range test

Results: In Experiment 1, sugar type effect and fats and oils type effect were observed for plasma triglyceride (TG) level, which was increased by fructose and decreased by fish oil. The interaction (sugar type*fats and oils type) was observed for hepatic TG level, which was lowest in the HGFO group and did not differ in the HFSO, HFFO, and HGSO groups. These results indicate that hepatic TG accumulation by excessive intake of fructose occurs differently with soybean oil or fish oil. In Experiment 2, sugar type effect and fats and oils type effect were observed for plasma TG level, which was increased by fructose and lard. Hepatic TG level did not differ among the groups, which was not match the gene expression results that showed up-regulation of fatty acid synthesis by fructose and MCT, and up-regulation of fatty acid oxidation by fructose and lard.

Conclusions: These results revealed a difference in the physiological effects of fats and oils in high-fructose and high-glucose diets.

IRW improves glucose tolerance via activation of AMPK pathways and endothelial nitric oxide regulated by ACE2 in the aorta of in high fat diet fed C57BL/6 mice

Fatemeh Ashkar[1], Khushwant S. Bhullar[1], Jianping Wu[1]

1. University of Alberta, Edmonton, Canada (Canada)

Background and objectives: IRW, an ovotransferrin-derived tripeptide, has demonstrated antihypertensive and anti-inflammatory activities in cells and rodents. In this study, we investigated the effects of IRW on endothelial function, inflammation, and glucose homeostasis in a high-fat diet (HFD) induced obesity model. Methods: C57BL/6 mice were fed HFD (45% of total calories) for six weeks and IRW was added into the diet (45 mg/kg body weight (BW)) for another eight weeks.

Results: HFD lead to endothelial impairment through the down-regulation of the endothelial 5'-AMP-activated protein kinase (AMPK)–eNOS cascade while up-regulation of MAPK pathway, probably related to high lipid levels and impaired glucose management. IRW improved glucose transporter 4 (GLUT4) abundance in membrane ($P< 0.05$), AMPK ($p< 0.05$), Sirtuin 1 ($p< 0.05$), and eNOS protein expression of IRW-treated mice. Angiotensin-converting enzyme-2 (ACE2) protein levels increased in aorta ($p< 0.05$) while angiotensin one receptor (AT1R) abundance significantly reduced ($P< 0.05$) in the aorta of HFD mice treated by IRW. Further, IRW down-regulated the inflammatory MAPK signaling to reduce inflammation and vasoconstriction.

Conclusions: In conclusion, IRW improves glucose uptake and Insulin resistance in HFD-fed mice, which contribute to causing vasodilation, anti-hypertrophy, and improving vascular function. IRW promotes vasodilation action in the aorta via multiple signaling pathways, including AMPK and eNOS, dependent on ACE 2 expression.

Keyword: IRW, insulin resistance, obesity, eNOS, ACE2

Antistress activity of some phytochemicals: screening, identification, validation, and potential applications

Huayue Zhang[1,2], Zhenya Zhang<[1], Sunil C. Kaul[2], Renu Wadhawa[2~]

1. University of Tsukuba (Japan), 2. National Institute of Advanced Industrial Science & Technology (AIST) (Japan)

Background and objectives: Environmental stresses have been shown to contribute to poor quality of life, tissue dysfunctions and ailments including metabolic disorders, cognitive impairment, and accelerated aging. Oxidative stress (an imbalance between the production and processing of highly reactive oxygen species) is largely associated with these phenotypes. Whereas drug development and disease therapeutics have advanced remarkably in last three decades, there are still limited options for stress management. Since the later can effectively decrease the disease burden, we aimed to screen phytochemicals with anti-stress activity using cell-based assays

Methods: We recruited chemical models of oxidative (paraquat), metal (cadmium nitrate) or hypoxia (cobalt chloride) stresses. Control and stressed cells were allowed to recover either in the control or phytochemical supplemented culture medium. Cell survival and protein expression/signaling were analyzed to select the useful compounds and/or plant extracts.

Results: Cells subjected to chemical stresses showed a decrease in their viability. Three rounds of blind screening of the 24 phytochemicals resulted in the identification of 5 phytochemicals (four compounds and one Ashwagandha extract possessing these compounds) that caused better recovery of cells. The selected phytochemicals were further examined for their ability to protect cells against metal and hypoxia stresses. We found that whereas stress caused increase in (i) apoptosis (ii) ROS accumulation coupled with mitochondrial depolarization (iii) DNA double-strand break (iiii) protein aggregation, the selected phytochemicals caused remarkable protection. Furthermore, two compounds, withanone (Wi-N) and triethylene glycol (TEG) were also observed to cause differentiation of brain-derived cells and promote the proliferation of senescent human fibroblast. Implication of the results with reference to stress and old age-associated ailments will be discussed

Conclusions: Taken together, the study strongly suggested anti-stress and neuronal differentiation potential of Ashwagandha withanolides and extract that may be recruited for management of stress and old age-related ailments.

Keyword: Cell based assays, phtochemicals, oxidative stress, metal stress, replicative senescence

Hormesis-associated mechanisms underlying stress-resistant effects of allyl isothiocyanate

Shiho Kawaguchi[1], Akari Ishisaka[1], Akira Murakami[1]

1. University of Hyogo (Japan)

Background and objectives: Most, if not all, previous studies on phytochemicals have so far evaluated their effects with a single treatment of cultured cells. In general, however, we ingest them multiple times or continuously in daily life. On the other hand, phytochemicals may exhibit hormetic effects since they are substantially xenobiotics to humans. This study aimed to evaluate the stress-resistant effects of multiple treatments with allyl isothiocyanate (AITC), a pungent in wasabi, by focusing on hormesis.

Methods and Results: RGM1 rat gastric mucosa cells were pretreated on four different schedules, in which treatment times and the concentrations of AITC are as follows, group (1) 0 and 24 hr: 0 μM (2) 0 hr: 10-30 μM, 24 hr: 0 μM (3) 0 hr: 0 μM, 24 hr: 10-30 μM (4) 0 and 24 hr: 10-30 μM. Then all four groups were treated with AITC (20 μM), then cell viability was measured. Pretreatment with AITC (10-30 μM) significantly decreased AITC (20 μM)-induced cytotoxicity in group (2)-(4). In group (3), the protective effect was highest at the concentration of 15 μM, then decreased and almost disappeared at 20 and 30 μM, respectively. Group (4) also exhibited a similar trend. In addition, the mRNA expression levels of catalase and HSP27 were higher in the cells exposed to double treatments with AITC (15 and 20 μM, 24 and 6 hr) than those by its single treatment (20 μM, 6 hr). Interestingly, pretreatment with AITC (2.5-15 μM, 1 hr) showed the cytoprotective effects in RGM1 cells, which were incubated in a low pH medium (pH 4.6, 1 hr).

Conclusions: We found that pretreatment with AITC enhances the resistance to cytotoxicity induced by a high concentration of AITC, suggesting that multiple treatments with AITC may increase its adaptation capacity against AITC exposures. Mechanisms underlying stress resistance to AITC, together with that to a low pH condition, are currently under investigation.

Effect of calcium-enriched pumpkin on calcium status and bone health in ovariectomized rats

Natalia Wawrzyniak[1], Anna Gramza-Michalowska[1], Bartosz Kulczynski[1], Joanna Suliburska[1]

1. Poznan University of Life Sciences (Poland)

Background and objectives: Calcium-enriched pumpkin may be a good potential new source of dietary calcium. This study investigated the effect of an enriched pumpkin with calcium carbonate and calcium lactate on calcium status and bone health in ovariectomized rats.

Methods: The study was conducted on 40 rats and lasted 12 weeks. At the beginning of the experiment, rats were divided into two groups: the control (n = 10) and the study group (n = 30), in which the ovariectomy was performed. The control group (C) and one of the ovariectomized groups (OVX_C) received the standard diet (no modification), the P_CaC group was fed pumpkin enriched with calcium carbonate and group P_CaL was fed pumpkin enriched with calcium lactate. Each diet contained the same amount of calcium (5 g per 1 kg of diet). The pumpkin has been enriched with calcium salts in the process of osmotic dehydration with the use of an osmotically active substance - inulin. At the end of the experiment, the body mass of rats was measured. Blood and tissues were collected, in which the concentration of calcium was determined using flame atomic absorption spectrometry (AAS), while the concentration of procollagen type I N-terminal propeptide (PINP), parathyroid hormone (PTH), estradiol (ES) and osteocalcin (OT) were measured in serum with enzyme-linked immunosorbent assay (ELISA) kits.

Results: Pumpkin enriched with calcium led to the accumulation of calcium in the kidneys of ovariectomized rats. Pumpkin enriched with calcium carbonate increased significantly calcium level in the femur and PTH serum concentration. A comparison of the effect of both salts resulted in significantly higher calcium levels in serum, liver, and kidneys and lower in the femur in rats with calcium lactate-enriched pumpkin.

Conclusions: In conclusion, enrichment of pumpkin with calcium carbonate has a more favorable effect than its enrichment with calcium lactate in increasing the content of calcium in bones with its lower accumulation in the kidneys.

Keyword: pumpkin, calcium salts, ovariectomy, kidneys accumulation

Docosahexaenoic acid inhibits interaction of RACK1 with PKCθ and represses melanoma and T cell leukemia cell proliferation

Hidetoshi Yamada[1], Raimu Miyasaka[1], Saki Igata[2], Aiko Uemura[3]

1. Faculty of Life and Environmental Science, Teikyo University of Science (Japan), 2. Graduate School at Teikyo University of Science (Japan), 3. Iwate Biotechnology Research Center (Japan)

Background and objectives: Docosahexaenoic acid (DHA) is a major marine n-3 polyunsaturated fatty acid. It has been reported that DHA elicits many physiological effects, including anti-tumor effects. However, the mechanisms of its anti-tumor effects are unclear. Previously we found that DHA interacted with receptor for activated C kinase 1 (RACK1), and that repressed melanoma cell proliferation by suppressing protein kinase C (PKC) signaling. These findings suggested that DHA might suppress PKC signaling by inhibiting the interaction of RACK1 with PKC. In this study we examined the effect of DHA on the interaction of RACK1 with PKCs.

Methods: There are nine genes of a human and mouse PKC superfamily. We constructed plasmids that expressed Halo-tagged PKCs and NanoLuc-tagged RACK1. We transfected the Halo-tagged PKCs and NanoLuc-tagged RACK1 in a B16F10 melanoma cell line, and analyzed the interaction of RACK1 with PKCs by bioluminescence resonance energy transfer (BRET).

Results: Phorbol 12-myristate 13-acetate (PMA) is a PKC activator-induced interaction of RACK1 with PKCα, β, γ, θ, ι, or ζ. DHA repressed the interaction of RACK1 with PKCβ and PKCθ. We examined by western blot the expression of PKC isotypes in B16F10 and the effect of DHA on PKC signaling. PKCα, θ, and ζ were expressed in B16F10, but PKCβ was not. DHA decreased the phosphorylation level of JNK protein in B16F10. Next, to examine the relationship of PKCθ expression and DHA's anti-proliferation effect, we analyzed PKC expression and DHA's anti-proliferation effect in B16F10, NIH-3T3, HepG2, DLD-1 and HeLa cell lines. PKCθ expression and DHA's anti-proliferation effect were observed in B16F10 only. PKCθ is well known as an important molecule in T cell activation and proliferation. We examined DHA's anti-proliferation effect on five T cell leukemia cell lines. DHA repressed the proliferation of Jurkat, MOLT-4F, CCRF-CEM, and HPB-ALL, but did not repress the proliferation of HD-Mar2. PKCθ expression was observed in Jurkat, MOLT-4F, CCRF-CEM, and HPB-ALL.

Conclusions: In this study we showed that DHA repressed the interaction of RACK1 with PKCθ, and that the anti-tumor effect of DHA was correlated with PKCθ expression in tumor cell lines. Our results suggest that suppression of PKCθ signaling is a new explanation of the anti-tumor effect of DHA.

Intestinal absorption of rare sugars, D-allose, D-allulose, D-sorbose, and D-tagatose via sodium-dependent glucose cotransporter 1 (SGLT1) or glucose transporter type 5 (GLUT5) in rats

Ayaka Watanabe[1], Yugo Nakamura[1], Tetsuo Iida[2], Takako Yamad[2], Yukiyasu Toyoda[3], Kunihiro Kishida[1]

1. Kindai University (Japan), 2. Matsutani Chemical Industry Co., Ltd. (Japan), 3. Meijo University (Japan)

Background and objectives: Intestinal absorption pathways of rare sugars (D-allose, D-allulose, D-sorbose, and D-tagatose) are not fully understood. D-allose is an isomer of D-glucose (Glu), while D-allulose, D-sorbose, and D-tagatose are isomers of D-fructose (Fru). We investigated whether these rare sugars are absorbed via sodium-dependent glucose cotransporter 1 (SGLT1) and/or glucose transporter type 5 (GLUT5) in rats.

Methods: Two experiments were conducted to clarify the pathway of rare sugar absorption. In Experiment 1, we tested whether rare sugars are absorbed via SGLT1. Rats previously fed a standard diet were fasted and divided into two groups. One group was orally administered KGA-2727, SGLT1-specific inhibitor, and each rare sugar. The other group was orally administered each rare sugar alone. Blood was collected from the tail vein over time. We also examined this experiment using portal vein cannulated rats. In Experiment 2, we tested whether rare sugars are absorbed via GLUT5. Rats were divided into a Fru group which were previously fed a high-fructose diet to induce GLUT5 in the small intestine and a Glu group which were previously fed a high-glucose diet served as a control. Each rare sugar was orally administered to the fasted rats, and blood was collected from the tail vein over time.

Results: In Experiment 1, KGA-2727 blocked the increase of plasma D-allose concentrations throughout the experiment after D-allose administration. No significant differences were observed between the groups after administration of D-allulose, D-sorbose, and D-tagatose. Similar results were obtained from the experiments using portal vein cannulated rats. In Experiment 2, the Fru group showed significantly higher plasma rare sugar concentrations than those in the Glu group after administration of D-allulose, D-sorbose, and D-tagatose while there were no significant differences when D-allose was administered

Conclusions: The results suggest that D-allose is likely absorbed via SGLT1 but not GLUT5. D-allulose, D-sorbose, and D-tagatose are likely absorbed via GLUT5 but not SGLT1.

Oral intake of ozonated triacylglycerol from olive oil reduces fatty acid synthesis and inflammation reaction in obese *db/db* mice

Yasunari Kato[1], Toshiharu Nagai[1], Koji Nagao[2], Nao Inoue[2]

1. Tsukishima Foods Industry Co.,Ltd. (Japan), 2. Saga University (Japan)

Background and objectives: In recent years, the number of patients with metabolic syndrome has increased due to overeating and lack of exercise, and chronic inflammation caused by excess fatty tissue has resulted in diverse diseases. We previously found that oral intake of ozonated olive oil alleviated liver damage in obese model mice and rats via lipid metabolism improvement. In this study, to investigate the active components in ozonated olive oil, we fractionated olive oil into triacylglycerol (TAG) and unsaponifiable matter (USM) and assessed bioactivity of each ozonated fraction.

Methods: TAG was prepared from the saponifiable fraction of olive oil using a silica gel column. The USM was extracted with diethyl ether from alkali-treated olive oil. Obese model *db/db* mice were fed one of experimental diets containing 6.5% corn oil + 0.5% olive oil (CO group), 6.5% corn oil + 0.5% ozonated TAG (zTG group), or 6.5% corn oil + 0.5% TAG + 0.0058% ozonated USM (zUS group). Normal model C57BL/6J mice fed a standard diet (NO group) were also assessed. After 4 weeks of rearing, growth parameters and lipid metabolism were evaluated.

Results: The CO group developed obesity, hepatomegaly, hyperlipidemia and fatty liver with increased food intake (compared to the NO group). In obese *db/db* mice, the zTG group showed a significant decrease in serum TAG, liver TAG and serum insulin compared with the CO group. As a mechanism of action, the enzyme activity of fatty acid synthase (FAS) and the expression of lipogenic genes (*ACC1*, *FAS* and *SCD1*) and inflammatory genes (*MCP1* and *TNFα*) were significantly decreased in the zTG group than the CO group. The zUS group was not significantly different from the CO group in any of the tests.

Conclusions: The results of this study suggest that ozonated TAG in olive oil shows bioactive functions in reduction of fatty acid synthesis and anti-inflammation.

PAB(T7-290)
Yam-Derived Nanovesicles Stimulate Osteoblast Formation and Prevent Osteoporosis in Mice

Jin-Hyeon Hwang[1], Dong-ha Kim[2], Young-Eun Cho2, Do-Kyun Kim[1]

1. Jeonbuk National University (Korea), 2. Andong National University (KoreA)

Background and objectives: Bone mineral density and function are maintained by the constant differentiation and mineralization of osteoblasts to prevent osteoporosis. The effects of yam-derived nanovesicles (YNVs) on the promotion of differentiation and mineralization of osteoblasts *in vitro* and in ovariectomized (OVX)-induced osteoporotic mice are investigated.

Methods: In this study, the isolated YNVs are verified as nanovesicle-containing biomolecules, including RNAs, proteins, and lipids, following an established method, including nanoparticle tracking, dynamic light scattering analysis, and electron microscopy

Results: These exogenously administered YNVs induce the proliferation, differentiation, and mineralization of osteoblasts by increasing the expression of Runx2, which is a key transcription factor for osteoblast differentiation. The YNVs stimulate osteogenic activation of the BMP-2/p-p38-dependent Runx2 pathway. Furthermore, oral administration of YNVs promotes longitudinal bone growth and mineral density of the tibia in the OVX-induced osteoporotic mice but not in normal mice. Significant increases in osteoblast-related parameters confirm these results.

Conclusions: Taken together, these results demonstrate that YNVs can serve as a safe and effective agent for enhancing osteogenic activity.

Keyword: exosome-like nanovesicles, yam-derived nanovesicles, bone mineral density, osteoporosis

PAB(T7-291)
Polyphenols from *Litsea cubeba* exert anti-inflammatory activity through Nrf2/HO-1 pathways in Caco-2 cells.

Shigeki Oogai[1], Kaede Yamasaki[1], Hiroyuki Katsuragi[1], Yasuo Nagata[1], Teruyoshi Yanagita[1,2]

1. Saga Prefecture Industrial Innovation Center (Japan), 2. Nishikyushu University (Japan)

Background and objectives: Inflammation has been known to trigger metabolic disorders such as insulin resistance and immune impairment. Intestine, where various types of immune cell are abundant, is continuously exposed to food-borne

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

pathogens and intestinal bacteria, causing chronic inflammation. Although commercially-available anti-inflammatory drugs have been used, long term usage of them often causes undesirable side effects. Natural compounds from plants accordingly have been investigated as safer alternative to provide anti-inflammation effects. Among them, *Litsea cubeba*, a seasoning in Asian countries, has been used as a traditional folk medicine to treat digestive anomalies. Few studies, however, have been carried out to determine how *L. cubeba* modulates inflammation in digestive system. We here aimed to investigate anti-inflammatory activity *L. cubeba* in Caco-2 cells.

Methods: Caco-2 cells were pretreated with *L. cubeba* 50% aqueous ethanol extract before H_2O_2 treatment. Western blotting and qRT-PCR were used to analyze the effects of *L. cubeba* on inflammation and anti-oxidant-related proteins such as nuclear factor (erythroid-derived 2)-like 2 (Nrf-2) and heme oxygenase 1 (HO-1). Besides, LC-MS/MS was employed to identify bioactive components present in the extract. To determine the possible mechanism of action, *in silico* molecular docking was also used.

Results: *L. cubeba* 50% aqueous ethanol extract was found to have a protective effect against H_2O_2 induced inflammation in Caco-2 cells. The extract dose-dependently downregulated the gene expression levels of IL-6. Moreover, the protein and gene expression levels of Nrf-2 and HO-1 were upregulated, and nuclear translocation of Nrf-2 was also promoted, which in turn may enhance the activity of antioxidant enzymes. Furthermore, LC-MS/MS analysis revealed the presence of several polyphenolics belonging to the flavonoid and alkaloid classes. Additionally, several kaempferol glycosides demonstrated high docking binding scores against Kelch-like ECH-associated protein 1 (Keap1), a regulator of Nrf-2.

Conclusions: These results exhibited anti-inflammatory potential of *L. cubeba* through anti-oxidant pathway of Nrf-2/HO-1, which may be due to the flavonoid presence.

Keyword: Litsea cubeba, inflammation, Nrf-2, HO-1

PAB(T7-292)
Extract derived from *Litsea cubeba* leaves increases glucose uptake in HepG2 cells via enhanced AMPK/GLUT2 pathway

Kaede Yamasaki[1], Shigeki Oogai[1], Hiroyuki Katsuragi[1], Yasuo Nagata[1], Teruyoshi Yanagita[1,2]

1. Saga Prefecture Industrial Innovation Center (Japan), 2. Nishikyushu University (Japan)

Background and objectives: With increased number of obese people, natural compounds have drawn attention to develop functional foods to maintain healthy body weight and blood sugar levels. *Litsea cubeba* grown and eaten in Asian countries, has been traditionally used to treat diabetes. Few studies, however, have shown anti-diabetic activity of *Litsea cubeba*. We accordingly aimed to investigate how leaves from *Litsea cubeba* modify glucose metabolism in HepG2 cells.

Methods: *Litsea cubeba* leaves extract was prepared as 50% ethanol aqueous extract. Total polyphenol levels in the extract were measured by Folin-Ciocalteu's method. HepG2 cells were seeded at 9.0 x 10^4 cells/cm^2 on culture plates and were then treated with 25 - 100 μg/mL of *Litsea cubeba* leaves extract. Glucose uptake and cell viability were measured by glucose uptake assay kit and cell counting kit, respectively. Cell surface glucose transporter 2 (GLUT2) expression was analyzed by flow cytometry. The protein expression of phospho-AMP-activated protein kinase (AMPK), total AMPK and sirtuin 1 (SIRT1) was determined by western blot.

Results: Total polyphenol levels in *Litsea cubeba* leaves extract were 180 μg gallic acid equivalent/mg extract. Glucose uptake was dose-dependently increased and was significantly elevated at the concentration of 100 μg/mL of *Litsea cubeba* leaves extract without affecting cell viability. The expression of cell surface GLUT2 was increased in a dose-dependent manner and augmented significantly with 100 μg/mL of the extract. Phospho-AMPK protein expression was significantly stimulated, but no increased expression of total AMPK protein was detected by *Litsea cubeba* leaves extract. SIRT1 protein expression, an upstream regulator for AMPK signaling, was not modified by the extract.

Conclusions: *Litsea cubeba* leaves extract increased glucose uptake in HepG2 cells via enhanced AMPK/GLUT2 pathway. *Litsea cubeba* leaves could be thus useful for normalizing glucose metabolism in the liver.

Keyword: Litsea cubeba leaves, glucose uptake, AMPK, GLUT2, polyphenols

PAB(T7-293)
Collagen tripeptide alleviates allergic rhinitis symptoms in mice

Madoka Tsujimoto[1], Marie Yabuki[1], Ken-ichi Kobayashi[1], Shoko Yamamoto[2], Yo Matsumoto[2], Yasushi Hayashi[1~]

1. Notre Dame Seishin University (Japan), 2. Jellice Co., Ltd., (Japan)

Background and objectives: Collagen tripeptide (CTP) is a collagen hydrolysate containing high concentrations of tripeptides with glycine-X-Y sequences. Residues X and Y are arbitrary but often occupied by proline, hydroxyproline, and/or alanine. CTP has excellent skin permeability and promotes the synthesis of hyaluronic acid. Further, CTP is reported to exert an anti-inflammatory effect on atopic dermatitis. Based on these reports, we evaluated the effect of CTP on allergic rhinitis, an inflammatory diseasefinal, using a mouse model of ovalbumin-induced rhinitis. In addition, we examined the effect of CTP on the immune system in the mouse spleen.

Methods:To prepare the rhinitis model, BALB/c female mice were sensitized with ovalbumin (OVA). CTP was dissolved in tap water and given *ad libitum* from a water bottle. Control mice received tap water only. CTP administration was continued for 5

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

weeks from the day of first sensitization in the study of preventive efficacy, and for 4 weeks from the time when rhinitis worsened in the study of therapeutic efficacy. Some mice were given normal collagen peptide (CP), which did not contain CTP. Rhinitis symptoms (sneezing and nasal rubbing) were observed once weekly. The plasma levels of OVA-specific IgE antibodies (OVA-IgE) were measured over time. After a final observation of rhinitis symptoms, mice were deeply anesthetized, and their spleens were removed. By real-time PCR, mRNA levels in the spleen were analyzed, with a focus on the master transcription factors of helper T (Th) cells.

Results: Repeated administration of OVA resulted in exacerbation of rhinitis symptoms and a marked increase in OVA-IgE levels. CTP administration prevented and treated the symptoms of rhinitis and reduced the OVA-IgE levels. Regarding therapeutic efficacy, rhinitis symptoms were alleviated for more than 4 weeks after cessation of CTP administration. In contrast, CP had no effect on rhinitis symptoms. Real-time PCR revealed that CTP decreased the activity of type 2 Th cells and of follicular helper T cells.

Conclusions: These findings suggest that CTP exerts an anti-rhinitis effect by restoring the Th-cell composition

Keyword: Collagen tripeptide, allergic rhinitis, IgE antibody, master transcription factor, helper T cell

PAB(T7-294)
Metabolites Profile and Antioxidant Properties of Fermented-Strawberry Drink: Non-Targeted Metabolomic Profiling and *In Vitro* Study

Melvin Junior Tanner[1], Fahrul Nurkolis[2], Happy Kurnia Permatasari[3], Hardinsyah Hardinsyah[4], Nurpudji Astuti Taslim[5]

1. Nutrition, Faculty of Public Health, University of Indonesia (Indonesia), 2. Biological Sciences, State Islamic University of Sunan Kalijaga (UIN Sunan Kalijaga) (Indonesia), 3. Biochemistry and Biomolecular, Faculty of Medicine, Brawijaya University (Indonesia), 4. Applied Nutrition, Faculty of Human Ecology, IPB University (Indonesia), 5. Clinical Nutrition, Faculty of Medicine, Hasanuddin University (Indonesia)

Background and Objectives: Strawberry or *Fragaria ananassa*, is a fruit rich in antioxidants and phytochemicals, which may have benefits for heart health, blood sugar control, and the ability to scavenge free radicals. The purpose of this study is to innovate strawberries into fermented drinks using the kombucha method or strawberry kombucha drink (SKD). Determination of metabolites profile and antioxidant activity of SKD was also carried out.

Methods: The ingredients of the SKD formula consist of 2,000 mL of water, 24 g of strawberry flesh, 300 g of cane sugar, 10 g of SCOBY gel, and 166 g v/v of SCOBY starter solution, bringing the overall total to 2,500 mL. After going through the usual cooking of kombucha, the material is stored in the bottle, then stored in anaerobic conditions (20 – 25 °C) for 12 days. This formulation was designed taking into account previous study formulations. After 12 days of fermentation, all beverage samples were stored at a refrigerator temperature of 4 – 8 °C for metabolomic profiling analysis by LC-HRMS and *in vitro* antioxidants using ABTS assay. ABTS Assay is used in concentration gradients of 50, 100, 150, 200, and 250 µg/mg of KSD, as well as Trolox as a control. Furthermore, data analysis on *in vitro* studies using independent sample T-test (CI: 95%; 0.05) and half maximal effective concentration (EC_{50}) using non-linear regression. The GraphPad Prism 9 Premium software was used in this regard.

Results: A total of 62 bioactive compounds were identified in SKD. The three high-abundance compounds in SKD are Theobromine ($C_7H_8N_4O_2$), Epicatechin ($C_{15}H_{14}O_6$) and Rutin ($C_{27}H_{30}O_{16}$). Based on the literature, the majority of these compounds exhibited several health benefits, ranging from antioxidant, neuroprotective, hypolipidemic, and protection against cardiometabolic risk factors. The ABTS inhibition activity of all doses of SKD is similar to Trolox (no significant difference; $p>0.05$). The EC_{50} value of SKD and Trolox regarding the inhibition of ABTS were 18.52 µg/mg and 19.61 µg/mg, respectively.

Conclusions: Based on this study, it can be concluded that Strawberries can be incorporated into a fermented kombucha drink (SKD) that has a metabolite profile and antioxidant properties with various health benefits as a functional food

PAB(T7-295)
Screening of citrus fruits on anti-atherogenic functionality of HDL

Harumi Kondo[1], Hibiki Kawauchi[1], Yukino Nakamaru[1], Keita Yamagishi[1]

1. Nihon University (Japan)

Background and objectives: ATP-binding cassette transporters (ABC) A1, G1and cavenger receptor class B type I (SR-BI) are key molecules in cholesterol efflux from macrophages, which is an initial step of reverse cholesterol transport, a major anti-atherogenic functionality of high-density lipoprotein (HDL). Citrus fruit intake protects against cardiovascular disease, it remains unclear through what mechanism of action it affects cholesterol homeostasis in macrophages. We therefore investigated the effects of citrus fruit on HDL-mediated cholesterol efflux and expressions of key molecules in macrophages.

Methods: We investigated water-soluble and oil-soluble extracts of twenty-three types of citrus fruit. The differentiation of THP-1 monocytes into macrophages was induced in the presence of 320 nmol/L PMA for 72 hours. The macrophages were labeled with [3H]cholesterol (1.0 µCi/mL) in RPMI 1640 for

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

24 hours and incubated in the presence and absence of HDL (50 µg/mL) for 24 hours. The percentage cholesterol efflux was calculated by dividing the media-derived radioactivity by the sum of the radioactivity in the media and the cells.

Results: Among citrus fruits, six types of oil-soluble extracts from citrus fruit peel (blood orange, minneola orange, kumquat, kabosu, navel and citron) enhanced cholesterol efflux from THP-1 macrophages mediated by HDL. Furthermore, we found that limonene, the major component in the oil of citrus fruit peels enhanced cholesterol efflux from THP-1 macrophages mediated by HDL. In supporting these enhanced cholesterol efflux mechanisms, limonene increased the protein levels of ABCA1 and ABCG1, but not SR-BI.

Conclusions: The potential cardioprotective properties of citrus fruit peel might be associated with an enhanced anti-atherogenic functionality of HDL.

Keyword: cholesterol, macrophage, HDL, citrus fruits, limonene

PAB(T7-296)
Effects of Sea grapes Extract Supplementation on Cholesterol Changes in 7,12-dimethylbenz [a] anthracene-induced Rat Models

Piko Satria Augusta[1], Fahrul Nurkolis[2], Happy Kurnia Permatasari[3], Nurpudji Astuti Taslim[4], Nelly Mayulu
[5]

1. Medical Study Programme, Faculty of Medicine, Brawijaya University (Indonesia), 2. Biological Sciences, State Islamic University of Sunan Kalijaga (UIN Sunan Kalijaga) (Indonesia), 3. Department of Biochemistry and Biomolecular, Faculty of Medicine, Brawijaya University (Indonesia), 4. Department of Clinical Nutrition, Faculty of Medicine, Hasanuddin University (Indonesia), 5. Faculty of Medicine, Sam Ratulangi University (Indonesia)

Background and Objectives: Increasing cholesterol levels is associated with higher cancer risk. Cholesterol-lowering supplements – as a functional food – exhibit beneficial effects by reducing the risk and mortality of cancers. The Caulerpaceae family contains polysaccharide and bioactive components that have antioxidant, antibacterial, and anti-inflammation properties. Therefore, this research aimed to study the anticancer activity of Sea grapes (*Caulerpa racemosa*) that is associated with cholesterol levels on 7,12-dimethylbenz(a)anthracene (DMBA) induced breast cancer in rats.

Methods: Fresh Sea grapes were collected from the shallow waters of Mantehage, North Sulawesi, Indonesia. Sea grapes extract (SGE) was extracted using 96% ethanol for 72 hours. Fifty Sprague-Dawley male rats (4 weeks) weighing 200-250 g were divided into 5 groups (A = normal control; B = negative control; C = 2.7 mg/200gBW of SGE; D = 5.4 mg/200gBW of SGE; E = 10.8 mg/200gBW of SGE). All rats received a standard diet and *ad libitum* water. Rats from group B until D was given 80 mg/kgBW of DMBA ($C_{20}H_{16}$; PubChem CID: 6001) on the 38th day of life to induce mammary gland tumors. Carcinogenic agents dissolved in rapeseed oil were selected as DMBA senders. After 8 weeks, the rats were decapitated. Their blood was taken from the heart and liver, weighed, and stored at -80°C for further analysis. The research protocol refers to the Declaration of Helsinki and the Council for International Organizations of Medical Sciences (CIOMS) and has received internationally ethical approval (International Register of Preclinical Trials Protocols; PCTE0000283).

Results: There was a significant decrease in LDL levels along with an increase in the number of sea grape supplements given to the group. A similar tendency was also observed in the increase of HDL levels and the decrease of triglyceride levels. The value of total cholesterol in each group given SGE also showed a very significant difference when compared to group B. There was no significant difference in the value of every lipid profile between the groups given 5.4 mg/200gBW of SGE with the 10.8 mg/200gBW.

Conclusions: Supplementation of SGE may improve lipid profile conditions by altering cholesterol levels in DMBA-induced rats. SGE has the potential as a functional food against breast cancer.

Keyword: Cancer, Cholesterol, Caulerpa racemosa, Breast cancer, 7,12-Dimethylbenz [a] anthracene

PAB(T7-297)
Effect of one week of consumption of brown rice fermented food on postprandial blood glucose levels

Masaki Taga[1], Shunsuke Higaki[2], Yukiko Sumida[3], Tomohisa Koyama[3], Tomoko Asai[4], Yuichiro Takei[3], Ayumi Suda[5], Reiko Inai[4]

1. Wayo Women's University (Japan), 2. Hokkaido Bunkyo University (Japan), 3. Kochi Prefectural University (Japan), 4. Nara Women's University (Japan), 5. Shitennoji University (Japan)

Purpose: We have reported that brown rice fermented food (FBR) has functional properties such as intestinal regulation, reduction of blood triglycerides, and antioxidant effect. We have also reported the effect of a single intake of FBR on the suppression of elevated blood glucose. In this study, we investigated the effects of one week of consumption of brown rice fermented food on the body in healthy adult women.

Methods: Five healthy young women were subjects. They consumed a brown rice fermented food (KAKUSAN Co., Ltd.) three times a day (3 g/treatment) for 7 consecutive days. Before and after consumption, dietary survey (FFQg), body composition, blood biochemistry test, stress measurement, intestinal bacteria test, and blood glucose level after rice ball consumption were measured. Blood glucose levels were measured at 9:00 a.m. on the morning of the measurement day, when the subjects consumed two rice balls (75.2 g carbohydrate) in a fasting state (fasted since 21:00 the previous day), and blood

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

glucose levels were then measured over time. Blood glucose levels were measured by the subjects themselves using a self-monitoring blood glucose meter (Roche DC Japan). Statistical processing was performed using SPSS Ver. 28, with a significance level of 5% or less. This study was conducted after ethical review by Kochi Prefectural University (Approval No.: 21-01).

Results: There were no significant changes in the subjects' nutritional intake, blood chemistry, stress status, or intestinal microflora before and after FBR intake. In the variation of blood glucose levels after consumption of rice balls, the increase in blood glucose levels was predominantly suppressed after consumption of FBR at 30 minutes and 120 minutes after the meal. The AUC was also predominantly lower after ingestion of FBR.

Conclusion: Although the single dose of FBR was found to suppress blood glucose, one week of continuous consumption of FBR significantly suppressed the increase in blood glucose level caused by onigiri consumption, although no change was observed in blood biochemical tests. Further investigation is needed to determine the inhibitory effect of FBR on blood glucose levels after one week of continuous consumption.

Keyword: brown rice fermented food, blood glucose, functional food

Effects of walnut milk beverage on gut microbiota in older adults with mild cognitive impairment: a pilot study

Ruyi Han[1,2], Jiawei You[1,2], Huibo Zhao[3], Bing Qi[4], Yafeng Sun[1,2], Junzhuan Wang[4], Su Tian[1,2]

1. Hebei Medical University (China), 2. Hebei key laboratory of environment and human health (China), 3. Hebei technology innovation center of walnut beverage (China), 4. Hebei yangyuan zhihui Co., Ltd. (China)

Background and objectives: Growing evidence supports that gut microbiota can regulate brain function and influence cognition and basic behavioral patterns through bidirectional connections with the brain. Walnut is a commonly consumed nut that is regarded as a traditional medicine and food in China. The objective of this study is to evaluate the effect of walnut milk beverage on gut microbiota in older adults with mild cognitive impairment.

Methods: Participants aged between 60 and 85 years were recruited from a nursing home and were assessed cognitive and memory function according to the Montreal Cognitive Assessment (MoCA) and Mini-Mental State Examination (MMSE). Participants who were diagnosed with mild cognitive impairment (MCI) (n=27) were required to drink one bottle of walnut milk beverage daily for 8 weeks. To ensure the reliability of the test results of the gut microbiota, in addition to the first test period from November 2019 to December 2019, the same test was repeated a second time from December 2020 to January 2021. Before and after the test, fecal samples were collected from the participants for gut microbiota analysis, and 16S rDNA sequencing and analysis were performed to compare the differences in Gut Microbiota.

Results: The results revealed no statistically significant difference ($P > 0.05$) in the alpha diversity of gut microbiota between the baseline and after consumption of walnut milk beverage, but the abundance of *cyanobacteria* increased significantly at the phylum level ($P < 0.05$) after drinking walnut milk beverage. The Tax4Fun level 2 analysis of gut microbiota functional gene prediction revealed that immune system, nervous system, and γ- GABAergic synaptic were also increased after walnut milk beverage consumption ($P < 0.05$). Among them, there is a positive correlation between the changes of GABAergic synaptic and attention.

Conclusions: Drinking walnut milk beverage may enhance GABAergic synapse functions of older adults with MCI, potentially preventing attention decline resulting from aging.

Keyword: walnut milk beverage, mild cognitive impairment, gut microbiota, γ- GABAergic synaptic, memory and cognitive function

PAB(T7-299)
Improvement in processing of Mongolian traditional dairy product

Chimedregzen Narangerel[1]

1. Mongolian University of Science and Technology, School of industrial technology (Mongolia)

BACKGROUND. Mongolian traditional methods of processing milk have thousands years of history, and contain most achievements of modern sciences in accordance with milk content and characteristics of pasteurized animal products. We are interested in improving processing of dairy products, especially traditional products such as "Eezgii" (coagulated and evaporated dairy product).

PURPOSE. The transition from traditional milk production methods into industrial manufacturing methods are motivated by the growing number of urban population.

METHODS. Milk obtained from five different animals was used: camel, horse, cattle, sheep and goat. Milk produced by different animals varies in quality and composition. We have investigated processing of "Eezgii" by 3 different evaporation methods, to know: traditional, vacuum evaporation, and ohmic heating. The parameters for "Eezgii" processing are: coagulation method, temperature and time, as well as evaporation method, temperature, time and pressure. Ohmic heating is an advanced thermal process. Food is heated by passing electricity and ohm resistance.

RESULTS AND DISCUSSION. *Traditional method*: Coagulation started after 5 minutes at 82^{0}C. Coagulated milk contained 135,61 g of curd and 400 ml of whey. *Vacuum evaporation:* Coagulated milk was boiled at 70^{0}C, in the rotary vacuum

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

evaporator at 190 HPa. This process took 1 hour 40 minutes. After drying eezgii's weight was 31,71 g. *Ohmic heating*: The coagulated milk started boiling after 5 minutes processing (P=1 kW, V_{cons}=100 V); at this time the current value 4,35 A. This process finished after 31 minutes, at which time the current value was 0,6 A.

CONCLUSION: Based on the intensive study on "eezgii" processing, there are various possibilities to produce many kinds of highly nutritous milk products.

Ohmic heating process was the best evaporation method for decreasing processing time and increased "eezgii" productivity.

Most likely traditional evaporation will be replaced by to Ohmic heating processing in the future.

The Effect of Galohgor Nutraceutical on Fasting Blood Glucose of Type 2 Diabetes Mellitus Subjects

Katrin Roosita[1], Rimbawan Rimbawan[1], Sri Anna Marliyati[1], Ratih Putri Damayanti[3], Makiko Sekiyama[2]

IPB University (Indonesia), 2. NIES (Japan), 3. Politeknik Negeri Jember (Indonesia)

Background and objectives: Galohgor Nutraceutical is a traditional poly herbal product from Indonesia containing antioxidant and other bioactive components which showed synergistic effect on controlling blood glucose in animal model. The aim of this study is to analyze the effect of Galohgor Nutraceutical on fasting blood glucose level of type 2 diabetes mellitus subjects. Methods: This study used experimental trial with pre-post-controlled design and applied on 26 diabetics (Type 2 DM) subjects which were divided into two groups, i.e. intervention and control. The study was conducted at Bogor District, West Java, for 38 days intervention periods. The differences of fasting blood glucose between groups were tested by ANCOVA. **Results**: The result showed that adjusted mean difference of fasting blood glucose for cookies and powder drinks of Galohgor group compared with control group were -57.7% and -2.4% (p= 0.05). **Conclusions:** Galohgor nutraceutical significantly reduced fasting blood glucose in type 2 diabetes mellitus subjects.

Regulation of Pancreatic *Interleukin-6* and *TNF-α* Expressions in the Diet-Induced Obese Mice through Short Chain Fatty Acids Supplementation

Ann Elaine Delos Santos Wagan[1,2], Merlyn Mendioro[1], Takayuki Anazawa[2], Ma. Cecilia Reamillo[1], Liezl Atienza[1]

1. University of the Philippines-Los Baños (Philippines), 2. Kyoto University (Japan)

Background and objectives: Short chain fatty acids (SCFAs) have been reported to modulate inflammation through various molecular mechanisms and could regulate physiological functions *via* neuro-hormonal circuit interaction. The study investigated the effects of SCFAs on pancreatic interleukin-6 and tumor necrosis factor-alpha expressions. The effects of SCFAs on food intake, body weight and blood glucose in mice were also reported.

Methods: The *Il-6* and *TNF-alpha* expressions were quantified using qPCR and sandwich ELISA for the mRNA and protein concentration, respectively, and compared with the negative control.

Results: The results showed that all SCFAs can downregulate the IL-6 mRNA expression but not significant enough to reduce the expression ($p>0.05$). The pancreatic IL-6 protein expression exhibited significant reduction when treated with acetate, propionate, butyrate and mixed SCFAs. The SCFAs were found to induce significant downregulation on TNF-alpha mRNA expression. The TNF-alpha protein expression also showed significant reduction in acetate, propionate, butyrate and mixed SCFAs-treated groups. All SCFAs treatment were observed to have significant increase in food intake and body weight while only the acetate and propionate-treated groups exhibited increase in the blood glucose level.

Conclusion: In conclusion, different SCFAs treatment had different levels of effective regulation in IL-6 and TNF-alpha expressions especially at the protein level.

Keyword: Short-chain fatty acids, cytokines, interleukin-6, tumor necrosis factor-alpha, acetylation

Anti-obesity effects of the waste rice media of *Cordyceps militaris*

Je-Ruei Liu[1], Jie-Hong Song[1]

1. National Taiwan University (Taiwan)

Background and objectives: *Cordyceps militaris*, a dietary therapeutic fungus, is a potential candidate for obesity alleviation. The fruit bodies of *Cordyceps militaris* are medically and economically valuable, while the waste rice media of *Cordyceps militaris* are usually discarded after the harvest of the fruit bodies. However, the waste rice media of *Cordyceps militaris* seems to have medical activity. In this study, the anti-obesity activity of waste rice media of *Cordyceps militaris* was evaluated.

Methods: The contents of cordycepin, the major bioactive compound that contribute to the anti-obesity activity of *Cordyceps militaris*, in the waste rice media of *Cordyceps militaris* were determined by high performance liquid chromatography (HPLC). The waste rice media of *Cordyceps militaris* was evaluated for its anti-obesity effect on adipocytes using 3T3L1 mouse adipocytes and high fat diet-induced obese rats.

Results: The contents of cordycepin in the waste rice media of *Cordyceps militaris* was about one third of that in the fruit body of *Cordyceps militaris*, indicating that the waste rice media of *Cordyceps militaris* might possess medical activity. The water extract of the waste rice media of *Cordyceps militaris* strongly inhibited adipogenesis of 3T3-L1 pre-adipocytes by upregulating mRNA expression of AMPK and proteins that related to Wnt10b signaling pathway, and consequently inhibited mRNA expression of C/EBPα and PPARγ. The water extract of the waste rice media of *Cordyceps militaris* also reduced lipogenesis in mature 3T3-L1 adipocytes by inhibiting lipogenesis and promoting lipolysis. The oral administration of the waste rice media of *Cordyceps militaris* by high fat diet-induced obese rats significantly reduced the serum concentrations of triacylglycerol and cholesterol. Moreover, fat diet-induced obese rats showed severe hepatic steatosis, and this condition was alleviated by the oral administration of waste rice media of *Cordyceps militaris*. Gut microbiota analysis reveals a marked abundance of *Akkermansia muciniphila* and *Parabacteroides goldsteinii*, both of which are reported to reverse obesity and insulin resistance, in the waste rice media of *Cordyceps militaris* administrated rats.

Conclusions: These results suggest that *Cordyceps militaris* spent rice media has a potential to be used in the treatment of obesity.

Keyword: Cordycepes militaris, cordycepin, obesity

Vacuum dried mulberry leaf powder: A promising functional ingredient and its application in alginate beads

Parunya Thiyajai[1], Ploypailin Akanitkul[1], Numphung Rungraung[1], Varongsiri Kemsawasd[1], Thunnalin Winuprasith[1]

1. Institute of Nutrition, Mahidol University (Thailand)

Background and objectives: Mulberry (*Morus alba* L.) leaf has been consumed as tea and seasoning powder in many Asian countries. Additionally, it is a well-known folk medicinal plant which have various pharmacological activities. Mulberry 1-deoxynojirimycin (DNJ) is a biologically active natural compound that exhibits hypoglycemic effect. This study aims to compare the active compounds and biological activities of leaf powder after vacuum (VML) and sun (SML) drying process, and in food application.

Methods: DNJ and total phenolics (TP), *in vitro* α-glucosidase inhibitory, and antioxidant (FRAP and ORAC assay) activities of VML and SML were evalutated. The selected powder with high amount of the active compounds and the biological activities was further evaluated the potential applications in food by addition in alginate beads, and reduced the harmful microorganism using high pressure processing (HPP) at 100 and 300 MPa for 5 min. The final products were compared those parameters with non-treatment sample.

Results: Our results showed the vacuum drying process had overcome sun dry method. The content of active compounds and the *in vitro* health benefits of VML were greater than that of SML (DNJ 614.05 ± 40.82 921.88 ± 33.14 µg/g; TP 14.93 ± 0.82 and 11.95 ± 0.10 mg gallic acid equivalent (GAE)/g; percent inhibition of α-glucosidase 77.34 ± 1.00 and 66.36 ± 1.07; FRAP value 60.86 ± 1.32 and 56.48 ± 0.96 µmol trolox equivalent (TE)/g; ORAC value 748.32 ± 35.11 and 604.80 ± 31.45 µmol TE/g in VMB and SMB, respectively). The VML was selected, and added in the alginate bead system. The HPP either 100 or 300 MPa did not reduce active components and *in vitro* health benefits (DNJ 8.31-8.79 µg/g; TP 9.21-9.64 mgGAE/g; percent inhibition of α-glucosidase 62.49-65.93; FRAP25.75-28.70 µmol TE/g; ORAC 158.76-162.63 µmol TE/g).

Conclusion:s: In summary, vacuum dried mulberry leaf powder is a potent functional ingredient that can be applied in food for reduce blood glucose. Our result showed that the HPP prevents loss of the both active compounds and their function. For further study, the clinical trial of the products should be conducted in order to support the health benefit of final products.

Analysis of the effect of coffee polyphenols on the prevention and/or improvement of renal fibrosis

Maiko Takasuga[1], Mayuka Takahashi[1], Mika Kittaka[1], Yoshiko Mori[1], Ken-Ichi Kobayashi[1]

1. Notre Dame Seishin University (Japan)

Background and objectives:In recent years, there is an urgent need to search for functional food ingredients that prevent and/or improve renal fibrosis, a complication of chronic kidney disease (CKD), but little has been done to date. In this study, we focused on coffee polyphenols such as chlorogenic acid (ChA) and its metabolites, caffeic acid (CA) and quinic acid (QA), and examined whether they have an inhibitory effect on renal fibrosis using cultured rat interstitial fibroblasts cells (NRK49F) and human tubular epithelial cells (HK-2).

Methods: NRK49F and HK-2 cells seeded at $1 \times 10_5$ cells and cultured for 1 to 2 days, added ChA, CA, and QA at final concentrations of 0, 50, 100, 200, and 400 µM and treat for 24 hours. To examine the effect of ChA, CA, and QA on cell survival, MTT analysis was performed. Total RNA was extracted from these cells, and real-time PCR was performed. The genes examined were smooth muscle actin (α-SMA) and collagen 1a1 (Col1a1), which are fibrosis marker proteins, and transforming growth factor (Tgf)- β1, β2, and β3, renal fibrosis-inducing factors. GAPDH was used as an internal standard. In addition, the same analysis was performed under the conditions in which these cells were stimulated with TGF-β to induce fibrosis.

Results: The results of MTT analysis in NRK49F cells showed a decrease in ChA and CA. Next, the gene expression levels of α-SMA and Col1a1 in NRK49F cells found no significant changes for ChA and QA, but a concentration-dependent decrease in Col1a1 gene expression for CA. Tgf-β1 and β2 gene expression levels were not affected, but a significant decrease in Tgf-β3 gene expression level was observed with the addition of 400 µM of CA. On the other hand, in HK-2 cells, neither cell survival nor the above gene expression levels were affected by the addition of ChA, CA, or QA. Addition of CA to TGF-β-stimulated NRK49F resulted in a significant decrease in α-SMA and Col1a1 gene expression.

Conclusions: These results suggest that CA may have an inhibitory effect on renal fibrosis induction in a renal interstitial fibroblasts cell-specific manner.

Kyword: renal fibrosis, chronic kidney disease, caffeic acid, chlorogenic acid, quinic acid

Search for inhibitors of advanced glycation end products formation from brown algae, *Sargassum macrocarpum* and *Ecklonia stolonifera*

Seiya Shinoda[1], Arisa Uno[2], Tomoya Masaki[2], Tetsuya Sasaki[3], Haruaki Ishiyama[4], Shin-ichiro Kurimoto[5], Takaaki Kubota[6], Mitsuhiro Sekiguchi[1,2]

1. Graduate School of Ishikawa Prefectural University (Japan), 2. Ishikawa Prefectural University (Japan), 3. Industrial Research Institute of Ishikawa (Japan), 4. Ohu University (Japan), 5. Showa University (Japan), 6. Okayama University (Japan)

Background and objectives: Advanced glycation end products (AGEs) are general group of compounds formed by non-enzymatic reactions between proteins and sugars. The accumulation of AGEs has revealed an association with diabetes, aging, neurodegenerative disease and many other diseases. Discovery of the AGEs formation inhibitors is important to prevent these diseases. To search for inhibitors of advanced glycation end products formation, we screened 18 seaweeds collected in Ishikawa prefecture. As a result of screening, brown algae, *Sargassum macrocarpum* and *Ecklonia stolonifera* were found to have strong inhibitory activity. Therefore, we carried out a search and evaluation of inhibitor from these two brown algae.

Methods: Brown algae, *S. macrocarpum* and *E. stolonifera* were collected at the coast of the Noto peninsula in Ishikawa prefecture. Collected brown algae were washed, dried, and extracted using EtOH. Sequentially, the extracts were purified using normal and reversed-phase chromatography, and reversed-phase HPLC. Isolated compounds were elucidated using NMR spectral analysis. The AGEs formation inhibitory and the DPPH radical scavenging activity of isolated compounds were examined and the structure activity relationship was studied from the results.

Results: As a result of searching for compounds with AGEs inhibitor, 12 meroterpenoids including one new meroterpenoid were isolated from *S. macrocarpum* and 7 phlorotannins were isolated from *E. stolonifera*. All isolated compounds showed AGEs inhibitory activity but trends were different from the DPPH radical scavenging activity. Comparing the AGEs inhibitory activity of phlorotannins, it was observed that the larger number of penta-substituted benzenes had higher activity of the AGEs formation inhibitory. Furthermore, evaluating model compounds of phlorotannins, it was inferred that AGEs formation inhibitory activity was stronger when electron-rich groups were present because of the addition of many oxygen atoms to the phlorotannins

Conclusion: Search for inhibitors of advanced glycation end products formation from brown algae, *S. macrocarpum* and *E. stolonifera* 12 meroterpenoids including one new meroterpenoid and 7 phlorotannins were isolated. As a result of comparing structure-activity relationships of AGEs inhibitors, it was inferred that electron density of the benzene ring is important for the inhibition of AGEs formation by phlorotannins.

Regulation of Nutritional Preference for Macronutrients by Orally Administered Specific Amino Acids

Daichi Shimizu[1], Miho Ishihara[1], Hiroshi Oneda[2], Tetsuya Masuda[1], Kengo Ishihara[1]

1. Ryukoku University (Japan), 2. Nagata Sangyo Co.,Ltd. (Japan)

Background and objectives: Nutritional preferences for macronutrients are significant components of modulating eating behavior. It is well known that Dietary protein intake correlates to appetite, but the relationship between amino acids (AAs) intake and preference for macronutrients remains unclear. In this study, we examined the screening test to identify the novel function of AAs to modulate nutritional preference for macronutrients in licking tests. A feeding test was also performed to confirm the results of the licking test.

Methods: In Experiment 1, eight C57BL/6 mice trained for the licking test for one week with a 5% sucrose solution were used. Twenty amino acid (AA) solutions (AA1~AA20) were prepared by dissolving them in water or 0.1% CMC. As controls, saline or saline with 0.1% CMC was used. AA solutions (1 g/10 mL/kg) or controls were orally administered 30 min before the licking test of 10 min. The solution for the licking test was 5% soybean oil (FAT), 5% sucrose (CHO), or 1% umami solution (PRO). In Experiment 2, eight mice were administered AA2 (1 g/10 mL/kg) or control, and dietary intake of 45% high-fat diet was measured for 60 min.

Results: In Experiment 1, oral administration of AA1 decreased lick rate of FAT, CHO, and PRO ($P< 0.05$). AA20 increased lick rate of FAT, CHO, and PRO ($P< 0.005$). AA19 increased lick late of FAT, and PRO ($P<;0.005$). AA2 decreased lick rate of FAT ($P<;0.005$). AA5 increased lick rate of CHO, PRO ($P< 0.05$). In Experiment 2, the feeding rate of a high-fat diet was significantly suppressed by oral administration of AA2 in accordance with the licking test($P< 0.05$).

Conclusions: In conclusion, we found five AAs that modulate nutritional preference for macronutrients in the licking test. The feeding rate of a high-fat diet was significantly suppressed by AA2. The feeding tests of other four AAs are ongoing.

Search for proteins that inhibit postprandial blood glucose elevation in rice bran and various rice varieties.

Nao Matsubara[1], Rio Ogawa[1], Kazumi Ninomiya[2], Shigenobu Ina[1], Yusuke Yamaguchi[1], Hitoshi Kumagai[2], Hitomi Kumagai[1]

1. Nihon University (Japan), 2. Kyoritsu Women's University (Japan)

Background and objectives: For the prevention of diabetes mellitus, it is effective to suppress or retard the increase in postprandial blood glucose levels. Previously, we showed that a non-digestible 16 kDa protein (REA) contained in the albumin fraction of japonica rice endosperm suppressed the postprandial increase in blood glucose levels. REA adsorbed glucose like dietary fiber and inhibited glucose absorption from the small intestine. In this study, we investigated whether proteins similar to REA could be obtained from other parts of rice or from other rice varieties, and have a suppressive effect on postprandial blood glucose elevation.

Methods: Albumin was extracted from japonica rice red-bran, japonica rice middle-bran, polished indica rice, and polished javanica rice. The presence of 16 kDa protein in albumins and the tolerance to digestion by pepsin and trypsin were evaluated by SDS-PAGE. In addition, the glucose adsorption capacity of albumins was evaluated using a dialysis membrane unit. Albumin with the highest glucose adsorption capacity was subjected to a glucose tolerance test (OGTT) in rats, and blood glucose and plasma insulin levels were measured. The 16 kDa protein in the albumin was subjected to LC-MS/MS analysis to see if it was identical to REA.

Results: The presence of 16 kDa proteins was confirmed in all samples, and they were resistant to digestion except for red-bran albumin. The glucose adsorption capacity was also confirmed in all samples, middle bran showing the highest value. Oral administration of middle-bran albumin with glucose in the OGTT suppressed rapid elevation of blood glucose and insulin levels. The 16 kDa protein obtained from the middle bran was identified to be the same as that from japonica rice endosperm by LC-MS/MS with the high coverage value.

Conclusions: Middle-bran albumin, wasted after polishing rice, is expected to be used as a less expensive food material that can suppress elevation of the blood glucose levels.

Blueberry stem extract prevents lacrimal hyposecretion in Sjögren's Syndrome-like model of non-obese diabetic mice

Kenjirou Ogawa[1], Karin Urata[1], Akane Tagashira[1], Yuta Ohno[2], Keitaro Satoh[3], Hisato Kunitake[1], Kazuo Nishiyama[1], Yo Goto[4], Takayuki Nakayama[4], Masao Yamasaki[1]

1. University of Miyazaki (Japan), 2. Asahi University (Japan), 3. Meikai University (Japan), 4. Biolabo Co., Ltd. (Japan)

Background and objectives: Sjögren's Syndrome (SS) is an autoimmune disease that causes dry eye and dry mouth symptoms. Since SS progresses gradually with aging after onset, it is necessary to establish methods for prevention and/or care of SS from an early stage. Functional foods possess preventive effects against some diseases; additionally, it is safe that we can continuously take them on a daily. In recent years, in Miyazaki, Japan, blueberry stems have been cultivated, and blueberry stem water extract (BSE), which contains polyphenols such as proanthocyanidins, catechins, chlorogenic acid, and rutin, has been studied for the development of health food material. However, no research about BSE has been conducted on eye health. The purpose of this study was to evaluate the effect of BSE on SS-like lacrimal hyposecretion in non-obese diabetic (NOD) mice.

Methods: Male NOD mice were fed diets containing 1% BSE or regular AIN-93G diets for 6 weeks. After pilocarpine I.P. injection under anesthesia, the tear secretion volume of mice was measured using a thread impregnated with phenol red. The length of the part where the color changed due to the tear was evaluated as the amount of tear secretion. The lacrimal glands of mice were collected for histological evaluation, measurement of inflammatory cytokines, IL-6, TNF-α, and IFN-γ, by ELISA, and detection of proteins by Western blotting.

Results:The tear secretion of NOD mice administered with BSE mixed diet was increased at 4 and 6 weeks. Infiltration area and inflammatory cytokines, IL-6 and IFN-γ, were decreased in the lacrimal gland tissue of BSE-treated mice. BSE administration also reduced autophagy-related protein ATG5, which is needed for SS progression. It prevented the downregulation of phosphorylated AMPK, which is involved in the regulation of inflammation in SS and other autoimmune diseases.

Conclusions: In the present study, continuous administration of BSE from the early onset of SS in male NOD mice suppressed inflammation and improved lacrimal secretory function. Further study of the immunomodulatory function of BSE administration is needed in the future.

Keyword: Sjögren's Syndrome, blueberry stem extract, lacrimal gland, tear secretion, inflammation

Blueberry stem extract prevents endoplasmic reticulum stress on blue light-induced retinal photoreceptor cell damage *in vitro*.

Takara Karitani[1], Karin Urata[1], Masao Yamasaki[1], Hisato Kunitake[1], Kazuo Nishiyama[1], Yo Goto[2], Takayuki Nakayama[2], Kenjirou Ogawa[1]

1. University of Miyazaki (Japan), 2. Biolabo Co., Ltd. (Japan)

Background and objectives: Our eyes are exposed daily to a variety of light. Blue light, which is a high-energy visible light, unlike ultraviolet light, reaches the posterior retina, and it causes photoreceptor cell damage. For this reason, blue light is associated with the onset and progression of age-related macular degeneration. The retinal cell damage caused by blue light exposure involves not only oxidative stress but also endoplasmic reticulum (ER) stress. In this study, we investigated the protective effects of blueberry stem water extract (BSE) and its active ingredients against blue light-emitting diode (LED) light-induced ER stress-related apoptosis of retinal photoreceptor cells *in vitro*.

Methods: Cultured murine retinal photoreceptor (661W) cells were seeded in 96-well plates, and cells were treated with BSE and *N*-acetyl-L-cysteine (NAC), which is an antioxidant as a positive control. After 24 h incubation, cells were exposed to 500 lx blue LED light (wavelength 470 nm) for 24 h. At the end of blue light exposure, cell death, apoptosis, and reactive oxygen species (ROS) were detected by fluorescent dye. Additionally, we performed Western blotting to detect the expression of mitogen-activated protein kinase (MAPK) and endoplasmic reticulum (ER) stress-related proteins.

Results: BSE prevented photoreceptor cell death and apoptosis induced by blue light in a concentration-dependent manner. ROS production and phosphorylation of p38 MAPK and c-Jun N-terminal kinase (JNK), which are related to apoptosis as a stress response to blue light exposure, were suppressed by BSE treatment. Furthermore, BSE increased the expression of ER-phagy markers, FAM134B and LC3, and it suppressed ER stress proteins, Bip and ATF4 expressions.

Conclusions: Our results newly show that BSE prevents blue light-induced photoreceptor cell apoptosis through suppressing the endoplasmic reticulum stress signaling pathway.

Taurine Alleviated Hepatic Steatosis in Oleic Acid-Treated-HepG2 Cells and Rats Fed a High-Fat Diet

Qi Song[1,2], Yuxun Ma[1], Tong Ou[1], Junxia Guo[1], Shengquan Mi[1], Yanzhen Zhang[1], Hiroaki Oda[2], Wen Chen[1]

1. Beijing Union University (China), 2. Nagoya University (Japan)

Background and objectives: Non-alcoholic fatty liver disease (NAFLD) is a widespread chronic liver disease defined predominantly by steatosis (triglyceride (TG) accumulation), but there is no approved pharmaceutical treatment. Taurine is an amino acid that has been proven in many trials to alleviate the symptoms of NAFLD. Here we investigated whether the protective effect of taurine against steatosis involves the modulating of AMP-activated protein kinase (AMPK) and insulin signaling pathway.

Methods: The steatotic HepG2 cell model, established with 0.05mmol/L oleic acid, was treated with 5mmol/L taurine and/or 10μmol/L dorsomorphin for 24h. Sprague Dawley rats were divided into 6 groups: control group (regular diet), model group (high-fat diet), and their corresponding high/low dose taurine groups (70 and 350 mg/kg BW/d). All treatments were conducted for 8 weeks.

Results: In steatotic HepG2 cell model, taurine significantly reduced the TG concentration and protein expressions of sterol regulatory element binding proteins-1c (SREBP-1c), peroxisome proliferators activated receptor γ (PPARγ), fatty acid synthase (FAS), acetyl CoA carboxylase (ACC), stearoyl-CoA desaturase1 (SCD1). With taurine supplementation, phosphorylation of mammalian target of rapamycin (mTOR), insulin receptor substrate 1 (IRS1) (Ser302) was decreased and phosphorylation of AMPKα, liver kinase B1 (LKB1), phosphatidylinositol 3 kinase (PI3K), protein kinase B (Akt), ACC was increased. However, the TG-lowering effect of taurine in steatotic HepG2 cells was eliminated by the supplement of AMPK inhibitor- dorsomorphin. In animal experiments, taurine reduced liver and serum TG, as well as serum ALT, AST, IL-1β, IL-4 and TNF-α in rats fed a high-fat diet. The effects of taurine on the main enzymes and regulatory factors in TG synthesis were consistent with most results in steatotic HepG2 cell experiments.

Conclusions: Taurine alleviated the inhibition of IRS1-PI3K-Akt pathway caused by steatosis, and reduced hepatic steatosis by activating LKB1-AMPKα pathway, suppressing mTOR, SREBP-1c and PPARγ.

Keyword: Taurine, AMP-activated protein kinase, Triglyceride

PAB(T7311)
Kudzu and foxglove roots extract improves metabolic dysfunctions through microbiome composition change in Korean menopausal women: A randomized, placebo-controlled trial

Eunbi Heo[1], Seunghee Kang[1], Hyeonjung Ham[2], Taesung Park[2], Oran Kwon[1]

1. Ewha Womans University (Korea), 2. Seoul National University (Korea)

Background and objectives: Kudzu (*Pueraria lobata)* is known as an important source of puerarin, an isoflavone compound. The dried root of foxglove (*Rehmannia glutinosa*) is among the most common ingredients to combine with kudzu to have complementary effects. Ovariectomized-induced rat studies reported that kudzu and foxglove roots extract (KF) supplementation could affect bone turnover rate and insulin resistance. However, its effect on humans has not been investigated. So, this study aimed to evaluate the effects of KF on menopausal metabolic changes in women associated with microbiome composition alteration.

Methods: In this randomized, placebo-controlled, double-blind trial, 75 menopausal women aged 45 to 70 were enrolled and assigned to receive either a placebo or low-dose (0.63 g/day) or high-dose (0.95 g/day) for 12 weeks. Out of 61 subjects who completed the 12-week intervention, 50 (25 in the placebo group and 25 in the high-dose KF group) were analyzed for 16S rRNA gene-based metagenomics in urine. To test differences in 32 clinical features between two groups, we accurately predicted whether subjects were treated with KF using the least absolute shrinkage and selection operator (LASSO)-panelized logistic regression model. The differential genera between groups that showed significant results in at least 4 out of 7 statistical methods were determined, and the correlation with the selected clinical markers was confirmed. Different functional Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways between groups were predicted through the Tax4Fun analysis.

Results: LASSO-panelized logistic regression model selected 17 clinical features, including body weight, C-terminal telopeptides of type I collagen (CTX), asymmetric dimethylarginine, and high-density lipoprotein cholesterol (HDL-cholesterol). In metagenomic analysis, the relative abundances of 16 genera were significantly different between groups. Spearman's correlation between 17 clinical features and 16 altered genera showed that CTX and HDL-cholesterol had negative correlations with *Lachnospiraceae* NC2004 group and *Escherichia-Shigella*, respectively. Moreover, functional prediction determined that three KEGG pathways in amino acid metabolism and two in xenobiotics biodegradation were different between groups.

Conclusions:The KF supplementation for 12 weeks may improve bone, vascular, and lipid-related metabolism in menopausal women by altering microbiome composition.

Enhanced immunity and hematopoietic function of *Litsea japonica* fruit extract in cyclophosphamide-induced immunosuppressed mice

Seon Yeong Ji[1,2], EunJin Bang[1,2], Hyun Hwang[1,2], Ki Won Lee[3], Yung Hyun Choi[1,2]

1. Dong-eui University College of Korean Medicine (Korea), 2. Dong-eui University Anti-Aging Research Center (Korea), 3. Kwangdong Pharm Co. Ltd. (Korea)

Background and objectives: Because the immune system plays a role in protecting the body from harmful substances and invasions, immune function is important for maintaining a healthy physiological state. Therefore, natural compounds that modify immune responses have attracted great interest for many years. This study was conducted to investigate improved activity of immunity and hematopoetic function of *Litsea japonica* fruit extract (LJFT) as a potential functional food.

Methods: The immunity-stimulating activity was observed in BALB/c mice supplemented with LJFT at low, medium, and high dosage for 7 days after administration of cyclophosphamide

Results: Our results showed that LJFT treatment significantly improved the spleen injury score and body weight change in cyclophosphamide-stimulated mice. The spleen-derived lymphocytes analysis demonstrated that numbers of $CD4^+$ and $CD8^+$T cells were notably enhanced by approximately 2-fold in the spleen of mice treated with high dosage of LJFT. In mice splenocytes differentiated into T and B lymphocytes, LJFT significantly induced proliferations. Furthermore, in hematopoietic analysis, LJFT significantly recovered numbers of white blood cells, red blood cells, and platelets. By an enzyme-linked immunosorbent assay analysis, serum levels of immune-related cytokines of tumor necrosis factor-α, interleukin (IL)-1β, IL-6, IL-2, and IFN-γ were notably recovered. In addition, serum levels of immunoglobulin (Ig) A, IgM, and IgG were restored by LJFT treatment.

Conclusions: Although further investigation is needed on the underlying mechanism of LJFT that stimulates immune function, this study has provided a reference for the development of *L. japonica* as a source material applied in functional foods to improve human immunity and hematological function

Keyword: Litsea japonica, immunity, hematopoetic function, cytokines, mice

Inhibitory effect of mixed tea of mulberry leaves and water chestnuts on postprandial blood glucose elevation

Midori Yasuda[1], Kenichiro Yasutake[2], Iori Yoshinaga[3], Madoka Saiki[1], Kanako Nakashima[1], Narumi Ehara[1]

Nishikyushu University (Japan), 2. Nakamura Gakuen University (Japan), 3. Nakamura Gakuen University Junior College (Japan)

Background and objectives: Since postprandial hyperglycemia is a risk factor not only for diabetes but also for arteriosclerosis, it is necessary to suppress the rapid rise in blood glucose levels after a meal. Mulberry leaves contain 1-deoxynojirimycin, which is known to inhibit α-glucosidase. On the other hand, we have shown that polyphenols in the husk of water chestnuts inhibited elevated blood glucose levels. In this study, we developed mixed tea of mulberry leaves and water chestnuts (mulberry-water chestnut tea), and investigated its effect on postprandial blood glucose elevation in humans with elevated blood glucose levels

Methods: The study subjects were 30 people (43.9 ± 8.4 years old, 21 males and 9 females) with fasting blood glucose levels of 100 to 126 mg/dL or hemoglobin A1c levels of 5.6 to 6.5%, randomly assigned to two groups. The tea used in the study was a mixture of mulberry leaves and the husk of the Japanese water chestnut (*Trapa japonica*) grown in Kanzaki, Saga, Japan. The total polyphenol and 1-deoxynojirimycin contents in the tea were 87.3 and 10.2 mg, respectively. The study was a randomized, placebo-controlled, double-blind, crossover comparative study. Subjects drank 200 ml of mulberry-water chestnut tea or placebo tea after taking blood on an empty stomach and immediately consumed 200 g of cooked rice. Subjects had their blood drawn 30, 60, 90, and 120 minutes later, respectively. Blood glucose and insulin levels were then measured.

Results: Mulberry-water chestnut tea significantly suppressed the increase in blood glucose levels 30 and 60 minutes after the meal compared to placebo tea. Mulberry-water chestnut tea was found to significantly suppress the rise in insulin at all postprandial times. In addition, the highest blood glucose and insulin levels were significantly lower in the mulberry-water chestnut tea group than in the placebo tea group. The time to reach maximum blood glucose concentration was also significantly delayed in the mulberry-water chestnut tea group compared to the placebo group.

Conclusion: Mulberry-water chestnut tea was suggested to be effective as a food ingredient for suppressing the increase in postprandial blood glucose levels in humans with elevated blood glucose levels.

Ethyl acetate extract of bitter melon enhances serum clearance and muscle uptake of dietary triglyceride in rats

Shoko Nishizono[1], Rintaro Uchino[2], Daiki Umeda[2], Shizuka Hase-Tamaru[2], Nana Fujiwara[3], Keisuke Uryu[3], Isafumi Maru[3], Nobuhiro Fukuda[4], Tsuyoshi Ikeda[1]

1. Sojo University (Japan), 2. Fukuoka Institute of Technology (Japan), 3. Bizen Chemical Co., Ltd. (Japan), 4. Miyazaki International College (Japan)

Background and objectives: Bitter melon (*Momordica charantia*, BM) is a tropical and subtropical vine of Cucurbitaceae family. In addition to the culinary use, BM is traditionally used in medical herb for the treatment of diabetes mellitus in some countries. We recently reported that dietary BM elevated respiratory exchange ratio in the proper exercise performance in adult healthy men, suggesting that BM contains some active components to enhance lipid oxidation. In this study, we analyzed the effects of these active components on lipid metabolism in rats

Methods: We fractioned BM by using ethyl acetate (EE) and water (WE) to isolate active component(s). Triglyceride concentration and fatty acid composition of EE were determined. EE was further fractioned using silica gel column and HPLC. The major component estimated as triterpene glycoside was analyzed by NMR spectroscopy. Sprague-Dawley rats, weighing 300 g were fasting for 12 h, and followed by oral injection of 0.75 g/kg BW of BM powder or WE, or 0.375 g/kg BW of EE. After 0.5 h, rats were orally injected 15 ml/kg BW intralipos (10% soybean oil). Bloods were collected from the tail vein at 0, 1.5, and 2.5 h of the injection. At 2.5 h, gastrocnemius and soleus muscles were excised and determined serum and muscle triglyceride concentrations.

Results: Recoveries of EE and WE were 4.5% and 97.7%, respectively. Triglyceride concentration of EE was 48.8%, and the major fatty acid composition of EE was 52% α-eleostearic acid. From the result of NMR spectroscopy, the isolated major compound of triterpene glycoside of EE was identified as momordicoside K. While there were no differences of serum triglyceride concentration among 4 groups at 0 and 1.5 h, those in BM, EE and WE groups were significantly lowered than the control group at 2.5 h. Triglyceride concentrations of muscle in BM and EE groups were significantly higher than those of the control and WE groups.

Conclusions: There was a negative correlation, at 2.5 h, between serum and muscle triglyceride concentrations in rats injected BM and EE, but not WE, and major active components of EE were speculated as α-eleostearic acid and momordicoside K.

The effect of inulin in a Jerusalem artichoke, *helianthus tuberosus* on postprandial blood glucose levels in healthy young women.

Yukiko Sumida[1], Shunsuke Higaki[2], Yuichiro Takei[1], Reiko Inai[1,3]

1. University of Kochi (Japan), 2. Hokkaido Bunkyo University (Japan), 3. Nara Women's University (Japan)

Background and objectives: Inulin is one of soluble dietary fibers contained in such as agave, wheat and burdock. It has been reported that the soluble fiber has several effects on the human being, e.g. improving gut microflora and its immune system, and suppressing the absorptions of sugar and triglyceride through the intestine. However, there are few studies targeting adult young females. Therefore, we decided to investigate the effects of inulin on biochemical examinations, postprandial blood glucose fluctuations, defecation status, gut microflora, and physical stress markers in the women who ate commercially available inulin derived from Jerusalem artichokes for 1 week.

Methods: Seven healthy female volunteers (21-22 years, height 160.7±2.7 cm, body weight 54.4±6.4 kg, BMI 21.1±1.9 kg/m^2) were recruited. They ingested 0.8 g of inulin derived from Jerusalem artichokes before every three meals a day, which means they had total 2.4 g of inulin per day for a week. We analyzed laboratory data such as postprandial blood glucose levels, and assessed body composition, a physical stress by checking salivary IgA levels, and intestinal bacteria at both before- and after ingestions of inulin. Postprandial blood glucose levels were measured by meal load. For the glycemic load of a diet, the subjects ate two commercially available rice balls (78.2 g of available carbohydrate), and their blood glucose levels were monitored at an empty stomach (0 min) and 30, 60, 90, and 120 mins after ingestion. In addition, a dietary survey was conducted using the food intake frequency survey and lifestyle habit survey by FFQgVer.6 and the 24-hour recall method.

Results: One week of inulin ingestions did not show any significant changes in body composition and biochemical examinations at Before- and After ingestions. Postprandial blood glucose changes after eating rice showed significant reduction of the maximum blood glucose levels and the incremental area under the curve (IAUC) of blood glucose levels on 0 to 120 mins. In addition, improvements of both defecation frequency and stool appearance, and alternations of gut microflora were observed after ingesting inulin for a week.

Conclusions: We confirmed that continuous intake of inulin improved defecation conditions, altered the intestinal flora, and suppressed postprandial blood glucose levels. Further research on functional ingredients is required to be utilized in nutritional therapy and nutrition education in the near future.

Piceatannol inhibits fat accumulation by promoting phosphorylation of hormone-sensitive lipase

Reona Maezawa[1], Ayumi Matsuoka[1], Natsuki Ozawa[1], Kotoko Arisawa[2], Ikuyo Ichi[1], Yoko Fujiwara[1]

1. Ochanomizu University (Japan), 2. Tohoku University (Japan)

Background and objectives: Piceatannol (PIC), one of the analogs of resveratrol, is a naturally occurring phytochemical and found to be contained in large amount in passion fruit (*Passiflora edulis*) seeds and known to have several beneficial effects such as antioxidant, anti-cancer, and anti-inflammatory activity. PIC also consists of a chemical structure like estrogen. In our previous study, we reported that PIC significantly suppressed visceral fat accumulation in ovariectomy mouse and found that the phosphorylation of hormone-sensitive lipase (HSL) in white adipose tissue was induced by PIC treatment. In this study, we investigated in detail the effects using 3T3-L1 adipocytes to clarify the mechanism by which PIC inhibits fat accumulation.

Methods: 3T3-L1 adipocytes were seeded in 6-well plates at 1×10^5 cells/well and induced to differentiate 2-day post confluency. The medium was changed every other day. Cells were differentiated for 6-10 days and subjected to each experiment. PIC was added to the medium at concentrations of 0, 25, or 50 µM with or without various agonists or antagonists. After extraction of total mRNA, expression levels of genes related to lipogenesis and lipolysis were measured by qRT-PCR. Phosphorylation of the protein was determined by Western blotting.

Results: At first, we confirmed that PIC reduced fat accumulation in 3T3-L1 as in OVX mice. PIC had no significant effect on lipogenesis-related genes expression. PIC promoted phosphorylation, meaning of activation, of HSL, an enzyme involved in lipolysis but not adipocyte triglyceride lipase (ATGL). This effect was not observed with RSV. Then, we investigated the mechanism by which PIC exerts its effect. The addition of PIC with propranolol, an antagonist of the β-adrenergic receptor, did not alter its action. However, when H89, an antagonist of PKA or G15, a selective antagonist of G-protein-coupled estrogen receptor (GPER) was added with PIC, phosphorylation level of HSL was lowered. In addition, PIC decreased the phosphorylation level of Akt, which is a downstream factor of insulin signaling.

Conclusions: It is suggested that PIC suppressed fat accumulation by promoting phosphorylation of HSL and that this effect may be mediated by GPER.

Dietary chrysin and quercetin ameliorate chemically induced colitis in mouse

Wen-Tzu Wu[1]

1. Asia University (Taiwan)

Objectives: The purpose of the study was to investigate the effects of chrysin and quercetin on the colonic damage and the levels of malondialdehyde in the organs of dinitrobenzene sulfonic acid (DNBS)-induced colitis in mice.

Methods: Male C57BL6/J mice were given chrysin (100 mg/kg, DC) or quercetin (100 mg/kg, DQ) while the control (CON) and DNBS groups were given vehicle every other day by oral gavage for 3 weeks. Then, colitis was induced by intra-rectal instillation of DNBS (4 mg per mouse) dissolved in 50% alcohol and the control mice were given the same volume of ethanol. The disease activity index (DAI) and body weight loss were measured from day 0 to 3 during DNBS treatment.

Results: All DNBS-treated mice resulted in a colitis characterized by weight loss, increased the score of DAI and loss of colonic architecture compared to the CON group. Chrysin attenuated the DNBS-induced colonic damage, as evidenced by the alleviation colon shortening and the decrease in mucin-producing goblet cells as well as the expression of MUC2. Besides, DC and DQ groups significantly reduced DNBS-elevated plasma interlukin-6, and malondialdehyde levels in the liver and ileum.

Conclusions:These results indicated that chrysin and quercetin could alleviate the colonic injury and oxidative stress in DNBS-induced colitis mice.

S -1-propenylcysteine suppresses inflammation by promoting anti-inflammatory M2c-like macrophage polarization

Satomi Miki[1], Miyuki Takashima[1], Mari Ishida[2], Hiroki Kokubo[2], Masao Yoshizumi[2,3], Jun-ichiro Suzuki[1]

1. Wakunaga Pharmaceutical Co., Ltd. (Japan), 2. Hiroshima University (Japan), 3. Yasuda Women's University (Japan)

Background and objectives: Chronic inflammation caused by aging and unhealthy lifestyle can trigger the development of more severe diseases, such as atherosclerosis, type 2 diabetes and chronic kidney disease. Macrophage polarization into inflammatory M1 and anti-inflammatory M2, especially M2c type, is dependent on the tissue microenvironment, and the balance between M1 and M2 macrophages is important for the maintenance of immune homeostasis. In chronic inflammation, damage-associated molecular patterns (DAMPs) from dead cells shift the macrophage polarization into M1 type, leading to the persistent inflammation. We have previously shown that *S*-1-propenylcysteine (S1PC), the characteristic sulfur-containing compound in aged garlic extract, has a variety of beneficial actions including anti-inflammatory effect. In this study, we evaluated the action of S1PC on macrophage polarization and its detailed mechanism of action.

Methods: Senescence-Accelerated Mouse Prone 8 (SAMP8) mice were orally administrated 5 mg/kg S1PC for 6 weeks and the splenic lymphocytes were isolated. Bone marrow-derived macrophages (BMDMs) from C57BL/6J mice were cultured with LPS and IFN-γ, IL-4 or IL-10 in the presence of S1PC to polarize them into M1-, M2a- or M2c-like macrophages. Macrophage population and protein levels of both macrophage markers and IL-10R/STAT3 signaling pathway-related proteins in these cells were analyzed using flow cytometry, quantitative PCR and western blotting.

Results: We found that S1PC increased $CD11b^+$ $F4/80^+$ $CD206^+$ $CD86^-$ $CD150^+$ cells (M2c-like macrophages) and decreased $CD11b^+$ $F4/80^+$ $CD206^-$ $CD86^+$ cells (M1-like macrophages) in splenic lymphocytes of SAMP8 mice. In addition, S1PC also increased the production of M2c macrophage markers, arginase 1 and IL-10. *In vitro* studies, S1PC increased M2c-like macrophages by acting directly on BMDMs in the presence of IL-10, resulting in the decreased M1-like macrophages and pro-inflammatory cytokines compared to those treated with IL-10 alone. Next, we investigated the mechanism by which S1PC enhanced the number of M2c-like macrophages and found that this compound promoted the production of IL-10, which is essential for the M2c macrophage polarization, by maintaining STAT3 activation through inhibiting the interaction between IL-10Rα and its negative regulator SH2 domain containing inositol polyphosphate 5-phosphatase 1 (SHIP1).

Conclusions:These results suggest that S1PC exerts anti-inflammatory effect by promoting M2c-like macrophage polarization through sustained activation of IL-10R/STAT3 signaling pathway.

The potential of a polyphenol-rich pomegranate extract as a nutraceutical to suppress the microbial conversion of L-carnitine into trimethylamine

Priscilla Day-Walsh[1], Julia Eva Haarhuis[1,2,3], Emad Shehata[1,5], Barbora Nemeckova[1], Shikha Saha[1], Lee Kellingray[1], Arjan Narbad[1], Salvatore Rapisarda[4], Paul Kroon[1]

Background and objectives: L-carnitine is an essential nutrient, found in red meat and metabolised by human gut microbiota to trimethylamine (TMA). In the liver, TMA is converted to trimethylamine N-oxide (TMAO), which it strongly associated with atherosclerosis and various cardiometabolic diseases. Previously suggested treatments to reduce TMAO are broad-spectrum antibiotics and 3,3-dimethyl-1-butanol (DMB), but these have adverse effects. Hence, we explored the effects of a pomegranate extract, naturally rich in polyphenols (e.g., ellagitannins and anthocyanins) that are thought to exert antioxidant and anti-inflammatory properties. In preliminary experiments, we found that anthocyanins reduced the conversion of another TMA precursor, choline, to TMA *in vitro*. Here, we aimed to explore the effects of a pomegranate extract on microbial L-carnitine metabolismo.

Methods: *In vitro* colon models were used, each comprising of a glass vessel that contained 1% fresh human faecal slurry from one of three separate donors. The models were inoculated with 2000 µM L-carnitine in combination with different doses of Dermogranate® pomegranate extract (5.7, 11.4, or 22.8 mg/mL). A control model with L-carnitine and without pomegranate extract was included for each donor. The models were maintained anaerobic (N_2 flow), at a controlled pH (6.6-7.1), and at 37 °C. Samples were collected at multiple time points over 48 hours and directly stored at -80 °C until further analysis. The samples were analysed for the concentration of L-carnitine, γ-butyrobetaine (γ-BB), TMA, and related metabolites, using LC-MS.

Results: The models that were treated with pomegranate extract showed slower formation of γ-BB compared with the control models in a dose-dependent fashion, with statistically significant differences at 8, 10, 12 and 20 hours after inoculation. In the control model, TMA appeared after 28 hours, while TMA did not appear in the pomegranate-treated models, with a statistically significant difference at 48 hours after inoculation.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Conclusions: These findings demonstrate that the pomegranate extract suppressed L-carnitine conversion to the intermediate metabolite, γ-BB, and to TMA. This may subsequently reduce the levels of the proatherogenic TMAO. Prospectively, the use of pomegranate extract as a nutraceutical to suppress the microbial l-carnitine conversion to TMA needs to be further investigated in human studies.

Effect of Chrysanthemum morifolium extract on the postprandial glucose responses in subjects with abdominal obesity

Eunok Lee, Soyoung Maeng[1], Oran Kwon[1]

1. Ewha Womans University (Korea)

Background and objectives: Chrysanthemum morifolium is a medicinal plant of the Asteraceae family, that exerts a wide range of health benefits including anti-diabetes, anti-oxidants and anti inflammatory effects. This study aimed to investigate whether Chrysanthemum morifolium extract (CME) may exert beneficial effects on postprandial glucose response and related metabolic disorders in abdominal obesity.

Methods: A randomized, double-blind controlled trial was conducted in abdominally obese with metabolic abnormalities. Seventy-eight subjects were randomly assigned to receive either a placebo or CME (750 mg/day) for 12 weeks. We measured body composition, anthropometric measures, glucose biomarkers and lipid profile before and at the end of the trial. For the postprandial test, at 12 weeks, the subjects consumed a 75 g glucose with either a CME or placebo. Postprandial blood samples were collected 30, 60, 120, and 180 min afterwards.

Results: In postprandial response, the blood glucose levels peaked at 60 min in both groups and decreased steadily after peak in the CME group compared to the placebo group. Particularly, blood glucose level at 120 min was significantly lower in CME group. In fasting state, the level of HbA1c was slightly increased from baseline in the placebo group, it maintained unchanged in the CME group.

Conclusions:These findings suggest that CME supplementation may improve postprandial glucose response in subjects with abdominal obesity.

Repeated supplementation of exogenous SOD can affect the endogenous antioxidant system as well as the microbial composition associated with oxidative damage.

Yea-eun Nam[1], Yunsoo Kim[1], Minji Jung[1], Hye Jin Kim[2,3], Oran Kwon[1]

1. Ewha Womans University (Korea), 2. The Research Institute for Veterinary Science (Korea), 3. Korea Mouse Phenotyping Center (KMPC) (Korea)

Background and objectives: Free radicals generated by various endogenous systems in our body cause redox imbalances and can lead to aging and degenerative diseases. Activation of superoxide dismutase (SOD), which is the first gateway of the antioxidative system, has been shown to protect the body from oxidative stress by boosting the redox cycle. However, since simple antioxidants research has been the major so far, evaluation of the effectiveness of SOD, an enzymatic antioxidant, is still insufficient. Therefore, the purpose of this study is to evaluate the effects of enzymatic antioxidants through changes in the antioxidant index and circulating microbiome according to long-term intake.

Methods: This study was designed as a randomized, double-blind, placebo-controlled in 80 healthy adults, and subjects consumed SOD (250 IU/capsule) or placebo daily for eight weeks. This study was designed as a randomized, double-blind, placebo-controlled in 80 healthy adults, and subjects consumed SOD (250 IU/capsule) or placebo daily for eight weeks. Functional indicators related to oxidative damage and antioxidant systems were evaluated using blood and urine samples collected before and after repeated consumption for 8 weeks. Also, the microbiome was analyzed by 16s NGS sequencing of blood and urine samples at the last visit.

Results: Endogenous antioxidant defense system and oxidative damage indicators were compared by considering the interaction between the group and time. Long-term intake of SOD activated antioxidant enzymes within the test group and remarkably decreased the level of oxidative damage markers, resulting in a difference between groups ($P < 0.05$). As a result of microbiome analysis, beta diversity analysis at the genus level showed differences between groups, and more than 15 critical genera with VIP scores > 1.0 and $P < 0.100$ were selected. And through the analysis of the relationship between clinical variables and microbiome at genus level, microorganisms such as *Gordonibacter*, *Peptoniphilus*, and *Slackia* showed a strong correlation with the enzymes in antioxidant system.

Conclusions: These findings suggest that repeated supplementation of SOD plays a role in altering the microbial composition, which can enhance the activity of endogenous antioxidant enzymes and mitigate oxidative damage.

Establishment of a simple screening assay system for identifying food-derived modulators of cytokine function

Hirotada Kojima[1]

1. Osaka Metropolitan University (Japan)

Background and objectives: The signal transducer and activator of transcription (ST) family are cytokine-driven transcription factors that regulate various genes important for determining cell fates. The gain-of-function mutations in the *ST3* gene or the constitutively activated state of ST3 proteins cause several types of early-onset autoimmune diseases and cancers. These findings make ST3 an attractive target for disease intervention. This study aimed to develop an efficient screening system for identifying food-derived modulators of cytokine signaling.

Methods and Results: To search for molecules that modulate cytokine-driven ST3 activity, we established a simple and efficient cell-based screening assay system. HepG2 cells (hepatocellular carcinoma cells) were transfected with the luciferase reporter gene plasmid containing a ST3-binding site inserted upstream of the minimal *JUNB* promoter. The selected cell clone has superior cytokine dose-responsivity with a high signal-to-noise ratio. We established a stable assay by optimizing the parameters: culture plate, media, and normalization method. Several crude extracts of herbal plants or food, as well as purified natural ingredients, were screened for attenuation of cytokine-induced luciferase activity. Pretreatment with two carboxylic acid species at a dose of 50 µM attenuated reporter activity. Cytotoxicity was not observed under these assay conditions. Each carboxylic acid partially inhibited the expression of the cytokine-inducible ST3-target gene, phosphorylation levels of ST3, and nuclear translocation of ST3. We also discuss the mechanism of how these two carboxylic acids affect ST3 activity.

Conclusions: Altogether, our data indicate that the newly established screening system enables the identification of modulators of cytokine signaling.

Keyword: cytokine modulator, assay system, screening

PAB(T7-323)
Prebiotics and resistant starches from dietary pulses differently modulate gut microbiome and metabolic health in a humanized murine model of aging

Saurabh Kadyan[1], Gwoncheol Park[1], Nathaniel Hochuli[1], Prashant Singh[1], Ravinder Nagpal[1]

1. Florida State University (USA)

Background and Objectives: Dietary pulses, being a rich source of fiber and proteins, are an ideal food choice for older adults and offer an inexpensive way to promote gut and metabolic health. Pulses-derived resistant starches (RS) are relatively less explored prebiotic ingredients compared to cereals and tubers' RS with no research conducted in examining its gut modulatory potential in old age. We herein investigate prebiotic effects of pulses-derived RS on gut microbiome in aged, humanized mice colonized with human microbiota.

Methods: One-year-old 'germ-free' C57BL/6J male and female mice were colonized with human gut microbiota and divided into six groups: Western Diet (WD, control), WD supplemented with pinto-bean (RS1), blackeyed-pea (RS2), lentil (RS3), chickpea (RS4), and inulin (from chicory). Gut microbiome after 8-weeks intervention was measured using Illumina MiSeq platform and analyzed for taxonomic and diversity metrics using QIIME2 workflow (version 2020.6). Statistical analyses were performed with python libraries.

Results: RS 1-4 and inulin induced distinct microbiome signatures and these signatures further varied between male versus female hosts. Among groups, *Bacteroides*, *Blautia*, and *Parasuterella* were significantly ($P < 0.05$) abundant in inulin; *Parasutterella* in RS 2; *Dubosiella* and *Turicibacter* in RS 3; *Streptococcus*, *Odoribacter*, *UCG_010*, *Tuzzerellam*, and [*Eubacterium*] brachy_group in RS 4. Besides, nine taxa were significantly increased only upon treatment with RS4 compared to the control/inulin-groups. RS supplementation induced microbiota alteration in sex-dependent fashion, with males (Inulin and RS 2-4) and females (Inulin and RS4) had different microbial profiles and composition. Only RS 4 increased the microbial diversity in females. In control group, *Faecalibaculum* and *Dubosiella* were more abundant in females, while *Enterococcus* was more dominant in males. Interestingly, *Dubosiella* increased and become the most dominant taxa in males after inulin and RS2-4 administration whereas *Faecalibaculum* significantly decreased in females after inulin and RS4 treatment

Conclusion: These findings highlight unique patterns of gut microbiome modulation by different RS-types. RS4 consumption resulted in highest bacterial composition differences among all groups which were consistent among both sexes. The correlation of these alterations with host gut and cardiometabolic health (*data analysis in-progress*) will further shed light on the potential of RS for nutraceutical applications.

Quantitative MALDI-MS imaging analysis of tissue accumulated food compounds by fluorescence-assisted spraying method

Taehun Hahm[1], Toshiro Matsui[1], Mitsuru Tanaka[1]

1. Kyushu University (Japan)

Background and objectives: The application of matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS) imaging to quantitative analyses is limited due to variability of matrix amount and inhomogeneity of matrix crystal formation on tissue sections. Thus, in this study, we aimed to establish quantitative (q) MALDI-MS imaging using a MS ionizable fluorescent reagent to provide constant matrix spraying amount and to normalize variability of MS intensity of analytes.

Methods: Ferulic acid (FA) was used as target food compound in tissue. Rhodamine 6G (R6G, 40 µg/mL) and *O* dinitrobenzene *O* -DNB, 10 mg/mL) was added to matrix 1,5-diaminonaphthalene (1,5-DAN, 10 mg/mL). FA (20 pmol/0.2 µL spot) spotted on kidney tissue section from rats was analyzed by MS imaging (negative mode) using fluorescence-assisted matrix spraying method to obtain desired fluorescent intensity (40,000 a.u.). Kidney was taken 0, 15, 30, and 60 min after FA (50 mg/kg) oral administration to Sprague-Dawley rats.

Results: Among fluorescent reagents (R6G, 7-methoxycoumarin-3-carboxylic acid, naphthalene, and 6-carboxyfluorescein) used in this study, R6G was added to 1,5-DAN solution as MS ionizable fluorescent reagent to compensate matrix spray amount and normalize MS intensity. Furthermore, *O* -DNB was used as matrix additive to form uniform matrix crystals on tissue sections. At the spraying condition using R6G in 1,5-DAN solution containing *O*-DNB, reproducibility (RSD = 3.1%) and linearity (0.5–75 pmol/mm^2, R^2 = 0.9972) of relative MS intensity of FA were significantly improved compared to those of cycle-number-fixed spraying (40 cycles, RSD = 31.1%, R^2 = 0.9349). Then, tissue accumulated FA was visually determined to be 3.5, 3.0, and 0.2 µmol/g tissue at 15, 30, and 60 min after FA oral administration (50 mg/kg), respectively. Moreover, a linear correlation was observed between the present qMALDI-MS imaging and LC–MS results (R^2 = 0.9906, n = 3).

Conclusions: Quantitative MALDI-MS imaging was achieved successfully by fluorescence-assisted matrix spraying by R6G (MS normalizing standard) in 1,5-DAN solution containing *O* -DNB as matrix additive, which successfully quantified tissue accumulated FA in rat kidney after the oral administration.

Microbial loads in foods served and sold in Senior High Schools in Central Region, Cape Coast

Jacob Setorglo[1], Philip Narteh Gorleku[1], Musah Anan[1]

1. University of Cape Coast (Ghana)

Background and objective: Improving the safety of cooked foods in School canteens is one of the ways of making foods wholesome for students who rely on this for their daily nutrient and energy supply. This study determined the microbial loads in foods served at dining halls and supplied points in sampled Senior High School (SHS) in the Cape Coast Municipality. **Methods**: The design was experimental, and convenience sampling was used to select four SHSs in the Cape Coast, Central Region. We sampled six frequently foods that are served to students during lunch breaks. Swabs from foods served in the canteen and from vendors and analyzed for microbial contamination based on the Codex Alimentarius Commission standards. Bacteria loads were separated into positive and negative gram and presented in CFU/g. We presented proportions for the number of microbes found in the foods and cooking materials. **Results**: Seven isolates were obtained from food samples and vendors. Most of the bacterial strains isolated were *Enterobacteriaceae* (71%). About 29% of the isolates were gram-positive bacteria (*Bacillus cereus*, and *Staphylococcus aureus*). Other types and amounts of isolates were: *Staphylococcus aureus* [canteen: (28-112CFU/g); vended: (23-84CFU/g)], *Bacillus cereus* [canteen:(8-34CFU/g); vended: (0-22CFU/g)] and *Corynebacterium spp.* canteen: (0CFU/g); vended(0-13CFU/g)]; **Conclusions**:Although the contamination was high, bacterial colonies found were within the safe limits of 150-300CFU/g, the amount of contamination is still high since students eat these foods on a regular basis in Cape Coast.

Current state of preserved foods for determining the cause of food poisoning while providing meals in Japan

Kikuko Hata[1], Yoko Horiuchi[1]

1. Morioka University (Japan), 2. Aichi Gakuin University (Japan)

Background and objectives: At a Japanese mass-meal facility, it was decided to collect 50g of raw foods and cooked foods and store them at -20℃ for at least 2 weeks per specific hygiene inspection standards, which is especially important in the event of food poisoning (Ministry of Health, Labor and Welfare, 2005). After storage, food is often discarded, which poses the problem of food loss and waste, the prevention of which is one of the Sustainable Development Goals . This manual does not specify the details of the foods to be collected and the facility's measures required to select preserved foods. Therefore, the purpose was to investigate the foods that are preserved and those not preserved in the mass cooking facility, summarize the description contents, and use it as the basic data for collecting preserved foods.

Methods: Two registered dieticians searched for the terms "mass cooking" and "preserved food" or "food inspection" using the Google browser in manuals published on the Internet. The contents of 36 cases with detailed descriptions of 66 preserved food manuals that could be viewed, were organized.

Results: The most common manuals for preserved foods were of school meals, with 31 cases. Regarding foods that do not need to be preserved, there were many descriptions of cereals such as rice, wheat, canned foods, seasonings, and dried foods stored at room temperature. However, some manuals indicated collecting several seasonings and dried foods for preservation. In the case of collecting foods being less than 50 g per serving, different collection methods were mentioned in each manual.

Conclusions: Manuals differed in the foods for which preserved foods were collected (or not) and the amount of preserved foods collected.

Effects of pseudo-parasitic infection on mouse behavior

Kyo Higuchi[1], Ayaka Okawa[1], Fuka Hirano[1], Aoi Urakawa[1], Anri Yamada[1], Shinya Matsumoto[1]

1. Kyoto Women's University (Japan)

Background and objectives: Recently, the relationship between intestinal parasites and physiological and mental states of host animals has been attracting attention, as exemplified by the fact that parasite *Toxoplasma gondii* induces change in behavior of host rodents. Throughout its evolution, human race has continuously been infected by and co-existed with numerous parasitic nematodes such as pinworm and tapeworms, which drive us to imagine that human behavior may also unawarely be affected by the coexisting parasitic nematode, just like the case of *Toxoplasma*-infected rodents. If so, the people in modern industrialized countries, who are mostly free from parasitic nematode, may have different behavioral pattern compared to people in the past when parasitis infection was more common. In this study, we hypothesized that the absence of parasites in modern humans has some effect on their mental and personality states, and attempted to test this hypothesis through behavioral analysis using “pseudo” parasite- infected mouse model.

Methods: We fed mice with non-infectious nematode *Caenorhabditis elegans*, which is used in molecular biology as model organism, for a long term to create a pseudo-parasite-infected state. By mouse intestine continuously exposed to the nematode-derived molecules and structures, we expected some aspect of parasite-infection was mimicked in this model. To measure the neurophysiological and behavioral changes between nematode-fed and control mice, hanging test, spontaneous running test, forced running test, and opposite-sex encounter test were conducted.

Results: There was no significant difference between the nematode-fed group and the control group in the hanging test, spontaneous running test, and forced running test, but in the opposite-sex encounter test, the nematode-fed group tended to spend less time in the opposite sex zone than the control group.

Conclusions:This experiment suggests that the presence or absence of parasites may have an effect on the sexual orientation and feeling of mice. This mechanism may be explained from the viewpoint of gut-brain communication, in which changes in the intestinal microflora caused by the administration of nematodes affect the brain. Therefore, we are analyzing the effects of *C.elegans* feeding on microbiota composition.

Effects of visual and aromatic stimulations on stress responses and taste perception.

Shin Kamiyama[1], Mayu Itoh[1], Aya Kitagawa[1], Harumi Ouchi[1], Mana Yamaguchi[1], Ran Watanabe[1], Hideyuki Sone[1]

1. University of Niigata Prefecture (Japan)

Background and objectives: Taste perception is affected by various environmental factors and plays a fundamental role in food selection. In the present study, we investigated the effects of visual and aromatic stimulations on stress responses and taste perception.

Methods: Fourteen young healthy participants were stimulated under five different conditions: normal (no stimuli), watching an action scene, watching a forest scene, sniffing a rosemary aroma, and sniffing a lavender aroma. The participants were assessed for their psychological and physiological stress response and suprathreshold taste intensity of five fundamental tastes before and after stimulation

Results: Compared to participants under the action scene condition, participants under the forest scene or under the rosemary aroma condition showed significantly lower stress levels. Furthermore, the forest scene condition significantly increased the saltiness intensity, whereas the rosemary aroma condition significantly increased the bitterness intensity. A positive or negative correlation was observed between the stress level and taste intensity of sourness and saltiness, respectively. Specifically, watching forest scenes significantly increased salt taste intensity, and the participants' stress levels were associated with salt taste intensity.

Conclusions: These findings indicate that visual image and aroma have the potential to change taste perception as well as modulate stress conditions.

Keyword: taste intensity, saltiness, visual image, aroma, stress condition

PAB(T8-6)
Edible insect migratory locust *Locusta migratoria*) is not only an alternative protein resource but also a potential candidate for improving agent of lipid metabolism

Masaru Ochiai[1], Yusuke Komiya[1], Takashi Akazawa[2]

1. Kitasato University (Japan), 2. Miyagi University (Japan)

Background and objectives: The world's population is estimated to reach 9.7 billion by 2050. This growing global population will require available resources to meet the nutritional needs of human health. Edible insects are increasingly recommended as novel sustainable food resources for human, but their nutritional and functional properties have not been fully evaluated. Migratory locust (*Locusta migratoria*), a representative edible insect, has been recognized as a novel food material by the European Food Safety Authority on 2021. If nutritional and functional properties are more clarified, migratory locust is expected to be developed as valuable and sustainable food resources. We have clarified that the migratory locust powder (MLP) contained rich in proteins, n-3 lipids (triglycerides and several kinds of phospholipids with α-linolenic acid), polyphenols, and indigestible fiber chitin, which are improving lipid metabolism. Here, dietary effects of MLP on lipid metabolism were investigated in rats.

Methods: The MLP, which was produced in Thailand and commercially sold in Japan, was used for the study. The 5-weeks-old male Wistar rats were fed with the casein (AIN-93G containing 20% protein and 7% fat) or MLP diet for 5 weeks. The MLP diet contained 10% MLP in AIN-93G diet. Growth efficiency and nutritional and biochemical parameters in the plasma, liver, and adipose tissues were investigated.

Results: Dietary MLP represented the favorable growth and improvement effect on hepatic lipid metabolism. Dietary MLP suppressed plasma lipid levels and low-density-lipoprotein (LDL) levels by upregulating liver LDL-receptor expression and suppressing proprotein convertase subtilisin kexin 9 (PCSK9) activity. Dietary MLP also altered fatty acid profile in the plasma, liver, and adipose and suppressed plasma arteriosclerosis-related factors. Additionally, dietary MLP downregulated the liver *de novo* lipogenic protein expressions and enzyme activities, leading to the improvement of liver function related factors. These findings can be comparable to the effects of statin, a dyslipidemia improving agent. N-3 lipids among several kinds of functional ingredients in MLP are mainly considered to contribute to the improvement of hepatic lipid metabolism.

Conclusions: MLP is expected as valuable and sustainable food protein and lipid resources with functionality and safety.

PAB(T8-7)
Effect of Ashitaba on the physical properties and allergenicity of bread

Hana Kozai[1], Mamoru Tanaka[1], Akiko Watanabe[1], Saya Ando[1], Kodai Onodera[1], Yuri Kusano[1]

1. Chubu University (Japan)

Background and objectives: *Angelica keiskei* Koidzumi (Ashitaba) is a large perennial herb native to the Southeast Pacific coast of Japan. Ashitaba contains abundant dietary fiber, vitamins, potassium, and polyphenols, such as chalcones and coumarins, and is expected to have a preventive effect on lifestyle diseases. We are developing Ashitaba bread as a functional food. The number of patients with food allergies is increasing in Japan and wheat is often the cause of these allergies. The objective of this study was to evaluate the effect of Ashitaba powder on the physical properties and allergenicity of bread.

Methods: Control bread and Ashitaba bread in which 5% of the bread flour in the control bread was replaced with Ashitaba powder were prepared using a bread machine. The specific volume and compressive strength were measured, and the hardness of each bread was evaluated. Allergenicity was evaluated by western blot assay and dot-blot assay using the gliadin fraction extracted from each type of bread and analyzed using ImageJ (analysis software).

Results: Ashitaba bread was significantly harder compared with the control bread because of its lower specific volume ($p < 0.05$) and higher compressive strength ($p < 0.05$). It was considered that the dietary fiber contained in Ashitaba inhibited the swelling of the bread. In the evaluation of allergenicity using the western blot assay, high molecular weight gliadin was detected in Ashitaba bread. A dot-blot assay was used to detect gliadin that had retained its tertiary structure, the value of the band for this gliadin was significantly lower in Ashitaba bread, compared with the control bread. It is possible that the addition of Ashitaba affected the reactions between sugars and proteins, including the Maillard reaction, and changed the properties of the wheat protein, making the gliadin fraction less extractable, and resulting in reduced allergenicity.

Conclusions: The addition of Ashitaba powder to bread may make the bread harder and reduce the allergenicity.

Keyword: Ashitaba, Bread, Physical properties, Allergenicity

PAB(T8-8)
Inhibition of growth and staphylococcal enterotoxin A production by *Staphylococcus aureus* in cooked rice and rice balls containing sodium chloride, vinegar, and commercial seasonings.

Satomi Tsutsuura[1], Masatsune Murata[2]

1. Niigata University (Japan), 2. Tokyo University of Agriculture (Japan)

Background and objectives: In Japan, staphylococcal food poisoning often occurs in rice balls made at home. Salt and commercial seasonings are usually used for making rice balls. The purpose of this study was to estimate the effect of sodium chloride (NaCl) on the growth of *Staphylococcus aureus* and staphylococcal enterotoxin A (SEA) production in cooked rice, and then to find the effective combination of NaCl and commercial seasonings to inhibit the growth and SEA production without impairing the taste of cooked rice.

Methods: To examine the effect of NaCl, we used cooked rice to which 1-7% NaCl was added. The pHs of samples were adjusted to 4.0-5.5 with vinegars such as rice vinegar, balsamic vinegar, and apple vinegar. To screen for seasonings that are effective in inhibiting SEA production, 80 types of commercial seasonings were added to 1.5% NaCl-added rice, inoculated with SEA-producing strains and incubated at 37ºC. The concentrations of SEA were estimated by a western blot analysis using the enhanced chemiluminescence method. The detection limit of SEA in cooked rice was ca. 400 pg/g.

Results: The SEA production was not inhibited in cooked rice containing 0.8-1.5% NaCl, the range usually used to make rice balls, although the production was decreased in those containing 3-7% NaCl. Among about 80 seasonings added to cooked rice containing 1.5% NaCl, 15 seasonings showed inhibitory effect against the growth. The addition of rice vinegar, balsamic vinegar, mustard paste, and rose hip tea prevented the growth of the bacteria and the SEA production although they survived up to 12 h after incubation at 37ºC. The bacterial count was also reduced to below the detection limit ($< 10^1$ CFU/g) by the addition of Worcester sauce or mustard paste to vinegared rice (pH 4.5) after 48 h.

Conclusions: We proposed some preparation examples of rice ball containing these seasonings without impairing the taste.

PAB(T8-9)

The influence of information provision on the acceptance level of genome-edited foods among Japanese consumers

Chie Taguchi[1], Kazunari Kondo[1]

1. National Institute of Health Sciences (Japan)

Background and objectives: The genome-edited (GE) foods are allowed to be distributed in Japan after submission of the notification to the Ministry of Health, Labor and Welfare (MHLW). However, the acceptance levels of the GE foods among Japanese consumers are not high. This study aimed to investigate the acceptance levels of the consumers toward GE foods both before and after watching an original video explaining about GE foods.

Methods: A web-based survey was conducted in Japan from December 2021 to January 2022, where 3,408 consumers aged 20-69 participated. The contents of the original video consisted of 'difference between GE foods and genetically modified foods,' 'mechanism of GE technology,' 'necessity of GE foods,' 'benefit of GE foods,' and 'processes until GE foods are distributed.' The acceptance level of GE foods was investigated in terms of three perspectives: (1) distribution of GE foods in the market, (2) consumption of them by others, and (3) consumption of them by yourself. The scales were measured on a 7-point semantic differential (SD) scale form 1 (unacceptable) to 7 (acceptable).

Results: The levels of all three types of acceptance towards GE foods increased after watching the video compared to the ones before watching the video (distribution: 3.6 to 4.4, consumption by others: 3.7 to 4.4, consumption by yourself: 3.5 to 4.2, $p < 0.001$, respectively). The increase of the acceptance level of GE foods after watching the video was larger by those who understood video's contents, either fully or to some extent, than that by those who had difficulty understanding ($p < 0.001$, respectively). Multivariable linear regression analyses demonstrate that the level of understanding in two areas, namely 'necessity of GE foods' and 'processes until GE foods are distributed,' was an important factor to increase all three types of the acceptance towards GE foods

Conclusions: Our results suggest that adequate information provision can help increase the acceptance levels of GE foods among Japanese consumers.

Keyword: genome-edited foods

A Change-Point Regression approach for estimation of NOAEL from systematic review: Safety assessment of L-arginine

Yui Kuramochi[1], Mai Murata[1], Akihide Sumino[1], Hideko Sone[1], Kohsuke Hayamizu[1]

1. Yokohama University of Pharmacy (Japan)

Background and objectives: In recent years, many amino acids have been used as functional foods and dietary supplements. However, there are no guidelines concerning the upper limit of their dose for safe use. Generally, the safety of chemical compounds is assessed in vitro, in vivo test method and human overdose test. When these methods apply for safety evaluation of amino acids, it is not realistic because the acceptable daily intake (ADI) calculated based on the NOAEL obtained from the in vivo test is lower than the requirement value. Therefore, the data obtained from the human study is important for safety assessment of amino acids.Currently, systematic review (SR) has been interpreted as the method with the highest evidence level and it is also used for evaluation of effectiveness and usefulness of medicines or nutrition factors. We've reported the safety assessment by SR with the results of the human studies, using L-lysine, L-Ornithine and L- Citrulline as a model. However, these are provisional value and there are not enough number of researches to assess NOAEL. For the reason, we will try to estimate a new algorithm of NOAEL by safety assessment of L-arginine (L-Arg).

Methods: We performed a comprehensive search of databases for randomized controlled trial in which L-Arg with orally administered to healthy subjects. For evaluation of bias risk, Jadad Score and The Cochrane Collaboration's tool were used. The estimation of NOAEL was analyzed with Change point regression model, which modified by heterogeneity of study.

Results: The four hundred and forty-four articles were hit in database search and finally 31 articles were selected for review. NOAEL was estimated 4000 mg/man/time (12000mg/man/day) by observation data, and 9500-12418 mg/man/time by using CPRM.

Conclusions: We performed CPRM approach for determining NOAEL of L-Arg, and the NOAEL was estimated 9500-12418 mg/man/time. The new method will be able to apply in the variety of fields more than amino acids and dietary supplements.

PAB(T8-11)
Improving diet through agriculture and gender equality in South Sudan

Hailu Badhane[3], Rebecca Isaak[1], Melani O'Leary[1], Alana Mascoll[2]

1. World Vision Canada (Canada), 2. World Vision South Sudan (South Sudan), 3. World Vision International (Ethiopia)

Background and objectives: Gender power dynamics and socio-cultural norms are significant drivers of equitable nutrition security within food systems. Protracted conflict and climate shocks, combined with outdated farming practices, have resulted in deteriorating food insecurity and diet quality in South Sudan. Discriminatory food consumption practices increase vulnerability for women/girls, including where men and boys eat first and best quality foods.

Methods: Fortifying Equality and Economic and Diversification (FEED) was implemented (2015-2018) in South Sudan by World Vision, Oxfam and CARE, with funding from Global Affairs Canada. It aimed to demonstrate how agriculture and women's empowerment affects nutrition in fragile contexts. FEED's activities focused on increasing agricultural productivity, income generating activities, and gender equality training. FEED created awareness on dietary diversification, food preparation, and hygiene through community dialogues and cooking demonstrations. Trained volunteers conducted home visits to promote optimal MIYCF practices. Women were supported to claim their productive assets and protection rights. Male allies/power holders were engaged to identify/address barriers that limited the decision-making power and resource control of women.

Results: Households that have year-round access to sufficient food to meet family needs increased from 21.3% to 31.4%. Children ate 2.53 meals/day on average compared to 1.6 at baseline. Households achieving minimum diet diversity increased from 31.3% to 71%; average number of food groups consumed increased from 2.96 to 5.14. There were significant behavioral/attitudinal changes towards gender equality, demonstrating impact on agency, resource control, and shifts in the informal/formal environment. Gender-Based Violence reduced from 33.1% to 27%, and the perception regarding ability of women to contribute to decision making improved from 54.5% to 79%. Engagement of women in income generating activities increased from 4.1% to 64.3%.

Conclusions: FEED is one of the first food security projects in South Sudan to adopt a gender-sensitive approach, specifically targeting female farmers and explicitly seeking to create behavioral/attitudinal changes towards more equal opportunities for women to claim their nutrition rights. The project demonstrated that improved nutrition is possible when women exercise agency over life decisions, have access and control over resources, and experience an environment around them as enabling opportunities to improve their nutrition.

Effect of mould fermentation on the nutritional and sensory attributes of different varieties of *Lablab purpureus* beans.

Sheila Munanie Kilonzi[1], Anselimo Ouma Makokha[2]

1. Karatina University (Kenya), 2. Jomo Kenyatta University of Agriculture and Technology (Kenya)

Background and objectives: *Lablab purpureus* is a drought tolerant legume grown in semi-arid areas of Kenya. Though it contributes to nutrition and food security among the communities living in these areas, the legume has received low research attention due the perceived economic importance. The utilization of lablab is also influenced by the alleged taste and flatulence caused by their consumption. The main objective of this study was to evaluate the effect of mould fermentation with *Ragi IndoPal tempeh starter* on the protein content, protein digestibility, oligosaccharides and the sensory attributes of three varieties of fermented lablab beans grown in Kenya.

Methods: The beans of three lablab varieties namely KATDL1, KATDL2 and KATDL3 were cleaned, soaked, dehulled and cooked before inoculation with the tempeh starter culture at 35°C. After fermentation for 48 hours, determination of protein, protein digestibility, oligosaccharides as well as sensory evaluation of the fermented beans was carried out. Analysis of variance was carried out to detect significant differences at p =0.05 in the parameters of interest among the three bean varieties.

Results: The results showed a significant increase in protein content and invitro protein digestibility compared to unfermented cooked beans across the varieties. However, there was no significant difference among the varieties. The levels of oligosaccharides; stachyose and raffinose were significantly reduced at p=0.05. But there was also no significant difference in oligosaccharide content among varieties. But there was significant difference in preference and overall acceptability among the fermented beans due to variety, where KATDL1 was more acceptable than the other two varieties.

Conclusions: Fermentation increased protein content and digestibility, and decreased oligosaccharides, which cause flatulence in the Lablab beans. However, there was no significant difference among the fermented bean varieties in the protein content, protein digestibility and oligosaccharide content. There was also significant difference in taste and overall acceptability among the varieties.

Keyword: *Lablab purpureus* , Protein content, Oligosaccharides , Lablab varieties, Sensory evaluation

Bread-making quality and postprandial blood glucose response of gluten-free high-amylose rice bread

Iana Korshunova[1], Tomoko Yamaguchi[1], Saori Kuremoto[1], Yasuaki Enoki[2]

1. Niigata University (Japan), 2. Bourbon Corporation (Japan)

Background and objectives: According to the World Health Organization, currently about 1% of the world's population suffers from celiac disease - a disease associated with a deficiency of enzymes that break down gluten and proteins close to it. Rice flour is completely hypoallergenic due to the absence of gluten and high-amylose rice is also suitable for people with diabetes. Given the increasing global incidence of gluten-related disorders and diabetes, the primary goal is to investigate the quality and postprandial glycemic response of gluten-free rice bread made with different amylose contents.

Methods: Two types of rice flour, intermediate-amylose Koshihikari rice flour (DK) and high-amylose Koshinokaori rice flour (KK), were used in this study. Gluten-free rice bread was made from rice flour, olive oil, sugar, salt, dry yeast and hydroxypropyl methylcellulose and baked at 180°C for 45 minutes. After baking the bread, the specific loaf volume, color parameters, and degree of gelatinization were measured. Physical properties (hardness, cohesiveness, adhesiveness) were measured using a TPU-2CL texture profile device (Yamaden Co., ltd). Glycemic response of rice bread was tested on eight healthy subjects (two males and six females) and compared with the equivalent carbohydrate dosage (50 g) of a control rice. The blood glucose levels were measured by self-measurement of blood glucose with finger pricking over time. Sensory evaluation was performed by 41 panelists on a 7-point scale.

Results: The specific loaf volume of KK bread was the same as that of DK bread. All indicators of color showed significant differences between DK and KK bread. When measuring physical properties, KK bread showed higher hardness and adhesiveness values, as well as lower cohesiveness, than DK bread. Fresh DK bread with better texture was preferred over KK bread. However, the sensory evaluation score of toasted KK bread was closer to that of DK bread. In eight healthy subjects, the glycemic response to KK bread was significantly lower than to DK bread.

Conclusions: These results show that amylose content affects bread quality and postprandial glycemic response to gluten-free rice bread.

Keyword: gluten-free rice bread, high-amylose rice, sensory evaluation, bread-making quality, physical properties

Physical, chemical and environmental characteristics of the acid buttermilk co-product: Case study in an eastern dairy in Algeria

Batoul Meghzili[1], Férial Aziza Krid Benyahia[1], Hassina Bougherara[2], Siham Sayoud[2], Ismahane Redjal[3], Sonia Berrabah[3], Karima Khedireche[3], Brahim Kebabi[2]

1. INATAA UFMC1 University (Algeria), 2. UFMC1 University (Algeria), 3. Numidia Dairy (Algeria)

The dairy industry is one of the most sectors negative impacts on the ecosystems due to the increase of waste dairy by co-products. Buttermilk is an environmentally harmful co-product coming from the activities of butter workshop, because it has a high content of organic matter. It cannot be discarded directly into the environment. Dairy industries in Algeria are released over then more than 20.0000 liters of buttermilk into the sewer system without being confirmed or estimated for their components which may become an environmental risk and an economic problema.

The aim of this study is to evaluate and to present a characterization of sour buttermilk relating to an Algerian dairy industry. The results demonstrate that buttermilk has a high Biochemical Oxygen Demand (BOD) 312110±0.57 and a high Chemical Oxygen Demand (COD) (90351±0.002), Nitrite (NO_2-1.22 mg/l ±1; Nitrate (NO_{3-}) : 0,0299 mg/l ±0.0003; total azote (0.467 ±0.003), pH: (4.33±0.125), T : (15.66 C°±0.75).

Thus, buttermilk shows negative environmental impacts harmful mainly to human, animal and even aquatic life. For this, we must ring the alarm bell and take decisions to solve this ecosystem problem this solution could be summed up in its incorporation into certain food matrices given its richness in nutrients, particularly lactose and proteins The reuse of buttermilk is an objective of the sustainability of the Algerian dairy industries for an economic and environmental interest.

Keyword: Butter milk, co-product, Algerian dairy industry, Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand (COD)

Changes of free amino acids and their effects on saltiness and palatability by the addition of spices in Japanese broths

Chikae Sakamoto[1], Hina Matsui[2], Kumiko Hisaki[3], Hiroshi Ueno[2], Toshiya Masuda[4], Yukiko Ueda[2]

1. Kyoto Bunkyo Junior College (Japan), 2. Ryukoku University (Japan), 3. Osaka International College (Japan), 4. Osaka Metropolitan University (Japan)

Background and objectives: We investigated the use of spices to reduce the amount of salt in diets. Previously, we have reported that some spices regulated the activity of glutamic acid decarboxylase (GAD67), which is expressed in type III taste buds, and affected the saltiness and palatability of food. However, the factors which may influence the effects of spices on food palatability remain unclear. In this study, we focused on free amino acids which exhibit various tastes, and investigated the relationship between the amount of free amino acids produced by spices and the saltiness and palatability of food. The study involved the use of Japanese broths, which are essential ingredients in Japanese cuisine.

Methods: Japanese broths (kombu, katsuo) were prepared in the traditional Japanese way, and each broth was mixed separately with 13 spice extracts at 0.02%.Free amino acids were analyzed using a Hitachi Ultra-High Speed Liquid Chromatography system equipped with UV-Vis detector. Sensory evaluation was based on the data obtained from the previous study.

Results: For the kombu broth, the total amounts of glutamic acid, proline, and alanine (umami and sweetness) increased in the presence of spices that control GAD67 activity. However, there was no correlation between the total amounts of histidine, cysteine, and arginine (bitterness), and GAD67 activity. For katsuo broth, there was no correlation between GAD67 activity and the total amount of umami, sweetness or bitterness Sensory evaluation data showed that saltiness of kombu broth decreased as the GAD67 activity increased. However, there was no correlation between saltiness of katsuo broth and GAD67 activity. In both, kombu and katsuo broths, palatability tended to increase as the GAD67 activity increased.

Conclusions: Addition of spices to either kombu or katsuo broth did not increase the saltiness itself but improved the overall palatability due to increased levels of free amino acids. Moreover, the results suggest that addition of spices may reduce the use of salt in food diets. Five out of the 13 spices (shiso, parsley, anise, yuzu, and basil) influenced free amino acid amounts in the broths. Therefore, these spices can potentially impact saltiness and palatability.

Keyword: spices, free amino acid, saltiness, palatability, GAD67 activity

PAB(T8-16)
Potassium content of partially cooked vegetables

Masako Yamada[1], Yoshiko Higuchi[1], Yasue Hosoyamada[2]

1. Tokyo Kasei Gakuin University (Japan), 2. Chiba Prefectural University of Health Sciences (Japan)

Background and objectives: Most of the cut vegetables on the market are raw and intended for use in salads, but there are cut vegetables that have been parboiled to make stews. These partially cooked vegetables are intended for use in Japanese dishes such as pork in miso soup and stewed beef and potatoes. These products can be used to make dishes by simply adding seasonings or a few other ingredients. Thus, these products can be used to effectively increase vegetable intake for people with a low vegetable intake. Vegetables are a source of potassium. However, potassium is water-soluble, so potassium in partially cooked vegetables presumably decreases during the manufacturing process. The aim of the current study was to ascertain the potassium content in parboiled vegetables.

Methods: Six products used to make pork in miso soup, 6 used to make stewed chicken and root vegetables, and 5 used to make stewed beef and potatoes served as samples. The samples contained a liquid, such as a broth, packaged with the vegetables, so the vegetables and liquid were first separated. After diluting vegetables, the potassium content in the vegetable dilution and the liquid was measured.

Results: The minimum and maximum potassium content per 100 g of a sample was 2.9 mg and 112.4 mg for the pork in miso soup samples, 10.7 mg and 104.9 mg for the stewed chicken and root vegetable samples, and 50.5 mg and 228.3 mg for the stewed beef and potato samples. There were significant differences in the minimum and maximum potassium content among all 3 sets of samples ($p < 0.01$).

Conclusions:Differences in the potassium content in the samples was presumably due to differences in how ingredients were cut, pretreatment, and methods of manufacture. Some samples required draining of the liquid packaged with the vegetables while some did not. Samples that did not require draining tended to have a higher potassium content. From the perspective of potassium intake, selection of products that do not require draining will result in greater potassium intake.

Effects of sucrose and non-nutritive sweeteners on blood glucose and adiposity in obese mice

Yue-Hwa Chen[1], Jessika Kar Man Woo[1], Yu-Cih Huang[1]

1. Taipei Medical University (Taiwan)

Background and objectives: Non-nutritive sweeteners (NNS) are sweeteners that provide minimal or no calories, and have been widely used in different foods. This study was aimed at comparing the effects of sucrose and different NNS, both natural and synthetic, on adiposity and blood glucose in diet-induced obese (DIO) animals.

Methods: After being fed with a 60% high-fat diet (HFD) for 8 weeks, the C57BL/6 obese mice were administered with different sweeteners, including sucrose, natural monoammonium glycyrrhizinate (MAG) and monk fruit extract (MFE), as well as synthetic acesulfame potassium (ACE-K) and sucralose (SUC), in drinking water with below ADI doses and with equivalent sweetness. The animals were sacrificed after 8 wk intervention, and blood, liver, muscle, and adipose tissues were collected.

Results: The sucrose group gained more weight, which was reflected in the higher water consumption, whereas all NNS, regardless of natural or synthetic, did not show any effects on the body weight. Other than that, all sweeteners, including sucrose, showed no effects on the weights of gastrocnemius muscle and white adipose tissues, nor on observable pathological changes, including monocyte infiltration or fat accumulation, in the liver and epididymal adipose tissue. In addition, all sweeteners showed no effects on blood glucose and blood lipid profiles, except that the natural MFE significantly decreased the blood glucose levels, and synthetic ACE-K and sucralose significantly increased the glucose area under the curve (AUC) from the OGTT test when compared to the control group.

Conclusions: The results suggest that 8-wk administration of NNS did not show any adverse effects on body composition or blood lipid profiles in DIO mice. Sucrose consumption further increased the body weight, but MFE showed a hypoglycemic effect.

Availability of locally based complementary foods in Senegal: Nutritional and microbiological quality

Olouwafemi Mistourath Mama[1], Fatoumata Bintou Tobe[1], Adama Diouf[1], Mahamadou Tanimoune[2], Ndeye Fatou Ndiaye[3], Babou Diaham[1], Nicole Idohou Dossou[1]

1. Laboratoire de Recherche en Nutrition et Alimentation Humaine-Universite Cheikh Anta Diop de Dakar (Senegal), 2. World Food Program Regional Office Dakar (Senegal), 3. Institut de Technologie Alimentaire Dakar (Senegal)

Background and objectives: Optimal complementary feeding practices are crucial in reducing stunting and essential micronutrient deficiencies in children aged 6-23 months. However, in Africa, mothers mostly have choice only between traditional porridges with little nutrient, and expensive imported flours. This study aimed at assessing the availability of local complementary foods in two regions of Senegal, and their nutritional and hygienic quality

Methods: This cross-sectional and descriptive study was performed during September-December 2019 in Dakar and Matam regions. An inventory of complementary foods was conducted in 47 World Food Program (WFP) retailers in Matam and 45 sales outlets in Dakar. Samples of local infant flours recovered from visited outlets were analyzed for macronutrients (proteins, lipids, carbohydrates) micronutrients (iron, zinc, calcium) content, and microbiological quality assessment (fecal coliform, salmonella, *Escherichia coli*, yeasts and molds). Compliance was evaluated according to Codex *Alimentarius* standards, WFP and GRET/IRD recommendations for complementary foods

Results: Complementary foods were more available in Dakar (86.7%) than in Matam (74.5%) and four types were listed, infant cereal flours being the most represented. All local complementary foods were infant flours (n=18) and were only found in 10.6% of WFP retailers in Matam and 35.6% of outlets in Dakar. All samples complied with Codex standard for energy value but only 16.7% and 27.8% met the GRET/IRD and WFP recommendations, respectively. For proteins content, 94.4% of the samples complied with Codex standard, 88.9% with the WFP recommendations and only 22.2% with the GRET/IRD recommendations. For lipids, 22.2% of the samples complied with Codex standard while 16.7% and 33.3% met the WFP and GRET/IRD recommendations, respectively. Less than half of the samples had a satisfactory micronutrient content while microbiological quality was satisfactory for *Escherichia coli* and Salmonella. However, fecal coliforms were present at levels above the threshold in 50% of the samples. Over 50% were moldy and yeasts were present in only 16.7% samples.

Conclusions: The availability of local complementary foods was lower than that of imported products in sales outlets, infant cereal flours being the most common products. Micronutrient contents and microbiological quality of these local product-based complementary foods need to be improved.

Keyword: local complementary foods, children 6 - 23 months, nutritional value, microbiological quality, standards

Universidad de Guadalajara-CUSur, Departamento de Ciencias de la Naturaleza (Mexico), 4. Instituto Tecnológico Superior de Tamazula de Gordiano (Mexico), 5. Tecnológico de Monterrey-Campus Querétaro, Escuela de Ingeniería y Ciencias (Mexico), 6. Tecnológico de Monterrey-Campus Monterrey, Escuela de Ingeniería y Ciencias (Mexico), 7. Universidad de Guadalajara-CUCEI, Departamento de Farmacología (Mexico)

Background and objectives: World consumption of avocados (*Persea americana* Mill. Var. Hass) and its industrialized derivatives has increased rapidly, and the volume of wastes production. In the avocado fruit, the edible and inedible fraction contains diverse bioactive compounds, whose content depends on the maturation degree attained at harvest. The study's objective was to evaluate the content of phenolic compounds and antioxidant capacity of the pulp, peel, and seeds of avocado (*Persea americana* Var. Hass) according to the degree of pre-harvest maturation.

Methods: An experiment was established with 18 avocado trees (*Persea americana* Var. Hass) in a commercial orchard in Jalisco, Mexico. 345 fruits were marked to record monthly growth. From the beginning of maturation on the day after fruit set (DAFS) 283, fruits were collected on five dates to study the changes in the chemical and functional composition of the pulp, peel, and seed until DAFS 402 (n=4).

Results: The decrease in moisture content and the increase in dry matter in all collections were significant only in the seed, while the fat content in the pulp increased continuously up to 28% ($p < 0.05$). The content of total phenols (CTP) measured in pulp, seed, and peel (1.13±1.08, 32.43±12.18, and 101.39±33.49 mgEAG/Kg, respectively) remained stable throughout the pre-harvest maturation ($p < 0.05$). The tendency of the antioxidant capacity measured in the same structures by DPPH (10.73±2.11, 221.37±58.53, and 443.98±109.52, µmolET/Kg respectively) and ABTS (2.984±0.67, 33.137±6.34, 79.757±23.78, µmolET/Kg respectively) corresponded to the CTP (p&0.05); however, in the peel, a significant increase occurred from the DAFS 360. In analyzing the samples by HPLC of 13 compounds studied, traces of gallic, dihydroxybenzoic, syringic, and p-coumaric acids were found. Catechin, caffeic acid, and chlorogenic acid were in the seed (3.14±5.49, 0.903±1.31 and 0.304±0.19 ppp, respectively) and peel (14.17±10.32, 59.83±22.13 and 0.39±0.13 ppp, respectively) in quantifiable amounts. In the latter, chlorogenic acid and catechin steadily increased as maturation advanced ($p < 0.05$).

Conclusions: During pre-harvest maturation, the edible faction of the avocado does not show essential changes apart from the increase in fat content; however, the peel presents the highest content of total phenols with an increase in the content of chlorogenic and caffeic acid.

PAB(T8-20)
Determination of rancidity of frying oil by using spectrometer

Yu-Shan Li[1], Yu-Ting Cheng[1], Chung-Mei Ouyang[1], Yung-Yu Huang[2], Hsi-Pin Li[2], Ching-Ting Tan[1]

1. National Taiwan University Hospital Hsin-Chu Branch (Taiwan), 2. InnoSpectra Corporation (Taiwan)

Background and objective: Deep–frying is a commonly cooking method for making crispy and delicious fried foods. Deep–frying oil should be changed in timely if it has an unusual color or odor, starts to smoke or starts to foam. The international oil quality standard is mostly based on total polar compounds (TPC) and the acid value (AV), a reliable benchmark for measuring the degradation of the oil. However, the traditional methods are time consuming with greater expense. The aim of this study was to examine the rancidity of frying oils by using near-infrared (NIR) spectroscopy.

Methods: We used 45 liters of soybean oil to fry 5 kg of chicken drumsticks each time. The temperature of the oil kept at 160±10℃ for 15±3 minutes until the chicken drumsticks were fully fried and the frying oil was repeated 40 times in total. The frying oils were collected each time and tested by oil quality test strips. Samples were scanned by NIR spectrometer and corresponded to the results by using the American Oil Chemists' Society (AOCS) official method Cd 20–91 and Cd 3d–63. The data from NIR spectrometer and the AOCS official method were calibrated by using partial leasts–quares regression (PLSR) method.

Results: We subjectively found that the oil color changed from clear to cloudy black, and the chicken drumsticks were also burnt brown during frying process. However, there was no significant differences in the oil quality tests strips. The TPC and AV of the frying oils were increased gradually. The PLSR models of TPC and AV showed good linearity. The TPC was in the range of 8~15±1%, and the AV was in the range of 0.09~0.8±0.08 mgKOH/g. The coefficients of determination for TPC and AV were as high as 0.972 and 0.969, respectively.

Conclusions: The results showed that NIR spectrometer can effectively measure frying oil quality and rancidity. Additional research is necessary to determine whether frying different

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

types of foods in an oil affects the reliability of the TPC and AV measurements.

Construction of enterotoxinogenic *Escherichia coli* infection model using Caenorhabditis elegans as an alternative host

Anri Matsuda[1], Takashi Ishida[2], Takayuki Wada[1], Eriko Kage-Nakadai[1]

1. Osaka City University (Japan), 2. Kyowa Hakko Bio Co., Ltd (Japan)

Background and objectives: Enterotoxigenic *Escherichia coli* (ETEC) is a major cause of traveler's diarrhea in developed countries and infantile diarrhea in developing countries. *Caenorhabditis elegans* (*C. elegans*) has been used as an alternative model animal for studying pathogen interaction. ETEC was previously reported to shorten the survival time of *C. elegans* (Hoshino et al. 2008). However, the genetic background of the ETEC strain and host defense responses remain largely uncharacterized. This study aimed to uncover the molecular basis of host-ETEC interaction and establish a simple model system for ETEC infection using *C. elegans*.

Methods: The clinical strain ETEC1 (O6:H16), used by Hoshino et al. (2008), was also examined in this study. The draft genome sequence of the strain was assembled using short reads obtained by Illumina Miseq. Existence of enterotoxin genes were verified by tBLASTn and VirulenceFinder 2.0. Colonization factors (CSs) were also verified as same as the toxin genes. Wild-type *C. elegans* N2 was used as the experimental animal. The synchronized L1 larvae were grown on mNGM medium (agar medium for nematode growth) with non-pathogenic *E. coli* OP50, a standard food, until they reached adulthood. Thereafter, they were divided into groups fed OP50 or ETEC1 for lifespan assay. Survival rates were calculated by the Kaplan-Meier method, and differences in survival rates between the two groups were compared by the log-rank test

Results: Whole genome sequencing revealed that ETEC1 possessed heat-labile toxin LT1 and heat-stable toxin STh. Out of the major CSs, CS2 and CS3 exist on the ETEC1 genome. Worms fed ETEC1 showed significantly shorter survival time in comparison with those fed OP50, as shown in the previous study. We are currently validating differentially expressed genes (DEGs) using RNA-seq and real-time PCR to estimate host defense responses to ETEC1.

Conclusions:We established an *C. elegans* -ETEC infection model. It could be valuable for understanding the molecular basis on host-ETEC interaction and screens of functional food materials for anti-infective effects.

Keyword: enterotoxinogenic Escherichia coli, Caenorhabditis elegans, infection

PAB(T8-22)
Effect of heating method and formulation on the aroma profile of sponge cake

Tomoko Matsuura[1], Toshihide Nishimura[2], Keiko Shibata[2]

1. Graduate School of Kagawa Nutrition University (Japan), 2. Kagawa Nutrition University (Japan)

Background and objectives: The microwave heating has the advantages of shorter cooking times and lower energy consumption compared to conventional oven. However, microwave heating products lack of color and aroma development, which leads to poor quality. There is few information on the effects of heating methods and formulation changes on the palatable quality including aroma profile of sponge cakes. This study aimed to examine the conditions of microwave heating to make sponge cakes with palatable quality by investigating the aroma profile of the sponge cake heated by an oven and a microwave.

Methods: The samples for analyses were the following four cakes: oven baked sponge cake containing 40% egg (OS); microwave-heated cake at the same ratio (MS); and microwave-heated cake containing 20.0% egg, 12.5% water and 7.5% vegetable oil (MB), oven baked cake at the same ratio (OB). In all samples, the contents of wheat flour and granulated sugar were fixed at 30%. The oven sample was baked at 170 ° C for 22 minutes and the microwave one was heated at 500 W for 100 seconds. The aroma compounds of each cake crumb were collected by HS-SPME and were analyzed using GC-MS and GC-O-MS.

Results: In each sample, alcohols, aldehydes, hydrocarbons and pyridines were commonly detected. Pyrazine was detected only in OS. The total peak area of sample by oven was larger than that by microwaves. GC-O analysis confirmed an almond-like, fragrant, and sweet odor in OS. Although egg-like odor was detected in MS and MB, these odor qualities were less than those in OS and OB. The final heating temperature of the cake crumb reached around 100 ° C with either heating method. However, long-time baking by oven promoted the lipid oxidation and the Maillard reaction, and caused richer aroma compounds, resulting in contribution to a production of complex flavor.

Conclusions: Since the complex flavor was not produced by microwave heating, the change of materials was thought to be required to improve flavor of cakes by microwave heating.

PAB(T8-23)
Comparison of physiologically functional compounds in Sika deer *Cervus nippon* meats obtained from different regions of Japan

Shiho Miyata[1], Kazuhiro Chiku[2], Toshihide Nishimura[1]

1. Kagawa Nutrition University (Japan), 2. Nippon Veterinary and Life Science University (Japan)

Background and objectives: Recently, the overpopulation of wild deer causes the serious crop damage in Japan, and many deer has been caught in many regions to resolve this problem. Although the promotion of effective use of these deer as food resource have been conducted, the demands is not sufficient. Thus, we examined physiologically functional compounds to find characteristics of Sika deer meats obtained from different regions of Japan.

Methods: Three deer, each around 2 years old were obtained from Hokkaido, and Wakayama, Tokushima and Miyazaki prefectures, respectively. Muscle samples (*M. biceps femoris, M. psoas major, M. longissimus thoracis, M. pectoralis profundus*) were taken from these fresh carcasses. All samples were stored at -30℃ until analysis, and then thawed at 4℃ for 16h. Samples for analysis were prepared by homogenizing muscle with water and adding 5% TCA to remove proteins. The amounts of imidazole dipeptides (carnosine, anserine, balenine), free amino acids, and carnitine were measured with HPLC, amino acid analyzer, and LC/MS/MS, respectively.

Results: The amounts of carnosine and anserine in meats of Wakayama were significantly lower than those in meats of other regions, while the amounts of glutamine, ornithine, and 3-methylhistidine in meats of Wakayama were significantly higher than those of other regions. The amount of carnitine in meats of Hokkaido was significantly lowest in all regions, and the amount of acetylcarnitine in meats of Miyazaki was significantly highest in all regions. In muscle parts, the amounts of carnosine and anserine in *M. longissimus thoracis* has shown to be significantly higher than that in other parts. These differences in physiological compounds between the origin of Sika deer may have contributed to the branding of deer meats. Analyses of correlations among physiologically functional compounds in Sika deer meat showed negative correlation between imidazole dipeptides such as carnosine and anserine and glutamine and ornithine.

Conclusion:The characteristics of physiologically functional compounds in Sika deer meats may contribute to branding in the region of production.

PAB(T8-24)
Study of the acidic compounds derived from triacylglycerol that contribute to acid value increment

Masayoshi Sakaino[1,2], Takashi Sano[1], Shunji Kato[2], Naoki Shimizu[2], Junya Ito[2], Jun Imagi[1,2], Toshiro Sato[1,2], Kiyotaka Nakagawa[2]

1. J-OIL MILLS, Inc. (Japan), 2. Tohoku University (Japan)

Background and objectives: The acid value (AV), which is widely used as an indicator of oil degradation, is defined as the titration value of free fatty acids (FFA) produced by hydrolysis of triacylglycerols. Although water is necessary for this hydrolysis, it has been reported that AV increases even when oil is heated without adding water. Hence, we hypothesized that acidic compounds other than FFA are formed from triacylglycerols (in particular, carboxylic acids that possess a glycerol backbone), and these carboxylic acids may be calculated as AV. In this study, we identified and quantified the acidic compounds formed in heated oil.

Methods: Pure canola oil was heated at 180°C for 6 h without adding water. The acidic compounds generated from the heated oil were derivatized with the 9-anthryldiazomethane reagent, which reacts selectively with carboxyl moieties. Derivatives were identified by ultra-high-performance liquid chromatography-time of flight mass spectrometry (UPLC-Tof/MS). Additionally, the acidic compounds formed during the oil heating process were quantified using gas chromatography-mass spectrometry. Finally, a deep-frying test of frozen French fries was conducted.

Results: When canola oil was heated without adding water, AV did indeed increase and was found to be significantly larger than the AV calculated from the amount of FFA measured by high-performance liquid chromatography-fluorescence detection. Then, we identified 9-carboxy-nonanoyl-triacylglycerols (i.e., dioleoyl-(9-carboxy-nonanoyl)-triacylglycerol and oleoyl-linoleoyl-(9-carboxy-nonanoyl)-triacylglycerol) as unique acidic compounds in the heated oil by UPLC-Tof/MS analysis. These compounds were considered to also be calculated as AV from the carboxylic moieties. We also confirmed this finding while cooking French fries; FFA and 9-carboxy-nonanoyl-triacylglycerols were increased, and the contribution of 9-carboxy-nonanoyl-triacylglycerols to AV increment was higher than FFA.

Conclusion:This study, for the first time, has successfully identificatied acidic compounds other than FFA which were formed during the heating of canola oil. These results suggested that AV not only is an indicator of triacylglycerol hydrolysis but also is an indicator of the thermal degradation of triacylglycerols.

Positive association between a Food Production Diversity Score and the Minimum Dietary Diversity for Women of Reproductive Age (MDD-W) Indicator.

Marta Mascarenas-Garcia[1,2], Garba Issa[3], Mahamat Bechit[3], Francois Kayitakire[4], Estefania Custodio[5]

1. University of Santiago de Compostela (Spain), 2. University Hospital of Santiago de Compostela (Spain), 3. Direction de la Nutrition et de la Technologie Alimentaire, Ministère de la Santé Publique in Chad (Chad), 4. European Commision Joint Research Centre (Italy), 5. Centro Nacional de Medicina Tropical, Instituto de Salud Carlos III (Spain)

Background and objectives: The Minimum Dietary Diversity for Women (MDD-W) indicator is used as proxy of prevalence of micronutrient adequacy in women of reproductive age. Information is needed on how MDD-W relates to agricultural indicators like households' farm production diversity, in order to inform agricultural nutrition sensitive programming. The objective of this study was to assess MDD-W and its association with a farm production diversity indicator in the rural area of Guerá region, Chad

Methods: We carried out a cross-sectional study in the region of Guerá (Chad). We randomly selected 984 women of reproductive age that were interviewed in March 2019. Sociodemographic data was obtained, as well as agriculture, food security, and dietary information through a 24 hours recall. We computed the MDD-W and the Household Food Insecurity Access Scale (HFIAS) scores using standard procedures. To evaluate food production diversity, we created a Food Production Diversity Score (FPDS) based on the following groups. For crops: “Grains and Tubers”, “Beans, peas and pulses”, “Nuts and seeds”, “Fruits” and “Vegetables”. For animals: “Cattle”, “Poultry” and “Goat and Sheep”. The FPDS was obtained summing all the groups. We assessed the bivariate association between MDD-W and FPDS and built a multivariable model to adjust this association by education and food security status.

Results: Only 32.8% of the women achieved MDD-W. The average FPDS was 2.9 with a standard deviation of 1.4 and 52.8% of the households reported severe food insecurity. A 48.5% of the sample had no education at all. The bivariate relationship between MDD-W and FPDS was found significant (p=0.001), with 45.4% MDDW reported in the 5-8 FPDS group, 32.8% in the 3-4 and 28.7% in the 0-2. In the multivariable model all associations remained significant. Women from households with 5-8 FPDS had 2.2 more chances to achieve MDD-W (IC95%: 1.5-3.3); as well as from educated households (OR 1.43; IC95%: 1.1-1.9). The likelihood of reaching MDD-W decreased a 9% with each point of the HFIAS (IC95%: 7%-12%).

Conclusions:In this context, policies and investments to increment households´ agriculture and livestock diversity might be useful to improve dietary diversity of women of reproductive age.

The influence of heating temperature on the amount of proanthocyanidins and saponins in adzuki beans and adzuki bean tea

Keisuke Hosotani[1], Masahiro Kitagawa[2]

1. (Former affiliation) Wakayama University (Japan), 2. Otemae University (Japan)

Background: There are more polyphenols in adzuki beans than in black soybeans. We hypothesized that the antioxidant effects of polyphenols may prevent metabolic syndrome, and that saponin in adzuki beans may have diuretic effects. Polyphenols tend to be water soluble; thus, we developed a tea made with adzuki beans. We aimed to investigate the effect of heating temperature on proanthocyanidins and saponins in adzuki beans and adzuki tea.

Methods: We used the local Tanba Dainagon variety of the adzuki bean. We soaked the beans in water for one night, and then heated them. The heating temperatures were: 120°C, 150°C, 180°C, 210°C, and 240°C for 15 minutes. Acetone-water-acetic acid(70:29.5:0.5) solvent was used for extraction of proanthocyanidins and saponins. After its addition, the sample was shaken for 3 hours and then left standing for 12 hours followed by centrifugal-separation. Proanthocyanidin was measured using the 4-dimethylaminocinnamaldehyde method and saponin using the vanillin/sulfuric acid method. Catechin extraction was confirmed using high-performance liquid chromatography and a photodiode array.

Results: Proanthocyanidin quantity in an adzuki bean tended to be maintained by heating; however, at 240°C proanthocyanidin quantity decreased. The same trend was observed with adzuki bean tea. When the heating temperature became high, there was an increase of saponin, which was clear visible at 240°C. The same trend was observed with adzuki bean tea.

Discussion: The fragrance and taste of adzuki bean tea become stronger as the heating temperature increases; however, our findings suggest that it is necessary to consider the heating temperature as it may affect the effectiveness of the tea.

Keyword: adzuki bean, proanthocyanidin, saponin, heating temperature, polyphenol

Inulin enrichment in strawberry egg white pudding and its better physical properties using high pressure processing

Chattraya Namlerst[1], Bootsrapa Leelawat[1], Supattra Supawong[1], Suteera Vatthanakul[1]

1. Thammasat University (Thailand)

Background and objectives: Egg has been used as a main ingredient to make egg pudding dessert. However, the whole egg contains higher fat and calories than only egg white. Inulin is a functional fiber or prebiotic dietary fiber which can promote intestinal health. This study aims to develop a high protein and high dietary fiber pudding. It will be a good choice for people who are conscious of their health.

Methods: To produce and improve the physical properties of strawberry egg white pudding dessert, high pressure processing (HPP) which is a non-thermal process technology, is used in this study (450, 475MPa for 10 min) and compared with egg white pudding produced by traditional thermal processing (80°C for 30 min). The egg white solution was mixed with strawberry syrup and 5-15% inulin. The pudding's hardness, springiness, color, syneresis, and microstructure were measured.

Results: Strawberry egg white pudding with 10-15%inulin showed a lower hardness value than the pudding with 5%inulin. Using 450MPa caused 2times lower hardness value than using 475MPa and almost 10times lower hardness when compared to thermal processing ($p< 0.05$). The lightness values of the pudding decreased when increasing inulin content while redness and yellowness values increased. After storage at 4°C for 15days, higher inulin content in the HPP pudding leads to lower water syneresis. The addition of 15%inulin in pudding treated with 450MPa and 475MPa caused25.86%and 13.85%lower water syneresis when compared to that of 5%inulin ($p< 0.05$). However, pudding treated with thermal processing had 6times lower syneresis than HPP treated pudding. Microstructure of the surface of the pudding indicated that higher inulin content in the HPP pudding leads to show a smooth surface and more puffy texture.

Conclusions: In summary, our pudding showed a very smooth and very soft texture when compared to those that go through traditional processing. Inulin has a potential to improve the soft texture and creamy mouthfeel of the pudding and retain water within its structure. One serving of our strawberry egg white pudding contains 25 g. of inulin (15% w/w) which meets the recommended daily intake value.

Qualitative and quantitative analysis of sphingomyelin from Atlantic salmon, *Salmo salar*

Saki Nishimoto[1], Shinsuke Mohri[1], Yuki Manabe[1], Tatsuya Sugawara[1]

1. Kyoto University (Japan)

Background and objectives: Sphingomyelin is the major phosphosphingolipid class of mammals and is generally known as a component of biological membrane. In recent years, sphingomyelin, especially from milk, has been reported to have several food functions such as improving skin barrier function and inhibiting lipid absorption. However, there is little information about food functions of sphingomyelin derived from marine sources, which has unique structures. In this study, we qualitatively and quantitatively analyzed sphingomyelin from Atlantic salmon to evaluate its potential as a new source of sphingomyelin.

Methods: Total lipids were extracted from lyophilized and powdered Atlantic salmon (*Salmo salar*) heads (n=3). After saponification of total lipids, sphingomyelin content was determined by HPLC equipped with an evaporative light scattering detector (ELSD). Sphingomyelin was purified by silica gel column chromatography, and the sphingoid base and fatty acid composition was determined by HPLC and GC, respectively, after hydrolysis and derivatization. In addition, intact molecules of sphingomyelin in Atlantic salmon were identified by LC-MS/MS analysis

Results: The content of sphingomyelin in the salmon heads used in this study was 1.6±0.2 mg/g dry weight (172.0±8.7 mg/head). Comparing the content of each tissue, sphingomyelin was relatively abundant in the eyes. Major constituent of sphingoid bases was d18:1 with d18:0, d18:2, and d19:1 also present.C14:0, C16:0, C18:0, and C22:1 were detected as constituent fatty acids. In LC-MS/MS analysis, 23 molecular species of sphingomyelin were identified. The sphingomyelin molecules in Atlantic salmon are highly unsaturated relative to those in milk and eggs.

Conclusions: Our results shows that Atlantic salmon head is a promising source of sphingomyelin ingredients. Sphingomyelin of Atlantic salmon attracts attention for its food functionality because of its unique chemical structure, which is different from those of milk and eggs.

PAB(T8-29)
Development of branched-chain amino acid rich pudding for the elderly using silkworm pupae

Chitraporn Ngampeerapong[1], Orakarn Kabkhum[1], Arpapon Tanalit[1], Nattapol Tangsuphoom[2]

1. Maejo University (Thailand), 2. Mahidol University (Thailand)

Background and objectives: Elderly tend to have insufficient protein intake due to their impaired chewing and swallowing abilities and gastrointestinal functions. About 10-27% of the older population worldwide is suffering from sarcopenia. Adequate daily intake of essential amino acids (EAAs), particularly branched-chain amino acids (BCAAs), can reduce the risk of sarcopenia by preserving the muscle mass. Edible insects are considered as a sustainable alternative source of high-quality protein. This study aimed to develop a pudding having suitable texture and adequate amounts of EAAs and BCAAs for the elderly by using silkworm pupae as major protein source.

Methods: Linear programming was performed to obtain the recipes containing silkworm pupae and other protein-rich ingredients, in which one serving provided ≦200 kcal energy, 10 g protein, ≧0.9 g EAAs, and ≧0.7 g BCAAs. Various amounts of gelling agents, including gelatin, agar, and xanthan gum, or their 2:2:1 mixture were used for modifying the textural properties of pudding. Sensory acceptability was evaluated by elderly panel. Nutritive value including amino acid composition of the product were analyzed. Protein digestibility was determined by *in vitro* gastrointestinal digestion. Protein quality was determined as Predicted Digestibility-Corrected Amino Acid Score (PDCAAS).

Results: The formulated pudding contained 15% silkworm pupae, 15% coconut milk, 8% Job's tears, 4% sunflower seed, 3% sugar, and 0.4% salt. Texture of the pudding became harder and less cohesive with more gelling agent, especially agar. The pudding with 1% (w/w) gelling agent mixture had the most suitable textural properties with hardness 1568 N/m^2, adhesiveness 824 g·s and cohesiveness 0.41. Such values met the criteria of Universal Design Foods Level 4, and IDDSI Level 4, suggesting that the pudding is puree-like and does not need chewing. The product was accepted by healthy elderly in all sensory attributes and portion size and was rated as easy to chew and swallow. One serving (120 g) of the developed pudding provided 182 kcal, 12 g protein, 3.2 g EAAs, and 1.7 g BCAAs, which was considered “high protein”. The protein digestibility and PDCAAS were 71.21% and 0.21, respectively.

Conclusions: Silkworm pupae could be a potential protein source for developing high-protein BCAA-rich food for the elderly.

Physical properties of cooked rice grown by organic cultivation under various storage conditions

Yukiko Kagohashi[1], Akira Yamamoto[2]

1. The University of Shimane (Japan), 2. Shimane prefecture farming technique center (Japan)

Background and objectives: The quality of polished rice as the raw material for cooked rice is influenced by various factors, such as the variety, production area, cultivation method, and storage environment.

Methods: This study compared the quality of ‘Kinu Musume' rice organically cultivated in Shimane Prefecture, cooked, and stored under various conditions. Polished ‘Kinu Musume' rice was washed, soaked, and cooked, and its physical properties, appearance (shape), and moisture content were measured after storage under each condition.

Results: On comparing the physical properties of the cooked rice immediately after cooking (Condition 1) and after 8 hours of storage in a warmer environment (Condition 2), the rice was significantly harder, with greater surface adhesion and elasticity, and it showed a lower (stickiness-hardness) balance value, which is an index for palatability evaluation, under Condition 2. As for its appearance properties, it showed significantly lower values for grain length and grain thickness under Condition 2. On comparing the physical properties of the cooked rice under Condition 1 and after 1 week (Condition 3)/1 month (Condition 4) of frozen storage at -30°C and reheating, the rice was significantly harder, with lower stickiness, poorer stickiness-hardness balance, and significantly higher adherence, cohesiveness, and elasticity under Conditions 3 and 4. As for its appearance properties, it showed significantly lower values for grain length, grain width, grain thickness, and weight under Conditions 3 and 4.

Conclusions: Based on the results, the physical and appearance properties of cooked rice grown by organic cultivation may vary according to the storage condition.

Effect of trehalose on the quality of gluten-free rice bread made from two types of rice flour with different amylose contents

Tomoko Yamaguchi[1], Iana Korshunova[1], Saori Kuremoto[1], Yoshie Matsuzawa[1]

1. Niigata University (Japan)

Background and objectives: Gluten ingestion has been linked to several clinical disorders includes celiac disease, wheat allergy, and non-celiac gluten sensitivity. Celiac disease is still rare in Japan; however, wheat allergy occupied 11.7% of food allergies next to egg and milk. Nowadays, the rising incidence of gluten-related disorders, promotes worldwide interest in various gluten-free products. Rice flour is completely hypoallergenic due to the absence of gluten. We reported the preparation of gluten-free rice bread without major food allergens—egg, milk, and wheat flour—achieving success by using 0.8% Hydroxypropyl methylcellulose (HPMC). However, when baking rice bread without gluten, it is easy to retrogradation. The objective of this study was to evaluate the effect of trehalose, disaccharide of glucose, on the quality of gluten-free rice bread made from two types of rice flour with different amylose contents.

Methods: Two types of rice flour, intermediate-amylose Koshihikari rice flour (DK) and high-amylose Koshinokaori rice flour (KK), were used in this study. Gluten-free rice bread was made from rice flour, olive oil, sugar/trehalose, salt, dry yeast and HPMC, and baked at 180 ° C for 45 minutes. After baking the bread, the specific loaf volume, color parameters (L*, a*, b*), water content, and degree of gelatinization were measured. Physical properties (hardness, cohesiveness, adhesiveness) of rice bread were measured using a TPU-2CL texture profile device (Yamaden Co., ltd). Sensory evaluation was performed on a 7-point scale.

Results: DK, DK with trehalose (DKT), and KK breads showed the same specific loaf volume, which were higher than KK bread with trehalose (KKT). The degree of gelatinization of DK and DKT breads were significantly higher than KK and KKT breads. When measuring physical properties, KK and KKT breads showed higher hardness value, as well as lower cohesiveness, than DK and DKT breads. The sensory evaluation score of chewiness and moistness in rice bread with trehalose showed higher than that of rice bread without trehalose.

Conclusions:These results show that amylose content and trehalose affects bread quality to gluten-free rice bread.

Higher amounts of proximates and minerals in locally formulated biscuit using African locust beans

Matilda Lenia[1], Setorglo Jacob[2], Christiana Asamoah-Nsiah[2]

1. Bolgatanga Technical University (Ghana), 2. University of Cape Coast (Ghana)

Background and objectives: Food insecurity is still endemic in most parts of sub-Saharan Africa. According to the World Bank, severe food insecurity in Ghana in 2019 was 8%. The majority of this population lives in the northern sector. This study was a quasi-experimental designed study carried out in the Wa Municipality to determine the proximates and nutrients in African locust beans (*Parkia biglobosa*). We also assessed the acceptability of biscuits manufactured from the proportions of fruit powder mixed with wheat flour.

Methods: Proximate analysis was carried out on prepared samples for the following parameters; protein, calcium, carbohydrate, crude fiber, fats and ash. Sensory analysis was performed to assess the acceptability of the products. We used a completely randomized design with two treatments: wheat flour (WF) and African locust beans fruit pulp flour at 100, 75, 25, and 0%. A total of 100 respondents were randomly selected to test the biscuits' appearance, taste, texture, scent, and general acceptability, using a 9-point hedonic scale questionnaire. Results: The age of the panellists ranged from 18 to 52years. The proximate composition of the locust beans flour was dietary protein (12%), fibre (6.2%), dry matter (92.59%) and ash (1.9%). The quantities were higher in locust pulp flour compared to the control (wheat flour) sample except for fat and oil. Minerals such as phosphorus (1678 µg/g), calcium (0.975 µg/g) and sodium (974.6 µg/g) were high in locust pulp flour compared to the control sample. Similarly, composite biscuits had higher nutrient composition compared to the control sample. Protein, fibre, carbohydrate were statistically significantly ($p < 0.001$) higher for sample 25/75 compared to the control and 50/50 and 75/25. Phosphorus, calcium, sodium, and magnesium content increased with increased locust pulp flour, with sample 25/75 recorded the highest mineral content. Conclusions: Proximate composition of locally produced biscuit is higher than wheat flour and also rich in essential minerals

PAB(T8-33)
Effect of different processing methods on the allergenic protein (tropomyosin) of house cricket

I-Ning Chen[1], Yi-Tien Chen[1]

1. Taipei Medical University (Taiwan)

Background and objectives: House cricket (*Acheta domesticus*) is a sustainable source of protein and micronutrients, and has been approved as a novel food by European Union. However, allergenicity is the potential risk of edible insects including house cricket. The previous studies indicated that sensitized individuals with crustacean allergy may be allergic to insects. Tropomyosin has been identified as one of allergenic proteins in edible insects. The various food processing methods including frying, baking and steaming are commonly applied to edible insects. Therefore, the objective of the study is to investigate the thermal stability of house cricket tropomyosin.

Methods: The house crickets were processed by different food processing methods including baking, frying and steaming with different temperatures. The crude proteins of processed samples were extracted and analyzed by gel electrophoresis and immunoblot.

Results: The results of gel electrophoresis and immunoblot indicate that tropomyosin is the most abundant thermally stable protein in the protein extracts of processed house cricket. The immunoblot results show that tropomyosin keeps its immunoreactivity and integrity in the samples with different processing treatments.

Conclusions: House cricket tropomyosin is the dominant allergenic protein that is resistant to common food processing methods.

Keyword: Food allergy, Edible insect, Tropomyosin

NIRS Prediction Modelling for Simultaneous Multi-trait Assessment in Diverse Cowpea *Vigna unguiculata* (L) Walp) Germplasm

Siddhant Ranjan Padhi[1], Arti Bartwal<[2], Racheal John[3], Kuldeep Tripathi[4], Kavita Gupta[5], Dhammaprakash Wankhede[6], Gyan Prakash Mishra[7], Sanjeev Kumar[8], Sunil Archak[9], Rakesh Bhardwaj[10]

1. Indian Agricultural Research Institute, New Delhi, India (India), 2. National Bureau of Plant Genetic Resources, New Delhi (India), 3. National Bureau of Plant Genetic Resources, New Delhi (India), 4. National Bureau of Plant Genetic Resources, New Delhi (India), 5. National Bureau of Plant Genetic Resources, New Delhi (India), 6. National Bureau of Plant Genetic Resources, New Delhi (India), 7. Indian Agricultural Research Institute, New Delhi, India (India), 8. Indian Agricultural Statistics Research Institute, New Delhi (India), 9. National Bureau of Plant Genetic Resources, New Delhi (India), 10. National Bureau of Plant Genetic Resources, New Delhi (India)

Background and objectives: Cowpea is one such legume which can facilitate to achieve goals on sustainable nutrition and climate change. Assessing nutritional traits conventionally can be laborious and time consuming. NIRS (Near Infra-Red Reflectance Spectroscopy) is a technique use for rapid determination of biochemical parameters for large germplasm.

Methods: NIRS prediction models were developed to assess protein, starch, TDF (Total dietary fibre), phenols and phytic acid based on MPLS regression. Paired t-test was used to determine the difference in the mean of analytical and predicted values.

Results: Higher $RSQ_{external}$ (coefficient of determination) values were obtained for different traits protein (0.882), starch (0.996), TDF (0.901), phenols (0.704) & phytic acid (0.955) in "2,4,6,1", "2,8,8,1", "2,4,4,1", "3,4,4,1" and "2,8,8,1" mathematical treatments respectively. Models for protein, starch, TDF and phytic acid displayed RPD (residual prediction deviation) values of &3 except phenolics (1.81) and low SEP (standard error of performance) indicating the excellent prediction of models. For all the traits worked, p value more than 0.05 implying the model's accuracy and reliability.

Conclusions: The developed models will facilitate high throughput screening of large cowpea germplasm present in the national gene bank at ICAR-NBPGR, New Delhi for identification of traits specific germplasm and selection of desirable chemotypes in any genetic background with huge application in cowpea crop improvement programme across the world.

Mining Nutri-dense Accessions from Assam Collections of Rice

Racheal John[1], Rakesh Bhardwaj[2], Christine Jeyaseelan[1], Harish G.D[2], Sudhir Pal Ahlawat[2], Jai Chand Rana[3]

1. Amity University (India), 2. ICAR-NBPGR (India), 3. Bioversity International (India)

Background and objectives: Rice is a staple crop for more than half of the population where North-East Indian states are primarily dependent on rice for their diets. Traditional rice germplasm or landraces are a good source of diverse phenotypic traits. The indigenous people of Assam conserve and grow various landraces which are highly diverse but still remain nutritionally uncharacterized.

Methods: Nutritional profiling of 395 landraces from Assam was done for total protein content (PC), starch, amylose content (AC), total dietary fibre (TDF), oil, phenol and phytic acid (PA) using AOAC and standard methods. Multivariate statistical analysis including principle component analysis (PCA) and hierarchical cluster analysis (HCA) was applied to decipher the similarities/differences in the multiple nutritional attributes.

Results: The mean total PC, starch, AC, TDF, oil, phenol and PA content of the landraces was 9.8%, 75.2%, 22.3%, 4.7%, 5.3%, 0.4% and 0.34% respectively. Compositional diversity existed between the accessions where landraces contained comparatively higher PC, oil and TDF than commercial rice varieties. PCA revealed that first four principle components i.e. PC1, PC2, PC3 and PC4 contributed to 81.6% of variance where maximum loadings were from protein, oil, starch and phytic acid. HCA revealed 16 clusters where major findings were Cluster I containing high PC (max. 11.7%) and moderate AC (22%), cluster II containing very low AC (min. 6%), cluster IV containing high oil (7%), TDF (5%), low starch (69%) and moderate AC (21%). Cluster XI which contained high AC (27%) and PA (0.5%). Cluster IX containing low phenols (0.2%) and PA (0.3%).

Conclusions: Based on the nutritional profiling and multivariate analysis, land races can be targeted to meet specific nutritional needs. Such as the one with high amylose, low starch and high protein for low glycemic value while low amylose with high protein for baby foods. Accessions with moderate AC could be utilized for their good cooking quality while those with high oil content could be extracted for high value rice bran oil. Landraces with low phenol and phytic acid could be consumed for increased bioavailability of minerals.

Dietary Alaska pollack protein increases skeletal muscle weight and decreases gene expression of negative regulators of skeletal muscle mass in rats

Mina Fujitani[1] >, Hinata Nakagawa[1], Naofumi Doi[1], Kenji Uchida[1,2], Takafumi Mizushige[3], Kohsuke Hayamizu[4], Shinji Okada[5], Taro Kishida[1]

1. Ehime University (Japan), 2. Nippon Suisan Kaisha Ltd. (Japan), 3. Utsunomiya University (Japan), 4. Yokohama University of Pharmacy (Japan), 5. The University of Tokyo (Japan)

Background and objectives: Our previous studies demonstrated that dietary Alaska pollack protein (APP), as the sole protein source, increased gastrocnemius skeletal muscle weight after only 2 days of feeding, and this hypertrophic effect was maintained for over 56 days of APP intake. However, the mechanisms responsible for this effect are unclear. Anabolic growth is achieved when muscle protein synthesis exceeds degradation. Balance between protein synthesis and degradation is controlled by multiple signaling pathways. In this study, we examined the effects of dietary APP on muscle protein content and gene expression of important regulators of skeletal muscle mass.

Methods: Male 5-week-old Sprague-Dawley rats were divided into six groups and fed AIN-93G diets with casein or APP, containing the same amount of crude protein, for 1, 2 and 7 d (n= 10/group).

Results: The gastrocnemius muscle weight of the APP group was significantly higher than that of the casein group after 1, 2 and 7 d of feeding. The gastrocnemius muscle protein content of the APP group was significantly higher than that of the casein group after 7 d of feeding, but not after 1 and 2 d of feeding. The gene expression of Mstn /Myostatin of the APP group was significantly lower than that of the casein group after 2 and 7 d of feeding, but not after 1 d of feeding. The gene expression of Trim63/MuRF1 and Fbxo32/atrogin-1 of the APP group were significantly lower than those of the casein group, regardless of the duration of APP intake. On the other hand, dietary APP did not alter Igf1 gene expressions, regardless of the duration of APP intake.

Conclusions: We demonstrated that dietary APP induces rapid increases in the gastrocnemius muscle weight and decreases in the gene expression of negative regulators of skeletal muscle mass, such as Mstn, Trim63 and Fbxo32. Dietary APP may induce skeletal muscle hypertrophy by promoting positive protein balance.

PAB(T8-37)
Assessment of zinc content in parboiled rice from popular varieties grown in Bangladesh

Victor Taleon[1], Zakiul Hasan[2], Luis Londono[3], Khairul Bashar[4]

1. International Food Policy Research Institute (IFPRI) (USA), 2. International Food Policy Research Institute (IFPRI) (Bangladesh), 3. Alliance Bioversity-CIAT (Colombia), 4. Alliance Bioversity-CIAT (Bangladesh)

Background and objectives: Rice is the main source of zinc for Bangladeshi population. Rice is consumed as parboiled rice in Bangladesh, however, the zinc content in rice is low after parboiling and milling. Rice millers tend to over-polish rice to improve its appearance and sell the rice as *Minikit* variety or type. Since over-polished rice contains lower zinc concentration, it is necessary to determine the zinc content of rice identified as *Minikit* and determine how different is to other popular varieties found in markets.

Methods: Rice samples (240) were collected from markets of 5 districts (Barisal, Bogura, Faridpur, Jamalpur and Rangpur), in each district samples were obtained from 2 urban and 2 peri-urban markets. Also, 24 rice samples were collected from households in rural villages in each of the 5 districts. The zinc content was measured in all samples. Zinc content was measured using a non-destructive energy-dispersive x-ray fluorescence spectrometry (XRF). Apparent milling degree and grain shape was also determined.

Results: Rice from urban and peri-urban areas had 8.1-8.3 µg/g which was lower than rice from households in rural areas (9.9 µg/g). The rice varieties with the lowest zinc concentration were *Minikit* (6.3 µg/g) and *Guti Swarna* (6.3 µg/g), which were 21–52% lower than 9 of the most common varieties found. The highest zinc concentration was found in rice variety *Ranjit* (13.2 µg/g). There was a significant difference in zinc content by district which could be due to the variety but also the severity of milling preferred in such districts.

Conclusions: *Minikit* rice had lower zinc content than the most popular varieties. Given the high zinc deficiency in Bangladesh and the evidence generated, it is necessary to create policies to discourage the over-processing of rice and create awareness of the poor nutritional content of *Minikit* rice compared to other varieties, especially in urban and peri-urban markets.

Keyword: Rice milling, Zinc content, Minikit, Parboiling

PAB(T8-38)
Effect of refrigerated storage on major crustacean allergen tropomyosin

Yi-Tien Chen[1], Hui Ju Mao[1]

1. Taipei Medical University (Taiwan)

Background and objectives: Crustaceans including shrimp, crab and lobster are popular seafood with health benefits. However, crustacean is also one of major food allergens. Tropomyosin has been identified as the major allergenic protein among edible crustacean species. Tropomyosin is a myofibrillar protein that is able to resist common food processing. Proteins in foods are affected and degraded by processing and storage conditions. Refrigeration is an important and common method used by industrials and consumers for preserving crustaceans. Therefore, the objective of the study is to examine the effect of refrigerated storage on crustacean tropomyosin.

Methods: The raw muscle samples of white shrimp (*Litopenaeus setiferus*), mud crab Scylla serrata) and American lobster (*Homarus americanus*) were refrigerated at 4°C up to 7 days. The proteins of samples were extracted by phosphate buffered saline. The protein extracts were analyzed by gel electrophoresis and immunoassay using anti-tropomyosin antibody.

Results: The results of gel electrophoresis showed that the protein profiles during the period of refrigerated storage were similar within each of species (white shrimp, mud crab and American lobster). The results of immunoassay revealed that the tropomyosin of three crustacean species tested kept the immunoreactivity and was not affected by refrigerated storage up to 7 days.

Conclusions: Generally, the shelf life of raw crustaceans at 4 °C is 2-4 days. The potential autolysis and microbiological growth in the raw crustaceans usually cause protein degradation. In the present study, the refrigerated storage does not affect the integrity and immunoreactivity of crustacean tropomyosin while the crustaceans are still fresh for consumption.

Color reaction of Tutankhamen's pea upon heating

Yuuki Maekawa[1], Miki Hiemori-Kondo[1]

1. Tokushima Bunri University (Japan)

Background and objectives: Immature Tutankhamen's pea, an ancient pea variety (*Pisum sativum* L.), has the unique characteristic of changing from green to reddish brown when heated. In this study, the mechanism underlying this color change was investigated by identifying the color source and pigment.

Methods: Water extracts of whole pea, seed coat, and pea endosperm were heated at 100 ℃ for 20 min to locate the color source. A water extract of the seed coat was treated with a Sep-Pak C18 cartridge and subjected to high-performance liquid chromatography using HILIC columns to isolate the color source. To clarify the detailed structure of the coloring source, a butanol-hydrochloric acid reaction, thiol decomposition, and acid hydrolysis were performed; the product was subjected to liquid chromatography–tandem mass spectrometry (LC-MS/MS) using an Atlantis T3 column. Pigment component generated by heating at 100 ℃ for 4 h the isolated color source was analyzed by LC-MS/MS. These compounds were characterized based on their unique fragmentation patterns in negative ion mode.

Results:The color source was located in the seed coat. LC-MS analysis of the compound provided signals at m/z 609.1 and 611.0 in the negative and positive ion modes, respectively. This indicates that the mass of the color source is 610. MS/MS analysis showed that the compound is a B-type prodelphinidin, and is a dimer of (–)-epigallocatechin (EGC) formed by a cleavage reaction between various flavans. Heating the isolated (–)-EGC dimer resulted in the production of a pigment component. LC-MS peak was detected at m/z 607.0 and 608.9 in negative and positive modes, respectively. The molecular weight of the pigment component in this case was estimated to be 608. This is consistent with the weight of an oxidized (–)-EGC dimer, which was identified as the color source.

Conclusions: The color source of Tutankhamen's pea upon heating was determined to be a dimer of (–)-EGC, and it was found to be located in the seed coat. This study revealed that the color reaction of Tutankhamen's pea upon heating is caused by the oxidation of the (–)-EGC dimer.

Keyword: Tutankhamen's pea, Color reaction, Cleavage reaction, (–)-Epigallocatechin dimer, Oxidation

Biofortification in Wheat: Research Progress, Potential Impact, and Policy Imperatives

Sendhil R[1], Adeeth Cariappa AG[2],Palaniswami Ramasundaram[3], Vikas Gupta[4], Gopalareddy K[5], Om Prakash Gupta[4], Anuj Kumar[4], Satyavir Singh[4], Gyanendra Pratap Singh[4]

1. Pondicherry University (A Central University) (India), 2. ICAR-National Dairy Research Institute (India), 3. Indian Council of Agricultural Research (India), 4. ICAR-Indian Institute of Wheat and Barley Research (India), 5. ICAR-Sugarcane Breeding Institute (India)

Background and objectives: Biofortification is a promising strategy to reduce the persisting micronutrient deficiency. Biofortifying wheat grains has the potential to alleviate malnutrition as it is one of the major consumed staple crops. In the milieu, an attempt has been made in this study to examine the research progress, and impact of agronomic and genetic efforts on wheat biofortification.

Methods: Data has been sourced from the Scopus database using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) approach. The compiled data were subjected to meta-analysis and bibliometric coupling (using the VosViewer visualization tool) to assess the impact and research progress of biofortification, respectively. In addition, the economic surplus model was used to capture the impact of adopting a biofortified wheat variety.

Results: Bibliometric analysis indicated that developing countries like India, Pakistan, and China lead the research in wheat biofortification, followed by Turkey, Australia, the United Kingdom, and the United States of America. Using meta-analysis we find that agronomic biofortification leads to a 1.6 standard deviation (SD) and 1.7 SD increase in zinc (Zn) and iron (Fe) concentration, respectively. Genetic biofortification efforts lead to a 74% and 79% increase in Zn and Fe contents, respectively. India's first biofortified wheat variety (WB 02), since its release, is cultivated in around 144,256 hectares generating an estimated economic surplus of INR 50.54 million at the constant price (base year as 2011-12).

Conclusions: The effects of biofortification were larger in Asia and Africa, where micronutrient deficiency and hidden hunger are widespread. In India, genetic biofortification has more potential than agronomic biofortification as the impact of the former on wheat micronutrient concentration was around three times higher than the latter. Further, genetic biofortification has been recognized as an economical and sustainable strategy. We propose policy inputs to strengthen the value chain on biofortification, followed by a framework to upscale the adoption of biofortified wheat varieties to combat hunger and improve its effect on nutritional outcomes.

Identification of transdermal sensitizing allergens in edible cricket protein and verification of cross-reactivity.

Nana Tanahashi[1], Suzuka Tokunaga[2], Rikiya Shimada[1], Sayaka Tsutsumi[2], Nobuhiro Zaima[1,2,3], Tatsuya Moriyama[1,2,3]

1. Kindai University, Graduate School of Agriculture, Major in Applied Biological Chemistry (Japan), 2. Kindai University, Faculty of Agriculture, Department of Applied Biological Chemistry (Japan), 3. Kindai University, Agricultural Technology and Innovation Research Institute (Japan)

Background and objectives: Edible insects are attracting attention as a new protein food resource to address the food crisis. However, there have been few studies on their safety and allergenicity. In addition, it has recently been shown that food allergy involves transdermal sensitization. Therefore, in this study, we examined whether edible cricket protein has the ability to sensitize transdermally using a mouse model system, and detected and identified transdermal sensitizing antigens and examined their cross-reactivity to other foods.

Methods: Powdered edible Acheta domesticus products were obtained and samples of the supernatant (protein concentration 5 mg/ml), which was agitated and extracted in 5% SDS solution, were applied to the backs of female Balb/c mice (n=6) at 25 µl four times a week for 5 weeks, while only 5% SDS was applied in the control group. During the application period, blood samples were collected and hair was shaved once a week under anesthesia. After blood collection, antigen-specific IgE and IgG1 antibody titers were measured by ELISA. Then, using the IgE and IgG1 binding activity evaluated by immunoblotting and ELISA as an indicator, purification and identification of candidate allergen molecules in cricket protein were attempted by ion exchange column chromatography and gel filtration HPLC. Cross-reactivity was evaluated by immunoblotting and ELISA using edible parts of shrimp, crab, clam, tuna, pig, and chicken as well as crickets.

Results: In the control group, there was no increase in antibody titer of both cricket-specific IgG1 and IgE. In the cricket group, antibody titers of cricket-specific IgE and IgG1 increased significantly at 5w compared to 0w. Immunoblotting analysis showed a distinct IgG1 binding protein band around 37 kDa. After purification and in-gel digestion, MS analysis showed that this molecule is tropomyosin, a pan-allergen of arthropods. The results also suggest that this molecule might be cross-reactive with tropomyosin in other species of edible crickets, shrimp, and crab.

Conclusion: This evaluation system suggests that edible cricket proteins can sensitize percutaneously, and the arthropod pan-allergen, tropomyosin was identified as one of the major percutaneous sensitizing antigens. Furthermore, tropomyosin from edible crickets was suggested to be cross-reactive among arthropods.

Keyword: edible insects, cricket, transdermal sensitization, allergens, tropomyosin

A novel culture medium for cultured meat production using microalgae-derived nutrients and mammalian cell-secreted growth factors: Development of serum-free and grain-derived nutrient-free medium

Kumiko Yamanaka[1], Yuji Haraguchi[1], Hironobu Takahashi[1], Ikko Kawashima[2], Tatsuya Shimizu[1]

1. Tokyo Women's Medical University (Japan), 2. IntegriCulture Inc. (Japan)

Background and objectives: Today, due to global population growth and increasing demand for meat products, shortage of food protein is a growing concern. Cultured meat production has been proposed as one of the solutions, and this technology has attracted worldwide attention for its potential to solve the global resource and energy consumption and animal welfare issues associated with conventional meat production. Cultured meat is produced by proliferating animal myoblasts using cell culture technology. To take this process from the lab bench to the industrial scale would require significant amounts of culture medium. The culture medium is composed of nutrients derived from grains and heterotrophic microorganisms and fetal bovine serum (FBS), which will impact the sustainability of cultured meat in future owing to high food prices, increased environmental impact from fertilizer and pesticide use, and ultimately livestock use. Compared to grains, microalgae have higher growth capacity and lower carbon footprint, making them a cost-effective and eco-friendly material. Several studies have claimed that cell culture supernatants containing growth factors, promote animal cell proliferation and have potential as an alternative to FBS. Here, we developed a novel medium containing nutrients extracted from microalga and cell-secreted growth factors without grain-derived nutrients and animal sera.

Methods: First, *Chlorella vulgaris* -derived nutrient medium (CVNM) was prepared by adding *Chlorella vulgaris* extract (CVE) to the inorganic salt solution that served as the basis for the culture medium. The mammalian immortalized cell line (provider cells; named after they 'provide' growth factors) were cultured in CVNM and the supernatant was obtained as the conditioned medium (CM). This CM, with CVE added as a nutrient source, was applied to primary bovine myoblast cultures.

Results: The provider cells were successfully allowed to survive in CVNM, and this CM promoted the proliferation of bovine myoblasts.

Conclusions: Bovine myoblasts, the main cell source for cultured meat, were found to be able to proliferate only with nutrients derived from microalgae and growth factors secreted by the provider cells. This study will contribute to improving sustainability of cultured meat as well as other industrial product based on cellular agriculture.

1. Food and Agriculture Organization of the United Nations (Kenya), 2. Washington State University (Kenya), 3. UNICEF (Kenya)

Background and objectives: The Food and Agriculture Organization of the United Nations in collaboration with UNICEF and Washington State University implemented a research project from August 2018 to September 2022, to assess the impact of livestock programming on nutrition improvement of children under five years and pregnant and lactating women, in Marsabit County, Kenya. The objectives of the USAID funded project were; to determine the effect of providing livestock feeds during critical dry periods on household milk yield; to determine the effect of providing livestock feeds and nutritional counselling on milk consumption by children under five years and pregnant and lactating women; and to determine the effect of providing livestock feeds and nutritional counselling on risk of acute malnutrition among children under five years and pregnant and lactating women.

Methods: A cluster randomized control trial study design was applied. The study targeted households with children under five years and pregnant and lactating women, divided into two intervention arms and one control arm. Intervention arm one consisted of 600 households receiving livestock feeds only during dry seasons; Intervention Arm two consisted of 600 households receiving livestock feeds and weekly nutritional counselling during dry seasons; Control arm consisted of 600 households receiving none of the two interventions but accessing routine human and animal health care. Anthropometric measurements of children and pregnant and lactating women, milk yield, food consumption data and human and animal health data were collected every 6 weeks. Household socio-economic data and demographics were collected every quarter.

Results: Households receiving livestock feeds produced 0.63 more litres per days, compared to households in the control arm; Children in arm receiving livestock feeds and nutritional counselling consumed an average of 240 ml more milk per day compared to those in the control arm while pregnant and lactating women consumed 210 ml more; Provision of livestock feeds to households was associated with 11% reduction in risk to acute malnutrition in children under fives.

Conclusion: Livestock feeding during critical dry seasons is associated with increase in milk production and consumption. Integrating nutrition counselling in livestock feeding programmes improves nutrition outcomes of children and pregnant and lactating women.

Development of LC-MS/MS method for determination of total choline in various foods using acid hydrolysis

Yoshinari Hirakawa[1], Kazuhiro Fujita[1], Toshiaki Yokozeki[1], Yushi Takahashi[1], Izumi Yoshida[1], Tomoji Igarashi[1]

1. Japan Food Research Laboratories (Japan)

Background and objectives: Choline is present in foods as free choline and choline esters (phosphocholine, phosphatidylcholine, glycerophosphocholine, and sphingomyelin). Acid hydrolysis is a method to quantify total choline. The AOAC official method 2012.18 describes a method for hydrochloric acid hydrolysis Phosphocholine is not sufficiently hydrolyzed by this method and requires phospholipase D treatment. The AOAC Official Method 2015.10 describes a microwave-assisted nitric acid hydrolysis method. This method is convenient due to its short acid hydrolysis time but requires a high concentration. Additionally, AOAC 2012.18 and 2015.10 are limitedly applied to infant formula and adult/pediatric nutritional formula. In this study, we optimized the conditions for acid hydrolysis, and developed a method of determination of total choline that can be applied to various foods.

Methods: An acid solvent was added to the homogenized sample, and heat extraction was performed. The extract was diluted appropriately, and the amount of choline was measured by LC-MS/MS. To optimize acid hydrolysis, we compared the type of acid solvent (hydrochloric acid, nitric acid, sulfuric acid), acid concentration, extraction time, and equipment (autoclave, microwave). To confirm degree of hydrolyzation of choline ester, we measured the hydrolysis rate of phosphocholine and glycerophosphocholine. The optimized method was validated.

Results: The optimal conditions for acid hydrolysis were found to be an 8-hour extraction with hydrochloric acid (0.055 mol/L) in an autoclave (121 ℃). The hydrolysis rates of phosphocholine and glycerophosphocholine by this method were 97.8% and 100.7%, respectively. Furthermore, using egg yolk and chicken liver, we examined the extraction time, and confirmed that the total amount of choline peaked at 8 hours. Based on the established condition, we determined total choline of a standard reference material (NIST 1869 Infant/Adult Nutritional Formula II) and obtained the accepted data for the certified value.

Conclusions: In this study, we optimized the acid hydrolysis conditions for total choline analysis and established a method to convert choline esters in various foods to free choline. This method is safer, requiring lower acid concentrations than previous acid hydrolysis methods, and is a novel method that can measure total choline in various foods.

Keyword: choline, LC-MS/MS, acid hydrolysis, various foods

Identification and characterization of percutaneously sensitizing fruit allergens

Rikiya Shimada[1], Nana Tanahashi[1], Serina Kinugasa[1], Eri Izumi[1], Nanoka Kimura[2], Shiho Tsukamoto[2], Nobuhiro Zaima[1,2,3], Tatsuya Moriyama[1,2,3]

1. Kindai University, Graduate School of Agriculture (Japan), 2. Kindai University, Faculty of Agriculture (Japan), 3. Kindai University, Agricultural Technology Innovation Research Institute (Japan)

Background and objectives: Recently, transdermal sensitization, in which food antigens enter through the skin and sensitize, has been attracting attention as a route for the development of food allergy. Fruits are used not only as food, but also in some cosmetics, and are often in contact with the skin. In this study, we investigated the dermal sensitization potential of cherries, kiwifruit (green/gold), and mangoes, and identified and characterized dermal sensitization antigens.

Methods: Six-week-old female BALB/c mice were divided into a control group and each fruit group. Once a week at the time of blood collection, the back of the head was shaved and tape-stripped, and 5% SDS was applied. Each sample was applied 4 times a week to each group. Only 5% SDS was applied for the control group and fruit extract/5% SDS for each fruit group, and serum levels of fruit specific IgE and IgG1 and the binding protein(s) of each antibody (candidate transdermal sensitization antigen) were detected by ELISA and immunoblotting (IB), and the antibody-binding proteins were purified by various chromatographic methods.

Results: Applied fruit specific IgE and IgG1 production was confirmed in each fruit group by ELISA. The IgE and IgG1 binding proteins were detected around 18, 23~25 kDa in kiwifruit, 27 kDa in cherry and 28 kDa in mango, depending on the IB. Obtained results suggest that these fruit proteins have transdermal sensitizing ability. Next, we purified and identified the sensitizing antigens and found kiwellin (Act d 5) in kiwifruit and thaumatin- like protein (Pru av 2) in cherry as the putative transdermal sensitizing allergens.

Discussion: Both kiwellin and thaumatin-like protein identified in this experiment are commonly found in plants and have a protective effect against infection. Therefore, it is suggested that the transdermal sensitization antigens of fruits might be related to plant defense proteins. In addition, it is notable that these proteins contain many S-S bonds in molecules. Identification of sensitizing antigens in mango is under progress.

Keyword: transdermal sensitization, allergens, mango, cherry, Kiwi fruit

PAB(T8-47)
Evaluation of Internal Structures in Rice Flours Using Small-Angle X-ray Scattering (SAXS) and Fourier Transform Infrared (FT-IR) Spectroscopy

Jiamin Yang[1], Kanna Yamada[1], Daitaro Ishikawa[2], Tomoyuki Fujii[1]

1. Tohoku University (Japan), 2. Fukushima University (Japan)

Background and objectives: Rice flour has both a nano-scale short-range ordered structure and a micro-scale long-range ordered structure. Physical conversion operations such as pulverization have controled of physical properties by disordering internal structures. Previous studies have shown that the milling method creates a core-shell structure in which only the surface is structurally changed and the internal crystal structure is maintained, and that it is possible to control disordered structure by humidity control. So, in this study, we attempted to evaluate the internal structure of rice flour with different milling methods by complementarily utilizing small-angle x-ray scattering (SAXS) and Fourier Transform Infrared (FT-IR) Spectroscopy.

Methods: White rice was pulverized using a jet mill to get six samples with a gradually different size (DM1-3 and WM1-3). α-formed sample was subjected to milling at 130°C.

Results: An order parameter using the SAXS curve was proposed to quantify the order structure of starch, and the true density was negatively correlated with the order parameter. In FT-IR spectrum, the band positions at 2927 and 990 cm^{-1} shifted to a lower wavenumber with an increase in the order parameter. Whereas the intensity of the band at 2927 cm^{-1} did not change, the intensity of the band at 990 cm^{-1}has a strongly negative correlation with the order parameter increased. When adjusting the moisture content of rice flour, the band position at 990 cm^{-1} shifted to a higher wavenumber above the water activity of 0.7. In addition, the band at 861 cm^{-1} also shifted to a higher wavenumber, whereas 572 and 436 cm^{-1} did not show a significant shift.

Conclusions: The order parameter was negatively correlated with the true density. This suggested that structural modification may have occurred at the lamellar structure (including amorphous /crystalline) level, and the ordered structure at lamellar level did not distributed densely. The behavior of the bands at 990 cm^{-1} > indicated the glass–rubber transition of starch owing to water sorption. These results demonstrate that the starch in rice flour formed a glass-like crystalline phase with low water activity and a rubber-like crystalline phase with high water activity.

PAB(T8-48)
Establishment of a recycling-oriented food production system using microalgae and mammalian cells

Yuta Okamoto[1,2], Yuji Haraguchi[2], Katsuhisa Sakaguchi[1,2], Naoya Sawamura[1], Toru Asahi[1], Tatsuya Shimizu[2]

1. Waseda University (Japan), 2. Tokyo Women's Medical University (Japan)

Background and objectives: Although demand for meat is increasing due to a variety of problems, the existing meat production system has sustainability issues, as it accounts for 33% of the greenhouse gas emission. Cultured meat has been attracting attention as a new meat solution to this problem, but one of the challenges in its production is the problem of consuming large amounts of the cultured medium. In this study, we propose a new food production system that uses mammalian cells and microalgae for a complete recycling system to promote the use of cultured meats in the future. Microalgae remove metabolites such as ammonia that accumulate in mammalian cell culture, and basic nutrients are recovered from the proliferated microalgae and used as mammalian cell nutrients again. This new system makes it possible to produce cultured meat without discarding the cultured medium.

Methods: Primary chicken cells were cultured in a conditioned medium prepared by growth factor-secreting cells and culture medium. Thereafter the supernatant was sued to culture *Chlorococcum littorale* (*C. littorale*). The same conditioned medium was then used again to culture primary chicken cells. In this process, the sustainability of this system was examined by measuring nutrient components such as glucose and amino acids in the medium and metabolites such as ammonia and lactic acid.

Results: It was shown that chicken cells and *C. littorale* can be proliferated in the same conditioned medium. Furthermore, additional growth of chicken cells was confirmed by nutrient solution extracted from the *C. littorale* using a catalyst. In this process, it was confirmed that nutrients such as glucose and amino acids were supplied by the extraction of *C. littorale*, and at the same time, ammonia was utilized by *C. littorale* and removed from the culture medium.

Conclusion: The culture system shown in this study, in which mammalian cells and microalgae are co-utilized, is expected to enhance the feasibility of a recycling-oriented food production system and to be applied to the production of drugs, which consume large amounts of culture medium.

Improving household food security and nutrition through nutrition sensitive agriculture programming in Ghana.

Angela Kimani[1,2], Yuji Inada[1,2], Kenjiro Ban[1,2], Akahiko Hata[3], Takafumi Nakase[4], Reimi Kobayashi[5], Kai Utsugi Nakai[5], Toru Takabayashi[3], Paulina Addy[6], Peter Aboagye[6]

1. Initiative for Food and Nutrition Security in Africa (IFNA) (South Africa), 2. Japan International Cooperation Agency (JICA) (Japan), 3. Sanyu Consultants Inc. (Japan), 4. International Development Centre of Japan Inc. (Japan), 5. Koei Research and Consulting Inc (Japan), 6. WIAD- Ministry of Food and Agriculture (Ghana)

Background and objectives: Eradication of hunger and malnutrition is the second SDG that countries are working towards achievement by 2030. In Africa, the Malabo Declaration recommits to increasing food security and improving nutrition by 2025. To contribute to these goals, the Initiative for Food and Nutrition Security in Africa (IFNA), an initiative launched by the Japan International Cooperation Agency (JICA) and the African Union Development Agency NEPAD (AUDA-NEPAD), implemented pilot projects in three countries - Ghana, Mozambique, and Kenya, with the objective of increasing the production and consumption of locally adapted nutrient rich foods to address malnutrition. IFNAs two approaches include Multi-Sectoral Approach (MSA) and Nutrient Focused Approach (NFA).

Methods: The activities in Ghana were implemented in 19 communities in Krachi West district between June 2021 and January 2022. Aiming to reduce iron deficiency anemia, 500 small-scale farming households with pregnant or lactating women or with children under five years were targeted. The activities included: (i) Production of local nutrient rich vegetables and poultry - through health and agriculture extension workers training and farmer training; and provision of farming inputs (ii) Promotion of consumption of vegetables and eggs and dietary diversity in household meals through food and nutrition education. A baseline and an endline survey of the project was undertaken.

Results: Through the NFA, the district counterparts identified 12 locally available iron-rich vegetables for production and consumption. There was 121% increase in dietary diversity among women consuming between 6 and 9 food groups per day. There was 123%, 83% and 93% increase in consumption of green leafy vegetables, eggs and legumes respectively. 95% of project beneficiaries setup their own kitchen gardens compared to 24% at baseline. At the endline, project beneficiaries cultivated an additional 5 iron rich crops compared to baseline.

Conclusions: Setup of kitchen gardens close to households to increase iron-rich vegetable consumption. Food and nutrition education is critical for improving knowledge and practice in food preparation. Further research on evidence of hemoglobin level improvement through continued promotion of consumption of iron rich foods (among other routine community interventions) is required.

Possibility of Isolating Plant Defense Proteins from Buckwheat Seeds

Yuko Tokuno[1], Mizuki Kinoshita[1], Saeko Sugawara[1]
1. Jumonji Univesity (Japan)

Background and objectives: Plants exposed to various stresses such as infection and injury from pathogenic bacteria, chemical substances including plant hormones, air pollutants, and ultraviolet rays initiate defense mechanisms to protect themselves. A group of proteins induced in this process is defense-related proteins. Recently, such a protein becomes a cross-reaction-related allergen. These are called incomplete food allergens. In addition, the *Pantoea* species attached to buckwheat may become disease-causing germs and produce an antibiotic derived from peptides. Therefore, I investigated whether *Pantoea* species did not attach to buckwheat and analyzed the protein of the buckwheat which varied in the soil environment with LC-MS/MS.

Methods: *Pantoea* species isolated from 5 buckwheat seeds produce by each different area with a semi-selective Lysine-Ornithine-Mannitol-Arginine-Charcoal medium (LOMAC). The provided separation stock decided on a nucleic acid sequence after amplifying *gyrB* using the universal primer of the *gyrB* gene. We identified a bacterial species using DDBJ. The few grains of buckwheat's seed were ground into a fine powder using a mortar and pestle. After centrifugation, the supernatant was collected. After TCA precipitation, samples were digested with Trypsin. The digested samples were prepared for mass spectrometry analysis by GL-Tip SCX. The recovered peptides were analyzed using Q Exactive Plus coupled on-line with a capillary high-performance liquid chromatography (HPLC) system to acquire MS/MS spectra. Data derived from the MS/MS spectra were used to search the protein database SWISS-Prot using the MASCOT Server and to identify proteins using the proteome software.

Results: The authors have no conflicts of interest directly relevant to the content of this article. species were gathered from each 5 buckwheat seeds. The distinguished bacterial species were four kinds. The common bacterial species were The authors have no conflicts of interest directly relevant to the content of this article.Two proteins of the buckwheat seeds which varied in the area showed wide molecular weight. And six kinds of protein of the peptide range where expression was seen in only one buckwheat existed.

Conclusions: *Pantoea* species were found on all seeds. We couldn't clarify the possibility of external stress such as the infection of disease-causing germs. However, the distribution of proteins that grew up in a different environment differed. we suggested the possibility of isolating plant defense protein, such as incomplete food allergens.

Prevent COVID-19 while enjoying meals. ~My Meal Style Finding Challenge~

Yuka Kobayashi[1,2], Sayuri Goryoda[1,2]

1. Yamagata University (Japan), 2. SABE (Japan)

Background and objectives: It is important to disseminate vital information to people to protect themselves and boost their health during the COVID-19 pandemic. Therefore, this initiative, called 'My Meal Style Finding Challenge' Project, provides individuals an opportunity to easily measure immune power (IgA: immunoglobulin A) in their saliva and gather helpful information to maintain immune power in their diet.

Method: A total of 79 people (including individuals and organizations) supported the project through crowdfunding. The participants took an immunological test, before and after the one-month meal challenge, to offer insights into changes in the immune system following lifestyle alterations based on meal choices. Once the participants became aware of their own immunity, we asked them to choose an easy-to-use food from 12 kinds of food to enhance immunity over a period of one month. The quantity and frequency of food intake was determined based on sex, age, and physical activity level.

Results: By encouraging healthy eating behavior and providing an opportunity to measure immunity, we were able to offer the participants an opportunity to reflect on their lifestyle. A detailed secondary analysis was performed with the permission of those participants whose immunological test values decreased after the meal challenge. We found that the degree of immune change varied, depending on factors such as participants' body temperature and environmental stressors.

Conclusion: The results indicated that the degree of change in immunity induced by the aforementioned meal challenge may vary based on the participants' background. In the future, we would take into account the background of the participants and chrono-nutrition aspects such as the timing of food intake. We would also like to extend this research into a longitudinal study for its social implementation as a public dietary intervention program that caters to personalized nutrition-based requirements

Factors influencing favourable and unfavourable dietary changes during the beginning of COVID-19 pandemic in Switzerland

Clara Benzi Schmid[1], Cindy Solliard[1]

1. Federal Food Safety and Veterinary Office (Switzerland)

Background and objectives :The COVID-19 pandemic has largely impacted work and life patterns around the world including in Switzerland, where the most stringent measures against its spread were implemented during spring 2020. In this work, we aimed to assess the changes in dietary habits and looked at the sociodemographic and behavioural factors that might favour these modifications.

Methods: An online-survey was conducted among 980 adults representative of the Swiss population to estimate the changes in dietary habits between 13 March and 26 April 2020.

We designed a nutritional score to cluster the participants according to their dietary modifications: no change, positive or negative changes. Amount of eating, snacking frequency, consumption of fruits and vegetables, ready-to-eat meals, soft drinks, sweets and salty snacks were considered as dietary modification and used for scoring.

A multivariate logit regression was performed to examine whether the adherence to one of these three groups was associated with sociodemographic and behavioural factors reported in this survey.

Results: 31.8% (n=327) of the respondents did not show any change in their dietary behaviour. 319 participants were classified in the group with favourable changes (31.0 %), whereas 334 of them were in the cluster with unfavourable changes (32.5%).

Men tended to be fewer in the favourable cluster (OR: 0.71; 0.52-0.95). Furthermore, the subgroup of the population living in rural areas were significantly less likely to belong to the unfavourable changes cluster (OR: 0.41; 0.28-0.61). The odds of developing favourable dietary changes was higher in residential areas (OR: 2.26; 1.48-3.53). Becoming physically less active was a significant feature of the cluster with unfavourable changes (OR: 1.65; 1.14-2.41). Higher odds of unfavourable changes were observed among participants sitting more than usual over the study period (OR: 2.37; 1.67-3.38). Feeling mentally worse during the pandemic significantly increased a person's chance of developing unfavourable dietary changes (OR: 2.37; 1.67-3.38).

Conclusion: This survey indicated that no change, favourable and unfavourable related to dietary modifications were symmetrically distributed among the Swiss population. This part of the population developing unfavourable changes raises concern and public health policies need to specifically tackle this new appearance of unhealthy behaviours.

Comparison of eating habits before and during the COVID-19 pandemic in elementary and junior high school students

Saeko Morii[1,2], Kaoru Sakamoto[1,2]

1. University of Hyogo (Japan), 2. Research Institute for Food and Nutritional Sciences (Japan)

Background and objectives: The changes in children's attitudes toward their living situations during the coronavirus disease 2019 (COVID-19) pandemic have not been clearly studied. Therefore, this study aimed to compare attitudes toward school lunches, eating habits, and lifestyle habits in elementary and junior high school students before (2015) and during (2021) the COVID-19 pandemic. **Methods**: To determine attitudes prior to the pandemic, we distributed a questionnaire survey to 3rd, 5th grade students and 2nd-year junior high school students in A city in Japan (2015 survey). To determine attitudes after the pandemic, we distributed a survey using the Internet (2021 survey). The survey items were based on questions in the "2010 Survey Report on the Dietary Habits of Children for Japan Sport Council." **Results**: In total, 1,913 children in 60 schools answered the 2015 questionnaire, while 10,914 children in 97 schools answered the 2021 survey. In both the 2015 and 2021 surveys, over 75% of elementary school students answered that they "love" and "like" school lunch. Compared with the 2015 survey, in the 2021 survey of 3rd grade elementary school students, the items to be careful about when eating such as "do not drink too many sweet drinks such as juice," "do not eat too much salty food," and "rotate and eat rice and side dishes" were significantly reduced. Compared with the 2015 survey, in the 2021 survey, time spent exercising and playing outside were significantly reduced in all grade and junior high school students. Furthermore, the number of 2nd-year junior high school students who answered that they would go to bed after 24:00 was significantly higher in the 2021 survey. Moreover, "shared mealtime with family" was increased in the 2021 survey. **Conclusions**: These findings suggested that the influence of COVID-19 pandemic has affected the living conditions and eating habits of children.

Coping strategy related to food insecurity among pregnant women in East Lombok District, Indonesia during the COVID-19 pandemic

Amanda Safiera Ameline[1,2], Nur Lailatuz Zahra[1], Dian Novita Chandra[2], Min Kyaw Htet[1], Umi Fahmida[1]

1. Southeast Asian Ministers of Education Organization Regional Centre for Food and Nutrition (SEAMEO RECFON) (Indonesia), 2. Department of Nutritional Science, Faculty of Medicine, Universitas Indonesia Dr. Cipto Mangunkusumo Hospital (Indonesia)

Background and objectives: The COVID-19 pandemic has negative consequences on livelihood and food insecurity. Food insecurity experienced during the vulnerable periods of pregnancy has a significant effect on maternal health and birth outcomes. This study aimed to describe coping strategies related to food insecurity during the COVID-19 pandemic among pregnant women in East Lombok Regency, West Nusa Tenggara Province, Indonesia

Methods: This cross-sectional study is part of a larger observational cohort study in East Lombok Regency, West Nusa Tenggara Province, Indonesia, entitled "UKRI-GCRF Action Against Stunting Hub (AASH)". The data collection was conducted among pregnant women aged 18-40 years old (n=470) in the third trimester of pregnancy (June 2021 to January 2022), including the interview about changes in household expenditure, income, and coping strategies related to food insecurity (RCSI) in relation to the pandemic situation. Hemoglobin, HbA1C, and Mid-Upper Arm Circumference (MUAC) were also assessed.

Results: Most respondents reported that their household income decreased (73.0%). As food prices rose, household food expenditures also increased (43.8%). However, only less than a quarter of the respondents received government food assistance during the pandemic. Coping strategies experienced by pregnant women were relying on less preferred and less expensive foods (66.8%); restricting adult's consumption to prioritize children (29.1%); borrowing food or relying on help from a friend or relative (28.7%); limiting portion size at mealtimes (25.5%), and reducing the number of meals eaten in a day (19.6%). Among them, 40.6% were anemic (Hb< 11.0 g/dL), 15.3% had chronic energy deficiency (CED; MUAC < 23.5cm), and 8.5% had gestational diabetes mellitus.

Conclusion: The COVID-19 pandemic significantly affected the food security of pregnant women. Pregnant women practiced coping strategies to adjust to the pandemic situation, which may have negative consequences on the pregnancy condition and birth outcomes. Further studies to explore the dietary intake of pregnant woman related to their coping strategy and their nutritional status is needed.

PAB(T9-6)
Long Covid in Africa – a hidden storm?

Ebiambu Ondoh Agwara[1], Bryndis Eva Birgisdottir[1]

1. NNEPro Global Centre for Nutrition and Health in Cambridge, Cambridge, UKp (UK)

Background and objective: Long Covid (LC) is defined as a condition that occurs in individuals after a confirmed SARS coV-2 infection or a history of a probable infection with symptoms that cannot be explained by another diagnosis and last for at least 8 weeks. This can be symptoms persisting from an initial illness, or new symptoms following initial recovery from a Covid-19 infection. The aim was to investigate what is known about LC in Africa and compare prevalence to Western world Methods: So far, only two studies on LC have been conducted in Africa, South Africa to be precise. Results: The studies reveal different proportions of LC. One showed that 60% of patients with mild Covid-19 had persistent symptoms after one month and 35% after two months, while the other showed that 82% of patients with severe Covid-19 had persistent symptoms or reported new symptoms one month after and 67% after three months. In more Europe and US the prevalence has been found to be much lower where 13% had LC after a month, 2,3% reported symptoms after 8 weeks and as low as 2,3% after 12 weeks.

Conclusion: These numbers are a cause of concern. The differences could be related to the severity of the Covid-19 illness, ethnicity or even the low vaccination rate. Furthermore, physicians still advise preventing nutritional deficiencies, as a way to prevent or reduce the likelihood of developing LC. With the African continent being among the most nutritionally deficient regions, especially in terms of vitamins and minerals important for the functioning of the immune systems, this could also explain the higher prevalence of LC in South Africa. The effects of LC extend beyond physical effects but also affects productivity, and thus struggling economies like those of many African countries. There is need for more robust research into LC within the continent. It is also important to increase awareness about this condition and debunk myths within the communities. Given the low level of attention that the continent currently gives LC, institutions and funding agencies need to increase this attention so that Africans are not left behind

Impact of COVID-19 pandemic on HIV and TB control and care in Zimbabwe: A situational analysis

Tonderayi Mathew Matsungo[1], Faith Kamazizwa[1], Vaida Kamazizwa[1], Prosper Chopera[1]

1. University of Zimbabwe, Department of Nutrition, Dietetics and Food Sciences (Zimbabwe)

Background: Africa is the most affected region with HIV, with 25.4 million [20.7 million to 30.3 million] living with HIV in 2020. **Objective**: To assess the impact of COVID-19 pandemic on HIV and TB management in Zimbabwe. **Method**: A mixed-methods approach was used. Primary data was obtained from a desk review, Key Informant Interviews (KIIs), and Focus Group Discussions (FGDs). While secondary data from the demographic and health information system DHIS-2 was analysed using a retrospective longitudinal (time series) approach. **Results:** The first COVID-19 case in Zimbabwe was reported on 21 March 2020. Our study revealed that there was a large negative impact on almost all aspects of HIV and TB case detection, diagnosis and treatment after onset of COVID-19. During lockdowns, travel restrictions and closure of some health facilities affected access to service delivery by patients. There was a drastic drop in HIV testing coverage (December 2019) and a decline in numbers initiated on ART (January 2020 to April 2020). TB notifications also declined in the COVID-19 period. **Conclusions:** COVID-19 associated lockdowns and travel restrictions disrupted health delivery in Zimbabwe particularly in urban settings. In general, HIV and TB preventative services like condom distribution and voluntary male circumcision were affected more compared to curative activities. The closure of nightclubs and prostitution hotspots resulted in a decline in new HIV infections. The impact of COVID-19 on HIV and TB patients was more pronounced in children, adolescents, women, and men who have sex with men (MSM).

Patterns of change in depression symptoms before and during COVID-19-related community quarantine among adolescents in lowland rural communities in the Philippines

Lowela Padilla Mughal[1], Zsuzsa Bakk[2], Hans Verhoef[1], Edith Feskens[1], Angelina Felix[3], Corazon VC Barba[3], Alida Melse[1]

1. Wageningen University & Research (Netherlands), 2. Leiden University (Netherlands), 3. University of the Philippines Los Banos (Philippines)

Background and objectives: The COVID-19 pandemic reportedly can increase mental health problems among children. Data on this association are sparse in Filipino adolescents. We aimed to identify and describe depressive states in selected adolescents from lowland rural communities in Nagcarlan, Laguna, Philippines before and during community quarantine (indicated by times T1 and T2). Additionally, we sought to identify patterns of changes in depressive states over time.

Methods: The Short Mood and Feelings Questionnaire (SMFQ), a depression screening tool, was accomplished by 285 participants aged 10-16 years before the COVID-19 pandemic (October-December 2019) while a subsample of 153 participants accomplished the questionnaire in August to September 2020, five to six months after the declaration of the quarantine in March 2020. Latent Markov (LM) analysis was used to identify predictive factors of depressive states at T1 and T2. Variables examined include weight, height, HAZ, measures of wellbeing, internal and external pressures to conform to societal ideal of body appearance, energy and nutrient intakes, food security, and biochemical parameters. Forward selection of blocks of covariates was undertaken to determine the final model, which was adjusted for socio-demographic variables, BAZ, physical activity, and inflammatory indicators.

Results: We identified three distinct states of depression that represented a development trend from non-depressed to a depressed state. At T1, factors found to be protective against anxiousness and depression were higher scores for happiness, higher serum zinc levels, and food security. In contrast, higher scores for internal pressure to be thin and media pressure to conform to a certain body appearance, and higher serum levels of soluble transferrin receptor increase the likelihood to anxiousness and depression. Depression decreased from 23.7% to 14.4% from T1 to T2. About 5% of the non-depressed transitioned to a depressed state while two-thirds of the depressed participants transitioned to a non-depressed state. None of the abovementioned covariates were found predictive of the transitions in class membership at T2.

Conclusion: In this study population, we found no evidence that COVID-19-related quarantine was accompanied by an increase in depression.

Keyword: Depression, Adolescents, Nutrition, Philippines, COVID-19

Conflict of Interest Disclosure: This study was funded by the Nutricia Research Foundation (NRF). Some support was also received from Unilab Inc., Gardenia Philippines, National Nutrition Council, Food and Nutrition Research Institute-Department of Science and Technology for tokens and instructional materials provided to the participants. LP Mughal received salary from NRF. At the time of data collection, LP Mughal was a consultant for Unilab Inc., a company that markets and sells various products that include micronutrient supplements. None of the abovementioned companies or government agencies had any participation in the design, implementation, data analysis, and write-up

Relationship between ABO blood group distribution and clinical characteristics in Covid-19 patients

Fadoua Ballouk[1], Jaafar Heikel[2], Hasnae Benkirane[1], Amina Bouziani[1], Fatima Zahra Laamiri[3], Baha Rabi[1], Noureddine El Haloui[1], Khalid El Kari[1], Amina Barkat[4], Hassan Aguenaou[1]

1. Ibn Tofaïl University-CNESTEN, Joint Research Unit in Nutrition, Health and Environment, RDC-Nutrition AFRA/IAEA, Laboratory Biology and Health (Morocco), 2. Mohammed 6 University of Health Sciences (Morocco), 3. Hassan First University of Settat, Higher Institute of Health Sciences of Settat, Laboratory of Health Sciences and Technology (Morocco), 4. Health and Nutrition Research Team of the Mother-Child Couple, Faculty of Medicine, Mohammed 5th University (Morocco)

Background and objectives: Since the onset of Covid-19, scientists have been studying the risk and susceptibility factors for developing this disease. Among these factors, LANDSTEINER's ABO blood types were also considered to be biological elements that could determine the susceptibility of a patient with Covid-19 to present a number of symptoms and/or a severe form of Covid-19. The objective of this study is to explore the relationship between the blood type (ABO) and the clinical and epidemiological characteristics in Covid-19 patients.

Methods: A total of 786 patients were included in this retrospective case-control study, seen in an outpatient consultation at the Covid-19 service level. Patient data from the four blood groups A, B, O, and AB were collected and clinical and epidemiological characteristics were studied and analyzed.

Results: The average age of the population studied is 45.58 years with a predominance of women (52.9%) compared to men (47.1%). Results of this study show that the distribution of different blood groups is the majority for the groups O and A with the prevalences of 42.2% 31.5% respectively, while the groups B and AB show only 18.8% and 7.5% respectively. Overall, the majority of patients with diabetes, hypertension, heart disease, and chronic respiratory disease present the Group O. In addition, analysis of the presentability of clinical signs and the specific symptoms of Covid-19 shows that the prevalence of certain clinical signs such as fever, myalgia, asthenia, dyspnea,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

anosmia and agueusia were significantly elevated in patients with O and A blood types.

Conclusions: Covid-19 patients with the O and A blood types are at higher risk of presenting a severe clinical and prognostic picture related to Covid-19 compared to patients with the other blood types (B and AB).

The occurrence of stunting among the under-five-year old children during the Covid-19 pandemic at Kuntum Mekar Integrated Health Post Depok Municipality, West Java, Indonesia

Lestari Octavia[1], Salsabila Auni Putri[1], Maskunah Maskunah[1], Grace Valentina[1], Faiza Assyifa[1]

1. Gunadarma University (Indonesia)

COVID-19 pandemic could challenge the nutrition fulfillment case, especially for under five-year-old children in low-middle-income countries, including Indonesia. Infection in children could be worsened by malnutrition, contributing to virus transmission. Local healthcare facilities monitored the nutritional status of under five-year-old children, particularly during the pandemic. This study aimed to identify the nutritional status of under-five-year-old children during the COVID-19 pandemic in the Integrated Health Post "Kuntum Mekar" in Depok District. This research used secondary data analysis. The study results involved 135 data from subjects included in the analysis. Those are one newborn (0-3 months old) who did not experience stunting, 27 toddlers (4-12 months old) with a stunting percentage of 7.4% and severe stunting of 3.7%, 31 children (13-23 months old) with a stunting prevalence of 12.9% and severe stunting 3.2%. Twenty-seven children ((24-35 months old) had a stunting prevalence of 14.8%, 22 children (35-47 months old) had a prevalence of stunting at 22,7%, and 4,5% of them were severe stunting. At last, the children aged 47-59 months old had a prevalence of stunting at 14,8%. The stunting eradication program required multi sectors approach to reach the goal of gold generation in 2045.

Comparison of eating places and food types between food secure and insecure groups: Before, during and after the COVID-19 pandemic

Youngmin Nam[1], Jungmi Kim[1]

1. Department of Food and Nutrition, College of Human Ecology, Seoul National University (Korea)

Background and objectives: The COVID-19 pandemic has caused substantial changes in dietary lifestyle. The purpose of this study was to compare eating places and food types between food secure and insecure groups before (year 2019), during (year 2021), and after (year 2022) the pandemic among South Korean adults.

Methods: The nationwide online survey was conducted with 2,196 adults aged 20~65 years in July 2022. The household food security during the year preceding the survey was assessed by using a question employed in the Korea National Health and Nutrition Examination Survey.

Results: About 88% (88.2%) of the respondents were classified into the food secure group and the rest (11.8%) were classified into the food insecure group. The frequency of eating home increased in both groups during the pandemic. The proportions of the respondents eating home were higher in the secure group than the insecure group across the three periods, and the gap between the two groups has grown; 84.0% of the food secure group and 76.2% of the food insecure group ate at home more than once a week during the pandemic (p=0.002). On the contrary, the proportions of the respondents eating at convenience stores were two times higher in the insecure group than the secure group across the three periods. The pandemic has widened the gap between the two groups; 21.8% of the secure group and 43.5% of the insecure group ate at convenience stores more than once a week after the pandemic ($p< 0.001$). The insecure group consumed ready-to-eat (RTE) foods more frequently than the secure group across the three periods. The difference in proportions of the respondents consuming RTE foods between the two groups has grown after the pandemic; 22.7% of the food secure group and 43.5% of the food insecure group consumed RTE foods more than once a week after the pandemic ($p< 0.001$).

Conclusions: The COVID-19 pandemic has intensified the differences in the food insecure group. Such differences between the food secure and insecure groups prompt the government to consider new measures in food and nutrition policy and programs in the new normal era.

Acknowledgement: This research was supported by a grant (22192MFDS093-1) from Ministry of Food and Drug Safety in 2022.

Food and Nutrition Security in the Philippines During the COVID-19 Panemic

Ana Kriselda Rivera[1,2], Ernani Bullecer[2], Raycha Lei Concess Rama[2], Rowel Malimba[2]

1. Tokyo Medical and Dental University (Japan), 2. University of the Philippines Manila (Philippines)

The COVID-19 pandemic placed the Philippines' food and nutrition issues front and center. The national government was swift to impose countermeasures that were designed to prevent food system disruptions. Distribution of food and financial assistance were extensive albeit rather insufficient considering prolonged lockdown restrictions. Constantly changing community quarantine guidelines affected movement of food supply, delivery of health services, and household economic security. Nutrition programs such as vitamin A supplementation, feeding for children, and micronutrient supplementation for pregnant women had lower coverage rates and by the latter half of 2020, the country reached its highest recorded hunger rate. Cases of both undernutrition and overnutrition are predicted to rise because of dietary imbalance and a variety of factors. Conversely, community members and some local government units took it upon themselves to improve the food situation in their areas. Provision of food packs containing fresh fruits and vegetables were lauded as it exemplified a conscious effort to deal with nutrition security. Efforts to address food security has always been about increasing accessibility, availability, and affordability – often neglecting the nutrition component of foods. Strategies that incorporate nutrition security in food security are much needed in the country, especially during emergency situations such as a pandemic.

PAB(T9-13)
Low Social Support is Associated with Maternal Depression among Pregnant Women during COVID-19 Pandemic in Rural Indonesia

Tiffany Cornelia Angelin[1], Min Kyaw Htet[1], Nur Lailatuz Zahra[1], Mifa Nurfadilah[1], Risatianti Kolopaking[2,1], Umi Fahmida[1]

1. Southeast Asian Ministers of Education Organization Regional Center for Food and Nutrition (Indonesia), 2. Universitas Islam Negeri Syarif Hidayatullah Jakarta (Indonesia)

Background and objective: Maternal depression during pregnancy has an adverse effect on the newborn, however there is lack of information on maternal depression during pregnancy in the period of COVID-19 pandemic. This present study aims to investigate the prevalence and determinants of maternal depression in pregnant women during COVID-19 pandemic in East Lombok, Indonesia.

Methods: This cross-sectional study was a part of larger observational cohort study in East Lombok, West Nusa Tenggara, Indonesia entitled "UKRI GCRF Action Against Stunting Hub (AASH)". Pregnant women in trimester-2 were recruited (February 2021 – September 2021) in this study. Sociodemographic and socioeconomic information was obtained from interview using structured questionnaire. Chronic energy deficiency (CED) was determined using mid-upper arm circumference (MUAC) < 23.5 cm. Edinburgh Postnatal Depression Scale (EPDS) was used to measure maternal depression. Global Measure of Perceived Stress (GMPS) was used to measure maternal stress and Multidimensional Scale of Perceived Social Support (MSPSS) was used to measure social support. These were administered by trained enumerator.

Results: A total of 702 pregnant women aged 18-40 years old were included in the analysis. Most of the pregnant women (66%) were completed secondary education. Maternal depression (EPDS >9) and moderate-high stress (GMPS >18) were experienced by 26.6% and 86.3%, respectively. Majority (65.2%) of pregnant women reported high social support (MSPSS >5). The prevalence of CED was 22.5%. Maternal depression was significantly associated with CED (OR = 1.56, 95% CI = 1.06–2.30, p = 0.024) and with maternal stress (OR = 5.38, 95% CI = 2.44–11.82, p < 0.001). Multivariate logistics regression, after adjusted with age and maternal education, showed that low-moderate social support (AOR = 1.75, 95% CI = 1.22–2.49, p = 0.002) was significantly associated with maternal depression. Friends provided less social support (36.1-58.5%) than partners (83.0-88.7%) and family (81.0-92.3%).

Conclusions: Low social support was significant determinant of maternal depression during pregnancy. Effort to improve social support may include improving friends support for pregnant women in this study area.

Keyword: maternal depression, stress, CED, social support, pregnant women

Household food waste and its determinants in urban and rural areas in southern Thailand

Jaruneth Petchoo[1], Kanthida Ratbompheng[1], Kewalin Samati[1], Nattapol Tangsuphoom[2]

1. Walailak University (Thailand), 2. Mahidol University (Thailand)

Background and objectives: Food loss and waste occurs at every stage of the food supply chain and threatens the global food security and sustainability. At consumption stage, food waste is mostly generated in households. Currently, there is insufficient data on household food waste in middle-income

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

countries, including Thailand. It is suspected that previous estimates of food waste from households may be underestimated. This study aimed to determine the amount of households' wasted food and the determinants of food wastage in urban and rural areas in southern Thailand

Methods: This cross-sectional study was conducted in 104 single-family households in representing urban and rural areas in southern Thailand during July-August 2021. The quantity of households' wasted food was self-reported on 2 weekdays and 1 weekend day. Behavior, attitude and awareness towards food waste of consumer and person responsible for food purchasing and preparation in each household were assessed using a validated self-administered questionnaire (content validity index=0.97, Cronbach's alpha=0.77).

Results: On average, the amount of food waste in households in urban area was 101.99 g/capita/day, which was significantly higher ($p < 0.001$) than that of rural households (83.18 g/capita/day). Majority of urban household members reported that they never thrown away most food groups, except bread and bakery products, and fruits and vegetables that were rarely and sometimes discarded, respectively. For most rural households, all food groups were wasted at the higher frequencies than did those of urban households, except fruits and vegetables. Based on the correlations between food waste quantity and household behavior, the factors that influence household food waste were moral norms, and perceived behavioral control of the consumer in household ($p < 0.01$). Shopping routines, planning routines, and household skills of household food buyer were also contributed to the households' wasted food.

Conclusions: The amount of household food waste was influenced by socioeconomic factors, as well as behavior, attitude and awareness towards food waste among the household members. Therefore, different strategies should be implemented for food waste reduction in urban and rural households. This study might be preliminary baseline data on household food waste in Thailand and other middle-income countries with similar context.

PAB(T9-15)
Improving the food environment through providing healthy meals in a food service business: Declaration of commitment to Tokyo Nutrition for Growth Summit 2021

Shizuka Hanashi[1], Kiyomi Shinagawa[1], Yoshiyuki Takato[2]

1. SHiDAX CONTRACT FOOD SERVICE CORPORARTION (Japan), 2. SHiDAX CORPORARTION (Japan)

Background and objectives: The Tokyo Nutrition for Growth Summit 2021 established a vision that encourages stakeholders to make a commitment to support the achievement of international nutrition goals aligned with the international priorities in nutrition. We examined how our food service business could make a meaningful commitment.

Methods: Our business provides meals to customers in designated food service facilities such as offices, dormitories, and universities We examined how we can contribute to to the following targets: Sustainable Development Goals 2.2 (end malnutrition in all forms) and 3.4 (reduce mortality from non-communicable diseases) and World Health Assembly targets on undernutrition, breastfeeding, non-communicable disease (NCD) and obesity, identified as international priorities in the commitment-making guide. We surveyed the current status of our food service and based on the findings, we set an ambitious goal for the commitment.

Results: In October 2021, 62.2% of the contracted facilities where our head office can check and change the menu provided healthy meals. Healthy meals were defined as those that contribute to the goals of reducing salt intake by 30%, reducing hypertension by 25%, and preventing the increase of diabetes and obesity. These are the global targets for the prevention and control of NCDs, which can be targeted at a food service business as an international priority. The final goal was set to provide healthy meals at 100% of the facilities by 2025, Actions to achieve the goal included (1) co-developing and providing delicious low-sodium meals /processed foods; (2) encouraging all customers, including those who may not focus on their health, to make healthy food choices by adding value to food, for example by providing healthy meals at events; and (3) educating registered dietitians/ nutritionist and licensed cooks who work at worksite cafeterias on how to provide healthy meals.

Conclusions: Our food service business aims to maintain and promote the health of our customers. We believe that improving the food environment can contribute to the achievement of the international priorities of nutrition. Our aim is to continue improving the food environment toward 2025.

Weaning Food Situation and Challenges in Developing Countries - From a JICA Overseas Cooperation Volunteer Dispatch Country-

Saki Horie[1], Mari Ujiie[1]

1. Japan Overseas Cooperation Volunteers Dietitian Network (Japan)

Background and objectives: One of the targets of the Sustainable Development Goals is to is to end preventable deaths of newborns and children under 5 years of age by 2030, and although the mortality rate is decreasing year by year, there are still many malnourished and stunted children. The purpose

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of this study was to understand the current state of nutrition in developing countries and to identify issues that need to be addressed.

Methods: A questionnaire on weaning food was administered to members of the Japan International Cooperation Agency (JICA) who were dispatched to developing countries to work as volunteers as part of Japan's Official Development Assistance program. The survey items included the content of the first bite, introduction age, and opportunities for parents to learn about weaning, etc. Simple and cross tabulation was conducted on the responses of 40 volunteers dispatched to 23 countries.

Results: The target regions were as follows: Asia, Africa, Oceania, and South America, with 65% in urban areas and 35% in rural areas. 42.5% of the respondents started weaning at 5 to 6 months, 50% of cases used seasonings from the beginning, and the first bite being the staple food in all regions. 52.5% of the respondents reported that guidance and opportunities to learn about weaning (information sources) and were mostly from family members or parents. Comparing urban and rural areas, 71.4% of rural areas had only familial guidance when learning about weaning. In 30% of cases, there were no national or regional guidelines for weaning food. In addition, in more than 77% of the countries, respondents were concerned about nutritional balance and hygiene. A small number of respondents stated that they were struggling to survive and that their children were taking care of them.

Conclusion: In order to avoid preventable deaths, it was suggested that expert knowledge and learning opportunities should be provided, and if there are no official national or regional guidelines, then guidelines should be developed to suit the diet and lifestyle of the country. These results are just the tip of the iceberg, and more information should be collected through surveys of the affected people.

PAB(T9-17)
Can a combined agriculture and nutrition behaviour change intervention improve women's empowerment in rural Bangladesh? A feasibility study.

Elizabeth Kirkwood[1], Michael Dibley[1], Wajiha Khatun[2], Gulshan Ara[1], Mansura Khanam[3], Anowarul Bokshi[1], Mu Li[1], Neeloy Alam[1]

1. The University of Sydney (Australia), 2. Food and Agriculture Organisation, Bangladesh (Bangladesh), 3. International Centre for Diarrhoeal Disease Research, Bangladesh (Bangladesh)

Background and objectives: Many agricultural and home gardening interventions aim to improve the nutritional status of women and children in low- and middle-income countries by focusing on women as the recipient of the intervention and make assumptions that women will be empowered as a result. This research examines the potential impact of an intervention that combined home garden training and support, and nutrition behaviour change communication, with a social safety net payment, on women's empowerment in rural Bangladesh.

Methods: Twenty in-depth interviews were conducted with randomly selected women that took part in the study. Qualitative data was coded using the following five indicators: control over use of income, input into productive decisions, respect amount household members, self-efficacy and input into nutrition and health care decisions. We assessed the implementation of this study in terms of feasibility, acceptability, and practical application. Results: Our study showed that a combined nutrition-specific (nutrition counselling) and nutrition-sensitive (agricultural training and unconditional cash transfer) intervention, delivered on a mobile platform, to women from low-income families in rural Bangladesh was feasible and acceptable. The study further revealed evidence on behaviour change across five key areas related to women's empowerment.

Conclusions: The study highlights the potential for such an intervention to impact women's empowerment and provides insight for the aid in the design of larger-scale trials implemented in similar settings

Keyword: Nutrition behaviour change communication, nutrition-sensitive agriculture, women's empowerment, social safety net, qualitative methods

PAB(T9-18)
Voluntary cooperation between the food industry and government for a healthier diet in the population—the case of Norway

Anne Hatloy[1], Anne Inga Hilsen[1], Ketil Bråthen[1], Svein Erik Stave[1]

1. Fafo Institute for Labour and Social Research (Norway)

Background and objectives: In Norway, there has been an initiative since 2017 to make the population's diet healthier through a voluntary agreement between the food industry and health authorities. The letter of intent has been signed by around 100 actors including the Ministry of Health and Care, and all the major actors in the food industry—food and trade organizations, food and beverage manufacturers, food retailers and food service industry. The overall aims of the initiative are to reduce the intake of salt, added sugar and saturated fat in the population, and to increase the consumption of vegetables, fruits and berries, whole grain products and seafood.

Methods: The initiative has been followed by a formative evaluation, including annual surveys to agreement partners from 2017 to 2021 and qualitative interviews with stakeholders from industry, organisations, and government in 2018, 2020 and 2022.

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

Results: The different measures utilised by the actors varied as expected, according to the aims. For the reduction of salt, sugar and fat, gradual changes over time and development of new products were the most dominant measures used by the actors. While for the increased consumption of vegetables, fruits and berries, whole grain products and seafood, marketing initiatives and changed product placement has been important. A few similar initiatives have been initiated earlier in other countries, however most of them has failed when government has changed. The Norwegian initiative is unique in the sense that it has survived changes of government. It is based on trust between the industrial partners and the health authorities. Both sides highlighted the value of a common meeting place.

Conclusion: The cooperation among partners becomes easier when they can settle upon meetings and discussions regularly. In addition, a strong motivation for the actors is to address public health as part of their corporate social responsibility. The contract thus contributed to an already shared objective between the partners and the authorities. Even though there have been challenges during the agreement period, the parties find the voluntary cooperation a useful way to work and have signed a new agreement for the period 2022-2025.

PAB(T9-19)
Building the capacity of consumers to demand diverse, safe and nutritious food

Hettie Carina Schonfeldt[1,2], Beulah Pretorius[1,2]

1. University of Pretoria (South Africa), 2. ARUA Centre of Excellence in Sustainable Food Systems (South Africa)

Background and objectives: Food systems are complex and are neither nutrition nor health driven. The decisions made at any stage of the food supply chain have implications on consumer choices, dietary patterns, and nutritional outcomes. How food is grown, distributed, processed, marketed, and sold determines which foods are available, affordable, and acceptable within the local cultural context. These factors guide food choices, influencing the quality of people's diets, and hence play a vital part in health. Food systems are broken and therefore guidance on nutritious food choices and diets are required. The objective of this presentation is to describe the actions required to enable consumers to demand diverse, safe and nutritious food.

Methods: Literature was reviewed, analysing different databases, and case studies to provide a synopsis of current knowledge and viewpoints on barriers and actions needed to enable consumers to make nutritious, healthy and culturally acceptable food choices. Given the nature of the topic, a broad search approach was used. Scientific databases were searched starting with the search string: “food systems”, with “food production”, “post-harvest practices”, “food choices” and “nutritious diets” as secondary search terms. Additionally, websites of international organisations linked to food systems research were interrogated.

Results: Actions and their impact that are required include those made by public institutions such as School feeding programs, business incentives, regulations and legislation, education and public awareness, as well as national guidelines. Investment and incentivised initiatives are needed to foster diverse food production, influence consumers' behaviour and consumption.

Conclusions: Food system transformation at the consumer level enable the consumer to make healthy food choices more of a default and effortless, thereby relying less on individual self-control and more on changes in the environment and social standards.

Keyword: Food systems, Food choices, Nutritious foods, Diets, School feeding program

PAB(T9-20)
The utilization of technology in food production in the context of sustainable food system and planetary health

Mutsumi Kitagawa[1], Momoka Saito[1], Mao Fujie[1], Miku Yokomizo[1], Kanako Masuno[1], Masako Yokotsuka[1]

1. Showa Women's University (Japan)

Background and objectives: Rapid growth of population and global climate change require the robust system of sustainable food production. At the same time, given the concept of “planetary health”, it is anticipated to minimize negative impact through food production against environment in order to pursue improved health and environmental benefits. To do so, objective monitoring and evaluation would be important. For example, there are global certification framework which assure sustainability via biological safety, chemical safety, and so on. However, the number of food acquiring global certification is quite limited in Japan. So, we aimed to find the bottleneck of this situation and explore the good example of sustainable food production in Japan.

Methods: Literature review and depth interview was adopted.

Results: As the major bottlenecks, following factors were suggested; 1)complicated recording work to prove sustainability, 2) low perception about global certification among food producer as well as consumer, 3) high cost of obtaining the certification, 4) aging and labor shortage in agriculture and fishery. Meanwhile, pioneering food producers are producing crops and marine products in a sustainable manner by utilizing digital devices for efficient sensing and recording. Also, precise climate data from satellite is now

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

available for appropriate prediction of resource allocation and waste reduction.

Conclusions: Although there are several bottlenecks to generalize sustainable food production, appropriate intervention such as sustainability education targeted at food producer and consumer would be an option to improve the situation. By doing so, the significance of sustainable food system will be enlightened and the changes of food production and purchasing behavior are expected. Also, the database of feasible and widely applicable method of sustainable food production is anticipated in order to meet Sustainable Development Goals(SDGs).

Ensuring integrity in science: Updated guiding principles for funding food science and nutrition research

Wendelyn Jones[1], Johanna Dwyer[2], John Erdman[3], Chi Hee Kim[4], Mark Fryling[5], Richard D'Aloisio[6], Brienna Larrick[1]

1. Institute for the Advancement of Food and Nutrition Sciences (USA), 2. School of Medicine and Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University (USA), 3. University of Illinois at Urbana-Champaign (USA), 4. Herbalife Nutrition (USA), 5. General Mills, Inc. (USA), 6. Richard D'Aloisio Regulatory Consulting LLC (USA)

Background and objectives: While the food and beverage industries play a critical role in advancing food safety and nutrition science, research funded by the private sector is subject to intense scrutiny as a result of various perceived and real biases related to funding source. The Institute for the Advancement of Food and Nutrition Science (IAFNS) [1] Assembly on Scientific Integrity has updated its Guiding Principles for Funding Food Science and Nutrition Research (Rowe et al, 2009) to provide a modernized framework for minimizing bias in industry-supported research.

Methods: To inform the development of the revised Guiding Principles, a team of public and private sector scientists discussed common concerns related to bias in industry-funded research and evaluated existing best practices for managing conflicts and maintaining trust in science. Feedback on the draft updates provided by a set of external stakeholders, including those from nutrition and food safety professional societies.

Results: The updates to the Guiding Principles aim to address common criticisms of industry-funded research. The revised Guiding Principles encourage greater transparency of interactions between funder and investigator, strengthen the guardrails that separate the funding from the science, and reflect the shift within the scientific community toward increased transparency and open science.

Conclusions: The revised Guiding Principles for Funding Food Science and Nutrition Research provide a modernized framework for separating the science from the source of funding, and for facilitating the advancement of transparent, credible research. If they are followed as intended, other than to debate the science itself, there should be little reason to dispute a resulting study.

[1]Now an independent organization, IAFNS evolved from ILSI North America

Keyword: conflict of interest, research integrity, transparency, disclosure, peer review

Conflict of Interest Disclosure: This work was supported by the Institute for the Advancement of Food and Nutrition Sciences (IAFNS) Assembly on Scientific Integrity. IAFNS is a nonprofit science organization that pools funding from industry collaborators and advances science through the in-kind and financial contributions from public and private sector participants.

What have global businesses pledged to transform nutrition and food systems? Examining the Business Constituency Group's 2021 Tokyo Nutrition for Growth (N4G) Summit commitments to support the Responsible Business Pledge for Better Nutrition.

Paige B Harrigan[1], Vivica I Kraak[1]

1. Virginia Tech (USA)

Background and Objectives: Transnational food and beverage companies and business organizations have important resources to influence and reach billions of people worldwide to promote safe and healthy high-quality diets within resilient, equitable, and sustainable food systems. The Business Constituency Group (BCG) represents six global business organizations that released voluntary commitments at the 2021 Tokyo Nutrition for Growth Summit (N4G) to support the Responsible Business Pledge for Better Nutrition. Methods: We examined relevant evidence to identify the BCG organizations, summarized their voluntary commitments, and explored 21 food and beverage BCG firms and pledges. We compared selected BCG members' N4G commitments to expert recommendations, examined business performance scores based on the Access to Nutrition Index and World Benchmark Alliance scores, and explored accountability processes to assess and report on progress toward implementing their N4G commitments. Results: Many voluntary nutrition pledges made by business organizations and transnational agri-food and business firms at the Tokyo N4G summit are unambitious and fail meet this moment to transform nutrition and food systems. Conclusions: The six BCG participants should expand its membership, strengthen their commitments, and enhance transparency and

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

accountability processes further to meet the Responsible Business Pledge for Better Nutrition

Keyword: voluntary commitments and pledges, food systems, business, accountability, nutrition

Conflict of Interest Disclosure: No conflict of interest. PBH and VIK did not receive any funding from the commercial or private-sector entities for research or consulting and have no conflicts of interest related to the content of this manuscript. This research did not involve human subjects and therefore, was exempt from institutional review board requirements.

Maximising nutrition: from theory to practice using a stepwise impact pathway approach

Integrating nutrition into agrifoodsystems: from theory to practice

Tomoko Kato[1], Patrizia Fracassi[1], Clement Lorvao[1], Serena Stepanovic[2], Jeffrey Tschirley[2], Random Dubois[2], John McCormack[2], Richard Ndou[2], Ambulah Mamey[2], Ti Kian Seow[1]

1. Food and Agriculture Organisation of the United Nations (Italy), 2. World Vision (USA)

Background and objectives: Malnutrition is exacerbated by gaps within the agrifood system. To address these gaps, the Food and Agriculture Organization of the UN together with World Vision, Action Contre la Faim and twelve country teams in Sub-Saharan Africa developed a participatory methodology that engages key actors across agrifood systems – from eco-systems to the production, processing, retail, consumption and disposal of food. The Impact Pathway (IP) approach focuses on the most vulnerable communities that are largely dependent on natural resources to sustain their economy, basic services, food security and dietary needs.

Methods: The IP approach involves a consultative stepwise methodology that solicits inputs from key stakeholders such as project formulators, target communities, policymakers, private businesses, and academia. In alignment with the high level panel of experts food systems framework, the scope of the Impact Pathways approach is tailored to a sub-sector, region, local community or food commodity. The scope, or problem statement, is used to form a Theory of Change, which is a diagram that gives a comprehensive description of why and how a desired change is expected. From this Theory of Change, several Impact Pathways with their own specific assumptions, trade-offs and gaps are drawn through a participative process. Activities and related information are mapped along the Impact Pathways to help decision makers with prioritizing and planning. In addition, external drivers that define cross-cutting issues are examined throughout the results chain.

Results: Implementing this approach provides decision makers with an accessible, common approach to monitoring ongoing field interventions, identifying gaps, establishing milestones and supporting final evaluations. It allows key entry points to be identified and optimised to best improve dietary diversity for key stakeholders within agrifood systems.

Conclusions: An agrifood systems approach allows key stakeholders to identify entry points for intervention without losing sight of how their collective work can lead to improved availability, accessibility and consumption of healthy diets. The involvement of vulnerable groups is critical to ensuring that opportunities and potential risks are adequately considered in the design and implementation of policies and programmes aimed at improving their health and socio-economic outcomes and increasing their resilience to environmental shocks and stresses.

Food and nutrition policy and action in China: past, present, and future

Zhenhui Li[1], Na Zhang[1], Man Zhang[1], GuanSheng Ma[1]

1. Peking University (China)

Background and objectives: Countries across the world have introduced a wide variety of policies to improve nutrition. While there has been increased nutrition policy attention to improving public health in China, there is a lack of summary on previous policies.

Methods: This review used the literature review to evaluate the Chinese government's nutrition policies. We also provide recommendations for how best to ensure future nutrition policies are genuinely implemented and likely to have a meaningful impact on public health.

Result: Categorizing and integrating Chinese nutrition works since 1949; summarizing the most critical nutrition policies, actions, guidelines, and standards at each stage; and explaining the significance of these documents in promoting public health. At the same time, we provide 4 suggestions on implementing China's nutrition policy from the aspects of legislation, nutrition monitoring, stakeholder cooperation, and nutrition education.

Conclusion: Encouragingly, the Chinese government is engaged in activities intended to increase Chinese citizens' health. Also, lots of policies have shown the effect on nutrition promotion. More needs to be done in China to implement the most potentially powerful nutrition policies, especially legislation.

Keyword: Public Health, Nutrition policy, Evaluation, China

PAB(T9-25)
Resilient Community Nutrition Groups in Times of Crisis in Centre Nord, Burkina Faso

Jean Nadembega[1], Meghan Pollak[1], Gilles Waongo[1], Carmen dibaya Dibaya[2]

1. Save the Children US, Burkina Faso (Burkina Faso), 2. Save the Children US, USA (USA)

Background and objectives: USAID-funded Victory Against Malnutrition Plus (ViMPus) aims to increase household food/nutrition security in Center Nord, Burkina Faso. Ongoing inter-communal violence and clashes are causing displacement, disrupting local economies and community-level activities/services. Community Nutrition Groups known as GASPA supported by ViMPlus have proven to be resilient, shock-responsive and inclusive platforms to respond to community needs in real time. ViMPlus has contributed to establishing 2,153 GASPAs (including the participation of 1,369 internally displaced persons (IDPs)) in 182 villages.

Methods: Led by "Mamans Leaders", GASPA lead screening/referral of malnutrition cases, trainings on storage of nutritious foods, and create infant flours using local ingredients coupled with interactive nutritional demonstrations. Members share their personal experiences and support each other to boost adoption of IYCF behaviors. Despite the security context, GASPAs remained active by involving community leaders in their establishment and monitoring, building social capital among women to work together and by encouraging IDPs to participate.

Results: GASPA enrolled 329 pregnant women, 422 lactating women (with children 0-6 months) and 618 pregnant women (with children 6-23 months), including 1,369 IDPs. Through collaboration with the Ministry of Health, ViMPlus conducted two successful GASPA trainings on drying and storing dark green leafy vegetables and supported GASPA in expanding screenings/referrals and interpersonal counselling. According to the SMART survey (2020-2021), GASPA activities may have contributed to improved IYCF practices in Centre Nord: exclusive breastfeeding increased from 62.9% to 86.2% and the proportion of children aged 6-23 months consuming 4+ food groups rose from 24.3% to 28.7%. In addition, global acute malnutrition in children under five decreased from 9.5% to 8.2% and the prevalence of underweight decreased from 20.6% to 17.5%.

Conclusions: Because GASPA garner social support among members, lead all community activities and have the support of community leaders and stakeholders, they are able to function effectively during times of crisis while improving IYCF behaviors. By encouraging the inclusion of IDPs, ViMPlus was able to address the needs of IDPs while reinforcing social cohesion between displaced and host communities. Lessons learned from the GASPA approach can guide effective community mobilization approaches promoted in similar contexts.

Keyword: IYCF, shock-responsive, nutrition, social support, resilience

PAB(T9-26)
Transforming Nutrition in West Africa – New Knowledge for Policy and Programme Actions

Roosmarijn Verstraeten[1,2], Richmond Nii Okai Aryeetey[5], Olutayo Adeyemi[4], Namukolo Covic[3,2], Stuart Gillespie[2], Jef L Leroy[2]

1. European Commission-Joint Research Center (Italy), 2. International Food Policy Research Institute (IFPRI) (USA), 3. International Livestock Research Institute (ILRI) (Ethiopia), 4. University of Ibadan (Nigeria), 5. University of Ghana (Ghana)

Background and objectives: Political commitment to addressing West Africa's high rates of maternal and child malnutrition is growing. The implementation of appropriate policies and programs at scale is however hampered by limited access and use of relevant nutrition knowledge. The *Transform Nutrition West Africa project* aimed to support effective nutrition policy making and program development through an inclusive and collaborative process of knowledge generation and mobilization.

Methods: The project's activities included i) knowledge generation and evidence synthesis, ii) knowledge mobilization, and iii) stakeholder engagement and leadership capacity strengthening. We assessed and analyzed nutrition-relevant data, programs, and policies for improving maternal, infant and young child nutrition (MIYCN). The analyses used a framework called the "5PD Cycle" (Problem, Policy, Program, People, Priorities, and Data and knowledge). Secondary data analysis, evidence synthesis, mixed-methods analysis, qualitative analysis, and policy/program reviews to identify emerging issues for the region were conducted (supply-driven approach). Ongoing engagement with stakeholders ensured local priorities were addressed (demand-driven approach), while leadership capacity strengthening ensured the knowledge generated was useful and used.

Results: The project informed regional priorities through various outputs over a 4-year period, including 117 knowledge products designed for decision-makers. We established 7 strategic institutional partnerships and 12 long-term engagements at the country and regional level. We reached West African decision-makers (n=400) through webinars (n=3) and regional events (n=3) that focused on key priorities for nutrition policy and programming, through newsletters (n=10) that synthesized nutrition-relevant evidence, and presentations on project results (n=63). We also ran 4 short courses for West African nutrition professionals (n=112).

Conclusions: Project activities helped build a network of decision makers, nutrition professionals, researchers, implementers and funders in the West African region. Its success provides indirect evidence that better, contextual knowledge and capacity to use and act on knowledge is potentially a limiting factor for better nutrition policies. It is too early to assess if this project actually led to improved policies and better nutrition outcomes. Finally, the return on investment for this project might have been larger with a longer project time-frame.

PAB(T9-27)
Assessment of the Contribution of the First Philippine Food Banking System to the Dietary Diversity of Enrolled Preschool Children in Taguig City and Bacolod City

Gabrielle Anne Gabriel De Ocampo[1], Ernani Ramos Bullecer[1], Ma. Socorro Endrina Ignacio[1]

1. College of Public Health, University of the Philippines Manila (Philippines)

Background and Objective: The latest Philippine National Nutrition Survey reported suboptimal dietary diversity among pre-school children. If left unaddressed, this could contribute to high levels of stunting and underweight and the development of health conditions which may hinder Filipino children from reaching their full growth and development potential. This study aimed to assess the contribution of the first food banking system in the Philippines to the dietary diversity of the daycare beneficiaries in two pilot cities.

Methods: Cross-sectional surveys at baseline and at the end-line of feeding (after 90 days) were deployed. The food intake of the 291 daycare beneficiaries were captured through two, non-consecutive 24-hour food recalls conducted at baseline and at the end-line. The dietary diversity scores (DDS) were computed based on the Guidelines on Measuring for Household and Individual Dietary Diversity developed by FAO and was adapted from the FANTA Household Dietary Diversity Score Indicator Guide.

Results: The overall mean DDS of the daycare beneficiaries of the food banking system was 3.77 (± 0.89, 95% CI: 3.67-3.87) at baseline and 3.81 (± 0.95, 95% CI: 3.70-3.92) at the end-line. At baseline, 83.56% of the daycare beneficiaries had low dietary diversity, while at the end-line, the proportion was 79.79%. The baseline and the end-line dietary diversity score of the daycare beneficiaries from Taguig City were almost similar at 3.69 (95% CI: 3.56-3.82) and 3.76 (95% CI: 3.55-3.79), respectively. An increase in the proportion of daycare beneficiaries with inadequate dietary diversity was observed [from 85.00% at baseline (95% CI: 80.05-89.95) to 88.11% at the end-line (95% CI: 83.44-92.77)], however, it was not statistically significant. For the Bacolod daycare beneficiaries, the mean DDS increased from 3.93 (95% CI: 3.78-4.08) to 4.06 (95% CI: 3.86-4.26), and a statistically significant decrease (p=0.004) in the proportion of daycare beneficiaries with inadequate dietary diversity was observed [from 82.57% (95% CI: 75.45-89.69) to 66.04% (95% CI: 57.02-75.05)].<Conclusion:The food banking system minimally contributed (1.06% score increase) to the dietary diversity of the daycare beneficiaries. Provision of whole, fresh food, more food recalls, and accounting for seasonal variations through extended observation are recommended moving forward

New Metrics and Assessment Tools to Support Innovative Financing of Nutritious Foods

Stella Nordhagen[1], Roberta Bove [1], Aime Kwizera[1], Lynnette Neufeld[2,1]

1. Global Alliance for Improved Nutrition (Switzerland), 2. Food and Agriculture Organization (Italy)

Background and Objective: Small- and medium-sized enterprises (SMEs), major contributors to the food sector, could play a key role in expanding access to nutritious foods in low- and middle-income countries. However, they often lack financing. Impact investment can help fill this need, but doing so effectively requires properly targeting firms that are likely to have an impact on nutrition – and on understanding this potential impact. We thus sought to define metrics for targeting and assessing nutrition-sensitive impact investment.

Methods: Based on a theory of change for how such investments could impact healthy diets, we determined a need for: clear, useable definitions of nutritious foods; prioritisation of firm types; prioritisation of consumers; and simple metrics for capturing outcomes. We undertook a review of available metrics used in impact investment, as well as within nutrition, and considered their feasibility and applicability to practical application by non-specialists in low-income settings.

Results: An actionable definition of nutritious foods can be applied to target SMEs but requires some simplification in order to make it applicable in a context of limited information and limited nutrition-specific expertise. Considering contextual factors is harder but can be accomplished at a basic level through simple multiple choice screening factors. Confidence in likely nutrition contribution is higher, and assessment of effects at the consumer level is easier, when considering value-chain segments closest to consumers (e.g., processors, retailers). To increase potential impact and minimize risk, however, it is also useful to include firms that are more distal (e.g., transporters, cold storage providers). Assessing consumer-level impact is challenging and may be impractical for most nutritious food financing investments; options exist for surmounting these challenges, but tracking indicators more proximate to

investments (i.e., outputs) is likely to be more feasible – and potentially sufficient in many cases.

Conclusions: Impact investment has considerable untapped promise for nutrition, and targeting such investments to maximize potential nutrition impact is feasible. However, it requires adapting—and simplifying—approaches and definitions usually used in the nutrition field. Applying such metrics, impact investment could be used to spur greater access to safe and nutritious food for all.

PAB(T9-29)
A case for sub-national investment into nutrition in Kenyan counties

Sakshi Jain[1], Sameen Ahsan[1], Dylan Walters[1], Geoffrey Kinyua[2], Martha Nyagaya[2], Johniere Smith[1]

1. Nutrition International (Canada), 2. Nutrition International (Kenya)

Background and objectives: By 2030, undernutrition will cost Kenya US$ 38.3 billion in GDP losses due to loss of workforce productivity. In 2018, multi-sectoral County Nutrition Action Plans (CNAPs) were developed to target undernutrition at the county level. This paper assesses the potential health impacts and economic benefits of scaling up the high-impact nutrition interventions in the CNAPs for five counties – Nandi, Busia, Makueni, Vihiga, and Elgeyo Marakwet.

Methods: The Cost of Hunger in Africa methodology was adapted to calculate undernutrition-related costs to health, education, and productivity sectors for one year. CNAP costing data were categorized into high-impact, nutrition-sensitive, enabling environment, and other public health interventions. Then, the Optima Nutrition tool was used to project the health impact of high-impact interventions from 2018 to 2022. The results were converted to DALYs to conduct benefit-cost analyses and cost-effectiveness analyses.

Results: The Cost of Hunger in undernutrition was nearly 1% of the GCP of the respective counties (USD $2-$5 million). The total CNAP budget ranged from USD$12-22 million, and high-impact interventions made up 35% of the total budget. Between 2018 and 2022, the five CNAPs aimed to reach 1.67 million children, 900,000 adolescent girls in schools, and 330,000 pregnant women. Vitamin A Supplementation programs for children 6-59 months, in-school weekly iron and folic acid supplementation programs for adolescent girls, and iron and folic acid supplementation programs for pregnant women had the highest reach. In total, high-impact interventions could avert 1800 child and 115 maternal deaths, prevent and treat 19,000 cases of stunting and 4700 cases of wasting in children under 5 and mitigate 67,000 cases of anemia in pregnant women and adolescent girls. County-level benefit-cost ratios ($5:1 to $14:1) and cost per DALY averted values hint at highly cost-effective interventions, though the cost per case averted values vary significantly.

Conclusions: CNAPs were the first set of plans to budget for nutrition interventions at the sub-national level. The results were used to lobby for increased investment in nutrition at the county level. Future analyses should consider a targeted sub-national approach for a higher return on investment.

PAB(T9-30)
In pursuit of understanding dietary intake: how FAO/WHO Global Individual Food consumption data Tool (FAO-WHO GIFT) is changing the way we use and visualize dietary data.

Agnieszka Balcerzak[1], Victoria Padula de Quadros[1], Teresa Bevere[1], Pauline Allemand[1], Jacqueline Tereza Da Silva[1], Rita Ferreira De Sousa[1], Giovanni Abblasio[1], Daniela Ichim<[1,2], Bridget Holmes[1]

1. Food and Agriculture Organization of the United Nations (Italy), 2. Istituto Nazionale di Statistica (Italy)

Background and objectives: Dietary surveys are a source of highly valuable information on what individuals eat and drink. They allow us to assess whether observed diets provide adequate nutrition and identify dietary practices that may increase the risk of non-communicable diseases. They also help to inform us about determinants of dietary intakes, such as food availability, accessibility, behaviors and customs. This knowledge is crucial for the global community to respond to the dietary transformation and promote healthy diets. High quality dietary data can be expensive and time consuming to collect, and is consequently lacking in many countries, especially low and middle income countries (LMICS). Where dietary data exists, it is often difficult to access, and is not harmonized, which hinders analysis and use. FAO, with the support of WHO and other international partners, created the FAO/WHO Global Individual Food consumption data Tool (FAO/WHO GIFT) to facilitate sharing of harmonized datasets of individual quantitative food consumption data as freely available microdata and summary statistics.

Methods: Three hundred and two potentially suitable dietary surveys were identified based on work with partner initiatives, and through a dietary data network. Data owners were approached and asked for permission to share their data publicly. All eligible datasets were harmonized and coded with the FoodEx2 food classification and description system.

Results: The platform currently includes 34 datasets and continues to grow. Robust algorithms are applied by standard

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

automatic procedures to calculate summary statistics and display them on interactive dashboards tailored for non-expert users. The platform offers indicators which provide information about the composition of the diet, quantitative information on the micro and macronutrient intakes and sources in the diet, and daily portion sizes of selected foods and food groups to support food safety risks assessment. New innovative indicators on the environmental impact of the diet and estimated usual intakes of nutrients are currently being added to the platform.

Conclusions: Harmonizing and sharing dietary data and presenting it in the form of easy-to-understand summary statistics increases the number of stakeholders who may use it to inform programs and policies for nutrition.

Keyword: dietary data, open data sharing, data harmonization, indicators

A synopsis of the policy and funding modalities of school food programs operating in the G7 countries

Suvadra Datta Gupta[1], Rachel Engler-Stringer[1]

1. University of Saskatchewan (Canada)

Background and objectives: The school food landscape is broad, and policies underlying the school food programs (SFPs) are often very complex. Purpose of this paper is to review the national policy and funding modalities underlying the school food programs in the G7 countries (Canada, France, Germany, Italy, Japan, the United Kingdom, and the United States) to help identify best practices, and their applicability in Canadian context.

Methods: National ministerial websites commonly responsible for school food programs were searched for school food policy and programs. Scientific literature, reports, grey literature published in English after 2000 were reviewed. Webinar with academicians, researchers and practitioners from Japan, United States (US), Italy, Germany and France were held to accumulate information otherwise scarcely available online.

Results: Focus of school food policies varied significantly across the G7 countries. While food education was at the core of SFPs in Japan, reducing negative impact of food production on climate change and biodiversity was key in the strategies formulated in Germany. A broad level influence of EU policies on the production and consumption of organic food was found on the school food programs in Germany, Italy, and France. In most of these countries, co-payment system was found where federal/provincial/municipalities funds through agricultural subsidies and parents contribute by paying ingredients and labour cost. Significant regional variation was found within these countries in program participation rate, school meal price as well as in enacting state-level school food policies resulting in a complex web of policy and program modalities. Multisectoral collaboration was found to be key for the success of these programs.

Conclusions: Our research gives a picture of the policy and legislative landscape of the school food programs in the G7 countries. Our findings will help the G7 countries to learn from one another and incorporate the best practices going forward.

PAB(T9-33)
Contribution of traditional food systems to food and nutrition security status of rural households in low-income communities

Lesley Macheka[1], Faith Angeline Manditsera[2], Prosper Chopera[3], Ruth Tambudzai Ngadze[4], Juliet Mubaiwa[2], Shingai Nyarugwe[5], George Kembo[6]

1. Marondera University of Agricultural Sciences and Technology (Zimbabwe), 2. Chinhoyi University of Technology (Zimbabwe), 3. University of Zimbabwe (Zimbabwe), 4. Wageningen University and Research (Netherlands), 5. University of Central Lancashire (UK), 6. Food and Nutrition Council of Zimbabwe (Zimbabwe)

Background and objectives: The climate change induced shocks and stressors have created poverty traps and increased the prevalence of food insecurity and malnutrition, especially in low-income communities. One of the adaptation strategies adopted include the increased reliance on traditional food systems, i.e., indigenous fruits and vegetables and wild harvested edible insects for household food and nutrition security. However, the potential contribution of traditional food system to food and nutrition security has not been fully researched resulting in lack of evidence to promote the inclusion of traditional foods in the programming of food and nutrition security interventions. In Zimbabwe there are limited scientific studies on the consumption and contribution of indigenous fruits and vegetables and edible insects to food and nutrition security. This study investigated the association between consumption of wild harvested edible insects, indigenous fruits and vegetables with nutrition outcomes such as minimum dietary diversity, women dietary diversity, food-consumption score, and coping strategy index.

Methods: Secondary data generated from 11,973 households during a nationwide livelihoods assessment survey conducted in 2020 was used. Paired sample t-test, Chi-square, and Pearson's correlation coefficient were calculated to determine the mean distribution differences, and correlations between nutrition outcomes consumption of wild harvested edible insects, indigenous fruits, and vegetables.

Results: The results revealed that at least 14 wild harvested edible insect species, 26 indigenous fruits and 10 indigenous vegetables are commonly consumed in rural Zimbabwe. The main findings are that (i) consumption of all the three (edible insects, indigenous fruits and vegetable) had a positive impact on women dietary diversity score, food-consumption score and coping strategy index, (ii) consumption of wild harvested edible insects had a positive impact on minimum acceptable diet, and (iii) consumption of indigenous vegetables had a positive impact on minimum meal frequency.

Conclusions: This study provides important evidence to the thematic area of traditional food systems and their contribution to food and nutrition security, which has received little attention from researchers and policy makers. Findings from this study are key for advocacy and programming of food and nutrition security and resilience building intervention programmes.

PAB(T9-34)
An optimization model for evaluating the food intake for meeting the nutrient requirements for the ICDS-SNP provisions with the optimal cost

Fathima Ayoob[1], Jawahar Ramasamy Manivannan[1], Abhishek Kumar[1], Anura V Kurpad[2], Tinku Thomas[2]

1. St John's Research Institute (India), 2. St John's Medical College (India)

Background: The nutritional status of young Indian children continues to be sub-optimal despite decades of programmatic interventions. The prevalence of stunting and wasting in < 5y old children are relatively stagnant at 35.5% and 19.3%, respectively, according to the latest National Family Health Survey (NFHS)-5. The critical period during which growth faltering occurs, starts from weaning, at 6 months of age, and continues up to 2-3 years of age, resulting in an increase in stunting prevalence with age, and this is borne out by the NFHS and other national surveys. This occurs despite the Supplementary Nutrition Program of the Integrated Children Development Service (ICDS-SNP) of the Indian Government. Since this program requires inputs to provide the best possible nutrition in different geographic and social circumstances, we created a nutrient optimisation model for the ICDS-SNP, which could recommend the quantities of selected raw foods to meet child nutrient requirements with a cost ceiling.

Methods: A linear programming optimization technique was used to derive the required quantities of different raw food items to meet the ICDS-SNP targets. The objective was to minimize total cost incurred, subject to the constraints of meeting the nutrient requirements and the fund allocation set by the ICDS-SNP. Additionally, user specific and nutrition expert-advised constraints were also considered. Since program delivery is operationally different for 1-3 and 3-6y old children in this age band, we considered separate optimizations for these ages.

Results: The model computed the required quantity of selected raw foods to be consumed by beneficiaries to meet the

ICDS-SNP mandated daily nutrient requirements of 500 kcal energy and 12-15g protein. These optimized solutions also met the requirements of selected micronutrients at 30% of their Recommended Dietary Allowances (RDA), within allocated cost constraints. We also created an interactive user-app for this purpose for use by stakeholders involved in the ICDS-SNP, as well as a separate interactive app for public use, hosted at https://icdslive.herokuapp.com.

Conclusions: By using the present model, it is possible to run an optimal and feasible ICDS-SNP that meets nutrition goals, and which can go a long way in improving the nutritional status of Indian children.

Keyword: Optimization Tool, ICDS-SNP, Cost Minimization

PAB(T9-35)
A report on the transition and current status of the school lunch system in Japan - Possibility of school lunch -

Satoe Kon[1]

1. Rikkyo University Geaduate School of Social Design Studies (Japan)

Background and objectives: In Japanese school lunches, menus are provided that not only promote Japanese cuisine but also promote understanding of other countries' culinary cultures. This report reports on the current school lunch system.

Methods: author investigated how school lunches have changed from the history to the present by examining various themes of literature and school lunch menus.

Results: The current school lunch system makes it possible to create menus that allow students to understand the cultures of other countries.

Conclusions: The Japanese school lunch system, which can provide a variety of menus, is a teaching material for "multicultural coexistence" that fosters understanding of other countries.

Keyword: multiculturalism, school lunch, nutrition education, public policy

Improving Nutritional Outcomes by Responding to Pandemics Through an Epidemiologically- Smart Social Protection Framework

Ana Solorzano[1]*, Michael Smith*[1]*, Juan Gonzalo Jaramilo Mejia*[1]*, Adhvik Shetty*[1]*, Manucheher Shafee*[1]

1. World Food Programme (Italy)

Background and objectives: There are 6.4 million deaths attributed to COVID-19 (WHO, 2022). However, COVID-19 is not the only global pandemic. Nearly 40 million people worldwide are living with HIV, with 1.5 million new infections in 2021. All while global outbreaks of tuberculosis, cholera, and influenza remain (UNAIDS, 2021). Furthermore, the incidence of Monkeypox is steadily increasing across the globe as a future pandemic.

Malnutrition is a catalyst for pandemics. Poor quality food exacerbated the spread of the Spanish flu while obesity increased the severity of COVID-19 ((Martini et al., 2019; Chu et al., 2020). Malnutrition also inhibits antigen responses and can lead to Nutritionally Acquired Immune Deficiency Syndromes (NAIDS) (Beisel, 1996). At the same time, pandemics like HIV can decrease the availability of and access to nutritious foods while increasing health expenditure (Weisar et al., 2007). Malnutrition and pandemics, therefore, exist in a vicious cycle.

Social protection can improve nutrition to disrupt this vicious cycle through its effects on prices, incomes, behaviours, assets, agency, and services. These modes of impact influence the underlying outcomes of diet quality and quantity, feeding and care practices, food environments, educational attainment, and gender equity. Together, these impacts can improve health outcomes and resilience to disease.

However, while these impact pathways appear axiomatic, little systematic research demonstrates how social protection responses can address nutritional outcomes in the face of pandemics.

This article addresses this gap and explains how social protection is a policy instrument of choice during pandemics to improve nutritional outcomes.

Methods: The article reviews literature in nutrition, epidemiology, and social protection to build an evidence-based analytical framework. This framework consists of five building blocks which rely upon a continuum of care model which looks at prevention, testing, treatment, adherence, and recovery in the context of a public health crisis.

Results: The article finds that the health and nutrition sectors have not fully explored how social protection can support the nutritional prevention, mitigation, and recovery from pandemics.

Conclusions: This blind spot leaves nations nutritionally vulnerable to future pandemics. The introduced epidemiologically smart framework represents a novel effort to bridge nutrition and social protection.

Mind the Gap: Evidence from Countries Across the World on Nutrition and Social Protection

Ana Solorzano[1], Michael Smith[1], Juan Gonzalo Jaramilo Mejia[1], Adhvik Shetty[1], Manucheher Shafee[1]

1. World Food Programme (Italy)

Background and objectives: Sustainable Development Goal Target 2.2 aims to end all forms of malnutrition by 2030. Access to and choice of nutritious foods are key determinants to meeting this target. The World Food Programme, along with partners, developed the Fill the Nutrient Gap (FNG) tool to highlight the risk of nutrient gaps and identify disenabling factors affecting nutritionally vulnerable groups. This tool estimates the cost and affordability of nutrient-adequate diets, supplemented by a review of the food supply chain and the environment, dietary practices, and nutrition situation. The FNG assesses the extent to which people can make the choice to purchase nutritious foods and seeks to understand these choices, recognizing that sustainable healthy diets must provide adequate nutrition. Additionally, the FNG models how interventions across sectors, including social protection, can contribute to making nutritious diets more affordable.

Building upon this work and the understanding that adequately designed social protection systems can improve nutrition outcomes, this publication highlights how the FNG analysis did or could inform nutrition-sensitive social protection systems and the effects of these systems on nutritious diets for households in fourteen countries.

Methods: Methodologically, the publication will provide an overview of the malnutrition burden, demonstrate its effects on human capital formation, provide a brief description of the integration of nutrition and social protection in national policy frameworks, and highlight existing challenges to nutrition-sensitive social protection. Next, the article will present an overview of the FNG analysis on the cost and affordability of a nutritious diet and highlight the modelled potential contribution of social protection in bringing healthy, nutritious diets more within reach.

Results: The synthesis found that malnutrition in all its forms continues to affect countries across the world, leading to substantial losses in human capital and economic growth. The case studies find that adolescent girls and pregnant and lactating women are particularly nutritionally vulnerable and face higher costs to meet their nutrient needs. <

Conclusions: The FNG analysis provided useful insights on how to make social protection more nutrition-sensitive, which have the potential to inform the integration of nutrition objectives into social protection programmes. >

Impact of Biofortified Foods and Food Products

Eva Monterossa[2], Valerie M. Friesen[2], Mduduzi N.N. Mbuya[3], Samantha Lee Huey[2], Annette M. Nyagaresi[4], Neel H. Mehta[1], Elsa M. Konieczynski[1], Arini Bhargava[1], Saiful Islam[1], Saurabh Mehta[1]

1. Cornell University (USA), 2. Global Alliance for Improved Nutrition, Switzerland (Switzerland), 3. Global Alliance for Improved Nutrition, USA (USA), 4. Global Alliance for Improved Nutrition, Kenya (Kenya)

Background and objectives: Biofortification is the process of increasing the concentrations and/or bioavailability of micronutrients in staple crops and has the potential to mitigate micronutrient deficiencies globally. Efficacy trials have demonstrated benefits of consuming biofortified crops; here, we sought to understand the research gaps, implementation barriers and potential solutions to increase the impact and scale up of biofortification.

Methods: We synthesized the evidence on biofortified crops across the domains of bioaccessibility and bioavailability; micronutrient retention; sensory acceptability; factors influencing adoption; efficacy trials; and effectiveness of biofortified food consumption on micronutrient status. For the latter (effectiveness), we considered different impact pathways including via direct purchase, informal and formal supply chains, and own production.

Results: For each domain, we found: 67 studies (bioaccessibility and/or bioavailability; 50 studies (micronutrient retention); 53 studies (acceptability); 42 studies (adoption); 16 trials (efficacy); and 25 studies (effectiveness). The baseline levels of micronutrient and cultivar/genotype were most impactful on bioaccessibility, bioavailability and micronutrient retention after post-harvest processing. Biofortified crops met sensory acceptability thresholds in most preparations and populations, and facilitators or barriers to adoption depended on crop and setting. Results from efficacy trials suggest that iron and provitamin-A biofortified crops improve some biomarkers of micronutrient status in the randomized control trials conducted to date. Results from effectiveness studies suggest an improvement in micronutrient status via consumption of biofortified crops from farmers' own production, mainly as provitamin A from orange sweet potato, in controlled interventions that involved the creation of demand, the extension of agriculture and promotion of marketing.

Conclusions: In summary, evidence supports that overall, biofortified crops are bioaccessible and bioavailable, retain micronutrients well, are sensorily acceptable, and can be part of food systems interventions to reduce micronutrient deficiencies in farmer households. Several gaps remain including understudied crops, populations, processing/preparation styles, and real-world effectiveness amongst urban consumers and in formal or informal settings. Ongoing and future research will help fully inform strategies to increase the impact and scale up of biofortified foods and food products.

Changes in the use of low-calorie sweeteners in packaged foods and beverages launched in the Brazilian food supply in the last 20 years

Mariana Fagundes Grilo[1], Camila Aparecida Borges[1,3], Lindsey Smith Taillie[2], Ana Clara Duran[1,3]

1. University of Campinas (Brazil), 2. University of North Carolina (USA), 3. University of Sao Paulo (Brazil)

Background and objectives: The use of low-calorie sweeteners (LCS) by industry in foods and beverages has increased in several countries. This increase may be even more accentuated as a response to the implementation of public policies to reduce added sugars. Because the effects of LCS consumption are still inconsistent, we aimed to assess changes in the use and types of LCS over time (2001-2021) in packaged foods and beverages launched in Brazil.

Methods: We used commercial data from 118,861 packaged foods and beverages provided by the Mintel Global New Products Database. We identified foods and beverages with LCS using the list of ingredients. We assessed changes in the prevalence of foods and beverages with artificial or natural nonnutritive sweeteners (NNS) and sugar alcohols that were launched in Brazil over a 20-year period, overall and by food category.

Results: The prevalence of foods and beverages with LCS launched in Brazil went from 8.9% (n=51) in 2001, to 10.9% (n=936) in 2021. Over a 20-year period, the most prevalent type of LCS in products shifted, with the use of artificial NNS becoming less prevalent over time (from 7.0% to 5.3%), while the prevalence of sugar alcohol increased (from 4.0% to 5.7%), as did the prevalence of natural NNS (from 1.4% to 6.3%). In 2001, non-carbonated sweetened beverages, candies, cakes and sweet pies were the products with the highest prevalence of LCS use, while carbonated and non-carbonated sweetened beverages and dairy beverages had the higher prevalence in 2021.

Conclusion: The prevalence of foods and beverages with LCS in the Brazilian food supply increased from 8.9% to 10.9% over a 20-year period and was accompanied by an increase in natural NNS e sugar alcohols use. Because of the unclear evidence that links LCS to better health outcomes, monitoring the prevalence of LCS is critical, particularly in countries with strategies that can lead to increases in LCS use, such as Brazil. In addition, clearer front-of-package information regarding the presence of LCS can help consumers make more informed choices.

High sugar and salt levels in commercial Food Products for Infants and Young Children in Malaysia: results from a pilot study using the World Health Organization Nutrient and Promotion Profile Model

Sue Yee Tan[2], Bushra ALsheibani[1], Kai Er How[1], Sangeetha Shyam[1], Ali Morpeth[3], Janet Cade[3]

1. International Medical University (IMU) (Malaysia), 2. Nutrition Society of Malaysia (NSM) (Malaysia), 3. University of Leeds (UK)

Background and objectives: The first 1000 days of life are critical in determining a child's growth, development, and future health risks. Hence, commercially available unhealthy food products for infants (up to 12 months) and young children (12-36 months) (FIYC) introduced in this critical period are a public health concern. Thus, the WHO proposed a Nutrient and Promotion Profile Model (NPPM) to evaluate these products according to nutritional and promotional criteria. Several European countries reported FIYC had high sugar and sodium content and employed inappropriate promotional strategies. Malaysia, a rapidly developing economy, has an extensive availability of commercial FIYC. Given the rapid increase in obesity and diabetes in the population, it is important to evaluate the FIYC sold in Malaysia.

Methods: We evaluated the nutrient profiles and promotional strategies of FIYC (n= 285) available in Kuala Lumpur using the WHO draft NPPM. We included (i) dry powdered and instant cereal/ starchy food (n=88), (ii) Soft wet spoonable, ready-to-eat-foods (n=60), (iii) Meals with chunky pieces (n=2), (iv) Snacks (n=130), and (v) Drinks (n= 5).

Results: Overall, only 27% of the products satisfied all nutrition criteria (Individual criterion satisfied (% products): sugar: 51%, salt 58%, energy density: 21%, protein: 91% and fat: 95%). Moreover, only 23% of the products met all relevant proposed NPPM promotional requirements. Only 62% of the products included a message emphasising the importance of breastfeeding while 92% of the products had inappropriate nutrition or health claims.

Conclusion: There is an urgent need to create awareness and dialogue among all stakeholders including baby food manufacturers and importers, the Malaysian Ministry of Health,

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

healthcare professionals, parents, and caregivers towards improving the quality of FIYC available in Malaysia.

Acceptability of multiple micronutrient-fortified bouillon cubes among women in 2 districts in the Northern region of Ghana

Sika M Kumordzie[1], Ryan K Wessells[1], Emily Becher[1], Jennie Davis[1], Charles D Arnold[1], Xiuping Tan[1], Stephen A Vosti[1], Katherine P Adams[1], Seth Adu-Afarwuah[2], Reina Engle-Stone[1]

1. University of California, Davis (USA), 2. University of Ghana (Ghana)

Background and objectives: Bouillon is a promising fortification vehicle in West Africa because it is widely consumed. We evaluated the acceptability of two different multiple micronutrient-fortified bouillon cube formulations, compared to cubes with iodine only.

Methods: We conducted a double-blind randomized controlled study in the Tolon (2 urban, 1 rural cluster) and Kumbungu (1 urban, 1 rural cluster) districts of the Northern region of Ghana (n = 84 women). Two formulations of multiple micronutrient-fortified bouillon cubes containing iron, zinc, folic acid, vitamins A and B12, and iodine at "upper" (45 - 125% of CODEX) or "lower" (15-50% of CODEX) concentrations, and a control cube that contained iodine only (50% of CODEX) were evaluated. Cubes were prepared specifically for this trial and similar to cubes commercially available locally. Baseline data included household composition and information on bouillon use. Women then participated in 2 days of center-based sensory testing (acceptance, preference, discrimination); using a randomized crossover design, women evaluated all three formulations as both raw cubes and cubes prepared in two common dishes (okra soup and jollof rice). Women were then randomized to receive a household ration of a single bouillon formulation to use in household cooking for a 14-day period. For acceptance testing, cubes and dishes (both center-based and household-prepared) were rated on a 5-point Likert scale (1 = dislike very much, 5 = like very much).

Results: Almost all (92.9%) participants reported bouillon use at least twice per day. Mean overall liking of the three raw cubes ranged from 4.3 – 4.5 on the 5-point Likert scale (p = 0.17). There were no differences in the liking of appearance, feel, aroma, or taste among the cubes, although one of the cubes was rated lower for crumble compared to the other cubes (85% vs. ≧ 94%; p = 0.03). There were no differences in overall liking or specific attributes (appearance, color, taste, aftertaste, saltiness) among the 3 cubes when they were used in the 2 dishes or household recipes.

Conclusions: All three cubes were well-liked by respondents, suggesting that any of the 3 cubes would be acceptable for use in future research.

Neural tube defects in Ghana, current trends and relevant strategies for policy actions

Obed Akwaa Harrison[1], Idole Ilfie[2], Jerry Joe Ebow Kingsley Harrison[1,3], Winfred-Peck Dorleku[4], Albert Kwame Gator[5], Emma Efua Adimado[6], Kafui Kofi Odoi[6,7], Kwesi Firibu Saalia[8], Matilda Steiner-Asiedu[9]

1. University of Ghana (Ghana), 2. University of Leeds (UK), 3. University of Ghana (Ghana), 4. University of Ghana (Ghana), 5. University of Regensburg (Germany), 6. Ghana Health Service (Ghana), 7. Ghana Health Service (Ghana), 8. University of Ghana (Ghana), 9. University of Ghana (Ghana)

Background and objectives: Neural tube defects (NTDs) are among the commonest congenital malformation affecting over 300,000 births globally each year. NTDs are one of the health consequences of Folate (Vitamin B_9) deficiency. NTDs are prevalent globally but there is little documentation on them. In Ghana, the NTD prevalence of 1.15/1000 births (in 1993 for KorleBu Teaching Hospital) and 1.6/1000 births (in 2017 for Tamale Teaching Hospital) have been reported. This study assessed the current trends of neural tube defects in Ghana.

Methods: Data were sourced from the District Health Information Management System (DHIMS2) of the Ghana Health Service, google scholar and PubMed searches as well as key-informant interviews. The ANOVA test was used to assess differences in NTD cases across the regions over 5 years period.

Results: The National NTD were 430, 441, 468, 483, and 420 cases between 2017 to 2021. There were no significant differences in the number of cases over the years (p-value = 0.976). However, there were significant (p-value < 0.001) regional disparities with the highest cases found in Ashanti, Greater Accra, Eastern and Central Regions. Savannah Region recorded the least cases. There is ongoing iron and folate supplementation for adolescent girls and pregnant women in Ghana. However, there is no direct surveillance targeting folic acid deficiency and its associated birth defects.

Conclusions: The current National prevalence NTDs is unknown/unreported. The prevalence of NTDs has not reduced over the years and this is an issue of public health concern. These NTD cases are likely under-reported in hospitals where the data was taken due to stigma and ignorance. There is a need for targeted surveillance by including folate assessment in the periodic surveillance by the Ghana Demographic Health Survey and research focusing on alternative economical assessment

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

techniques as well as the extent of folate fortification of cereals and staples.

PAB(T9-43)
Assessing the transition of Vitamin A supplementation to routine delivery in Côte d'Ivoire

Landry Koffi Kouadio[1], Romance Dissieka[1], Fougnigue Soro[1], Ahmenan Claude Liliane Konan[1], Ibrahim Foungotin Bamba[1], René Koffi Oka Kouamé[2], Fatou Bérété NDiaye[1], Melissa Baker[1], Jacob Yao Niamien[1], Djeinam Touré[1]

1. Helen Keller International (Cote d'Ivoire), 2. Programme National de Nutrition (Cote d'Ivoire)

Background and objectives: Transitioning vitamin A supplementation (VAS) from a campaign model to delivery through the routine health system is a priority to ensure sustainable coverage, and was started by the government of Côte d'Ivoire in 2016. To date, only 41 of 113 districts are in routine delivery and facility-based coverage remains low. The aim of this research was to (i) assess routine delivery and (ii) identify barriers related to the transition with the aim of developing corrective strategies.

Methods: Following the Consolidated Framework for Implementation Research CFIR), the study identified five domains of the health delivery system for assessment: (i) the characteristics of the intervention, (ii) the external framework, (iii) the internal framework, (iv) individuals involved in the implementation, (v) the process of implementation. Relevant sub-domains (n=32) and specific measures were identified. We conducted (i) quantitative surveys of 1826 households, 76 Facility Managers, 96 Health Workers, 112 Community Health Workers (CHW) and (ii) 52 qualitative interviews of regional, district, and community actors in 24 districts.

Results: We identified four major constraints to routine delivery of VAS. **First**, while health districts can estimate the number of children eligible for VAS each month, many communities' health posts do not. Without clear targets, coverage is low (35%), and often rectified by ad-hoc, costly campaigns. **Second**, 78% of facility managers reported regular stockouts. Incomplete reporting of capsules delivered results in poor stock planning, as stock is replenished based on the number of supplemented children. **Third**, caregivers are not aware of the availability of routine VAS. Community criers are the most widespread source of awareness. **Fourth**, while constructive feedback and community appreciation contribute significantly to community health workers motivation, this is insufficient to overcome their lack of remuneration and high perceived workload.

Conclusion: We identified four actions that could increase routine VAS coverage by health posts: (i) coach health post staff in monthly planning and target setting; (ii) revising and simplifying monitoring tools; (iii) train and mentor health post staff in routine, accurate record keeping; and (iv) build systems to ensure regular resupply.

Key failure factors in Vitamin A Supplementation: Lessons from Nigeria

Philomena Ogochukwu Orji[1], Delphine Danboyi[1], Faith Ishaya[1], Chinedu Okoye[1], Amarachi Ogwuma[1]

1. Helen Keller Intl (Nigeria)

Background: Vitamin A deficiency remains prevalent among children under 5 years in Nigeria and vitamin A supplementation (VAS) is organized bi-annually during Maternal, Newborn, and Child Health Week campaigns. In 2021, Helen Keller International, Nigeria, supported the implementation of two rounds of VAS campaigns in six states covering approximately 5 million children each. The aim of this research was to assess VAS coverage and identify factors affecting coverage and campaign success.

Methods: Post-event coverage surveys (PECS) were administered after the second round of VAS to determine coverage and highlight factors affecting coverage. Using the WHO population probability to size, 30 households, one community leader, and one health worker, from 30 communities each were randomly sampled and interviewed in Akwa-Ibom, Benue, and Nasarawa states (2880 persons in total). Data was collected by trained enumerators using ODK (Open Data Kit) and analyzed using thematic analysis techniques and descriptive statistics.

Results: A total of 2,433,117 children in the three states (target = 2,807,261) received VAS during the second round. Coverage in Akwa-Ibom, Benue, and Nasarawa states was 64.1%, 68.1% and 76.1%, respectively. Factors affecting coverage include (i) poor community mobilization for the MNCHW which was most frequently cited, (ii) late arrival of commodities and insufficient commodities due to inadequate health worker forecasting capacity, (iii) insecurity and communal clashes which made some communities inaccessible, (iv) disruption due to other competing interventions i.e., Covid-19 mass vaccination campaign, (v) shift from door-to-door implementation strategy (started in 2020 due to the covid-19 pandemic) back to facility-based supplementation.

Conclusion: VAS coverage was moderate and fell below the effective coverage of 80% in the 3 states assessed. Factors affecting coverage were related to the program, health system, and insecurity. Adequate community mobilization, proper

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

planning, coaching of health workers, and integration of VAS with other health activities can mitigate these factors and potentially increase coverage.

Keyword: VAS - Vitamin A Supplementation , PECS_-Post Event Coverage Survey

PAB(T9-45)
Anemia and iron folic acid supplementation in India: recent progress and missed opportunities

Samuel P Scott[1], Purnima Menon[1], Soyra Gune[1], Kapil Yadav[2], William Joe[3]

1. International Food Policy Research Institute (India), 2. All India Institute of Medical Sciences (India), 3. Institute of Economic Growth (India)

Background and objectives: Anemia prevalence in India has not decreased in the past 50 years. To address this severe public health issue, a national 'Anemia Free India' program was launched in 2018, with iron folic acid (IFA) supplementation as a core component. We sought to examine 1) recent trends in anemia prevalence and IFA coverage, 2) failure points along the IFA supply chain from delivery platform to consumption.

Methods: Data on anemia prevalence in children 6-59m, non-pregnant women 15-49y and pregnant women 15-49y were from the 2015-16 and 2019-21 rounds of India's National Family Health Survey (NFHS). NFHS follows a systematic sampling procedure and is representative down to the district level. Burden estimates were derived using 2020 population projected from 2011 Census data. Additional data from NFHS included IFA delivery platforms (antenatal care, postnatal care, childcare center, in school), IFA receipt and IFA consumption. Principal component analysis of assets was used to generate a wealth index and the sample was divided into wealth quintiles to assess inequities in IFA coverage. Monthly Health Monitoring Information System (HMIS) data from 2015 to present were used to examine IFA provision.

Results: Between 2015-16 and 2019-21, anemia prevalence remained at 50% in pregnant women and 53% in non-pregnant women but increased from 59% to 67% in children. HMIS data show increasing IFA provision at critical life stages: pregnancy (77% in 2015-16 to 91% in 2019-21), postnatal (35% to 50%), childhood (7% to 15%); adolescence (23% to 39%). IFA provision dropped sharply during the COVID-19 pandemic but recovered to pre-pandemic levels within 2-3 months for pregnant women; recovery was slower for children and adolescents. Though HMIS data show that 91% of pregnant women were provided 180 IFA in 2019-21, NFHS data from the same period show that only 26% of women consumed 180 IFA during their pregnancy. A pro-rich gradient was observed from platform to receipt to consumption.

Conclusions: A recent increase in IFA provision and consumption may indicate early success of the 'Anemia Free India' program. Further programmatic efforts are needed to reach children and adolescents and to increase compliance, especially among the poor

Keyword: anemia, iron folic acid, implementation science, women, children

Digital monitoring of anemia control measures in a district using Anemia Mukt Bharat Health Management Information System indicators

Surabhi Puri[1], Kapil Yadav[1], Shashi Kant[1], Sanjay Kumar Rai[1], Partha Haldar[1], William Joe[2]

1. All India Institute of Medical Sciences, New Delhi (India), 2. Institute of Economic growth (India)

Background and objectives: Anemia is a severe public health problem in India affecting more than fifty percent individuals across most age groups. Anemia Mukt Bharat (AMB) programme, with target of 3-point reduction in anemia prevalence per year, developed a monitoring mechanism based on a set of 18 indicators and 6 key performance indicators (KPIs) derived from routine reporting in Health Management Information System (HMIS). Objective of the study was to assess status of anemia control measures in district Faridabad, Haryana using AMB HMIS indicators for the period of April 2018 – March 2019.

Methods: A cross sectional study was conducted in district Faridabad, Haryana from May 1 to June 15, 2019 (Reference period - April 2018 – March 2019). Status of existing activities for anemia control was assessed by documentation of HMIS indicators identified by AMB programme to be used for routine monitoring. Sources of data were HMIS, programme reports and district annual reports. Denominators provided by AMB programme were used for ascertaining proportions. Critical review of the generated data was done along with description of collection and reporting process.

Results: Activities in place to control anemia were prophylactic iron and folic acid (IFA) supplementation and deworming to 6 – 59 months children, adolescents, and pregnant and lactating women. For children 5 – 9 years of age, IFA was not provided in the district but deworming was done. Coverage of IFA prophylaxis in children 6 – 59 months was 22.5%, in adolescents was 50.7 %. The 180 days IFA supplementation in pregnant women was 33.8 %. IFA stock status was not being captured in the district. AMB index for district Faridabad (April 2018 – March 2019) was 26.8. Gaps in understanding of data elements, and mismatch between AMB denominator data and census forecasts limited the data accuracy.

Conclusions: Overall, the status of anemia control measures as assessed by HMIS indicators was not satisfactory in the study district. Number based reporting and issues with data quality limited the use of data for decision making. Periodic evaluations

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

of anemia control measures at district level maybe required to achieve the targets set by Anemia Mukt Bharat programme.

Assessment of free sugar, added salt, fortification levels and selected labelling practices of commercially produced complementary foods sold in Cambodia and Indonesia

Anzelle Mulder[1], Lara Sweet[1], Kroeun Hou[2], Senveasna Chum[2], Dian Hadihardjono[3], Eva Juniza[3], Jane Melissa Badham[1]

1. JB Consultancy (South Africa), 2. Helen Keller International (Cambodia), 3. Helen Keller International (Indonesia)

Background and objectives: Global guidance on the appropriate composition, fortification and labelling of commercially produced complementary foods (CPCF) exist to assist countries in determining if available CPCF are suitable for older infants and young children, do not interfere with breastfeeding, and are unlikely to contribute to overweight and non-communicable diseases. This study assessed the presence of free sugar and added salt, the appropriateness of fortification levels, and selected labelling practices of CPCF marketed in Cambodia and Indonesia against Codex Alimentarius and WHO standards and guidance.

Methods: CPCF products were purchased in Khsach Kandal, Cambodia (n=68) and Bandung City, Indonesia (n=211). Using product label information, this cross-sectional study assessed the presence of free sugars, added salt, calcium, zinc and iron fortification levels, age of introduction, and daily ration recommendations against Codex Alimentarius (Codex) and WHO standards and guidance.

Results: This study found that in Cambodia almost all (90%) and in Indonesia nearly three quarters (74.3%) of CPCF products listed free sugars in the ingredient list. All puddings and cereal-based snacks in Indonesia, and all yoghurts and 94.6% of cereal-based snacks in Cambodia contained free sugars. Eighty percent of Indonesian and 100% of Cambodian cereal-based snacks contained added salt. Of products fortified with calcium, zinc, or iron, 44.6% 12.1% and 65.8% in Indonesia and 5.0%, 0% and 32.1% in Cambodia, respectively, provided the Codex recommended minimum of 50% RNI per daily ration. Seventeen percent of Indonesian and 5.8% of Cambodia products failed to provide an age of introduction greater than or equal to 6 months and few provided a daily ration (38.4% in Indonesia and 11.8% in Cambodia).

Conclusion: None of the products assessed complied with the Codex Alimentarius and WHO standards and guidance against which they were assessed, thereby falling short of the WHO prerequisites for promotion of CPCFs. National governments must adopt global guidance into national regulatory frameworks and enforce national regulations before global policies can aid in improving the quality of commercial foods fed to older infants and young children.

Keyword: commercially produced complementary food, infant and young child nutrition, infant and young child feeding, Codex Alimentarius, WHO guidance

Early program assessment of the Haryana wheat flour fortification program, India

Mona Duggal[1], Jorge Rosenthal[2], Manmeet Kaur[3], Neha Singh[4], Nupur Shandil[5], Sonia Trikha Khullar[6], Rachita Gupta[7], Parveen Bhalla[8], Jennifer Williams[9], Lorraine F Yeung[10]

1. PGI, Chandigarh (India), 2. CDC, Atlanta (USA), 3. PGI, Chandigarh (India), 4. PGI, Chandigarh (India), 5. PGI, Chandigarh (India), 6. SHSRC, Haryana (India), 7. WHO (India), 8. FFI (India), 9. CDC, Atlanta (USA), 10. CDC, Atlanta (USA)

Background & Objective: In 2018, a wheat flour fortification program with iron, folic acid, and vitamin B12 fortificants was established within the government-run Public Distribution System (PDS) in Ambala District, Haryana, India to address micronutrient deficiencies. PDS provides basic food and non-food commodities to the families below poverty level at subsidised prices. This study aims to assess household fortified wheat flour consumption among PDS recipients.

Methods: In 2021, we conducted a household survey and interviewed women aged 18-49 years (WRA) about consumption of wheat flour. A systematic probability sample design was used to select 358 households with WRA from a listing of all household beneficiaries enrolled in PDS who were living in the Naraingarh and Barara communities in Ambala District where the wheat flour fortification program was implemented. We assessed the percentages of households who have received and consumed fortified wheat flour from PDS, and assessed the perceived quality of fortified wheat flour compared to non-fortified wheat flour from other sources. <

Results: We were able to reach 88% of the selected households (314/358) and 291 WRA agreed to participate (response rate 93%). Almost 99% (288/291) of households were eligible to obtain fortified wheat flour through PDS and among those eligible, 285 (99%) obtained fortified wheat flour monthly. Household consumption of fortified wheat flour was 98%, and 71% consumed all the fortified wheat flour supply before consuming other non-fortified wheat flours. Among households that reported consumption of fortified wheat flour, 63% reported quality of the fortified wheat flour was similar or better than non-fortified wheat flour from other sources.

Conclusions: Receipt and consumption of fortified wheat flour among PDS beneficiaries was very high. A majority of households reported consumption of fortified wheat flour first before other non-fortified wheat flour and that the quality of fortified wheat flour was similar or better than other non-fortified wheat flour. Periodic assessment of the wheat flour

fortification program would be helpful to ensure continual high consumption of fortified wheat flour by PDS beneficiaries.

Assessment of maternity protection policies in the Philippines and their role in creating an enabling environment for breastfeeding

Jyn Allec Ramos Samaniego[1], Cherry Maramag[1], Mary Christine Castro[1], Tuan Nguyen[2], Jennifer Cashin[3], Paul Zambrano[4], Janice Datu-Sanguyo[4], Roger Mathisen[2]

1. Nutrition Center of the Philippines (Philippines), 2. Alive & Thrive Southeast Asia/FHI360 (Viet Nam), 3. Alive & Thrive Southeast Asia/FHI360 (USA), 4. Alive & Thrive Southeast Asia/FHI360 (Philippines)

Background and Objectives

The Philippines has enacted maternity protection policies, such as the Expanded Maternity Leave Law and the Expanded Breastfeeding Promotion Act, to create a more enabling environment for breastfeeding. Our objective was to review the content and implementation of maternity protection policies in the Philippines, examine their impact on women in the workforce, and determine the role of policy interventions in improving breastfeeding practices in workplaces.

Methods

Policies, guidelines, and related documents on maternity protection were reviewed and their contents compared with international recommendations. In-depth interviews were conducted with policy makers, employers, employed pregnant women, mothers of infants, and mothers' partners. Data were analyzed with thematic analysis using NVivo software.

Results

Results indicated that the Philippines' policies on maternity protection are aligned with the majority of International Labor Organization recommendations, except for 1) coverage of maternity leave payments for all, including informal workers, and 2) allocation of public or social funds for paid maternity leave. Although policies are in place, gaps in monitoring and enforcement systems to ensure functionality and uptake of services for breastfeeding were observed. Barriers to uptake of maternity entitlements, especially in the informal sector, exist. The current policies to support breastfeeding in workplaces do not necessarily translate into improved breastfeeding practices. This is due to poor communication of entitlements, and insufficient breastfeeding support and promotion within workplaces. Due to inadequate breastfeeding assistance and advocacy, challenges to continuing breastfeeding while working can overpower mothers' decisions to breastfeed their baby. The Philippine maternity protection policies operate separately from breastfeeding promotion programs, resulting in poor recognition of how maternity entitlements are intended to enable breastfeeding.

Conclusion

Although maternity protection policies are in place, they are not yet aligned to create an enabling environment to improve and sustain recommended breastfeeding practices. Strengthening enforcement mechanisms and revisitation of entitlements in the workforce are needed. Partnerships with both government and breastfeeding advocates are needed to strengthen breastfeeding advocacy in workplaces, by facilitating the creation of technical assistance and educational materials as well as assist in crafting corporate procedures and advocacy plans. Lengthening maternity leave duration to align with the recommended six months of exclusive breastfeeding may improve breastfeeding practices.

Trends for early initiation of exclusive breastfeeding under six months in DRC : results from the Multiple Indicator Cluster Surveys of 2001, 2010 and 2018

Landry Mongondi Egbende[1], Branly mbunga[1], Paulin Mutombo[1], Marie claire Muyer[1], Mala Mapatano[1]

1. Kinshasa School of Public Health (Democratic Republic of the Congo)

Background and objectives: Breastfeeding is one of the most effective ways to ensure child health and survival. According to the WHO, increasing rates of exclusive breastfeeding can help drive progress against other global nutrition targets. This practice is one of the most powerful tools that policy-makers have at their disposal to improve the health of their people and their economies. Despite progress made generaly in the country, some regions have still now low proportion of exclusive breasfeeding. The current study provides an update in national trend in exclusive breastfeeding from 2001 to 2018, taking advantage of data from the multiple indicator

cluster surveys to see the progress toward the Global nutrition targets.

Methods: Data from three waves of the Multiple Indicator Cluster Survey for 2001, 2010 and 2018 were used to estimate crude the trends over time for two outcomes, early initiation of BF and exclusive BF. We assessed the national and provincial trends of these two indicators.

Results: The trend in breastfeeding is growing generaly, within one hour of delivery, exclusive breasfeeding and breastfeeding up to the age of 2 years. Breastfeeding is high in rural areas and is increasing, except in 2001 when the AME was higher in urban than in rural areas.

Conclusion: Our results suggest to improve breastfeeding practices in the country to achive the Global nutrition targets and especially in urban areas. Child nutrition programmes worldwide continue to require investments and commitments to improve infant feeding practices in order to have maximum impact on children's lives.

Keyword: Breasfeeding

PAB(T9-51)
Breastfeeding related services and practices among women in Madina community

Jamilatu Alhassan[1], Sandra Essuman[1], Agartha Ohemeng[1]

1. University of Ghana (Ghana)

Background and objectives: The global breastfeeding scorecard data revealed that the prevalence of early breastfeeding initiation and exclusive breastfeeding were 43% and 43.5% respectively. Some breastfeeding-related services have been provided to help enhance breastfeeding practices worldwide. These have been of help but are still not effective enough to obtain optimal breastfeeding practices in Ghana. This study aimed to assess the breastfeeding-related services and practices among women in the Madina community.

Methods: The study was cross-sectional and included 150 mothers with infants aged 1-24 months attending post-natal/child welfare clinical services in two health facilities in Madina. Semi-structured questionnaires were used to assess their knowledge on breastfeeding, factors that influence breastfeeding, challenges associated with breastfeeding, and the breastfeeding services provided to them (using the ten steps to successful breastfeeding of the baby-friendly hospital initiative). Data were analyzed using SPSS version 26.0. Bivariate analysis (Fisher's exact test) was used to analyze the relationship between the breastfeeding practices of the mothers and the services provided.

Results: The percentage of respondents who had knowledge on early initiation and exclusive breastfeeding were 92.7% and 84.7% respectively. The prevalence of early breastfeeding initiation and duration of exclusive breastfeeding was 68.5 and 50.2% respectively. The average overall breastfeeding services score was 6 out of 8. The relationship between the aid to initiate on time and the actual initiation of breastfeeding among mothers was statistically significant (p-value = 0.00) There was no association between the other services such as; rooming-in (p-value = 0.29), how to maintain lactation without infant (p-value = 0.22), referral to a breastfeeding support group (p-value = 0.58) and the exclusive breastfeeding practices of the mothers.

Conclusions: There was no association between rooming-in, maintaining lactation without an infant, referral to a breastfeeding support group, and the mother's breastfeeding practices. Therefore the breastfeeding-related services and practices of the women in Madina are sub-optimal.

PAB(T9-52)
Consideration of adolescent nutrition in Senegalese policies: a scoping review

Mariame Sy[1], Adama Diouf[1], Nicole Idohou-Dossou[1], Abdou Badiane[1], Mane Hélène Faye[1]

1. Cheikh Anta Diop University (Senegal)

Background and objectives: Adolescents have only recently been recognized as a priority nutrition target group at global level. Although some nutrition interventions are implemented, there is a lack of data on their nutritional status and diet to guide them, especially in developing countries. This work aimed to identify adolescent nutrition gaps in policies in Senegal compared to the global level.

Methods: A Literature review was carried out to collect global guidelines on adolescents from the health organization websites and PubMed. Then, the official websites of the 12 sectors involved in the multisectoral strategic plan for nutrition in Senegal were visited to collect national documents using the following keywords: policy, nutrition, adolescent, sector, letter, program, plan, and strategy. Other global and national relevant documents were also collected from main resource persons of the different sectors. Documents were identified and reviewed by using key words such as nutrition, adolescent, indicator. An Excel template was developed and used to collect data on strategic areas, nutrition interventions, gender mainstreaming, multisectoriality, nutrition indicators and to analyze its consideration according to World Health Assembly (WHA) targets.

Results: Overall, 11 global and 52 national documents were collected and reviewed. The main gaps identified in global policies were the missing of specific target and nutrition and dietary indicators for adolescents. At national level, only 16 documents mentioned directly the adolescents and 7 of its mentioned nutrition among adolescents, especially in health and education sectors. Only health sector included adolescent nutrition indicators and 3 sectors included nutrition interventions. Gender mainstreaming among adolescents were

Ann Nutr Metab 2023;79(suppl 1):14–1172
DOI: 10.1159/000530786

poorly highlighted in documents, only in 6 documents. The difference by sex was not consider in nutrition indicators. In comparison to the global level, Senegal was aligned to supplementation intervention but not to obesity and overweight indicator. Dietary and wasting indicators were also identified as gaps at global and national level.

Conclusions: This review revealed limited information that reflected the low level of adolescent nutrition consideration in Senegalese policies. Therefore, further attention should be paid to the definition of indicators and interventions and a better consideration of gender at national level.

PAB(T9-53)
Trial of simulation-based learning practice for dietetic students using online systems

Takayo Kawakami[1], Sayaka Yamamoto[2], Keisuke Toda[1], Yuko Yoshimoto[3]

1. Okayama Prefectural University (Japan), 2. Graduate School of Health and Welfare Science, Okayama prefectural university (Japan), 3. Graduate School of Life and Environmental Sciences, Kyoto Prefectural University (Japan)

Background and objectives: Simulation-based learning practice has been widely used among health professionals. In this study, we conducted online SP (Simulated Patient) practice on dietitian students using two scenarios with interviews on nutritional needs and a dietary survey for diabetes patients, and examined the problems and effects.

Methods: Twenty-seven third-year students in a 4-year registered dietitian course were enrolled. Students were divided into groups of six or seven persons and into two teams, with one team conducting SP and the other team observing. Before the simulation activity, the facilitator provided information on the case scenario and SP practice lasted approximately 30 minutes, including the simulation activity and debriefing. After the practice, we evaluated students' perceived achievement, whether the scenarios were realistic, ease of conducting interviews with other students, equipment used and reception status through a web survey.

Results: Fifty-two percent of students answered that they had sufficiently achieved their learning goals, and the rest of the students said they had achieved some of their goals. The students who answered that they sufficiently achieved their learning goals were also highly likely to be able to “act like the scenarios were reality” and “interview with other students”, even online. Most students did not have any problems with audio or image quality, and these were not related to achievement of learning goals. Half of the students answered that face-to-face interactions are better for reading emotions from others' facial expressions.

Conclusions: SP practice can be conducted online, but there are some limitations. Therefore, it is effective for communication learning to be performed in combination with face-to-face learning.

The applicability of quantum computers to nutritional problem

Taro Suzuki[1], Hirotaka Yauchi[2]

1. Ryukoku University (Japan), 2. Kio University (Japan)

Background and objectives: Japan is facing a super-aging society, and increasing national medical expenses and extending healthy life expectancy due to an increase in lifestyle-related diseases are urgent issues. In addition, Society 5.0 has been proposed, and although it is in a period of major social change such as the rise of artificial intelligence, there is an urgent need to adapt it to the fields of nutrition and health science. It is enormous to realize the optimal individual medical / nutrition guidance and public health problem policy for each individual corresponding to lifestyle, biometric data, genomic information and disease risk, including automatic menu creation called kitchen informatics and recipe devising. Since it is necessary to handle various data in a complicated manner and conventional computers and statistical methods are insufficient, it is necessary to utilize next-generation computers such as quantum computers, and it is also advantageous in terms of high speed and power saving.

Methods: We tried to nutritionally optimize the simplest snacks in combination. We prepare to build a model that can be used practically with a quantum computer or that optimizes a simple combination of nutritionally appropriate food selection and menu settings on a trial basis. In the quantum computer, Quadratic Unconstrained Binary Optimization corresponding to the Ising model $H = J_{ij} S_i S_j + h_i S_i$ was calculated using Python, D-wave Leap and IBM qiskit.

Results: It is shown that the energy of snacks is expressed as a combination in the following range of vitamin and mineral condition values, such that 200 kcal or less, which is 10 to 15% of the estimated energy requirement for 6 to 7 years old, is appropriate (Lipid energy ratio 30% or less, protein 4.4 g, Ca 76.3 mg, iron 0.86 mg, Vit.B_1, B_2, C 0.1,0.12,7.4mg or more, respectively) in Japan. Foods high in calcium (milk, cheese, pudding, yogurt), foods high in vitamins (fruits, green tea, orange juice) were selected.

Conclusions: Although there are still barriers to practical application, it was suggested that quantum computers could be used for nutritionally appropriate food selection and menu settings. It seems that condition setting, numerous simulations, and development are required.

Keyword: Nutritionally appropriate, Society 5.0, Snacks, Kitchen informatics, Quantum computers

PAB(T9-55)
Exploring input characteristics that influence the development and functioning of a North and 3South Higher Education Institutions (HEIs) partnership: a GROWNUT-2 case study

Silondile Luthuli[1,2], Marguerite Daniel[2]

1. Centre for Rural Health, University of KwaZulu-Natal, Durban (South Africa), 2. University of Bergen (Norway)

Background: Partnerships between countries in the global north and south are crucial for improving global health inequities and achieving the Sustainable Developments Goals (SDGs). North-South partnerships between Higher Education Institutions (HEIs) play an important role in the sharing of skills and resources to improve global health outcomes. However, it is vital to build partnerships that are tailored to the specific needs of south partners to improve sustainability of collaborative projects.

Methods: The GROWNUT-2 partnership aims to develop a cadre of African nutrition scholars and academic leaders to address nutrition disorders and influence nutrition policy in Democratic Republic of Congo (DRC) and Tanzania. Using the Bergen Model of Collaborative Functioning (BMCF), the study formatively evaluates the GROWNUT-2 partnership functioning in developing and implementing a Nutritional Epidemiology curriculum program in (DRC) and Tanzania. The study utilises Participatory Action Research (PAR) methods embedded in qualitative research approach. The study will be conducted in three phases over the three year study period. In this paper we report findings from phase one of the study, where in-depth interviews (IDIs) were conducted with principal investigators, finance administrators, supporting staff, and stakeholders in each site to explore their initial perceptions of the partnership functioning and challenges experienced.

Findings: The participants understood the mission to be building research capacity in DRC and Tanzania through the development of a master's and PhD program based on the nutrition priorities in DRC and Tanzania. Building strong relationships, communication, sharing of resources/expertise, and having a common vision about the project were mentioned by the participants to be important factors in building a successful partnership and achieving the partnership goals. However, finances and financial administration were reported to be a challenge in the functioning of the partnership. The North partner oversees funding allocation to ensure this is aligned to the requirements of the funder, and this creates a hierarchy in decision making between partners.

Conclusion: Phase one of study indicates that the partners are committed to building a successful and sustainable partnership through the input factors mentioned by partners

Development of the advanced education and networking offer *Diätetikforum Fulda* in participation with the target group dietitians

Maren Peuker[1], Nathalie Rothe[1], Kathrin Kohlenberg-Müller[1]

1. Hochschule Fulda – University of Applied Sciences (Germany)

Background and objectives: An involvement in networks can offer an added value for dietitians. The *Diätetikforum Fulda (DF)* is a regional network for advanced education and professional exchange initiated by the transfer project MoDiVe of the Hochschule Fulda – University of Applied Sciences for education and implementation of process guided work. Participation is a central quality criterion which should enable an active integration of the target group and a sustainable constitution beyond the termination of the MoDiVe-project. The research question was: How can the DF be sustainably implemented in participation with the target group dietitians of the region East Hesse – Germany?

Methods: A structured literature research was conducted and an evaluation concept developed. Eight guided interviews with participants of the DF were analysed using the *Qualitative Content Analysis by Mayring*. The achievement of goals so far by the DF was checked with the results of the evaluation. Recommendations for a participative further development of the DF were derived.

Results: The DF is currently the only offer of this type in East Hesse – Germany. Main motives and incentives for attendance are establishing contacts, exchanging experiences and knowledge about process guided work, receiving continuing education credit points and the regional anchoring. The events, especially the topics and the participative mode of operation get largely positive feedback from the interviewees. An exchange of experiences in the events is quite possible but limited to them. In the DF a potential is seen to increase the regional visibility of the occupational field. The majority of the interviewees express willingness to participate actively in the format which can support a sustainable establishment. All interviewees wish for continuity of the DF.

Conclusions: The differentiated evaluation shows that the DF has already achieved positive results. The current concept of the format has proven itself. The following recommendations are made for a participatory further development of the DF: Expand networking and exchange of experiences of regional dietitians, 1158rganize and carry out feedback loops, secure the results of discussion and use them for further strategies, continue regular evaluations, plan consolidation and create sustainable structures, become more visible through public relation activities.

Survey on the Use of Health Supplement in Malaysia

Yasuko Sannomaru[1], Sanae Yamada[1], Masahiro Wada[1], Akira Terao[2]

1. Josai University (Japan), 2. Sanyo-Onoda City University (Japan)

Background and objectives: Demand for health foods expected to increase as the aging society in the World. However, it is considered that the demand and distribution of health foods differ depending on the social background, such as ethnicity and religion, and lifestyle of each country. In this study, a survey was conducted in Malaysia, a multi-ethnic and multi-religious country, to clarify the relationship between the use of health foods (Health Supplement in Malaysia:HS) and ethnicity/religion. <

Methods: In July 2018, online survey was conducted for Malaysian (Rakuten Co,,Ltd, Japan). The subjects were 300 people aged 20 to 70 (150 men and 150 women). The contents of the survey consisted of attributes (ethnicity, religion, occupation, residence type and etc.), HS (image, health claim, approval agency, Halal labeling, use or non-use, purpose of intake, type, frequency and etc.), and lifestyle habits (dietary intake, exercise, sleep and etc.). All data was analyzed using IBM SPSS, Ver.27.0.

Results: There was a significant relation between ethnicity and religion, with Malays being Muslims, Chinese being Buddhists, and Indians being Hindus. There were no characteristic differences in HS usage among lifestyle, ethnicity and religion. However, Halal logo in HS had been checked by many Malays and Muslims. Approximately 60% of all subjects were currently using HS and 36% had previously. The main purpose of HS was health promotion. The HS mainly used was vitamins and minerals, but the traditional Malaysian health foods was also used. Dispensing pharmacies were the most popular purchase method. About 75% knew the legal definition of HS (Ministry of Health, Malaysia). The most required level of HS claims was 'health promotion'. The national/governmental bodies were considered suitable as HS certification bodies.

Conclusions: There was no significant difference between Malaysian ethnic groups (Malays, Chinese, Indians) and HS use and lifestyle habits. It was revealed that Malays and Muslims believe that HS should have a Halal logo and that they confirm this at the time of purchase.

Keyword: Health Supplement, Malaysia, Halal logo

PAB(T9-59)
Comparison of the policies on dietary supplements among the USA, China, and South Korea

Linxi Huang[1], Hye-Jong Yoo[1], HyunJeong Park[1], Woojin Byeon[1]

1. Seoul National University (Korea)

Background and objectives: As interest in and demand for dietary supplements have increased worldwide, many countries are developing policies to regulate them. This study aimed to compare the policies on dietary supplements in the USA, China, and South Korea.

Methods: The data was collected from the websites of government agencies in each country. We compared the terms, definitions, and policies of dietary supplements and the institutions establishing and implementing policies on dietary supplements among these three countries.

Results: The terminology for dietary supplements varies slightly among the three countries: 'dietary supplement' in the USA, 'health food' in China, and 'health functional food' in South Korea. Nevertheless, they are all defined as foods that are beneficial to health. In the USA and South Korea, it is the food and drug government agencies that administrate policies on dietary supplements, while the State Administration for Market Regulation assumes this role in China. There is no approval for pre-marketing dietary supplements in the USA, hence the word "dietary supplement" is usually displayed on the products. In contrast, China and South Korea allow the "health food" or "health functional food" mark to be attached on the products only if they are approved by government agencies. Because the USA has no singular official standards regarding ingredient management, a set procedure is required only when a new dietary ingredient (NDI) is used for a dietary supplement. 87 types of ingredients are subject to the Chinese registration system for dietary supplements. Korean functional raw materials are managed separately from publicly announced raw materials (96 types) and individually recognized raw materials (33 types). China indicates the suitable group in addition to the basic product information on the label, while the other two nations indicate the allergy ingredients. These three countries all implement laws and regulations such as ingredients, labeling, good manufacturing practice (GMP), and guides for dietary supplements in common.

Conclusions: Despite the above differences in the policies on dietary supplements, the USA, China, and South Korea all actively implement them. Considering such national differences may be helpful in benchmarking for future promotion in the field for dietary supplement policies.

Keyword: Dietary supplements, Functional food, Policy, Regulation, South Korea

Body composition measurement and risk factors for Non-Communicable Diseases (NCDs) among migrant workers in Chiangmai, Northern Thailand

Yoshihisa Shirayama[1], Thin Nyein Nyein Aung[2], Saiyud Moolphate[3], Thaworn Lorga[4], Warunyou Jamnongprasatporn[5], Myo Nyein Aung[1], Motoyuki Yuasa[1]

1. Juntendo University (Japan), 2. Chiang Mai University (Thailand), 3. Chiang Mai Rajabhat University (Thailand), 4. Mae Fah Luang University (Thailand), 5. Provincial Health Office, Chiang Mai (Thailand)

Introduction: Quite a few migrant workers from Myanmar reside and work in Northern Thailand, especially Chiang Mai. A cross-sectional face-to-face interview survey was conducted to measure their body composition and study potential risk factors for Non-Communicable Diseases (NCDs).

Methods: With written informed consent, we recruited study participants in December 2017. Based on WPRO WHO guidelines, Body Mass Index (BMI) was categorized into three groups: normal, overweight, and obese. Central obesity was determined by using WHO cutoff points for sex specific waist and hip ratio. Using a questionnaire, trained interviewers who were able to speak the languages of study participants (Thai, Myanmar, and Shan languages) collected information regarding risk factors.

Results: The mean age of the respondents (n=414) was 29.5+-9.0. 231(55.8%) were male and 183 (44.2%) were female. The average length of years of stay in Thailand was 6.36 +-5.70. Based on BMI, 16.4% were overweight and 4.3% were obese. 25.8% were found with central obesity. Four (1.0%) reported that they were diabetic, while 18 (4.3%) never got tested. Regarding the health risk behaviors, 75.8% had no habit of regular exercise, 26.3% were currently smokers. 40.8% drink alcohol, and 68% did not have enough sleeping hours. 310 (74.9%) reported 7 days (everyday) to the question asking how many days in the last week they ate vegetable.

Discussion: As high prevalence of hypertension (27.8%) was observed from the same study group (reported elsewhere), our body composition measurement showed that over 20% of the study participants were overweight/obese. Body composition measurement is important to detect hypertension and other NCDs. Overweight and obesity levels in Thailand have been steadily increasing over the years. Thailand came second after Malaysia in the ranking of obesity in the ASEAN region. Appropriate intime health/nutrition education intervention is necessary to control the rise of NCDs among migrating valuable populations in the region.

Keyword: Body Mass Index(BMI), Non-Communicable Diseases (NCDs), Myanmar migrant workers

PAB(T9-61)
Analysis of non-communicable diseases policies, and implementation in Nigeria

Mary Oyeronke Oyewole[1], Gideon Onyedikachi Iheme[2]

1. Texas Tech University, Lubbock, Texas, USA. (USA), 2. Michael Okpara University of Agriculture Umudike, Abia state. (Nigeria)

Background: Despite efforts by the Nigerian government to develop and adopt policies to reduce the burden of non-communicable diseases (NCD) and their mortality. 29% of all death in 2019 was attributed to NCD and this has consistently increased over the years in Nigeria.

Objective: This paper appraises government efforts in formulating, implementing policies and programs that will reduce the burden of non-communicable diseases in Nigeria.

Methods: A descriptive desk review design to analyze national and state policies on non-communicable diseases prevention and management. Policy search was done using scoping review of electronic search of Google and online databases (Google Scholar, Science Direct, and PubMed) to identify articles and policy documents with no date restrictions. Public documents, reports, or articles relevant to policy formulation and implementation were identified. Appropriate findings from all the articles were reviewed systematically.

Results: Our findings revealed that the Nigerian government and relevant stakeholders have adopted credible national policies and plans of action to curb NCD risk factors. Although, there is no decentralization for states' policy implementation. Bans on the promotion of tobacco use, increased excised tax on alcohol, sugar tax, food label regulation, breast milk substitutes marketing restrictions are implemented. However, these policies have not been fully implemented within the country; there has been a paucity of awareness to sensitize people to adopt a healthy diet and lifestyle, guidelines for prevention and management of NCD are not implemented. Nigeria is not on track for achieving NCD targets and indicators for UN Sustainable Development Goals to reduce one-third premature NCD deaths by 2030.

Conclusion: The use of sustainable policy implementation strategies may likely contribute to a reduction of the burden of non-communicable diseases. We recommend strict compliance monitoring and accountability for ongoing programs in Nigeria. Simultaneously, routine screening for NCD risk factors to identify people at high risk for early management to curb NCD premature deaths

Non-communicable diseases in Morocco: results from World Health Organization STEPS survey

Hicham El Berri[1], Latifa Belakhel[2], Fatima Zahra El Mouzouni[2], Samir Mounach[2], Naima Saeid[1], Hasnae Benkirane[1], Noureddine El Haloui[1], Kaoutar Benjeddou[1], Khalid El Kari[1], Hassan Aguenaou[1]

1. Ibn Tofail 3Ibn Tofaïl University-CNESTEN, Joint Research Unit in Nutrition, Health and Environment, RDC-Nutrition AFRA/IAEA, Laboratory Biology and Health, Rabat-Kénitra, Morocco;University (Morocco), 2. Ministry of Health, Morocco (Morocco)

Background and objectives: Noncommunicable diseases (NCDs) are the leading cause of death across the world. In 2016, they were the cause of 40 million deaths. In this blackboard, we find the deaths from cardiovascular diseases (CVD), with a share of 50% in the total deaths (WHO, 2019). The prevalence of this type of pathology is explained by sedentary lifestyles and the main risk factors, such as hypertension, diabetes and obesity. The aim of this survey is to determine the prevalence of common risk factors for NCDs in adults. **Methods**: We used the STEPwise approach of the World Health Organization (WHO) through a questionnaire, physical and biochemical measurements. The survey pooled data from 5,429 people. **Results**: overall, the incidence of overweight and obesity was higher in women (34.4% and 29%) than in men (31.6% and 11%) respectively, more pronounced in urban areas (34.7 % and 22.8%) than in rural areas (29.8% and 14.9%). For high blood pressure, the values were almost identical between women (29.8%) and men (28.7%) whether in rural (29.9%) or urban (29%). For diabetes, there was a prevalence of 12.6% for women, 8.6% for men and a higher incidence in urban areas (12.1% against 8% in rural areas). **Conclusion**: This survey will update data on NCDs risk factors in Morocco, given that the most recent values are 17 years old. Thus, we will be able to update, adapt and improve the various strategies put in place by the WHO and the Ministry of Health.

Peri-conceptional diet and the risk of gestational diabetes mellitus in South Indian women – findings from the BAngalore Nutrition Gestational diabetes LiFEstyle Study (BANGLES)

Anvesha Mahendra[1,2], Sarah Helen Kehoe[1], Kalyanaraman Kumaran[2,1], Krishnaveni GV[2], Nalini Arun, Caroline HD Fall[1]

1. MRC Lifecourse Epidemiology Centre, University of Southampton (UK), 2. Epidemiology Research Unit, CSI Holdsworth Memorial Hospital (India)

Background and objectives: Gestational diabetes mellitus (GDM) affects 20% of Indian pregnancies[1]. Diet may be important to prevent GDM[2], but data from India is sparse. BANGLES investigated the associations between women's 'peri-conceptional diet' and GDM risk. **Methods**: BANGLES was a prospective observational study (n=785), in which women of various socioeconomic-status were recruited at 5-16 weeks' gestation. Peri-conceptional diet was recalled at recruitment, using a validated 224-item Food Frequency Questionnaire, that was reduced to 21 food-groups for the food-group-GDM analysis, and 68 food-groups for the principal component analysis (PCA) for a diet pattern-GDM analysis. Diet-GDM associations were examined using multivariate logistic regression, adjusting for '*a priori*' confounders determined from the literature. GDM was assessed by a 75-gram Oral Glucose Tolerance Test at 24-28 weeks' gestation, applying WHO 2013 criteria. **Results**: Women who consumed: whole-grain cereals (aOR: 0.58, p=0.03), moderate egg (>1-3 times per week) compared to < 1/ week (aOR: 0.54, p=0.01) and a higher weekly intake of pulses and legumes (aOR: 0.81, p=0.03), nuts and seeds (aOR: 0.77, p=0.01) and fried and fast food (aOR: 0.72, p=0.002) had a lower GDM risk. None of these associations were significant (p< 0.05) after correction for multiple-testing. Using PCA we identified 3 diet patterns: a) High-diversity, urban (HDU) characterised by diverse, home-cooked and processed foods was associated with older, affluent-educated-urban women; b) Rice-fried snacks-chicken-sweets (RFCS), characterised by low diet-diversity, was associated with younger, less-educated, and lower income-rural-joint families; c) Healthy, traditional vegetarian (HTV), characterised by home-cooked-vegetarian and non-processed foods was associated with less-educated and affluent-rural-joint families. The HDU pattern was associated with a lower GDM risk (aOR: 0.80, 95% CI: 0.64, 0.99, p=0.04). BMI possibly mediated diet-GDM associations. **Conclusions**: The same food-groups that were associated with a lower GDM risk were components of the HDU pattern. The findings suggest that one 'healthy' diet pattern may not be relevant to India[3]. They support global recommendations to encourage women to attain a healthy pre-pregnancy BMI [4] and increase diet-diversity [5] & [6] to prevent GDM. Findings support evidence for national policies to increase the affordability of wholegrains, fruits and vegetables to achieve diet-diversity[5].

Home blood pressure monitoring and its associated factors among hypertensive patients in 3 counties of Guizhou Province

Yi Liang[1], Danqing Zhao[1]

1. Affiliated Hospital of Guizhou Medical University (China)

Background and objectives: The study determined the status and factors associated with hypertensive patients' use of home blood-pressure monitoring (HBPM) in primary care in Guizhou Province China.

Methods: Randomized crosssectional questionnaire survey of hypertensive patients managed in Renhuai City, Yuping County and Fenggang County of Guizhou Province. The study was conducted 2230 hypertensive patients.

Results: The proportion of HBPM was 32.8%. The results of logistic regression analysis showed that hypertensive patients with following characteristics were more likely to have HBPM behaviors: Living in a city or town (OR=1.747, 95% CI: 1.326-2.302), Han ethnicity (1.709, 1.345-2.172), family history of hypertension (1.461, 1.193-1.790), junior high school education or above (1.361, 1.048-1.766), central obesity (1.320, 1.046-1.666), married (1.277, 1.011-1.613).

Conclusions: Family history, Han nationality, urban residents, central obesity, married and higher educational level are related to the use of HBPM.

Comparative laboratory validation of blood sampling methods and analytical devices in the measurement of hemoglobin in population surveys

Laura S. Hackl[1], Kidola Jeremiah[2], Crystal Karakochuk[3], Dora I. Mazariegos[4], Omar Obeid[5], Tolulope Oginni[6], Desalegn A. Ayana[7], Omar Dary[2,8], Silvia Alayón[1], Denish Moorthy[1]

1. USAID Advancing Nutrition (USA), 2. Mwanza Medical Research Centre, National Institute for Medical Research (Tanzania), 3. University of British Columbia (Canada), 4. Instituto de Nutrición de Centroamérica y Panamá (Guatemala), 5. American University of Beirut (Lebanon), 6. eHealth Nigeria (Nigeria), 7. Haramaya University (Ethiopia), 8. USAID (USA)

Background and objectives: Using different hemoglobin [Hb] assessment methodologies in population-based surveys has resulted in differences in anemia prevalence estimates and led to uncertainty among policymakers on best practices for reducing anemia. The aim of this laboratory-based multi-site comparative cohort study is to identify the most appropriate procedures and methods for Hb assessment in population surveys. The mode of blood collection (venous versus capillary, and the latter pooled or a drop) and other factors can influence the accuracy and precision of Hb measurements.

Methods: This study is being conducted in Cambodia, Ethiopia, Guatemala, Lebanon, Nigeria, and Tanzania. Each study site will include up to four cohorts of apparently healthy participants (women 15–49 years of age and children 12–59 months of age). Each cohort will be recruited to resolve one aspect related to Hb concentration measurement using venous and capillary blood samples via three different HemoCue® device models (201+, 301, 801) and a certified autoanalyzer. One cohort will provide a single venous and a pooled capillary blood sample to compare the accuracy of venous Hb measurements between autoanalyzer and HemoCue models, and between venous and pooled samples on all devices. Other cohorts will provide a single venous and a single-drop capillary blood sample to compare results of venous Hb measurements between an autoanalyzer and one of the three HemoCue models and also between venous and single-drop samples for the three devices. We will evaluate each device in a separate cohort to decrease participant burden by conducting only one fingerprick per participant.

Results: Data collection in all six study sites will be completed by June 2022. For the pooled sample and for each site, we will estimate concordance and correlation coefficients by comparing HemoCue Hb concentrations from different types of blood samples to a venous blood sample from the same individual measured via autoanalyzer. Agreement and bias among the methods will also be evaluated. Across study sites, we will compare results from similar cohorts to assess inter-site variability.

Conclusions: Results will provide insight into the reliability of different blood samples and analytical devices for Hb determination in population surveys.

Understanding the association between low-dense nutrition food and mental disorders: a systematic review

Ervine Chastine Marind[1], Fatimah Syakura[1], Nya' Jeumpa Madani[1], Salma Luthfiyah Sani[1]

1. University of Indonesia (Indonesia)

Background and objective: With the rising global prevalence of mental disorder, the urgency to seek its further risk factors become more apparent. This research reviews existing articles to identify evidence of the association between mental disorders with low-dense nutrition food intake.

Methods: A systematic search was conducted on four online databases including JSTOR, Cambridge Core, Scopus, and ProQuest. 484 articles from the initial search were further reviewed referring to the inclusion and exclusion criteria until 10 eligible final articles obtained. The final articles consist of selected study design of cohort, case control, or intervention studies. There were variations in age group settings and the operational definition of low-dense nutrition food in the final articles which are going to be discussed further.

Results: Literatures analysed showed different correlation between the two variables. 8 studies showed positive correlation between low-dense nutrition food intake and the risk of mental disorders (depression, anxiety, and ADHD). In contrast, the other 2 studies showed insignificant correlation between intake of low dense nutrition food and the onset of mental health disorder, specifically to sugar sweetened beverages consumption.

Conclusions: This systematic review shows that there is a strong relationship between low-dense nutrition food intake and the risk of mental disorders. The understanding arises on the basis that this review only include research with study design that can indicates causal effect relation between its variables. Further research upon similar topics with an abundant resource of database is encouraged to be conducted in order to gain deeper and broader comprehension.

Analysis of an effective combination of multisectoral interventions for stunted children

Marika Nomura[1,2], Shunichi Nakada[1,3], Yo Oshi[4], Yukio Ikeda[4]

1. Japan International Cooperation Agency (JICA) (Japan), 2. National Institutes of Biomedical Innovation, Health and Nutrition (Japan), 3. The University of Tokyo (Japan), 4. Kaihatsu Management Consulting, Inc. (Japan)

Background and objectives: Without especially addressing the first 1,000 days, healthy development and growth of children, and sustainable economic activity are not possible. While both nutrition-specific and nutrition-sensitive interventions are needed to eliminate maternal and child undernutrition, there is insufficient evidence on how to combine them effectively. This study aims to examine which combination of multisectoral interventions effectively reduces stunted children under 23 months of age.

Methods: Individual data from 17 African and 7 Asian countries in the Demographic and Health Surveys (DHS) program were pooled in a cross-sectional dataset. A regression analysis was then conducted where the prevalence of stunting of children under 23 months of age is the objective variable, and the indicators of interventions in health (e.g., ANC attendance), food (e.g., Minimum Acceptable Diet), and WASH (e.g., access to improved water) sectors are explanatory variables. R version 3.6.2 was used for the analysis. ~

Results: Of the total sample of 56,406 children under 23 months of age, only 2% received services from all the three sectors of health, food, and WASH, indicating that few children benefit from multisectoral interventions. Results of the cross-sectional analysis show that the interventions of food only, WASH only, and combination of the interventions of these sectors are not significant for the reduction of stunting. However, when the intervention of one of these sectors is combined with that of health, the reduction is significant. Furthermore, the absolute value of the coefficient increased as the number of intervention sectors increased. This trend was the same for the African and Asian countries, and all countries.

Conclusions: The results suggest that multisectoral interventions to reduce stunting are more effective as the number of sectors increases, and that a combination with health sectors is effective.

Current status of HACCP-based food hygiene control implementation in Viet Nam hospital kitchens

Hang Thi Thu Dang[1,2], Yasutake Tomata[2], Yuuka Mukai[2], Huong Thi Le[1,3]

1. National Cancer hospital (Viet Nam), 2. Graduate Course of Health and Social Services, Kanagawa University of Human Services Graduate School (Japan), 3. School of Preventive Medicine and Public Health, Ha Noi Medical University (Viet Nam)

Background and objectives: Hospital meal should promote nutrition care management and quality of life among inpatients. Although the HACCP-based food hygiene control in hospital is necessary to ensure safe food service, it has been unclear whether Vietnamese hospital kitchens properly apply that. This study aimed to describe the current status of HACCP-based food hygiene control in Vietnamese hospital kitchens, and to identify major food processing hazards to prevent foodborne diseases caused by patient meals.

Methods: A self-administered survey was conducted across 17 hospitals of grade II and above in major cities, Ha Noi, Ho Chi Minh and Quang Ninh province in Viet Nam, via the Internet. The questionnaire comprised three main sections; 1) Attributes of the facility (20 items), 2) Compliance status of food hygiene control (70 items), 3) Attribute of respondents (3 items). Responses are scored on a Likert scale ranging from none (0) to excellent (3). The Chi-squared test, Spearman's correlation analysis, analysis of variance, and the Kruskal–Wallis test was used to compare characteristics.

Results: The present analysis included 14 hospitals and showed that some questions relating to temperature, hand washing, hand sanitizing, and cutting boards, the average scores were lower than “Acceptable” (i.e. < 2 points). The majority of low-score questions on food hygiene control were related to microbiological hazards. The total number of kitchen staff was positively correlated with the questions about pollutants in the kitchen, patient meal time, and cooked food temperature. A positive correlation was found between the patient meal service time and the question about the cooking process. There was no statistically significant correlation between the number of dietitians and the food hygiene control questions.

Conclusions: The present findings implied that the current status of HACCP-based food hygiene control in some Vietnamese hospital kitchens is partially inappropriate. The nutrition department should pay more attention to critical control points, such as cooking time and temperature. Human resources may play important roles in kitchen hygiene.

Keyword: HACCP, food hygiene control, Vietnamese hospital kitchen

PAB(T9-69)
UK Dietitians' understanding of the nutrition and health properties of mycoprotein: findings from a survey.

Holly J. Roper[1], Emma Lanza[2], Jo Lewis[2], Hannan E. Theobald[1], I. Tess Kelly[1]

1. Marlow Foods Ltd, Stokesley (UK), 2. British Dietetic Association, Birmingham (UK)

Background and objectives: Mycoprotein is a protein derived from the fermentation of filamentous fungi, e.g. Fusarium venenatum. Foods derived from mycoprotein have been available to consumers since the 1980s (e.g. Quorn, 1985). Mycoprotein is well-documented as being a source of protein, fibre and micronutrients, and of having a low environmental impact. Human research has demonstrated that mycoprotein can support skeletal muscle protein anabolism in both young and older adults. Additionally, mycoprotein consumption has been shown to lower total and LDL cholesterol concentrations and improve acute postprandial glycemic control in humans.

Methods: To assess dietitians understanding of both the nutritional and health properties of mycoprotein consumption, all dietitians who are members of the British Dietetic Association (BDA) were invited to participate in an online survey (Google Forms, Menlo Park, California) via e-mail between 25th November and 18th December 2021. The survey assessed understanding of mycoprotein as part of a larger multiple-choice survey, which aimed to identify views on various public health issues. In total, four questions specifically focused on this mycoprotein benefits.

Results: A total of 188 responses were received. Respondents worked in a wide variety of specialties including 23.9% (n=45) in weight management, 18.6% (n=35) in parenteral nutrition and 16.5% (n=35) in diabetes. A total of 96.3% (n=181) of dietitians had heard of mycoprotein and 60.1% (n=113) were able to correctly identify mycoprotein as a source of protein; 69.7% (n=131) identified fibre and 81.4% (n=153) identified that mycoprotein is low in saturated fat. 54.8% (n=103) also correctly identified mycoprotein as a source of some micronutrients. When asked about clinical benefits, 43.6% (n=82) were aware of cholesterol-lowering effects; 26.6% (n=50) were familiar with the satiety effect following ingestion, and the effects on glycaemia, while 16.5% (n=31) equally were aware of protein anabolism effects, and gut health benefits.

Conclusions: We have identified knowledge gaps and misunderstandings of the nutrition and health properties of mycoprotein amongst UK dietitians. This demonstrates that there is a need to educate UK healthcare professionals about the benefits of mycoprotein in healthy, sustainable diets. These findings are likely to hold true in additional countries where mycoprotein is available.

PAB(T9-70)
Survey of local residents' attitudes toward accepting Muslims in evacuation centers during disasters

Ayaka Yazawa[1]

1. Osaka Metropolitan University (Japan)

Background and objectives: In recent years, the number of Muslims has been increasing worldwide. In Japan, Muslims constitute a minority. On the other hand, the number of Muslim tourists visiting Japan is increasing. Muslims live according to Islamic precepts that prohibit the eating of pork (including its derivatives) and the drinking of alcohol. In the event of a disaster, Muslims may also take shelter in evacuation centers and may live in shelters with local residents. Therefore, this study investigated residents' attitudes toward accepting Muslim travelers at evacuation centers.

Methods: A total of 914 non-Muslim Japanese individuals (451 males and 463 females) were surveyed online. The average age of those surveyed was 44.9 years old. The study questionnaire asked respondents what they thought about accepting Muslim travelers at evacuation centers in the event of a disaster. The study was conducted after receiving research ethics approval.

Results: Regarding the acceptance of Muslims in evacuation centers during disasters, 64.9% of those surveyed answered that they “do not particularly care” or “do not mind if there is a system in place to accept them.” On the other hand, 23.1% indicated that while they would be willing to accept them, they were concerned about possible problems. Meanwhile, 11.6% did not want to accept them. Additionally, when asked if Halal food could be served in shelters on par with special meals for people with allergies or illnesses, 30.7% answered “unacceptable” or “not very acceptable.” Meanwhile, 68.9% responded that they “accept it because of religious reasons” or “do not have any particular concern.”

Conclusions: Most participants had a positive view of accepting Muslim travelers in shelters. However, participants raised some concerns about possible troubles and some negative views, suggesting that consideration for both residents and Muslims is necessary when accepting Muslim travelers in shelters.

In-Field Survey of Energy Expenditure during Disaster Activity Emergency Fire-Fighter Support Team Training Utilizing a Tri-axial Accelerometer and Wearable Heart Rate Monitor

Nao Koizumi[1]*, Hitomi Ogata*[2]*, Yutaro Negishi*[1]*, Hisashi Nagayama*[1]*, Miki Kaneko*[3]*, Ken Kiyono*[3]*, Naomi Omi*[1]

1. Graduate School of Comprehensive Human Sciences, University of Tsukuba (Japan), 2. Hiroshima Univrsity (Japan), 3. Osaka University (Japan)

Background: An accurate estimation of energy expenditure is crucial for planning disaster relief and rescue operation as an expedition team, because they need to prepare and transport their own food supplies in advance. However, the energy expenditure of such operation remains unclear.

Objectives: Large-scale disaster response activities were sampled using tri-axis accelerometers and wearable heart rate monitors for activity training that is closer to actual activities in order to examine how much energy expenditure is there for emergency fire support personnel involved in disaster response activities clarifying the amount of energy expenditure for each of the activities.

Methods: We targeted 30 members who participated in the emergency firefighting support team Kanto Block joint training, which is one of the activity trainings that are considered to be the closest to the actual disaster response activities. Energy expenditure for each activity was examined by combining the accelerometer (AC) method and the heart rate monitor (HR) method, attained every hour. Since the survey subjects are expected to wear numerous equipment's and bend down to enter narrow spaces, they used wearable devices that are less invasive and easily portable.

Results: Energy expenditure was measured from 28 firefighters excluding two defective equipment's. The total energy expenditure (TEE) was determined to be about 4840 kcal. In addition, energy expenditure per hour (excluding resting energy expenditure: REE) (per average body weight of participants) was calculated for 10 types of large-scale disaster response activities. The energy expenditure of rescue from a narrow space was about 240 kcal, rescue from the traffic was about 260 kcal, transport of the victim was about 260 kcal, rescue search was about 270 kcal, fire-fighting was about 280 kcal, gas leak accident was about 320 kcal, rescue from sediment was about 340 kcal, rescue from tunnel accident was about 340 kcal, and rescue from high-rise buildings was about 410 kcal.

Comparison of Nutrient Analysis Values in Dishes Prepared by Cook-Serve and Cook-Chill Systems -For fish meuniere, pumpkin with mayonnaise, and sauteed beef-

Tomoko Koda[1], Natsuki Ashizawa[2], Tadashi Akao[3], Takako Takahashi[4], Akiko Kuwabara[5], Jun Uda[6], Yoko Ichikawa[7]

1. Doshisha Women's College of Liberal Arts (Japan), 2. Social welfare corporation Ichihara-ryo (Japan), 3. Osaka Shoin Women's University (Japan), 4. Osaka City University (Japan), 5. Osaka Prefecture University (Japan), 6. Graduate School of Health Care Sciences, Jikei Institute (Japan), 7. University of Shizuoka (Japan)

Background and objectives: This study was conducted at elderly care facilities that have a central kitchen and supply meals to Facility A and Facility B. Facility A is situated next to the central kitchen and meals are cooked and served on the same day using the cook-serve system, while Facility B uses the cook-chill system in which food delivered from the central kitchen is served after 4-5 days of cooking. As the cook-chill system includes a chilling process after cooking and reheating, the nutritional value of the food may be different compared to the cook-serve system. The purpose of this study was to compare the nutrient analysis values of dishes served at elderly care facilities using the cook-serve system and the cook-chill system, and to examine the degree to which the nutrient components of dishes prepared using the cook-chill system are retained compared to the cook-serve system.

Methods: The eligible dishes were "fish meuniere" (one main ingredient that required reheating), "pumpkin with mayonnaise" (one main ingredient that did not require reheating), and "sauteed beef" (meat and vegetables as main ingredients that required reheating), all of which were served at elderly care facilities. The nutritional analysis of the food was carried out by Japan Food Research Laboratories. The t-test was used to compare the nutrient analysis values of the two groups.

Results: Under the conditions of this study, there were no significant differences between the nutrient analysis values of fish meuniere and pumpkin with mayonnaise prepared using the cook-serve and cook-chill systems. It was considered that the same nutrients were retained in the cook-chill system. In contrast, for sauteed beef, the nutrient analysis values of water-soluble vitamins (vitamins B_1 and C) in the Cook-chill system were about 70%, and those of iron, β-carotene, and vitamin B_2 in the Cook-serve system were about 80-90%.

Conclusions: When operating with cook-chill, it is necessary to consider the cooking method and the degree of loss due to reheating.

Keyword: nutrient analysis value, cook-chill system, cook-serve system

PAB(T9-73)

Influence of the name of the green tea production area as auditory information on taste perception

Haruki Ishikawa[1], Motoki Yamada[1], Daichi Yuki[1], Ayano Kondo[1], Humi Hoshino[1], Hiromi Inaba[1]

1. Niigata University of Health and Welfare (Japan)

Background and objectives: It has been reported that the taste of food perceived by humans varies depending on whether or not a brand logo is present. As a result, the purpose of this study was to examine whether taste perception varies depending on the presence or absence of a brand in the auditory approach, one of the five human senses.

Methods: The subjects were 39 healthy females who were approached and consented to participate in a "Preference survey of green tea under development by a company and green tea produced in Shizuoka Prefecture." Shizuoka Prefecture is well-known in Japan for its green tea, which is widely regarded as delicious. The subjects were not informed of the study's purpose. For a total of four trials, two types of green tea, one under development and one from Shizuoka Prefecture, were presented under visual and auditory conditions. The beverage used in all four trials was 15 ml of commercial green tea from Shizuoka Prefecture. Sweetness, strength, and deliciousness were evaluated using the 100 mm Visual Analog Scale. R ver. 4.0.2.Software was used, and repeated analysis of variance was conducted.

Results: In terms of taste, green tea under development in the auditory condition was 65.21 ± 18.22 (mean ± SD) and Shizuoka green tea in the auditory condition was 69.26 ± 16.87. No significant differences were observed between these two conditions. However, there was a significant difference in the visual condition between green tea under development and Shizuoka green tea ($p < 0.05$), indicating that the same beverage tasted better when presented as Shizuoka green tea rather than green tea under development only in the visual condition.

Conclusions: This study suggests that visual information has a higher perception ratio by the five senses than auditory information. Since it is easier to make an impression with visual information, the green tea appears to be delicious. Thus, it is necessary to examine which regions are generally associated with the image of tasty green tea in the questionnaire since these regions vary depending on the food consciousness of each individual.

PAB(T9-74)
Implementation of the use of iodized salt in processed foods in the Philippines: where are we now?

Nikka Marie Villa Oliver[1], Cherry Maramag[1], Mary Christine Castro[1], Karen Codling[2], Jacky Knowles[2]

1. Nutrition Center of the Philippines (Philippines), 2. Iodine Global Network (Canada)

Background and objectives: In the Philippines, food manufacturers are required by law to use iodized salt unless this results in adverse organoleptic effects on the product. Processed foods reportedly make up a fifth of total household food consumption. Based on estimated intake, foods such as bread, instant noodles, soy sauce, and canned sardines, could contribute 8-10% of the adult Recommended Nutrient Intake for iodine if produced using iodized salt. Understanding the contribution of processed foods to population iodine intake will help guide related iodized salt policies. We aimed to review the status and identify gaps in implementation and monitoring of the use of iodized salt in processed foods.

Methods: Desk review of documents related to the Philippines' salt iodization program and interviews regarding experiences and recommendations of stakeholders from government agencies, development partners, salt and food industries were conducted. All interview proceedings were processed using NVivo software.

Results: The Philippines has a policy requiring domestic food manufacturers to use iodized salt in packaged processed food products and declare it on the ingredients list, however, it does not specify the inclusion of imported processed foods. Unregistered domestic food manufacturers remain unregulated and unmonitored, while data on compliance of registered food manufacturers are not available. Monitoring the use of iodized salt among food manufacturers is not regularly conducted therefore compliance is dependent on internal quality control (QC).

Conclusion: Policies on the use and regulation of iodized salt in processed food products by domestic manufacturers, whether registered or not, should be revisited and strengthened. At minimum, there should be a system for reporting internal QC outcomes. Inclusion of imported packaged food products in the policy should be explored.

Keyword: Iodized salt, processed foods, quality control, imported food, policy

Development of “Mitate meat “ ,a product that utilizes local soybeans, and development for regional revitalization

Yuka Mukouda[1]

1. HBG Junior college (Japan)

Background and objectives: the global movement of meatless, the use of soybean products is required. I had conducted the eating frequency investigation of the soybean product for the general consumer, and the consciousness investigation for the substitute meat. I had also run a vegan restaurant. I cooperated with the regional revitalization volunteer in the Akitakata City in Hiroshima Prefecture, and advanced this research. Using soybeans, a food resource of Akitakata City, the goal was to engage in regional revitalization activities aimed at the sixth industry.

Methods: The first meeting was held in October 2021 to confirm the purpose and product delivery method. And in December 2021, a draft recipe was prepared. In January 2022, we held our first tasting party to examine the recipes. The second tasting party was held in February 2022, and we exchanged opinions with the workshop. From March to April, we will further brush up on the recipes and shoot promotional photos and promotional videos.

Results: Based on the survey results on soybean products, we added the viewpoint that it is a product that does't contain additives as much as possible, and that it lasts for a long time. Koya-tofu and boiled soybeans last a long time, but they take time and effort to cook. Therefore, in order to realize convenience and deliciousness, this product "Mitate meat" was decided to be sold as frozen food, and rather than positioning it as an alternative meat, it was a product strategy that could be selected as a new soybean product. In addition, we selected the Human Worker's Work Center, a welfare facility for persons with disabilities in Akitakata City, as a factory to be commissioned.

Conclusions: Although it is an alternative meat market that is expanding, it is necessary to lead to food safety and regional contribution. I think that this research helps to solve the negative part for the alternative meat. As one of the SDGs initiatives, we would like to make research to promote local production and sixth industrialization. In the future, a pop-up store will be launched.

Research on water hardness in soft water areas suitable for Japanese food

Kaoru Sakamoto[1,2], Saeko Morii[1,2], Kaoru Kitayama[1], Yuriko Ishii[1], Nami Arakaki[1], Soma Takeda[1], Yui Sueyoshi[1], Wakana Tada[1]

1. University of Hyogo (Japan), 2. Research Institute for Food and Nutritional Sciences (Japan)

Background and objectives: Japanese food has been cultivated in Japan, where a lot of soft water is available. It is known that soft water is suitable for cooking Japanese food, but what level of softness is suitable has not been studied. Therefore, we conducted research to clarify the hardness of water in the soft water area, which is optimal for Japanese food.

Methods: Calcium sulfate and magnesium sulfate, food additives, were dissolved in RO water having a hardness of 0 mg / L to prepare water having a hardness of 0, 30, 60 and 120 mg / L. The ratio of calcium to magnesium was set to 2: 1 according to the recommended amount of Japanese dietary intake standards. Using these water, cooked rice, kelp soup stock, dried bonito stock, and simmered dishes were cooked. Then, the hardness of water suitable for Japanese food was examined by measuring the taste component, texture, and sensory evaluation.

Results: Rice cooked in water with a hardness of 60 and 120 mg / L had higher amount of reducing sugar. Rice cooked in water with a hardness of 30, 60 mg / L had higher amount of amino acids. The result of the sensory evaluation was that rice cooked in water with a hardness of 60 mg / L was more preferred. More amino acids and sugars were found in the kelp and dried bonito broth extracted with water with a hardness of 0 and 30 mg / L. Since the simmered food contains minerals included in the food itself and seasonings, the difference in water hardness in the soft water area did not significantly affect the taste of the simmered food.

Conclusions: From the above, it was concluded that the hardness of water suitable for delicious Japanese cooked rice and Japanese-style soup stock is 30 to 60 mg / L.

Changes in the gaze movements and the sense of taste due to the different food form

Wataru Masuda[1], Mie Shiraishi[1]

1. Kyushu Women's University (Japan)

Background and objectives: As a nutritional therapy for deterioration of mastication and swallowing function, the dietary form may be changed from a normal diet to a swallowing-adjusted diet / swallowing training food such as a chopped diet or a paste diet. However, swallowing food has a large visual gap from normal food, and it leads to a decrease in appetite because of lowering it's image and taste of the food, which is one of the factors for the decrease in the amount of food consumed. In this study, we investigated the relationship between gaze movements and feeling when different dietary forms of meals were provided. Methods: Twenty healthy female university students were used as subjects. Dishes with different food forms (nomal and paste) were provided side by side on the desk to the subjects wearing the eye movement detector, and the gazing point and the line-of-sight residence time were measured within a certain period of time. We used two types of dishes, "grilled salmon with salt" and "boiled vegetables" for measurements. In addition, the preference sensation for the two forms at the time of measurement was investigated by free description. Results: In both types of dishes, most of the subjects had a longer residence time in the gaze point on to the nomal than the paste form. The average residence time of the gaze point was also significantly longer for the normal than for the paste form for both types of dishes. The subjects during the measurement felt that the normal food was "delicious" and "the color was beautiful", while the paste food was "I don't want to eat much" and " I don't know what kind of paste food". Conclusions: The suggestion of a relationship between the length of the line-of-sight trend and the sense of taste considered to be an index for improving the taste of swallowing food in the future.

Expressions of three α-glucosidases observed in *Tetrahymena thermophila* cultured in the medium containing different monosaccharides or disaccharides

Mikako Tsukada[1], Emi Sato[1], Ayaka Ishikawa[1], Kano Miura[1], Miku Okamura[1]

1. Seirei Women's College (Japan)

Background and objectives: The physiological aspects of various kinds of saccharides are yet unknown. We examined this theme by using *tetrahymena*.

Methods: 1. *Tetrahymena thermophila* were cultured in the medium containing one percent monosaccharides (glucose, fructose or galactose) or disaccharides (maltose, trehalose, sucrose or lactose). Maximum cell density was measured during steady state. 2. Enzyme activities of disaccharidases in the cytosol of *tetrahymena* cultured with various medium were assayed. 3. Total RNA were extracted from cells cultured with six kinds of medium. From those RNA, cDNA were derived by reverse transcription. With use of three primer sets, we assayed the amounts of mRNA corresponding three α-glucosidase.

Results: 1. While cell density was over 10^6 cells/ml in the culture medium including monosaccharides or maltose, it was less than that in the medium including disaccharides except maltose. In the medium including no saccharides, cell density was low also. Therefore there were observed two types of culture medium (high cell density group and low cell density group). 2.Maltase activity was the highest among disaccharidases. Though trehalase activity was the second, its activity was one sixth of maltase. Sucrase or Lactase activity were slightly observed. Maltase activities from cells of high cell density group medium were lower than those of low cell density group medium. 3. The copy numbers of threeα-glucosidase were different by the medium including different kinds of saccharides.

Conclusions: It was not found α-glucosidase gene which expressed weakly in the high cell density group medium and strongly in the low cell density group medium. But all three genes were differently expressed in the cells of different medium. It means thatα-glucosidase expression is affected by external saccharides.

Is anti-gliadin IgG antibody useful diagnostic biomarker for gluten sensitivity?

Mikuni Motoyama[1], Hisashi Yamada[1], Kensei Maebayashi[1], Chiho Yoshimura[1], Hisato Matsunaga[1]

1. Hyogo Medical University (Japan)

Background: Gluten sensitivity is a syndrome characterized by several physical and psychological symptoms such as abdominal pain, constipation, diarrhea, headache, foggy brain, tiredness, anxiety, and depression, related to the ingestion of gluten. Although anti-gliadin IgG antibody has been presented as an immunological marker of gluten sensitivity, the diagnostic criteria have not been established yet, and much remains unclear about gluten sensitivity. Hyogo Medical University has the specialized outpatient unit for gluten sensitivity since 2019 and we have already reported the association between treatment-resistant schizophrenia and gluten sensitivity. We present finding regarding immunological gluten sensitivity in patients with subjective gluten sensitivity who visited our outpatient unit.

Method: From 2019 through 2021, patients with subjective symptoms of gluten sensitivity aged 20-70 years who visited our outpatient unit and healthy controls aged 20-70 years without subjective symptoms of gluten sensitivity were recruited. We determined immunological gluten sensitivity using anti-gliadin IgG antibody, and psychiatric and physical symptoms were evaluated by medical interview and self-administered questionnaire. We excluded participants on a strict gluten-free diet because their anti-gliadin IgG antibody levels seem to be reduced. This study was approved by the ethics committee at Hyogo Medical University. Detailed explanations of the study procedures were provided to each participant at the time we received their informed consent.

Results: The final sample consisted of 19 patients with subjective symptoms of gluten sensitivity and 173 healthy controls participated. Among 19 patients with subjective gluten sensitivity, 7 (37%) were determined as immunological gluten sensitivity. Of the 173 healthy controls, 20 (12%) were determined as immunological gluten sensitivity. As a marker of gluten sensitivity, the sensitivity and specificity of the anti-gliadin IgG antibody were 36.8% and 88.4%.

Conclusion: There is a large discrepancy between subjective and immunological gluten sensitivity. Using anti-gliadin IgG antibody solely as a biomarker are not sufficient to diagnose gluten sensitivity. Using a combination of several biomarkers is desirable to establish accurate diagnostic criteria of gluten sensitivity, and that other indicators, not only anti-gliadin IgG antibodies, are also needed. The association between the effectiveness of the gluten-free diet and changes in Anti-gliadin IgG antibodies also needs further investigation.

Involvement of transcription repressor Bach1 in function of intestinal goblet cells

Akari Yonezawa[1], Katsura Mizushima[2], Yasuko Hirai[2], Hiroaki Tateno[3], Akihiko Muto[4], Kazuhiko Igarashi[4], Tomohisa Takag[2], Yuji Naito[2], Yasuki Higashimura[1,2]

1. Ishikawa Prefectural University (Japan), 2. Kyoto Prefectural University of Medicine (Japan), 3. National Institute of Advanced Industrial Science and Technology (Japan), 4. Tohoku University (Japan)

Background and objectives: Intestinal mucus functions as a barrier that protects epithelial cells from harmful factors such as bacteria and virus existing in the intestinal lumen. The main component of mucus in the intestine is Mucin 2 ‹MUC2› produced by intestinal goblet cells and its proper structure such as highly O-glycosylation and disulfide band is critical for the mucus barrier. Several studies indicated that high MUC2- producing goblet cells are exposed to oxidative stress, suggesting that antioxidant pathways are important in maintaining goblet cell function. BTB domain and CNC homolog1 ‹Bach1› is a transcription repressor, which are mainly involved in the regulation of antioxidant pathway. Although Bach1 is ubiquitously expressed genes, its effect on intestinal goblet cells is still unclear. In this study, we investigated the function of Bach1 in intestinal goblet cells using Bach1-deficient mice ‹Bach1KO&rsaquo.

Methods: The colon was removed from C57BL6/J mice ‹WT› and Bach1KO, and the MUC2 expression and colonic mucus were evaluated with immunohistochemistry and Periodic acid-Schiff ‹PAS› staining. Fecal mucin contents were measured using a fecal mucin assay kit based on fluorescent labeling of GalNAc located at the reducing end. Using lectin array, we performed a comprehensive glycan profiling of fecal mucin. Furthermore, lectin blotting was performed to verify the lectins showing different profiles in WT and Bach1KO.

Results: Histochemical analyses of the colonic sections showed that MUC2-positive cells and PAS positive areas were significantly increased in Bach1KO compared to that of WT. Meanwhile, there were no difference in fecal mucin content. The results from lectin array showed that fecal mucin exhibited a significant difference in glycan profiles between WT and Bach1KO. In particular, the binding of a GalNAc-binder SBA and that of a α2-6Sia-binder SSA was increased in Bach1KO. These glycan changes were verified by lectin blotting analyses.

Conclusions: Our data indicate that Bach1 is involved in the formation of proper glycosylation of fecal mucin. The detailed molecular mechanism and effect to the secretory process of mucin is currently under analysis.

Effect of long-term vibration stimulus on skeletal muscle mass and body composition in rats

Yusuke Koga[1], Tatsuhiro Matsuo[1]

1. Kagawa University (Japan)

Background and objectives: Many studies are being conducted on the effects of nutrient intake on exercise effects such as the promotion of muscle hypertrophy, but it is not easy to make experimental animals exercise. The main method of exercise model applied to animals is forced muscle contraction by treadmill running or electrical stimulation. However, these methods have problems in that they put excessive stress on rats and cost a lot of equipment. Therefore, it is necessary to create a model that is more affordable and has a high exercise effect. In human studies, whole-body vibration stimulus by a vibration machine has been confirmed to have effects such as improvement of muscle strength and prevention of bone density decrease. However, the effects of long-term exposure to vibrational stimulus on skeletal muscle mass, body composition, and blood components have not been fully verified, and there are few studies using rats. In this study, we examined the effect of long-term vibration stimulus on rats for 12 weeks and whether vibration stimulus was appropriate as an animal exercise model.

Methods: Twenty male Wistar rats (3 weeks old) were randomized into two groups of ten rats, the control group (C) and vibration group (V), and fed with a commercial diet ad libitum for 12 weeks. Only the V group performed an exercise program using a vibration machine every day. The vibration stimulus was gradually increased from 5 min at 9 Hz to 30 min to 15 Hz. After the experimental period, all rats were sacrificed by beheading. The hind skeletal muscle, heart, liver, and abdominal adipose tissues were quickly removed and stored at −80°C until analysis. The carcass samples were stored at −20°C until analysis.

Results: The relative weights of the heart, soleus muscle, and flexor halluces longus muscle were significantly higher in the V group than in the C group. However, the weight of abdominal adipose tissues and carcass fat did not differ between the two groups.

Conclusion: These results suggest that long-term vibration stimulus may be an effective exercise program with aerobic and resistance exercise effects in rats.

Effects of Remote Assistance-focused Resistance Exercise and Nutritional Guidance on Body Composition, Muscle Strength, and Physical Function in Community-dwelling Japanese Older Adults

Shiro Izumi[1,2], Shino Ujike[1,2], Aya Shimosaka[1,2], Tomomi Kitajo[2], Chisato Sawada[1], Satomi Yamamoto[1], Kazuhiro Sako[3], Junko Suzuki[2]

1. Nayoro City University (Japan), 2. Tenshi College (Japan), 3. Nayoro City General Hospital (Japan)

Background and Objective: To clarify whether long-term implementation of a frailty and sarcopenia prevention program using a remote assistance-focused method is as effective as a face-to-face program in community-dwelling Japanese older adults.

Methods: Forty-nine community-dwelling older adults (16 males, 33 females, age: 70.0 ± 4.8 years) were randomly classified into the following three groups: face-to-face guidance group (FGG; n=17), remote guidance group (RGG; n=17), and control group (CG; n=15). Adults in the FGG performed 60 minutes face-to-face supervised resistance exercise once a week for the first 4 weeks plus similar exercise once a week at home, followed by 8 weeks of no face-to-face instruction and performed the same exercises twice a week at home while watching an instructional medium (DVD) for a total of 12 weeks. Nutritional guidance was provided once in person, followed by guidance over the telephone once a month, for a total of three sessions. Adults in the RGG performed the same exercises at home while watching an DVD twice a week and were provided nutritional guidance over the telephone once a month for a total of three times for 12 weeks. Body composition, muscle strength, and physical functions, such as five times sit-to-stand test, were examined before and after intervention. Adults in the CG were only examined before and after intervention and did not undergo any intervention.

Result: Lean body mass, muscle mass, lower limb muscle mass, appendicular skeletal muscle mass, skeletal muscle index (SMI), and grip strength increased significantly, and the body fat percentage decreased significantly in the FGG compared to pre-intervention measurements ($p < 0.05$). In the RGG, only grip strength increased significantly ($p < 0.05$). However, there was all no significant difference in the rate of change among the three groups. In the female-only sub analysis (FGGf; n=12, RGGf; n=12, CGf; n=9), SMI and grip strength increased significantly compared to pre-intervention measurements, and the rate of change was significantly different between the FGGf and CGf groups ($p < 0.05$).

Conclusion: These 12-week combined interventions may help improve muscle mass and muscle strength in older adults. However, a remote guidance program may be maintain them but challenging to improve.

A Data science approach to develop growth cut-offs for graded care of malnutrition

Aswathi Saji[1], Jeswin Baby[2], Tinku Thomas[3], Bireshwar Sinha[4], Uma Chandra Mouli Natchu[5]

1. St John's Research Institute (India), 2. St John's Research Institute (India), 3. St John's Medical College (India), 4. Society for Applied studies (India), 5. St John's Research Institute (India)

Background: The recommended classification of malnutrition by the World health organization (WHO) is based on cut-offs derived from the standard distribution of anthropometric measurements. These cut-offs are used to study the relationship between physical growth and childhood outcomes like death and morbidity. Since treatment decisions are taken based on these cut-offs, developing a new cut-off based on the risk of death as an outcome associated with anthropometric indicators will be a significant improvement on current distributional-based cut-offs.

Methods: Pooled data from 4 interventional and non-interventional studies across India were used for the analysis. Anthropometric measurements as well morbidity information of children less than 2 years was used for the analysis. A Bayesian hierarchical generalized additive model has been used to find the association of WAZ (Weight for age Z score) with a latent risk of death derived from the morbidities experienced by the child with the assumption that the association changes for different risk groups by Bayesian IRT. Cut-offs for both male and female groups in each malnutrition category were identified using segmented regression analysis.

Results: A non-linear decreasing relationship exists between WAZ with risk of death in children. Compared to males, a lesser risk of death has been found for females. Four cut-offs were identified for both males and females. Cut-offs for males were identified at -3.27(-3.29, -3.24), 0.012(-0.01,0.04), 1.64(1.6,1.69), 3.25(3.03,3.47) and -3.39(-3.41,-3.37), -0.01(-.05,0.014), 1.56(1.51,1.61), 3.13(2.90,3.35) for females.

Conclusions: A finer categorization of malnutrition based on the risk of death can be used to develop and then deliver tailored optimized therapeutic options for what is essentially a far more eclectic group than what is captured by a current classification of undernutrition.

Designing a new Nutrient Profiling model to quantify the Nutritional Footprint of seafood products: Nutrient Rich Food 12.2 index

Sandra Ceballos Santos[1], Maria Margallo[1], Jara Laso[1], Israel Ruiz-Salmón[1], Rubén Aldaco[1]

1. University of Cantabria (Spain)

Background and objectives: The water-energy-food nexus (WEF) approach has been promoted as a powerful tool to assess environmental impacts, and to highlight and enhance synergies between the three pillars involved, thus ensuring better resource management, and contributing to the achievement of the Sustainable Development Goals. Nutrient profiling (NP) models allow food to be classified and diets to be assessed according to their nutritional quality. Among them, the Nutrient Rich Food (NRF) indexes, which combine both nutrients to promote and nutrients to limit, have been proposed as potential indicators in the nutritional footprint to be integrated in the WEF nexus. Recent research has revealed that NRF9.3 index is the one that correlates the best with the health-related nutritional impacts of products.

Methodology: For the assessment of nutritional footprint of seafood products, we aim to develop a new index by redesigning the NRF9.3, as it does not consider certain nutrients for which fish stands out for having high contents. The modified version of NRF9.3 is the specific seafood model NRF12.2, in which a macronutrient (fibre) and one nutrient to be limited (added sugar) are excluded because they are absent in this type of food. On the other hand, one fatty acid -docosahexaenoic acid (omega-3)- and two minerals -iodine and selenium-, are considered since seafood products are important sources of these nutrients in diets. Therefore, the NRF12.2 is based on twelve nutrients to encourage and two nutrients to be limited per reference amounts customarily consumed (RACC).

Results: When the seafood product assessed is a processed product composed by different ingredients, such as those typical added in the processing (e.g., olive oil), it is necessary to adapt the NRF index to each case study. We propose the use of weighting factors based on the proportion in which each ingredient is found in the final product.

Conclusions: The main outcomes prove that the new index specially designed for seafood products offers a complete and robust characterisation of their nutritional impact. The NRF12.2 model allows the study of the best choices of products to include in nutritious and balanced diets, also ensuring through the WEF nexus approach, that they are environmentally sustainable.
